When to Plant. In a short-season area, plant outside as early as possible—on the frostfree date. Or plant indoors in peat pots no more than 6 weeks before the frostfree date and transplant on that date. It won’t transplant well if the roots have developed for more than 6 weeks or are disturbed too much during the process. If you have a very mild winter, you can plant in late fall for a spring crop.

How to Plant. Plant presoaked seed about 2 per inch. Cover with $\frac{1}{4}$ inch dirt. You can make rows as close as a foot. Plant some radish seeds (about 1 every 3 inches) in the row to mark it for tilling since, like any parsley, it will take a month for the Hamburg to come up. Keep the seed row moist until the plants are up and well started. After that, expert gardeners put on a heavy mulch and don’t water any more unless it gets radically dry. Thin first to an inch apart, later to 4 to 6 inches apart. Hamburg prefers cool weather, growing best in the 50–70°F temp range.

HARVESTING GREENS: The top of the plant is true parsley. You can harvest and use Hamburg parsley greens just like any other parsley (see “Parsley” in [Chapter 5](#)). The problem is that if you cut off more than 1 or 2 stems per plant, you’ll harm its root development. So the best way to harvest Hamburg parsley greens is to refrain from clipping them until you dig up the roots. At that time, harvest the greens too, and freeze or dry for flavoring or garnish.

HARVESTING Roots: For greatest growth of the root (they’ll get as long as 6 to 8 inches or more), Hamburg parsley needs a long season—seeds planted in March will have finished roots in October or November. But you can harvest the root whenever you like. Roots 5 to 7 inches long are the most tender and sweet. The longer you wait to harvest, the bigger they get, but roots larger than that are not as nice. If you wait to harvest until after several fall frosts, the sugar content of the roots will be greater. Hamburg is very frost-resistant and is not killed by it, although it won’t grow at low temps. If your area is mild, put a heavy mulch over the plants and leave them in the ground all winter to harvest as needed. (Hamburg is a biennial and will bolt to seed the second year, when temps get up to 75°F.) Hamburg left in the ground will stay crisper than Hamburg in a root cellar, but if your ground freezes hard, dig up before that happens and store in a moist, cool (32–40°F)

place, as you would carrots. They can last as long as 4 to 5 months that way.

USING HAMBURG Roots: Scrub well or precook. Peel to get rid of the hairy outer skin. But it's better to keep the peel on until after cooking; otherwise the roots discolor. Serve Hamburg roots raw in strips with any dip. Cooked Hamburg can be substituted in any parsnip or turnip recipe, although it has a milder flavor, more like celeriac, than those two. Add to stews and soups; it's good cooked together with roast beef.

Jerusalem Artichoke

The Jerusalem artichoke (*Helianthus tuberosus*) is from the sunflower family; it's not a relative of the globe artichoke at all. These perennial crunchy white tubers grow wild in the eastern part of the United States and Canada. Or they can be cultivated. In seed catalogs and stores, you might also see them called "crosne du Japon," girasole, Japanese artichoke, sunchoke, sunroot, and winter artichoke. Some folks call them "chokes" for short, and I do too. Native Americans cultivated and used them for food. They do not suffer from any insect or disease—and can handily defeat any known weed in plant-to-plant combat. They can be an exceptionally useful food for diabetics since they are tasty and nutritious like potatoes.

Chokes are such prolific growers that they sometimes tend to take over the garden like a weed. But you can make use of that abundance. Dig your extras and feed them to the chickens, goats, or pigs. They are so easy to grow that you might want to plant extras on purpose to serve as part of your animal feed.

PLANTING: Choose an area of your garden where the choke's ambition to be the only vegetable in your entire garden can be curbed, where a 6–8-foot plant won't cause a problem by shading other plants, and where a perennial can live undisturbed. If you're starting a new patch, you'll need about 4 qt. of choke "seed" to plant a 50-foot row. You either plant them in rows, 1 seed every foot with 2 or 3 feet between your rows, or plant in "beds" about 4 × 4 feet, as some flowers grow. Plant 4 inches deep. You'll see the plants above dirt in 8–12 days.

Once the chokes get going, they'll choke the weeds. Give them a designated space and just let them grow as much as they want to in there. If you've planted some chokes last year, when spring comes they'll naturally start multiplying. You can either let them spread where they are or, if you must, dig them and replant in rows. To increase your artichoke crop quickly, cut them before planting, as you do with potatoes; that increases your "seed" amount. Just lay them one by one on a cutting board and cut an × on each one, which gives you 4 "seeds."

HARVESTING: It takes newly planted chokes about 130 days to be ready for harvest. The chokes look like small, light brown potatoes. Dig them anytime from after the first frost until spring, about October 1 to March 10, when the new growth starts. You could harvest about 1½ bushels per 50-foot row, but don't dig up too many at one time because they don't keep well.

STORING: Using a heavy mulch on chokes in the winter season will help prevent the ground from freezing and will make it easier for you when you want to dig some up. Freezing underground doesn't hurt the chokes, but it makes it kind of hard to dig them up. If you need to store them out of the garden, put them in plastic bags or in a container of damp

sand. They keep best at 32–40°F, 90–95 percent humidity. But even so, chokes out of the garden will last only a few months. If you wash but don't peel and keep them in an airtight, refrigerator-type container or a plastic bag, they might last a month in your fridge.

To PEEL OR NOT TO PEEL: That is the question. People can really get worked up over peelings. And so it is with Jerusalem artichokes: There are pro-peelers and anti-peelers. I don't think it makes a whole lot of difference, since if you have 'em, you have lots of 'em. But if you are an anti-peeler, just scrub well, remove any dark blemish, and slice off lumps. If you steam the chokes about 5 minutes, most of the skin will just slip off.

If you are a peeler, wash them thoroughly and then peel thinly with a vegetable peeler. If you're going to use them raw in salads, drop them into a bowl of cold water with some lemon juice or vinegar in it; otherwise they quickly turn black if exposed to the air. They can also be cooked in their skins and the skin removed after cooking. But if you boil them in the skins, you should remove the skins while they are quite hot, or you'll lose a lot of artichoke with them.

RECIPE IDEAS: Mix somewhat finely chopped cucumbers, 'chokes, apples, and nuts and moisten with mayonnaise for a kind of Waldorf salad. You can substitute them for water chestnuts or jicama in any recipe. Since they are free from starch, you can eat them uncooked. Raw Jerusalem artichokes are good grated or ground on a bed of lettuce with salad dressing and a bit of grated onion. Or served sliced and mixed in salads, where they taste like water chestnuts. Add to your salad dressing the leftover lemon juice that you marinated them in. Or cook them ...

Boiling. Boil them quickly, since overcooking toughens them. Serve with a white sauce or a butter-lemon juice-parsley sauce. Chives and parsley really get along with artichokes.

Baking. First boil about 10 minutes. Then peel and arrange around the meat as you would potatoes, or put into a baking dish with dots of butter, salt, and pepper.

Pureeing. Cook until tender (in stock if you have it). Peel. Put through a sieve, or mash with a little butter and seasoning. (Garlic flavor is a good addition.)

Deep Frying. Cut into strips and fry in shallow oil until golden brown, or slice as thin as a penny and fry like potato chips in deep fat at 375°F.

➲ **ARTICHOKE FRITTERS** *Dip chokes into a batter (mix egg, flour, milk, and salt) and fry in deep fat until golden brown.*

Jicama

Jicama, a Mexican vegetable, is also called "sincama," "sa gord," "yam bean," "Mexican potato," and "Mexican water chestnut." Its Latin name is *Pachyrhizus tuberosus*. The jicama sold in U.S. markets is a subtropical tuber (most suited for zones 9 and 10). It's the root of a climbing vine related to the legumes, so it also enriches your soil. Jicama resembles a flattish turnip both in its shape and in its white, crisp inside flesh. It tastes like a water chestnut crossed with an apple. (Good!) The best place to grow jicamas is in southern zones, where you can harvest as needed for months and an individual tuber may weigh up to 6 lb. However, gardeners everywhere except the most northern tier of states can grow tubers weighing at least ½ lb.

VARIETIES: The name jicama is used in South America and Mexico to mean the edible roots of several different plants. *Ipomoea bracteata* and *Exogonium jicama* are two of these from the morning glory family. *Dalia rosea* is a dahlia variety that Mexicans grow for its edible tuber as well as its lovely flowers. But the standard grocery-store jicama is *Pachyrhizus tuberosus* (also called *P. erosus*), a leguminous species. *P. tuberosus* itself has 2 varieties: jicama de agua, so called because its juice is clear, and jicama de leche, named for its milky juice.

PLANTING

NOTE: *Jicama plant seeds are poisonous to humans and insects. The seeds contain rotenone, an organic insect poison that also kills fish, incidentally, so don't drop the seeds in your pond either. (You don't have to worry about bugs getting this crop!)*

You can order jicama seeds from Exotica, Gurney, Hudson, Nichols, or Redwood City. Low-nitrogen soil is best for getting good roots rather than leafy growth. Plant outdoors on last frost date in coastal and southern areas. In northern climates, soak seed to speed germination; then start seed indoors in individual peat pots 4 to 8 weeks (or more) early—the colder your climate, the earlier you need to start them (120 days to harvest). Or plant in a large container.

GROWING: Keep moist until the plant is up. Transplant outside when the ground gets warm. In a short-season area, space plants about every ½ foot; the longer your season, the wider you should space the plants—up to a foot apart if you have a growing season as long as 7 months. In the south, the vines may grow 10 to 15 feet long. Consider providing a trellis or arbor for the glossy, heart-shaped leaves to climb. In the north, the plants will loaf until late summer and then take off, growing 10 to 15 feet in length, and make your harvest. This is a good plant to train up a trellis, arbor, or fence (plant 1 row on each side, staggered). It gets white or purple flowers (late in the season) and big, shiny, heart-shaped leaves. Pinch off every vine blossom to get the biggest, best-shaped jicama tubers. The plants need plenty of water to make crunchy roots. Mulching helps them. Water if they get dry under there.

HARVESTING

NOTE: *Jicama flowers, leaves, seed pods, and seeds are all poisonous to humans—and also insects. The very young pods are not yet poisonous but develop poison as they mature. Keep the "beans" away from children. But there is absolutely no poison in the tubers.*

Pinch off the first few flowers to save strength for later fruit. The longer your growing season, the bigger your jicamas will get. They can get up to grapefruit size and will still be juicy, slightly sweet, and good to eat. Start to harvest whenever you feel the roots are big enough to bother with, and continue harvesting as needed to season's end. In the tropics, you may still be harvesting as long as 2 years after you plant. In northern regions, the vines will die as the weather gets more chilly. Harvest before frost! If you do not wash them, jicamas will keep in a cool place (fridge or root cellar) up to a month.

USING: Jicama doesn't discolor after peeling and doesn't lose its crunchiness, so it's good for a vegetable tray. To prepare, peel thinly. Mexicans like them cubed and raw, sprinkled with red chili powder, lime juice, and salt. Or thinly slice and add to any variety of salad. Or cut into long sticks and dip into guacamole, or cook with a chicken or seafood stir-fry. Or boil, mash, and season with cilantro-flavored butter. Or cut in half, bake like a potato,

and serve with chopped green onion and yogurt or sour cream. Or substitute in any recipe that calls for water chestnuts. When you have a big jicama, just cut off what you need and leave the rest for later. It keeps fine like that.

Lotus Root

The water lotus (*Nelumbo*) comes from Southeast Asia. A distant relative of the avocado, it is a perennial that can live in zones 5 to 10. (Don't let the roots freeze.) Seeds for *Nelumbo nucifera*, the Buddhist Sacred Lotus, are available from Deep Diversity. Lotus seeds remain fertile for hundreds of years. For quickest germination, you drill a tiny hole into the dense outside shell, wrap the seed in a lump of clay, and drop it into a body of shallow water such as a pool, a bog garden, or even a water container. Or propagate from rhizomes. It needs full sun.

RECIPE IDEAS: You harvest the edible, submerged, enlarged rhizomes that are strung together. Technically they aren't "roots," and they are not actually found underground. They grow along the top of the underwater soil. Their skin is reddish brown; the inside flesh is whitish-orange with holes. The texture is crunchy, the taste mild. The roots are best when young. To serve, peel raw lotus roots, slice across the width, and add to a salad. Or peel, cut into chunks, and add to any vegetable soup or stew. Or peel, cut into carrot-stick-type lengths, and add to any stir-fry. Or peel, boil, and mash. Or peel, slice, color with food coloring, and use to ornament other foods. Lotus leaves, flower petals, and seeds are edible too. Use leaves raw in salad or cooked as a green, but don't take too many off a plant.

Parsnip

The parsnip (*Pastinaca sativa*) is a member of the Apiaceae, or "carrot," family. It is just about the hardest-to-grow root vegetable. But parsnips are worth the trouble because of their winter-keeping ability. Parsnips come from northern Europe, and successfully growing them is just a matter of knowing what they need and giving it to them. A pale relative of the carrot, the parsnip resembles that vegetable in having a long tapered root (up to a foot long); smooth, light-colored skin; and a soft, sweet inside. More than any other vegetable in the garden (even the carrot), parsnips can handle and even thrive on being left in the garden all winter to be dug as needed. It's with soil, seed, and season that they have problems.

PLANTING

Soil. Parsnips need a deep, finely cultivated soil. If your soil is very sandy naturally, that makes it easy. They'll love it. If it's not, you have some work ahead of you. But the same manuring and composting treatment that benefits your other garden vegetables also helps parsnips. The parsnip patch in your garden needs more, though. You need to work the soil thoroughly, 1–1½ feet deep, getting out stones and such so the roots don't catch on them and get deformed and discouraged. A heavy clay soil is the hardest kind to get ready for parsnips. Working in extra cinders and compost will help make your soil loose and crumbly. You can work the soil without turning your good topsoil under and digging it to the bottom—it's good enough just to get the soil loose. Some people have grown parsnips 3 or 4 feet long for fun by digging the soil loose that deep and supplying plenty of manure-compost.

How to Plant. Parsnip seed doesn't keep well over a year or so. If it doesn't come up, the problem may be old seed. But don't despair too soon, because parsnip seed has the distinction of being slower to germinate, even under the best conditions, than any other kind of seed I know of. Figure on waiting 21 to 28 days after planting before you'll see something green above the ground! Parsnips must be planted very shallow and gently. They have trouble getting up if there is any sort of crust on your soil. Water well before you plant. Ideally plant $\frac{1}{2}$ inch apart, although you can't possibly do that in real life because the seed is so fine. Cover very lightly, no more than $\frac{1}{4}$ inch deep. If you think the seeds need extra protection from birds or some such, add a $\frac{1}{2}$ -inch layer of peat moss or other light mulch, and remove it as soon as the parsnips begin to come up. In a short-summer climate, the right time to plant is immediately after your last frost date, since parsnips can't take the hot midsummer weather. Plant in the fall or early, early spring. The parsnip rows can be anywhere from 18 inches to 3 feet apart. If you choose 18 inches, be sure to get plenty of manure-compost into the soil.

Weeding and Thinning. Because parsnips are so slow to come up, you've got to do something extra to avoid losing them in weeds. So mix radish seed with your parsnip seed. The radish seed comes up fast and shows you where the parsnip row will be, and that makes it possible for you to cultivate and keep out the weeds without accidentally cultivating out your parsnips-to-be. After they get going, you can thin to 3 to 6 inches apart depending on how much space you can spare and how rich your soil is. Or let them go as long as you can and figure on eating the thinnings. Keep weeding faithfully all summer long.

HARVESTING

Saving Seed. Parsnip is an insect-pollinated biennial, so seed is made the second summer. Leave in the ground the ones you want to make seed, collect the seed when it's mature, and store for use. Collect parsnip seed generously, because you can't count on all the seed staying alive and germinating; having lots of extra seed is good insurance. Parsnip seeds stay viable only 1 to 2 years. (Also see "Saving Seed" under "Carrot.")

About Garden Frozen Parsnips. We rush sweet corn from garden to cooking pot because its abundant natural sugar starts changing to starch the minute it leaves the stalk. Parsnips reverse that process. They contain lots of starch which, when the plant freezes, changes to sugar! That's why you're ahead, tastewise, if you leave parsnips outside in the ground until after at least 3 weeks of frosty weather. Or you can leave them in the ground all winter, because more freezing only improves them. Tastewise they are best if left in the ground until spring. You can harvest them until they start to make new leaves. Then they'll get completely woody and inedible.

Digging. Basically, your harvest season for parsnips is from October to May. The technical problem is that you can't dig anything out of frozen ground but must do your harvesting during thaws; if you want parsnips and no thaw comes, you're out of luck. And you must *dig* parsnips. Pulling them is likely to result in a break at the halfway point of that long, skinny root. That's the advantage of some alternative preservation systems (see the next section). Or, after the first frosts, put a mulch over the parsnip row to keep it from freezing solid again.

PRESERVATION SYSTEMS

Root-Cellar Storage. Parsnips can be stored in a root pit: Lay right on the ground; cover with soil, then with straw or leaves, and then with a waterproof tarp or plastic. If you want to keep them in a root cellar, pack in moist soil. They will soon start to develop again in the spring. Then the roots all become too woody to eat. Or you can store dug-up parsnips between layers of damp sand in a tub in a cool outbuilding. Or preserve them by freezing or canning.

Freezing. About 50 lb. of parsnips will give you about 40 frozen pints. Trim off parsnip tops. Wash the roots well. Peel. Cut into $\frac{1}{2}$ -inch cubes or lengthwise into slices about $\frac{3}{4}$ inch thick. Scald 2 or 3 minutes. Cool in 2 successive ice-water baths. Package and freeze.

Drying. Avoid parsnips old enough to have a woody core. Slice or cut into chunks—or, easiest of all, shred with a salad maker. The shreds dry very quickly and evenly. Then you can reconstitute by overnight soaking and cook and eat. Or add to soups, stews, and casseroles. Or powder them and add to your instant vegetable soup mix.

COOKING: Generally speaking, you can catch parsnips at any of 3 stages. In the first, they are garden-fresh and young, starchy rather than sweet, but tender all through, without the woody center core that comes later. Stage 2 is when they are full grown and have their frost treatment but are still “young.” Stage 3 is the “older parsnip.”

Young Parsnips. Scrape rather than peel, wash, and French-fry or whatever. Some people like to eat parsnip tops, which taste a little like watercress and can be used in salads. Other people get an allergic reaction from wet parsnip leaves that blisters tender skin.

Older Parsnips. The large, older parsnips may taste better, but you’ve got a woody center core as well as a peel to get rid of. Really old parsnips get too woody to eat—you might as well let them go on and make seed. Boil unpeeled, washed parsnips until tender; it takes about 10 minutes for a 1-inch-wide parsnip. Now peel by skinning, as you would a potato, or run a razor blade the length of the parsnip, just cutting the skin, and roll out the vegetable. If the parsnip has a woody core, next slit it lengthwise down to the core and remove it. Or if you are going to cut the parsnip into sections, do that and then push the core out of each section.

Recipe Ideas. Serve boiled like carrots, with butter. Or bake 20 to 30 minutes at 350°F and serve with a brown-sugar glaze. Or add to a vegetable soup. Or cook slices in a frying pan with broccoli and other vegetables. Boiled parsnips are good served cold with mayonnaise. Or creamed. Cut in slices and brown in butter. Or add to any potato-turnip kind of stew or soup. Or mash and serve with salt, pepper, and butter. Or mash, season, and shape into cakes; lightly flour, fry till brown, and serve. Or glaze in a frying pan in a mixture of salt, pepper, butter, fruit juice, and brown sugar or honey. Or, instead of boiling, roast them in the jacket with meat as you would potatoes.

➲ **PARSNIP FRITTERS** Boil 2 to 3 peeled and sliced parsnips in salted water. When tender, drain and dip parsnip chunks into a batter of $\frac{1}{2}$ c. milk, 1 egg, $\frac{1}{2}$ t. baking powder, a dash of salt, and enough flour to thicken batter to the consistency of griddle cakes. Fry in deep fat or cooking oil until golden brown. From Wilma Litchfield.

Radish

Radishes are the vegetables that spring-starved fanatics get out and plant because they're early and quick—you might have the first ones to eat as soon as 3 weeks after planting. Children love to grow these brassica roots, because they grow so easily in a pot or outdoors. The quick red globe kinds are the most commonly grown, often to mark the rows of slower-germinating plants like carrots. Or you can plant them with parsnips or parsley; the robust radish sprouts help those frailer creatures break through the soil's crust. All parts of the radish are edible (but the leaves aren't usually eaten), and there's much you can do with them.

VARIETIES: *Raphanus sativus* is your basic radish, but there are many different varieties (red, white, yellow) with maturing dates ranging from 20 to 60 days. (Horseradish is not a radish.) The red radishes don't usually do as well once the days get short, but there are winter varieties that can be planted in the fall. Some radish varieties look and are used rather like turnips. One almost rootless variety is grown for its green top, which is used in salad, and one is grown for its seed pods! Every major Asian country developed its own favorite radish variety centuries ago, and Asians include radishes in their daily diet much more than we do. Available from Bountiful Gardens, Cook's Garden, Kitazawa (winters!), Nichols, Park, Shumway, and Territorial.

Red Radishes. The short "cherry" radish is the most familiar one in the United States: red skin, white flesh, green leaves, cherry-sized, quite hot. These are fast and easy, best for container growing. Use sliced (not peeled) in salads or as raw, edible garnishes. You can also boil them or add them to soup, as you would carrots. There are also long, red varieties. Use them raw like the small ones, or roast with meat, as you would turnips, or chop and saute them together with other vegetables.

White or "Winter" Radishes. These close relatives of the reds are generally larger, milder in flavor, harder to grow, and longer to mature. They also stay crisp longer—several weeks instead of several days. Icicle, a 4-inch white, is the quickest-to-mature long white; it straddles the categories of red and white. The other whites are the true "winter radishes," so called because they are often planted in mid-or late summer, harvested in

fall, and stored during winter in damp sand. Winter radishes taste better cooked than the summer ones do. One of the best winter radishes is daikon.

Daikon. This is a very large (2–4 inches across, 6–20 inches long), white, Asian radish variety (*Raphanus sativus longi pinnatus*.) With its peppery taste (milder than the reds), it is the most popular Japanese vegetable, a fixture in Japanese cuisine. But writer Lane Morgan and some other folks say that daikon has a problem in the United States because it's so attractive to the cabbage-root-maggot butterfly. Plant in late summer (1 inch deep). They take a long time. Seeds are available from Cook's Garden, Johnny's, and Kitazawa. Harvest, store, and cook like any root vegetable.

Daikon contains diastase, a starch-digesting enzyme, so it goes well with a heavy-starch meal. Daikon leaves can be substituted in any cooked greens recipe. In Japanese edible art, daikon is carved into shapes such as a rectangular fishnet made of one continuous peeling of the daikon that is then laid over seafood dishes. The Japanese serve grated or slivered daikon with raw fish on rice (sushi) and with rice in general. Daikon can also be slivered and made into Instant Pickles (see recipe in "Cucumbers"). Or substitute in regular pickle recipes. Or use raw slices in green salad, stir-fry, or cook in soup.

Sakurajima. It takes 70 days to mature and needs as much room to grow as does a tomato plant. I've heard that a single specimen can get to 10, 20, or even 50 lb. in size. This variety is not eaten raw because it is extremely hot. Cook it turnip-style. Plant seeds 2 feet apart.

Lobak. This is a Korean radish, spicy rather than mild. It's white, with some pale green shading at base. It's as wide as a potato and is 6–8 inches long. You can cut into strips and serve with a dip, or use in the famous Korean relish called kim chee. It's good chopped into an omelet, sauteed as a side dish with carrots and onions, sliced in an avocado salad, or cooked in a soup.

Black Radishes. There is a Chinese black radish and a Black Spanish one. Some black radishes look like daikon (7–8 inches in length, 2–3 inches in diameter). Some are turnip-shaped. The black ones are also "winter radishes," so plant them like winter radishes and cook like turnips. Seed is available from William Dam.

Rat-Tail Radish. This "podding radish" is raised in order to harvest the long (9 inches or more!) seed pods, which develop late in the season. This is a very uncommon but fascinating-looking variety of radish. The seed pods are long and beanlike, but they are wide at one end and dwindle to a tip at the other. Rat-tail radishes are grown just like other radishes. Harvest after only a few weeks, while still tender. Use like edible-podded peas, or stir-fry or pickle them. The taste is moderately hot, like other radishes. Seed is available from Bountiful, Cook's Garden, and Seeds of Change.

Wasabi. This green, very hot Japanese radish is dried and powdered before it's used. To use, mix the powder with enough water to get a smooth paste. Let rest 10 minutes. Then use cautiously with Nori rolls or soy sauce. Seeds are available from Kitazawa.

PLANTING

When to Plant. Timing is critical to success with radishes. Reds can be planted as soon as the soil thaws and can be ready in 20 days. But wait to plant your salad crop until the lettuce that it will be served with is half-grown. Radish roots don't grow as well in summer's heat; compensate by planting late reds in a shady spot and mulching. Since reds don't last long, if you want a steady supply of radishes, you'll have to make successive

plantings every 2 to 4 weeks—or else plant a combination of early-maturing and late-maturing varieties. The white winter radishes absolutely must be planted at such a time that they'll have cool weather when the root is maturing. Some varieties go entirely to leaf and seed and make hardly any root at all if they mature in summer instead of fall. But they can survive frosts. Plant about 8 weeks before the average date of your first fall frost.

How to Plant. Loose, humusy (but not nitrogen-rich) dirt is best for them. Fight root maggots by adding wood ashes to their soil and moving your radish plantings around. Plant $\frac{1}{4}$ to $\frac{1}{2}$ inch deep. Red radishes don't need much room; plant 12 or more to an 8-inch container. Six-inch-deep soil is enough. They're soon grown and harvested, so just tuck them in anywhere. Let your density in planting be guided by expected radish size. Try to plant red radishes 2 inches apart; they'll end up closer, because the seed is so small and hard to control. Plant winter radishes 3–4 inches apart. They'll be up in 3 to 6 days. Thin enough so they have room to grow without deforming each other. The exact distance depends on how big a root you're expecting. If you're cramped for space, make your red-radish rows as close as 6 inches, your winter-radish rows $1\frac{1}{2}$ foot apart.

Water. Poor soil or dryness slows up radishes' growth and can cause tough roots that are too hot. So for mildest radishes, keep their soil damp. With winter radishes, dryness results in woody as well as tough texture. If water is scarce, planting them in a comparatively shady spot helps keep their soil moist.

HARVESTING

Saving Seed. Radishes are bee-pollinated and self-incompatible; they may cross between varieties blooming within $\frac{1}{4}$ mile. The reds are annuals, the winters biennial. It can be hard to get seed unless there are plenty of bees, weather under 90°F, and reasonable moisture. Radishes left in the ground past their prime soon send up a stalk, flower, and then form seed pods. Discard the early bolters. Let the seed pods develop, ripen, and dry on the stalk. If the stalk looks fragile, you can stake it to keep from losing the seed in case it falls over onto the ground. Then harvest the seed pods by breaking off the stalks. Don't open until you can rattle the seeds around in the pod. If they aren't dry enough to rattle, continue drying pods in a shady, airy place out of direct sunlight. Once dry enough to rattle, the pods will be easy to open. Spread out the seeds and continue drying. When completely dried, store in an envelope or jar marked with radish variety and year saved. Store in a dry place. They stay viable about 4 or 5 years. Radish sprouts have a nice pungent flavor. (Also see "Saving Seed" under "Carrot.")

Harvesting. Red radishes are one of the quickest-growing vegetables, about 50 days to harvest. But they have to be pulled, washed, and used promptly when they reach their prime—tender and young—which is soon gone, leaving them too pithy and soft to be very good. You can combine thinning with harvesting. Take the fattest ones early in the season, leaving the slower ones to catch up. Reds store best right in your fridge and will last up to a month.

Winter radishes can be pulled young and used like the reds (that's a good way to thin them). Once winter radishes mature, you have about 3 weeks before they lose their prime in the garden. After that, they gradually get tougher.

PRESERVING

Storing. So although winter radishes will survive if left in well-mulched ground to winter,

they're normally dug up and stored in a root cellar. Digging them up stops the toughening process. Store winter radishes between layers of moist sand in a box or tub. (See "Introduction to Roots.") Or freeze them. You can also preserve red or winter radishes by drying or canning, but people usually don't bother.

Freezing. For winter radishes: Wash, peel, stir-fry briefly, package, and freeze. Good as a buttered vegetable and in stews, soups, and stir-fry dishes.

Drying. Wash, trim off top and root, and slice $\frac{1}{8}$ inch thick. Spread over drying trays and dry until brittle. Good broken up into small pieces and scattered over a salad. Or use them like "chips" for dipping. Or add boiling water, simmer till tender, season, and serve.

Canning. Follow directions for canning carrots.

➲ **ROSY RADISH RELISH** From Cathy Tate, a supergardener from Keller, WA: Makes $2\frac{1}{2}$ pt. Use 3 c. stemmed radishes, 2 large ribs celery, 1 large mild red onion, 2 t. salt, 1 c. sugar, 1 T. mustard seed, 2 T. dill seed, $\frac{1}{2}$ t. celery salt, and 1 c. cider vinegar. Put the radishes, celery, and onion through the coarse blade of a grinder, or chop them finely. Mix with the remaining ingredients and allow to stand for 3 hours. Bring to a boil in a large pan and cook 5 minutes. Pour hot into half-pint or pint jars, leaving $\frac{1}{2}$ inch headspace. Process in boiling-water bath. At up to 1,000 feet above sea level, process 30 minutes; at 1,001–3,000 feet, 35 minutes; 3,001–6,000 feet, 40 minutes; and above 6,000 feet, 45 minutes.

RAW RADISHES: My family enjoys occasional raw radishes, especially the first few batches from the garden. They're good plain or dipped in salt or mayonnaise. Radishes are also good grated or sliced thin in a tossed salad. You can add sliced raw radish to cucumber or tomato sandwiches on homemade or dark store bread. But with the first exciting appearance of radishes at the table, I go all out and make radish roses.

Radish Roses. Choose round radishes without blemishes. Wash. Trim off the roots and part of the stalk, leaving on a few of the best-looking short leaves. With a sharp knife, starting at the root end, peel down the red skin. Make about 5 of these "petals." Once you have the knack, the petals will open right out as you peel—the trick is to get them the right thickness and width. Experiment!

Radish Mouse. Cut off the widest end. Leave the other for the tail. Cut 2 ears (radish-rose-style). Stick in 1 large clove for the mouth and 2 very small ones for the eyes. Stick in a toothpick for the tail.

➲ **BRAISED RADISHES** Also from Cathy Tate: Take 2 T. butter, 2 c. sliced radishes, 1 bouillon cube, $\frac{1}{4}$ c. hot water, $\frac{1}{8}$ t. ground marjoram, and salt. Melt butter in saucepan, add radishes, and cook 5 minutes. Stir frequently. Dissolve bouillon in hot water (or substitute $\frac{1}{4}$ c. beef broth), add to radishes, and simmer 3–4 minutes. Add marjoram and serve as a hot vegetable.

➲ **CREAMED RADISHES** If you're still having trouble using up your radishes (I don't know any families who can eat all the radishes they can grow!), make this dish. It also makes use of your large, strongly flavored radishes. Wash, pare, and slice the radishes to get about $1\frac{1}{2}$ cups. Boil until tender. Make a white sauce from 2 T. flour, 2 T. fat, 1 c. milk, salt, and pepper. Mix the sauce with the radishes and serve.

➲ **RUTH'S VEGAN CREAMED RADISHES** Steam radishes 5 minutes instead of boiling them. Make white sauce of 1 c. water or rice milk and $\frac{1}{4}$ c. whole wheat flour. (Toast flour over dry heat, remove, whisk in liquid, and then return to low heat, stirring occasionally till thickened.)

Season with basil, tarragon, and/or marjoram.

⇒ **FRIED WINTER RADISH** Cut into long strips. Dip each strip into beaten egg, then into crumbs, and then fry it.

⇒ **WINTER RADISH GREENS** The greens of radishes are edible, especially those of winter radishes. Cut; throw out the stems and imperfect leaves. Wash and slice into salad-sized chunks or strips. Substitute in cooked leafy greens recipes.

Rutabaga

The rutabaga (*Brassica napobrassica*), called “Swede” or “Swedish turnip” in England, is a cross between a turnip and a wild cabbage. It was created back in the Middle Ages. Rutabagas don’t like hot weather and are a natural northern vegetable, good in the northern United States and cooler parts of Canada. Grow them as you would turnips, although they get bigger (4–5 inches wide) and take about a month longer to mature. They’re fairly hardy but dislike heat.

PLANTING: Seed is available from William Dam, Territorial, etc. Like any root vegetable, rutabagas like a well-tilled, fertile soil. If you plant in early spring (good started in a cold frame), they’ll probably do well for you unless you have a very hot summer. Hot weather during the later part of their growth causes big tops but small, tough roots. If you plant in June to mid-July, they’ll mature in the cool, fall weather, and that will be better for them if you have a hot summer. Plant $\frac{1}{4}$ – $\frac{1}{2}$ inch deep; thin to 8 inches apart (crowded rutabagas don’t get big), rows 2 feet apart. Expect 5 to 10 days to germination and about 90 days to harvest. They’re pretty tough about frost; like parsnips, a light frost sweetens them. So wait to harvest them until after a few of those frosts. Or else mulch heavily so they don’t freeze, and you’ll be able to dig as needed.

HARVESTING AND PRESERVING: Harvest anytime you want to, once they’re big enough to bother. The biggest roots are better livestock food than people food. Light frosting of the top growth improves the flavor, but freezing of the root gives it a bad flavor and shortens its keeping time.

Saving Seed. Rutabagas are biennial and bee-pollinated, and they will cross, just like beets and turnips, which are biennials too. Mulch to keep the plant alive over winter. Take off the cover early in spring. Seed lives about 5 years.

Storing. Store in a cellar the same way you would a turnip. Rutabagas store 2 to 6 months in any cool, moist darkness—a cellar, a pit, or a big box with sand, sawdust, moss, or dirt in it. If you have a crop and decide you don’t like them, feed them to your cows, goats, etc. They will love them and the rutabagas can provide a substantial part of their winter nourishment.

Freezing. Harvest rutabagas while very young, small, and tender. Remove tops, wash, peel, and cut into $\frac{1}{2}$ -inch cubes. Scald 2 minutes, chill, and package. To cook them, just thaw, mash, and season.

Drying. Wash, peel, slice $\frac{1}{8}$ inch thick, spread on trays, and dry until crisp. Eat dried slices plain, with dip, or chopped in salad or soup. Or pour boiling water over them and simmer until tender. Then mash and season.

COOKING. Store-bought rutabagas have usually been dipped in wax for preservation. Peel. They're good grated raw in salads. Or cook like turnips, but longer. Use in any winter soup or stew. Or cook and mash, or bake in pies, custards, and baked goods (substitute for pumpkin or squash in recipes). Or serve cooked with cream and nutmeg mashed in. Or boil, dice, and use in a veggie salad. Or roast with meat and other veggies.

Salsify

Salsify (*Tragopogon porrifolius*), also called “oyster plant” or “vegetable oyster” in old-time cookbooks, is a very hardy biennial of the family Compositae, grown for its long white root. The roots are hairy and off-white—not much to look at, not very sweet, but flavorful in a different way. Salsify is grown much like parsnips and has all the same problems. In addition, if salsify likes your climate, you have a problem of overabundance if you let it get away from you and do some self-seeding. Then it deserves the name of weed.

PLANTING: In the south, plant in summer for a winter crop. But if you plant before June or July in a warm climate, you may get seed instead of root, even though it is technically a biennial. In the north, plant in April, because it takes 120 to 150 days for the roots to get big enough that there's something left after the peeling. It's also good to plant early, because later plantings have a poorer germination rate. Seed is available from Thompson & Morgan, etc. Plant in very loose, well-tilled soil so that the long, slim roots can find their way down. Plant $\frac{1}{2}$ inch deep, 2 inches apart (thickly due to poor germination); thin later to 6 inches apart. Salsify doesn't like soakings, so don't water unless it's truly bone-dry. Be careful when weeding so that you don't pull out your salsify plants, mistaking them for grass—which is just what salsify plants look like!

SAVING SEED: Salsify is a self-pollinated biennial with “perfect” flowers (meaning they have both male and female parts). You don't need to worry about it crossing with something. Choose the best of your roots to raise seed from in the spring. If your plants are crowded, replant at least a foot distant from each other and in rows 3 feet apart. In its second year, salsify shoots up to 4 feet or higher. In June it grows sizable purple blooms, which are followed by feathered seeds (like those of dandelions). *Don't let salsify seeds get away from you. That's how it can turn into a weed.* Choose your seed heads to save. Harvest in the morning. Dry a few days. Rub those dried heads between your hands to loosen and separate out their seeds. Winnow to clean. The seeds will keep for at least 2 years.

HARVESTING AND PRESERVING: The part you eat is the long, tapering white root; when boiled, mashed, and fried it supposedly has an oyster flavor. At maturity the roots are at least 8 inches long and an inch thick. They don't have their best flavor until they've been through frost, although the youngness, freshness, and tenderness of smaller ones right from the garden can make up for that.

Winter Storage. You can store salsify as you would beets, carrots, or parsnips, but out of the ground it has a tendency to shrivel. The best way of all to store salsify is to leave it right where it is growing. It can survive the winter right in the garden, even as far up as northern Vermont. But put over it a mulch, like a bunch of straw. That will keep the ground from freezing so hard that you can't dig up your salsify. Or you can dig it up in the spring. Or if you're leaving and want to take your salsify with you, dig up the roots, leave

1½ inches of stalk on them, and store between layers of damp sand in a root cellar. To store in the fridge, wash but don't peel. They'll keep several weeks.

Drying. Clean and scrub or peel salsify. Make ¼-inch slices and then either dip them into mixture of 1 T. lemon juice per 1 qt. water, blanch about 3 minutes in boiling water, or steam about 4 minutes. Dry slices in a single layer in a dehydrator or oven at 120°F for about 18 hours. They're done when crisp. Or dry in full sun about 2 days (take inside overnight). Use plain as a snack, toss dried chips in salad, or grate for casserole topping. Or reconstitute with boiling water and simmer till tender.

COOKING: If the salsify is garden-fresh, just scrub the roots, scrape them, and boil or steam in a covered pan until they are fork-tender (10 to 20 minutes). With old or store-bought salsify, use 1 T. lemon juice in the boiling water to prevent darkening. After cooking till tender, serve with lemon juice. Or drain, season with butter, salt, pepper, and parsley if you have it. Or cover with a white sauce.

⇒ **SALSIFY GREENS** You can cook the fresh, slender leaves of spring using any cooked greens recipe. Or use raw in a salad.

⇒ **QUICK SALSIFY FRITTERS** Mash cooked, seasoned salsify and shape into cakes. Roll the cakes in flour and brown in butter.

⇒ **RUTH'S SALSIFY FRITTERS** Mash steamed salsify with tamari. Shape into cakes and fry on a skillet rubbed with a raw potato.

⇒ **MOCK FRIED OYSTERS** Wash, trim, and cook a bunch of salsify in boiling salted water until tender. Drain and scrape off the skin. Mash. (If stringy, put mash through a colander.) For every 2 c. mashed salsify, add 1 t. flour, 1 T. butter, 1 beaten egg, salt, and pepper. Take a spoonful and shape it into an "oyster." Dip the oyster in flour or cracker crumbs. Brown in butter on each side in the frying pan.

⇒ **CREAM OF SALSIFY SOUP** Cook at least 3 salsify roots until tender. In another pan melt ¼ c. butter or margarine. Stir in ¼ c. flour. Gradually add 3 c. milk. Cook until thickened (stir constantly). Add salsify and seasonings (salt, pepper, and/or herbs) to taste.

Scorzonera

Not only does *Scorzonera hispanica* come after "Salsify" in this alphabet of roots, but this long, slender root also tastes, looks, and is grown much like salsify. They are botanically related, although not as closely as scorzonera's other names of "black salsify" and "black oyster plant" would make you think. Like salsify, scorzonera is biennial, has leaves that look like a clump of grass, originated in the Mediterranean area, can grow throughout the United States, was used by the Romans and Greeks, and is important in Spanish and Russian cooking.

How is scorzonera different from salsify? *Scorzonera*, like *Jerusalem artichokes*, contains inulin and can be a good carbohydrate food for diabetics. It has yellow dandelion-like flowers rather than salsify's purple, and its roots are longer, straighter, and thinner. It's dark-colored rather than whitish on the outside, and it's brown inside. Scorzonera produces somewhat bigger harvests than salsify. You can order scorzonera seed from William Dam, DeGiorgi, Johnny's, or Redwood City.

HARVESTING: If you leave scorzonera roots in the ground for 2 growing seasons rather than

just one, no harm is done and your roots will be bigger when you do harvest (as long as 18 inches). Be careful not to accidentally cut off the bottom section of that long, thin, straight root that just goes down and down. Also be careful not to break, scratch, or scrape the root because scorzonera “bleeds” through any such cut and literally loses flavor. The leaves are also edible and can be chopped and added to salads. It discolors when cut, so have ready some water or marinade with lemon juice or vinegar in it. Scrub the outside of the root well, but don’t peel it; peeling seriously diminishes the flavor. If there is any bitterness, soaking in water before cooking will help. Cook and drain; *only then do you rub off the skin.*

RECIPE IDEAS: If your variety of scorzonera has a bitter taste, scrubbing the roots and soaking in water before cooking should help that. Scorzonera usually tastes much like salsify, with the same sweet flavor, and can be substituted in any salsify recipe. It takes about 45 minutes to cook to tenderness. Cook with carrots and potatoes/onions, or boil in any soup or stew. Or serve pureed with milk and butter, like mashed potatoes. Or serve plain, boiled scorzonera with melted butter or a white sauce. Or bake or fry it. Or thinly slice and serve in a vinegar marinade like instant pickles. Or cook first; then slice thin and marinate in that vinegar sauce.

➲ **GOURMET SCORZONERA** Preheat oven to 400°F. Steam 2 lb. peeled scorzonera until tender (about 8 minutes). Remove from heat and dice when cool enough to handle. Mix together scorzonera and 1 medium minced onion, and spoon into greased casserole. Melt 2 T. butter in small pan. Stir in 1 T. flour and simmer 1 minute. Add 1 c. sour cream (heavy or light), plus salt and pepper to taste. Heat gently. Don’t let it boil. Spoon cream sauce over vegetables and toss lightly to blend. Sprinkle with grated Swiss cheese and crumbs. Bake 15 to 20 minutes and serve. From Lane Morgan’s Winter Harvest Cookbook (Sasquatch Books, 1990).

Skirret

Skirret (*Sium sisarum*) is part of the Apiaceae family (carrot, parsley, etc.). An Asian vegetable, it was discovered and adopted in Europe by the time of the Roman Empire, but it’s little-known and seldom grown in the United States. Also called “zuckerwurzel,” “crummock,” and “suikerwortel” in Europe, skirret is a hardy perennial whose edible portion is a cluster of thick, knobby, grey roots that hang down under its crown, kind of like a handful of carrots, so you get about 8 roots from a plant instead of just one.

PLANTING: Skirret can be started from seed or from root divisions, but in the United States it’s usually started from seed. Seed available from Nichols. Plant seed toward the end of March or early April for a fall crop. Plant in well-tilled, loose (sandy is best) soil. Plant in the autumn to get a spring harvest. Plant sparsely. Keep seedbed moist until germination. Once you can see what you’ve got, thin to about a foot apart. Weed and water like carrots. Because the leafy above ground part of the skirret plant is so sparse, it doesn’t shade its neighbors and does fine interplanted with something like lettuce, which will grow and get out of there.

To make root cuttings, follow the instructions for horseradish propagation (in [Chapter 5](#)) since, like that plant, skirret makes thin side roots which, once they develop an “eye” or “bud,” can then be cut off and planted separately any time of year.

HARVESTING: Spring-planted skirret will be ready around October. Basically, you wait to

harvest until the roots are big enough. Skirret is like salsify in that cool fall weather actually improves the crop and the roots get sweeter after frost. Also like salsify, you can leave skirret roots in the garden all winter, digging them up as needed. Or dig in the fall and store like carrots. The colder it is (short of freezing), the better skirret keeps.

COOKING: Clean the roots. Prepare like a carrot or parsnip, except also remove the woody core before cooking. Then boil and serve with butter. Or substitute in salsify or parsnip recipes. Or add to soup or stew. Or mash like potatoes. Or serve like broccoli, with a cheese sauce. Or grate and toss with a salad, like turnips or carrots.

Turnip

Seventh edition. After 2 months of hard work I'm nearing the end of the rewrite of this chapter. As of this moment I'm alternating typing with my new baby, Jacob, on my lap with not typing and holding him on my shoulder and patting him. He is just about the fussiest baby I've ever had. He has a bit of diarrhea, which is getting better, and a bit of a rash, and he sneezes several times a day. It's enough to keep me a nervous wreck. He sure is husky though. The more they yell, the more quickly the lungs and limbs get strong. That's true, if a small comfort, when you're trying to make a squally baby happy.

Turnips (*Brassica rapa*) are easy to grow and good for high altitudes and chilly climates (but switch to rutabaga in the coldest zones). In the South, turnips are a good winter vegetable. You can eat the top for greens. We really like the taste of turnip, both raw and cooked.

WHEN TO PLANT: Turnips have maturing times anywhere from 35 to 70 days. Turnips hate hot weather, especially hot nights, so plant either an early crop, about 35 days before the last spring frost date, or a late one (plant in July or August). If you try to grow turnips through a hot summer, you're likely to get a stringy, strong-tasting root. The late turnips won't be bothered as much with wireworms, and they are the only crop suitable for root-cellар storage. If you live in a really mild-wintered area, plant in late fall for a winter crop.

HOW TO PLANT: Prepare fertile, deeply cultivated soil. Turnips like wood ashes too. Plant seed $\frac{1}{4}$ inch deep and an inch or so apart, 5 to 10 days to germination. If you have really rich soil and are short of garden space, you can put rows of turnips as close as a foot apart or do intensive planting. In containers, plant about 3 in each 12-inch pot. To plant an acre of them (they're good winter animal feed), broadcast-sow and rake lightly to cover. Then give a good watering. When your turnips are 4 to 6 inches high, or when they start to crowd one another while trying to grow, start thinning—to about 6 inches apart. You can eat the thinnings ... or freeze or can them.

HARVESTING

SAVING SEED. Turnips are bee-pollinated, self-incompatible, biennial roots that easily cross with many other brassicas: turnip, radish, rape, mustard, rutabaga, Chinese cabbage, and the wild varieties of turnip and mustard. You're safe from crossing only if your seed bearers are not within $\frac{1}{4}$ mile of any of those related plants while both are flowering. But the problem the first year is to get the parent plant through the winter. In the coldest zones, dig and store the root, and then replant the next spring. In warmer areas, mulch

and leave it in the garden. Allow 18 inches between seeding plants. After seed pods become yellow, cut the stalk and manage like cabbage. Turnip seed is very strong; with care it should keep its germinating power for 5 years or more.

Digging. Turnips can stand some frost. They'll keep on growing if you have some decent weather after the first frost. But the nicest ones for people food are no bigger than 3 inches in diameter. In very mild winter areas you can leave them in the ground and dig as needed until the weather gets so warm that they start to grow again, which ruins them for eating. Turnips can stand top frosting, but alternate freezing and thawing of the root will ruin them. After digging, cut off the tops. Definitely harvest before a hard freeze, or if the tops look yellow and withered.

STORING AND PRESERVING

Ground, Pit, or Cellar Storage. I have neighbors who raise huge, lovely turnips and store them in a root cellar. To do this, leave them in the ground until it's time for a heavy freeze. Then dig up—don't wash!—and store undamaged ones in a vegetable pit or root cellar. If your storage place is too warm, they may start to grow and get pithy. They'll keep 2 to 4 months. Turnips and rutabagas have an odor in storage that can affect celery.

Freezing. Because of my wireworm troubles, I harvest all my turnips early, peel, cut into chunks, blanch a few minutes, cool, bag, and freeze. When I want them, I just turn them out of the bag into a little water and thaw. I usually serve them mashed with a little butter and seasoning.

Canning. Use instructions under "Beet."

Drying. Use young, tender turnips. Peel, thinly slice, shred, or make into $\frac{1}{4}$ -inch cubes. Spread on tray and dry at 120°F until hard and crisp. Use slices as a snack with dip. Add dried bits to salad. If broken up in a blender, it can be added to any casserole or meat loaf. Or add to soup. Or reconstitute by pouring boiling water over and simmering till tender.

RECIPE IDEAS

Raw Turnips. These are good sliced thin and dipped into a seasoned sour-cream dressing (let each person do their own dipping) or served grated with such a dressing. Turnip slices are good with carrot sticks and celery; the sharper taste of the turnip slices complements the blander vegetables. I also love turnip grated, added to a tossed green salad, and served with a dressing.

➲ **TURNIP SLAW** Prepare 4 c. pared and shredded turnips and 2 cored and diced red apples. Mix with 2 T. chopped parsley and 2 T. minced onion. Stir together $\frac{1}{2}$ c. sour cream, 1 T. vinegar, 1 T. honey, and salt and pepper to taste. Combine dressing with vegetables.

Cooked Turnips. Cook turnip greens like any cooked greens. Turnip roots can be eaten from 1 inch in diameter on up. Cook small ones whole. Slice larger ones about $\frac{1}{2}$ inch thick. Small turnips can be cut into wedges and used in a stir-fry. Cook larger ones by steaming or boiling until tender enough to pierce with a fork. Serve plain or with lemon juice or tamari drizzled over cut surfaces while hot. Or add to any sort of potato, cabbage, or meat dish. Or make a pea-carrot-turnip soup. Or serve sliced cooked turnips with cream or a white sauce. Or cook in just enough stock or consomme to cover, and save liquid; take out and mash turnips, return them to the liquid, and simmer until all is absorbed. Or peel,

slice, blanch, briefly pre-cook, and then bake ½ hour in a sauce of dry mustard, brown sugar, maple syrup, salt, and pepper. Or roast with meat and other vegetables. Or wash and wipe turnips (but don't peel), bake until tender, peel, and serve either mashed or with a white sauce.

Water Chestnut

The water chestnut (*Eleocharis dulcis*) is a Chinese aquatic plant distantly related to chufa. You harvest the brown-or black-colored base of the stem, a corm. This tender perennial (suited for zones 7–10) will need protection from winter cold. Propagate by planting offsets (offshoots). Plant in a pool, a bog garden, or a large container of water. Harvest the corms in the fall. They're delicious fresh. If you blanch them, the skin easily comes off. To preserve the white color, store in water that has a little lemon juice or vinegar added. This vegetable stays crisp even when cooked. Serve raw sliced in a veggie salad, or plain with dip. Or add to an omelet, a soup, or a stir-fry dish (good with green beans).

Buy this and other wonderful aquatic plants from:

THE GOURD FAMILY

These are squashes, melons, and cukes. Botanically, the gourds' closest relatives are the brassicas, that other great cluster of related food plants. Along with bean and cereal crops, edible gourds were humankind's first cultivated crops. Squashes, pumpkins, and chayote, developed by the civilizations of the ancient Americas, are now grown worldwide. Watermelon and muskmelon originated in Eurasia and Africa. They're all part of what's variously called the gourd family, "gourds" (but the gourds technically are an ornamental kind of squash), cucurbits (Latin for the squash portion of the family), or "melons" (another subdivision of the family). (Are you confused yet?) Most cucurbits are tropical perennials grown as annuals, so they generally won't germinate if your soil is cold and wet, although squashes are more tolerant of cold than the others.

Botanical Groups and Seed Saving

There are 3 main botanical groups of cucurbits (gourds):

- Squashes: Species of the *Cucurbita* genus, including all the squashes (summer, winter, and exotic) and pumpkins
- Melons: Netted and smooth-skinned muskmelons (*Cucumis melo*) and watermelon (*Citrullus lanatus*)
- Cucumbers: *Cucumis sativus*, including citron and all the cucumber varieties

SQUASHES: Seed saving is most complicated with the squash group because the group doesn't subdivide in a simple way. But you'll be able to save seed if you have just one kind each of

C. pepo and *C. maxima* flowering at once. Or grow them at least 500 feet apart. Remove seed from ripe fruit, wash away the pulp, and spread out to dry. (See “Saving Seed” section in “Cucumbers.”) If stored in a cool place, they will survive up to 7 years. To help you better understand what will and will not cross, here are the squashes’ botanically based subdivisions.

***Cucurbita maxima*.** All the big, hard-shelled winter squashes (Hubbards, Marblehead, Chestnut, and Sweetmeat), the giant types of pumpkins (Hungarian Mammoths, Big Macs, Buttercup, Boston Marrow, Delicious, Turban, etc.), and the Japanese varieties (Green Hokkaido, Orange Hokkaido, and Red Kuri).

ABOUT VINES

Most of the members of the gourd family have trailing (“running”) vines with large, lobed leaves and pretty white or yellow edible flowers. Every year we set aside a big section of the garden for these vine-type crops that are planted in hills instead of rows—the cucumbers, watermelons, muskmelons, pumpkins, and summer and winter squashes. But space is a problem for lots of people, so some squashes now come in “bush” varieties, which have smaller fruits but don’t spread out as far.

Or you can hold back the vines by picking off their fuzzy, growing tip. Not only do you save space, but you may increase fruit production and speed up fruit ripening if you continuously take off all the fuzzy ends starting in August. And they’re edible. Use in any greens recipe.

Another method of compensating for the space the vines need stems from the fact that they start slowly, so it’s a long time before they need all that space between the rows. You can grow early beans or peas between the squash rows and then take them out after your harvest in June or July, when the cucurbits are starting to seriously run.

Or send the vines up instead of across by providing a trellis or pole. In that case, you tie the plant to the support at about 1-foot intervals, or just twist its stem gently around the support. Some will climb on their own. If you plant cukes next to chicken wire or staple the wire to poles next to the young plants, they will climb it as they grow.

These will not cross with *C. pepo* but will cross with each other and with *C. moschata*. The *C. maxima* members need a little more warmth to sprout and take several weeks more to mature (about 120 days) than do *C. pepo* members. They have the nicest seeds for eating, bigger vines, larger leaves, and a soft, round, hairy stem. If you don’t get them completely mature, the seed won’t germinate well and the flesh won’t taste as good as it could. If thoroughly cured after harvest, they have very good storing qualities and maintain their quality and smooth texture all winter.

***Cucurbita mixta*.** Less-familiar Asian varieties (cushaw squashes, certain tropical pumpkins). Will cross with each other and with *C. pepo*.

Cucurbita moschata. Butternut, melon squash, and calabaza. These will cross with each other and with *C. maxima* and *C. pepo*. They are long-maturing (120 to 130 days) for seed or flesh and generally require even more heat than *maxima* or *pepo*, getting fully ripe only in the southern zones. They have a 5-sided coky but smooth stem, which flares out at the site where it meets the fruit.

Cucurbita pepo. All the summer squashes (crooknecks, zucchini, etc.), some winter squashes (acorn, Delicata, Benning's, Green Tint, Vegetable Gourd, Vegetable Spaghetti, White Bush Scallop, and Gem), common orange Halloween pumpkins, the lagenarias (including cocozelles and ornamental gourds), and 2 Japanese varieties (Hyuga Black and Kikuza White).

C. pepo members will not cross with *C. maxima* members, but they will cross with each other and with *C. moschata* and *C. mixta* members. *C. pepo* members have small seeds and are quickest to mature (about 90 days), thus best for northern gardeners. They come in bush or vine and have a 5-sided stem like *C. moschata*, 5-sided branches, and spines. For winter storage, the winter squash-type *C. pepo* members (such as acorns and pumpkins) don't require as much curing as *C. maxima* members, but they also don't keep their good flavor or texture longer than a couple of months.

CUCUMBERS: The cucumbers don't cross with any of the others, only with each other and with citron. Grow different cucumber varieties 1,000 feet apart, or hand-pollinate. Seeds are ripe only when fruit is dead-ripe and yellow. (See "Saving Seed" section in "Cucumbers.")

MELONS: The netted-skin cantaloupes don't cross with the smooth-skinned muskmelons, and neither cantaloupes nor muskmelons cross with watermelons, so you can raise all of these three in the same garden for seed. Seeds are ripe when the fruit is ripe enough to eat. (See "Saving Seed" section in "Cucumbers.")

Pollination and Flower Eating

Cucurbits usually have both male and female flowers on each plant, but sometimes plants have only one sex of flower, so always plant at least three to be sure they'll fruit. Another potential difficulty is that all cucurbits are bee-pollinated, and bees are sometimes scarce nowadays due to pesticide spraying. Lack of bees results in small or poorly shaped fruit or no fruit. If you have no bees, the only way to get a crop is to hand-pollinate.

HAND-POLLINATING CUCURBITS: There are 2 kinds of blossoms: males and females. You can tell a male by its thin stem. The female is bright yellow and generally has a tiny cucumber or pumpkin or such already formed at its base. When a male blossom is so full of ripe pollen that some will dust off on your fingertip, cut off the blossom and carefully touch the sticky stigmas in the center of each female blossom with this pollen. That solves your problem. There are typically more male than female flowers—although some recently developed plants have only female flowers (are "gynoecious"), and they bear more fruit.

CUCURBIT BLOSSOM RECIPE IDEAS: Fried squash blossoms are a traditional native American delicacy. But all the cucurbits have edible blossoms. If you pick only the male flowers (the ones with long, thin, upright stems), you won't be depriving yourself of any fruit.

⇒ **SQUASH BLOSSOM FRITTERS** From Jan Franco, Hamden, CT, who also wrote me these beautiful words: "I used to work in a library, and I love books and used to buy them when

possible—being especially partial to anything with ‘complete’ in the title. Well, my husband says this is the first truly ‘complete’ book I have, because it’s the only one that includes the most important topic: the Lord, in addition to all the self-sufficiency information. After all, no matter how self-sufficient we may be, we’re all dependent on Him ...

“Pick a dozen or so male flowers. Pick at a time when the flowers are open to make sure there are no bees trapped inside. Make a batter from 1 egg, $\frac{3}{4}$ c. whole wheat (or white) flour, 1 t. baking powder, and a little milk. Coat the flower with batter and fry in a little oil until lightly browned. Yum. Also can be frozen; warm it in the oven. We use flowers from zucchini or pattypan squash. An Italian favorite!”

⇒ **STUFFED BLOSSOMS** Lane Morgan says, “You also can stuff blossoms with cheese and herbs before frying. Just sort of twist the flower tips into a spiral to hold the stuffing in.”

Eating Cucurbit Seeds

Originally, the flesh of the squashes was inedible. Students of ancient humankind think that the first parts of the squash plants that were eaten were the seeds. The seeds of almost any mature, large-seeded squash can be dried, roasted, and eaten. But over centuries, Incan, Mayan, and Toltec gardeners gradually selected the most promising seeds until they got the familiar edible-fleshed squashes.

The problem is shelling them. Some people chew and eat them shells and all, but they taste sort of woody that way. But modern seed savers have taken squash seed evolution one step farther, and now we have the Lady Godiva variety, whose seeds have no shells!

The following recipes will work with any *large* cucurbit (or gourd family) seeds.

⇒ **PUMPKIN SEEDS** My friend Jeanie gave me this recipe. She used to live in the Bronx, and now she lives down the road with her husband, mother, father, sister, and sister’s husband. Open the pumpkin and remove the seeds. Let the seeds dry for 2 days. They can be spread on a tray or on newspaper. Just before roasting, rub the seeds between your fingers to remove that thin, papery outer skin. Then dry in the sun a few days, in the oven a few hours, or in the broiler under a low flame for about 15 minutes. (When they’re brown and start popping out of the tray, they’re done.) A moment before removing them from the oven, sprinkle them with tamari. Or just toast and then brush with melted butter and sprinkle with salt. In Latin America, roasted squash seeds are ground, transformed into a seasoning paste, and used to thicken and flavor sauces.

⇒ **SALTED ROASTED PUMPKIN OR SQUASH SEEDS** Wash seeds. Boil them in salted water (2–3 T. salt per 1 qt. water) for about 15 minutes. Drain. Spread on a cookie sheet with a little oil or melted butter. Roast in a moderate oven (350°F) until brown and crisp. Flavor as above.

Also see Watermelon Seeds recipe under “Watermelon.”

The Gourd Family, Classified by Use

The following sections contain detailed information about growing and using each member of the gourd family. I’ve sorted the gourds into the following groups.

I. Squashes

A. Summer squashes (zucchini, etc.)

- B. Winter squashes (including pumpkin)
- C. Exotic squashes (bitter melon, calabaza, chayote, fuzzy and winter melon, Lady Godiva, and spaghetti squash)
- D. Craft gourds (*lagenarias*, including cocozelle)
- E. Squash sponge (luffa)

II. Melons (cantaloupe, honeydew, and watermelon)

III. Cucumbers (including citron)

SQUASHES

Summer Squashes

When somebody tells you zucchini is Italian soul food, that's okay. But if they say zucchini came over on the boat with Columbus, inform them they've got the direction backwards. Both summer and winter squash are natives of the United States that migrated to Europe! A meal of squash, beans, corn, and venison was a basic native American supper. Summer squashes are grown, cooked, and preserved quite differently than are winter squashes (see next section). Zucchini, marrow, scalloped pattypan squash (or "white bush scallop" or "cymling"), cocozelle (see "Craft Gourds"), yellow crookneck, and yellow straightneck are some varieties of summer squash.

CLIMATE AND SOIL: I've never heard of a place you couldn't grow summer squash. The longer the growing season, the longer they bear. In 40 to 55 days your first young summer squash is ready to eat. There's no point in starting them indoors and transplanting because they can't take having their roots disturbed. Summer squashes need to be planted in warm soil, well past frost, and they need warm weather to grow in. They like well-manured, well-composted soil and wood ashes. Keep down the weeds.

PLANTING: How many plants? Summer squashes are prolific—especially zucchini! Even when small children plant and care for it, it grows. It blooms abundantly without fail and produces abundantly. Two plants are probably enough for a small family, 4 plants provide plenty for you plus some to give away to friends, and 8 plants give a large family

a whole winter's supply. If you plant a whole package of zucchini seed, it will grow and grow and grow. There will be no way to eat, use, or give away all that summer squash—unless you have animals, that is. We grow it for pig feed. Plant summer squash 1 inch deep, 4 feet between hills and 4 feet between rows. For a container garden, plant 1 per 8-inch pot, 1 foot deep, 5 gallons of soil per plant, 2 feet between plants if they're in something like a window box.

HARVESTING: Pick your zucchini when they're small. You'll get the tastiest, tenderest ones if you harvest them very young, when they're less than 4 to 6 inches in diameter (if they're the kinds that grow long). Harvest when the skin is so tender that you can easily press your fingernail through it. You'll also be spared wondering how to use the extra pounds of veggies that will grow if you leave them on the vine a few days longer. As long as you keep picking, your plants keep producing. If you leave squashes unpicked, they get bigger, their skin gets tougher, and their seeds get bigger and tougher. But the squashes are still edible. If you're fully supplied and your summer squash plants are still producing—which they will do as long as you keep picking and frost hasn't arrived—you can quit watering them. Or let them grow the last squashes undisturbed for a seed crop. Or attack the plants with an ax while screaming!

PRESERVING: Cellar-store, freeze, can, or dry your summer squashes.

Cellar-Storing. Let the squashes grow as big as they will; pick and store in a cool place. They'll keep a couple of months or so. From Kat Atkins, Coquille, OR: "I save the huge zucchinis and put them in with the winter squash. They turn from green to yellow. Out of an average 20, I have to cut off a 6-inch section as one starts to soften. The rest I cook whole, cut in half and, depending on how we had it last, I clean it out and fill it with butter and syrup, honey, hot applesauce, or ... Here I've already started my seedling plants for this year, and I have 2½ boxes of zucchini left. Maybe a cake?"

Freezing. Wash; peel if you like. Slice about ½ inch thick. Blanch about 3 minutes, chill, and package. This works fine with great huge summer squashes as well as with little ones. I don't freeze more than a few bucketfuls though, because my family just doesn't have that much desire for frozen zucchini.

Drying. Wash; peel if you like. Slice ¼ inch thick. Recommended: Steam 6 minutes. Spread in thin layer. Turn as necessary while drying so they won't mildew. Dry until brittle. Dried summer squash is good with dips (eat like potato chips—it's better for you!). Try them with a yogurt-based dip or in soup.

➲ **ZUCCHINI CHIPS** *From Ruth of Bonaire: "Slice zucchini in ¼-inch slices and dunk in tamari. Sprinkle with paprika and then dry until crispy using a dehydrator (12 hours), a 100°F oven (16 hours), or the sun (time varies). Store in plastic bags at room temperature." Yellow straightneck squash is good fixed this way.*

➲ **DRIED OVERGROWN ZUCCHINI** *To manage overgrown zukes, cut into sections, peel, remove seeds, shred, and dry. Don't blanch. Use in soup and spaghetti sauce and in casseroles (mix with shredded cheese), where it will soak up broth and thicken.*

Canning. The USDA does not recommend canning summer squash. However, here are 2 recipes for summer squash combos that are recommended by the USDA.

➲ **CANNED TOMATOES WITH ZUCCHINI** *An average of 12 lb. of tomatoes and 4 lb. of zucchini is needed per 7-qt. canner load. An average of 7 lb. of tomatoes and 2½ lb. zucchini*

is needed per 9-pt. canner load. Wash tomatoes and zucchini. Scald and peel the tomatoes. Slice or cube the zucchini. Bring tomatoes to a boil and simmer 10 minutes. Add zucchini and boil gently 5 minutes. Fill jars with mixture, leaving 1 inch headspace. Add 1 t. salt per quart if desired. Adjust lids and process in a pressure canner: 30 minutes for pints, 35 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

⇒ **SUMMER SQUASH BREAD-AND-BUTTER PICKLES, CANNED** Substitute zucchini or any other slender (1 to 1½ inches in diameter) green or yellow summer squash for the cucumbers in the Bread-and-Butter Pickle recipe in the “Cucumbers” section.

COOKING: Mary Ann Shepherd, Del Mar, CA, wrote me: “Last year we really overprogrammed on zucchini, and one of our house guests reported that when you visit the Shepherds, you have zucchini for breakfast (bread), lunch (raw in salads and pickled), dinner (as a vegetable—grated and stir-fried with mushrooms) and dessert (chocolate cake) as well as for canapes (raw sticks marinated in salad dressing or raw sticks to dunk with), and she expected the furniture to be made from it next year!”

Both these garden-to-table cookbooks have very good zucchini sections: *The Home Garden Cookbook, from Seed to Plate* by Ken and Pat Kraft and *The Kitchen Garden Book* by Stringfellow Barr and Stella Standard. Lane Morgan says: “I like *The Zucchini Cookbook* by Paula Simmons [Seattle: Pacific Search, 1975]. She has good recipes for stuffing the great big ones. The *Territorial Seed Co. Cookbook* has 33 mostly wholesome zucchini recipes, including my personal favorite.”

RECIPE IDEAS: With zucchini that has been harvested young, frying, baking, or steaming give you better results than boiling because summer squash is mostly water anyway. You don’t have to peel ’em unless they’re old and tough-skinned. For more recipes suitable for summer squash, see “Using” under “Chayote” and “Recipe Ideas” under “Fuzzy Melon” (both are in the “Exotic Squashes” section).

Raw. Serve raw in sticks with a dip. Or serve grated or chunked in a tossed salad with a zesty dressing. Or make into a salad dressing: peel, de-seed, chop 2 or 3 large cucumbers, liquefy in blender, add a few squirts lemon juice and a dash of garlic powder (or 1 small minced clove), and thicken with tahini.

Sautéed. Slice and cook in butter 10 minutes. Or slice, dip in egg batter and then flour, and French-fry. Or fry in butter in a pan with chopped onions. Or mix chunks with chopped parsley and basil and add to an omelet. Or stir-fry with onions, carrots, meat strips, garlic, and a bay leaf. Or stir-fry with sliced mushrooms, sprouts, beef slices, tomato slices, and soy sauce. Or sauté sliced zuke with precooked chopped onion and bacon, canned tomatoes, and a bit of seasoning (garlic, oregano, basil, salt, and pepper) until all is cooked and hot (from a precious saint, reader Tannis Prosser). Or stir-fry shredded summer squash and onions together in a little tamari with a pinch of curry, or use tomato sauce instead of tamari and add a pinch of basil and oregano (from Ruth of Bonaire).

Baked. Or bake in an oiled casserole dish (with tomatoes, garlic, and basil or fennel) with Parmesan cheese on top. Or bake in a casserole dish halved or quartered summer squash layered with pork chops and halved onions. Or slice into ½-inch slices, put into a baking dish, dot with butter, sprinkle with salt and finely chopped onion, add just enough water

(or cream) to cover the bottom of the dish, cover, and bake until tender. Or slice into a baking dish, add enough tomato juice to barely cover, and bake—or cover with homemade tomato sauce mixed with a little soft tofu (this makes a good main dish). Or grate and add to any bread mix.

⇒ **MASHED ZUCCHINI** *Mash 1 zucchini. Mix with 1 grated onion, 1 c. mashed cooked cauliflower, garlic, and a dash of tamari. Add ¼ c. whole wheat flour and ½ t. baking powder. Bake 1 hour at 350°F.*

Boiled. Boil in a little water until tender; then drain, season with butter, and serve. Or cook, mash, season, and serve. Or boil briefly with cut-up green peppers and tomato, garlic, and oregano. Or simmer chunks with onions, tomatoes, and fennel until tender. Or slice zuke into frying pan; add 1 T. tamari, 1 T. water, a bunch of sliced green onions, and 1 T. chopped fresh herbs for each zuke; cover and steam until tender (about 5 minutes).

⇒ **LANE'S MOM'S ZUCCHINI SOUP** *"My mom makes the best zucchini soup: Steam and puree a bunch of young zucchinis. Add a little milk and/or chicken stock, some sauteed onion, some parsley and dill or other herbs to taste, and a bit of salt and pepper. Serve hot or cold, with a little yogurt or sour cream on top. Use the nicest, youngest zucchinis for this—that's where the good flavor comes from."*

⇒ **CHEESE SUMMER SQUASH** *Cut maybe 9 little squashes in half and steam in water 10 minutes. Then lay in a buttered ovenproof dish, sliced sides up. Sprinkle with salt and ½ t. sage. Dot with butter. Sprinkle about ½ c. grated Cheddar cheese over the top and put in 325°F oven until cheese is melted.*

⇒ **SOUR CREAM SUMMER SQUASH** *Cut about 2 lb. squash into 1 inch slices. Sprinkle them with ½ t. salt. Let stand an hour and then drain. In a frying pan, saute squash in margarine or oil with ½ c. chopped onion. When squash is tender, add 1 c. sour cream mixed with 4 t. flour. Bring to a boil. Sprinkle with paprika and serve.*

⇒ **BAKED SQUASH SOUFFLE** *From Arlene Jackson, Santee, CA: Boil 3 or 4 zucchini squashes until tender. Mash. Brown 1 diced medium-sized onion in margarine. Add to mashed zucchini some onion, grated cheese, 2 or 3 beaten eggs, a pinch of garlic, and salt and pepper to taste. Mix and pour into casserole. Dot with butter and, if desired, grated cheese (Parmesan) or cracker meal. Bake about 1 hour at 350°F. Slivered almonds browned in margarine can be added to topping.*

Winter Squashes

You never use winter squash when it's green and small, the way you do summer squash. You let winter squash thoroughly ripen on the vine. Winter squash tastes way different too. It's a very nourishing vegetable, different from summer squash that way too, resembling sweet potato in taste, texture, and uses.

VARIETIES: The winter squashes look very different on the outside, but all are grown, harvested, and prepared in a similar way, and they taste similar too. You can grow 5-lb. butternut or buttercup squashes, a 15-lb. Hubbard (a good pumpkin substitute in recipes), 25-lb. Marblehead squashes (seed available from Abundant Life), or 600-lb. giant pumpkins. The banana squashes get quite large too. Among the smallest winter squashes are the acorn, Delicata, and Sweet Dumpling squashes. All of those are just the right size for 2 servings. You can order Red Kuri and Pink Banana from Southern Seeds. Tahitian

squash can be eaten like a summer squash when immature and treated like a winter squash when fully grown (up to 2 feet long). The “turban,” or buttercup, squash can grow bigger than a foot in diameter and is a very good winter keeper. “Sweet dumpling” is a little one (4 inches across) from the Philippines. Use like an acorn. Delicata tastes best when its skin looks yellow and its stripes are nearly orange. The Asian “kabocha” squash, or “Japanese pumpkin,” gets very big. The banana squash is a kabocha relative from Asia.

Pumpkin. Pumpkin is a kind of squash, a *C. pepo*. The pumpkins and the big winter squashes grow more pounds of flesh per plant than any other garden veggie I can think of. My problem has always been finding a way to use them other than letting the children make 6 jack-o’-lanterns apiece. When we harvest, the nicest ones are set aside to be jack-o’-lanterns. Lane Morgan says she likes to “go out in the field when they are getting big but are still green and thin-skinned, and incise the kids’ names or designs or whatever into the skin with my thumbnail or a pocketknife. The cuts heal into a raised scar as the skin hardens (I’ve never had one rot from this treatment), and the result is a delight to the young ones when they search for their own monogrammed pumpkins at harvest time.” After the jack-o’-lanterns have run their course, they go to the pigs.

Seeds from the world’s biggest (500–700 lb.), smallest (2” × 3”), and many other varieties of pumpkin are available from pumpkin specialist Howard Dill Enterprises, RR#1, Windsor, Nova Scotia, B0N 2T0, CANADA; 902-798-2728; fax 902-798-0842; www.howarddill.com.

PLANTING: Your winter squash will be ready to harvest in 80 to 120 days after planting, pumpkins in 100 to 120 days. Plant squash or pumpkins in early midsummer, after the weather is definitely past the last frost and has warmed up comfortably. Plant 1 inch deep, about 4 seeds to a hill, hills about 3 to 6 feet apart each way depending on your variety. Allow 7 to 10 days for germination. After the vines start to grow, be careful not to hurt them when weeding. And water—all winter squashes need lots of water, especially once they start making fruit.

HARVESTING AND CURING: Leave winter squash or pumpkins out there until after the first frost or longer, but don’t let them freeze. Then go out and cut the stems about an inch from the fruit. Let cure in the field for a few days or up to 2 weeks, depending on your weather. Then bring them into the warmest room in your house for the next stage of curing. At temperatures of 80 to 85°F, the rind will harden and the fruit will heal its own surface cuts. But handle gently, because the fruit can’t heal itself of bruises, and the bruised places will rot first. Squashes so blemished they won’t keep go to the pigs. If the squashes freeze, as soon as they start to thaw they also start to spoil, and your only alternative is to cook

them all right away; then mash and freeze them, or can them.

Storing. Commercial squash crops are stored here in special barns where a fire is kept burning all the time in cold weather, so they won't freeze before markets open up for them. Then they are cut into big chunks and sent to market in an insulated truck. *Stored squash and pumpkins must never freeze. That ruins them completely.* It's best if they don't touch each other in storage; they tend to go bad at the point where they touch one another. If your regular checks show that you have one with a bad spot, just cut out the spot and cook up the rest of it. We keep ours in the attic, spread out on newspapers. Fortunately, I have a very large, cool attic. Wooden shelves would work fine for them, too.

I read a university handout which says that at over 60°F they get too dry, and at under 50°F they get "chilling injury." Everybody around here simply does the best they can to keep them from getting frozen, and that's good enough. Everybody's system is different. You just have to think about all the nooks and crannies of your own set of buildings, and don't put the squash in the root cellar (don't put onions or pumpkins there either) because dampness really harms them and will soon result in rot. We eat acorn squashes during the first part of the winter and then switch to the Marbleheads. With luck, some of those big squashes harvested in October will still be fine in late March; at worst, they'll make it to February. The ones that go bad are passed on to the pig. After the Marbleheads are gone, frozen squash is the best thing. You can freeze squash in the late fall and all winter at your leisure.

Squashes for Fodder. The big winter squashes are useful as winter food for people and for animals too, especially goats. If you can't raise grain, you can winter your goats on stock beets, carrots, and squash, along with just a little purchased grain and hay. Cows or pigs will use winter squashes for winter feed too. Rotted squashes or bad spots you've cut out can go to the pig. Squashes have to be cut into pieces before you give them to the animals.

Cutting. Cutting big stored squash is really a job. The longer they have been in storage, the tougher the peel gets. You can open tough squashes by literally hammering a butcher knife through the shells. Or saw the shells. Always cut lengthwise.

PRESERVING SQUASH OR PUMPKIN

Freezing. Cut open your winter squash or pumpkin. Remove stringy fibers and seeds (save them for seed or snacks). Cut into pieces and cook until soft in as little boiling water as possible. Or steam in a pressure cooker or bake in the oven. You can bake a whole big squash; it takes about 2 hours. Then you cut open, remove seeds, and mash. Or bake or boil sections and, after the squash is cooked, scrape off the rind and mash the insides (use a masher or rotary colander or push through a sieve). (Using a masher is by far the easiest way.) Then package and freeze. There's no good way to cool it, so just don't put more in the freezer than it can handle each day.

I thaw a bag of frozen squash in a frying pan with a little water, butter, and honey. Mix well and serve hot. Substitute for sweet potatoes on Thanksgiving or at any other time. Around here, squash is much cheaper and easier to grow than sweet potatoes. You can use it in pies or add it to bread dough.

Drying. Pioneer Americans dried pumpkins a lot. Their method was generally to slice the pumpkin around in circles, scrape out the seeds and strings, peel it, and let the circles hang in the air, out of direct sunshine, until they were dried. Another method: Cut into

small pieces, seed, peel, cut into 1-inch strips, and cut those $\frac{1}{4}$ inch thick. Or shred it. Dry until tough.

⇒ **SQUASH/PUMPKIN LEATHER** Cook and puree. For each 2 c. puree, add $\frac{1}{2}$ c. honey, $\frac{1}{4}$ t. cinnamon, and $\frac{1}{8}$ t. each of nutmeg and cloves. (Other options: Combine with apple puree. For spices, substitute ginger and pumpkin pie spice. Sweeten with white or dark corn syrup rather than honey. For each 1 c. steamed squash, pumpkin, yam, or sweet potato, add 1 c. mashed banana, 1 t. pumpkin pie spice, $\frac{1}{2}$ t. vanilla, and $\frac{1}{2}$ c. chopped nuts; dry like a fruit leather.)

Canning. Wash; remove seeds. Cut into chunks and peel. Cut the peeled chunks into 1-inch cubes. Add just enough water to cover. Boil 2 minutes. Optional: Add salt. Put chunks into clean canning jar. Pour cooking liquid over, leaving 1 inch headspace. *Caution: Do not mash or puree before canning.* Process pints 55 minutes, quarts 90 minutes, in pressure canner only. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

COOKING SQUASH AND PUMPKIN: Basically you start any recipe by boiling, baking, or pressure-cooking the flesh. If you then mash, you've got the equivalent of the canned pumpkin that is called for in most recipes. Just substitute from there.

Boiling. Halve the fruit and scoop out the seeds and stringy fibers that are mixed up with them. Peel and cut what's left into cookable-sized pieces. Boil until tender (a half hour or so). To pressure-cook, cook the peeled pieces 15 minutes at 15 lb. pressure.

Baking. Arrange your peeled pieces cut side down in some sort of baking pan. Bake about an hour at 400°F. Then scoop out the part that stayed soft and mashable. Another system is in Ruth's Vegan Squash Pie recipe a bit later on. Of that one, Lane Morgan says, "That's how I always prepare my pumpkins for pies, except I scrape out the seeds before I bake because I don't know how good they'd be for roasting after being cooked in all that moisture. You don't have to peel or chunk the pumpkin, and I hate peeling pumpkin. Don't use a rimless baking surface because the pumpkins will 'weep' as they cook. I save that liquid to get the puree going in the blender."

Instant Mashed Squash/Pumpkin. Blend 2 c. cut-up pumpkin with $\frac{1}{2}$ c. water until smooth. If you aren't going to use your puree in a recipe where it will get cooked, you can cook it plain in a pan, but you have to stir constantly to prevent burning.

Recipe Ideas. For more recipes suitable for winter squash, see the recipe ideas under "Winter Melon" (in the "Exotic Squashes" section).

⇒ **SQUASH HALF (OR CHUNK) BAKED IN THE SHELL** This is my family's winter squash favorite. We use acorn squashes. I cut them in half (or into appropriate-sized baking sections) and remove seeds. In the cavity of each squash half, I sprinkle a little brown sugar and butter. Or some cooked bacon bits and butter. Or maple syrup. Or a honey/mustard mix. Or I mix $\frac{1}{2}$ c. orange juice concentrate, $\frac{1}{2}$ c. honey, salt, 2 T. butter, and $\frac{1}{8}$ t. nutmeg and divide this among the squashes. Or combine prefried crumbled bacon (about 4 slices), half a small onion (cut up and sauteed), $\frac{1}{2}$ c. brown sugar, a big pinch of ground cloves, and $1\frac{1}{2}$ c. peeled apple sections. In any case, put filled squashes in a loaf pan, sprinkle bacon bits on top, and bake in a loaf pan at about 350°F until fork-tender. Or stuff with a meat-loaf mix and bake. Or fill with a mixture of chopped apples, raisins, bread crumbs soaked in orange juice, a little honey,

cinnamon, and cloves.

Then serve. Since it's hard for any child (or most adults) to eat an entire half of an acorn squash, we carve them up at the table and serve the pieces, trying hard not to lose much of the filling in the process. Then just spoon the squash off the rind into your mouth. Use mashed leftover squash in any baked goods (bread, cookies, cakes, and muffins).

⇒ **SQUASH STUFFING** Mix together 2 c. mashed squash, 1 egg, 1 c. each finely chopped onion and celery, 1 T. chopped parsley, 1 chopped green pepper, 2 T. melted butter, ½ t. sage, and a dash of thyme.

⇒ **VEGAN SQUASH PIE** From Ruth: Cut 1 large or 2 medium butternut squashes (you can substitute any other winter-keeper squash) in half lengthwise and bake, cut side down, for an hour (till very soft when forked). Discard seeds. Then scoop out flesh and puree in blender till smooth—add ½ c. maple syrup or honey, 1½ t. cinnamon, ½ t. nutmeg, ½ t. ginger, 2 T. tahini (sesame seed butter), and ½ c. rice (or soy milk). Bake in pie shell or glass baking dish at 375°F for 30 minutes, till slightly browned.

⇒ **BANANA SQUASH SEEDS** The banana squash has very big seeds that taste great when roasted.

Pumpkin Recipe Ideas. Check out a copy of *The Pumpkin Eater Cook Book* by Phyllis E. Strohsahl, or substitute in a squash or sweet potato recipe. Or try one of these ...

⇒ **PUMPKREAM PIE** It was a red-letter day for me indeed when this one came in the mail from Esther Shuttleworth, mother of the famous editor of Mother Earth News (John): Mix together 1 c. granulated sugar, a pinch of salt, 1 t. cinnamon, ¼ t. cloves, and ¼ t. nutmeg. Beat in 2 eggs. Then add 1 c. well-cooked-down (cooked-dry) pumpkin. Add 1 c. thick cream or whipping cream. Bake in an 8-inch pie pan, which will be full, for 20 minutes at 425°F. Then reduce to 375°F and bake until it rises and then makes small cracks around the edge.

That reminds me of another exciting day. I answered the telephone, and it was a lady from California wanting to order a hardcover copy of the book for her grandchildren. The address she gave me was "Marian Anderson ..." I asked, "Are you Marian Anderson, the great singer?" And she said, "Yes!" She had a strong, lovely voice, even just talking over the telephone, and she was a thoroughly enjoyable lady to talk to.

⇒ **IVY'S PUMPKIN PIE FROM SCRATCH** Ivy Isaacson lives here in Kendrick and helped me a lot with mimeographing earlier editions of this book. I got a request in the mail for a pumpkin pie recipe from scratch, and Ivy offered hers. Here it is for everybody: Cut pumpkin in pieces; peel and cook in small amount of water. Drain well, mash, and put through strainer. Line a 9-inch pie pan with plain pastry. Set oven at 450°F. Mix 1½ c. of your cooked and strained pumpkin, ⅓ c. brown sugar, ⅓ c. white sugar, 1 t. cinnamon, ½ t. ginger, ¼ t. nutmeg, ½ t. salt, 2 slightly beaten eggs, 1½ c. milk, and ½ c. cream or evaporated milk. Pour into pie shell. Bake 10 minutes; then lower heat to 300°F and bake until firm (about 45 minutes). For spicier filling, add ¼ t. cloves.

⇒ **VEGAN PUMPKIN PIE** From Ruth of Bonaire: "Take 2 c. cooked-down pumpkin, 1 c. rice cream cereal (cooked and cooled), 2 T. tahini, ½ c. apple juice (or ¼ c. juice and ¼ c. honey), 2 t. each of allspice and fresh grated ginger root, and ¼ t. cloves. Puree all that in a blender until very smooth, and then bake in an ungreased glass baking dish 30 minutes at 375°F or until set."

Exotic Squashes

These include the bitter melon, calabaza, chayote, fuzzy and winter melons, Lady Godiva, and spaghetti squash.

BITTER MELON: Bitter melon (*Momordica charantia*) is also known as “foo gwa,” “balsam pear,” “kareli,” and “bitter cucumber.” It’s native to Asia and India. Perennial in the tropics, it can be grown annually in zones 5–10. The vine will climb up to 20 feet.

Using

NOTE: *Don’t eat the seeds of a ripe bitter melon. They’ll make you sick.*

The fruit is very bumpy and ridged on the outside; otherwise it resembles a light green cucumber. It does indeed taste somewhat bitter because of the quinine it naturally contains; the taste resembles quinine water. The fruits get more bitter as they get older, so harvest them when they’re young. Soak in a brine for a half hour, or boil in a brine for 5 minutes, before using. For recipes, look in Indonesian, Sri Lankan, and Indian recipe books. Or boil, peel, take out seeds, mash like winter squash, and add spices. Or precook and then add to a stir-fry with either curry flavorings or garlic and soy sauce. Or add to any spicy soup. Or stuff and bake.

CALABAZA: *Cucurbita moschata* (or *Cucurbita foetidissima*) is like a large pumpkin, but it’s not of the same cross-pollinating group as the regular pumpkins. Also called “Cuban squash,” “calabazilla,” and “green” or “Indian” pumpkin, it’s grown a lot in Central and South America. It keeps like a winter squash and grows great in hot climates like Florida. The vines will cover a large area (they get up to 60 feet long) and produce prolifically.

Using. The shell is hard. Saw into it or use a big, sharp-edged knife. Substitute in any pumpkin or winter squash recipe, or use in stew, soup, casseroles, and breads. Or bake pieces with brown sugar and butter sprinkled on them. Or boil a chunk, mash like potatoes, and add seasoning. The taste resembles sweet potato. The blossoms are good eating, and so are the seeds if roasted.

CHAYOTE: Chayote fruit (*Sechium edule*) is shaped like an avocado and is green outside but white inside. Its many names include “brionne,” “christophine,” “chocho,” “mango squash,” “mirlton,” and “vegetable pear.” It comes from Central America, was grown by the Aztecs and Mayas, and is now popular in Latin America and India. Its vines are eager growers (30 to 100 feet a year, in a style resembling kudzu). It’s a perennial in places where the ground doesn’t freeze, such as Florida and California.

Planting. Chayote takes a long time to get going and needs a hot summer, which makes it a tricky crop to grow farther north, although in the hot interior it can produce if started indoors in March and transplanted later. It needs constantly moist, fertile soil and no frost. To start, plant sprouted fruits. You can start with grocery-store fruits, or mail-order them (Southern Seeds). As with other cucurbits, even though the vine gets so large, you need to plant several because some plants have flowers of only one sex. Plant them 10 feet apart in every direction and with something *strong* (fence, tree, outbuilding, high trellis) to climb on because the fruit shouldn’t be on the ground. Plant the seed in compost or aged manure tilted at about 45 degrees, with the small end up and just barely sticking out of the ground. Or do vegetative propagation by planting the small shoots that grow off the crown (you’ll have to keep a plant base alive all winter).

Harvesting. Chayote needs a minimum of 12 hours of sunlight per day to set off flower production. The first fruit will be ready about a month later. Once they get going, your vine will start fruiting in October and thereafter will produce fruit year-round unless stopped by cold. Night temps down to 40°F will terminate fruiting until next spring. But this cucurbit is quite different from the others in that it has many other edible parts besides the little squash: You can also eat its seed; harvest tender leaves from its growing tips anytime and use them raw or cooked; harvest young shoots in late spring and early summer and serve them asparagus-style; or dig up and eat the tubers, which resemble potatoes and can get big as 25 lb! In fact, in the tropics the tubers are an even more important chayote crop than its squash. Dig up the tubers as soon as your vine dies from cold, although the tubers will be small. To get good-sized ones, wait to harvest until after a vine is at least 2 years old. Discarded vines are good animal fodder.

Preserving. If you've got chayote, odds are you have too much fruit, because it's the Mexican equivalent of zucchini. If you wrap and store chayotes in the fridge, they keep for weeks. Or dice, blanch 2 minutes, chill, package, and freeze.

Using. Wash; take off stem and blossom ends. The male fruits will be smooth and the female ones prickly, but both are edible. You can eat very young chayotes unpeeled, raw, or cooked. For an older one, the peel gets tough and will need peeling. But older ones are sweeter because their starch changes to sugar. Peel, cut in half, and take out the seeds. You can eat the youngest chayote fruits raw, as in a salad, where it tastes a bit like cucumber. You can also make a pie of it using an apple pie recipe. The bland flavor needs help. Serve in strips with a spicy dip. Or boil, mash, and season. Or saute strips in any stir-fry dish. Or add to an onion/meat soup.

Fuzzy Melon: Fuzzy melon (*Benincasa hispida*) is a Chinese member of the gourd family; it's also known as "hairy melon" or "wax gourd." The many Asian varieties of this species come in various shapes. It's most comparable to our summer squash. The name "hairy melon" refers to its fuzzy, kiwi-like outside. In shape and color, it's like a fat green cuke. The melons can grow up to 2 lb. You'll be harvesting in late summer and fall.

Recipe Ideas. Wash your fuzzy melon, cut it in half, and scoop out the seeds and pulp. It has a spongy texture and a bland flavor. Substitute in any summer squash recipe. It's good when added to a stew or soup and cooked slowly. You can also prepare fuzzy melon by cleaning out the cavity and then stuffing it with a mixture of vegetables (shrimp is good too) and baking until all are cooked through. Or stuff with a mixture of poultry meat and mushrooms seasoned with crushed garlic cloves and ginger, and bake. Or saute strips of it with slivers of chicken and Asian greens, which is a favorite way the Chinese prepare it. The Japanese like it stir-fried in sesame oil with strips of carrot, broccoli, and tofu and served with soy sauce. Or make a plain fuzzy-melon stew by simmering chunks of the flesh slowly until fork-tender and then thickening with cornstarch.

Lady Godiva: This European *Cucurbita pepo* has naturally hull-less seeds! The seeds are about half protein and half polyunsaturated fat, with some other vitamins and minerals thrown in. Some Lady Godiva varieties have seeds that are good people food but flesh that isn't (it's good for animals, though). But Nichols sells a new hybrid whose seeds *and* flesh are good to eat. Grow it like a pumpkin (which it resembles). Harvest when cracks begin to appear where the fruit is attached to the vine. To prepare, halve the fruit, scrape out the seeds, and soak them in water (use the instructions in "Seed Saving" under

“Cucumbers”) until the seeds are nicely separated from the other stuff. Then spread them out to dry for up to a week. Add them to recipes, eat straight as a snack, roast, mix with sunflower (or other flower) seeds and grind for a spread, or press for oil. (For roasting and oil-pressing directions, see “Flower Seeds.”)

SPAGHETTI SQUASH: This thin-skinned *Cucurbita pepo* is full of long strands of flesh instead of a solid mass like the others. It’s also, and appropriately, called “vegetable spaghetti.” Nichols carries an improved 85-day variety. Plant and grow like other cucurbits. When ripe and ready, it looks yellow. Some people claim it cures and stores as well as a *maxima*. Others prefer to preserve by cooking and then packaging and freezing the “spaghetti.”

Preparing. It’s usually first cooked whole, either boiled (about a half hour) or baked (poke with a fork and bake about 90 minutes at 350°F). Then cut in half lengthwise and take out the seeds and central pulp. Rake out the shreds of “spaghetti.” There will be enough to cover a big plate. Stir cream and melted cheese in with the strands and serve. Or serve with plain salt, pepper, and butter. Or serve with pasta sauce, chili, garlic butter, or mushroom soup. Or preboil and then cook in a casserole mix with meat chunks. Or stir-fry the strands with onions, carrots, and garlic and serve stirred in with real spaghetti. Or substitute for the noodles in a lasagna recipe. Or cook, chill, and toss some squash strands with a green salad.

WINTER MELON: Winter melon is another Chinese variety of *Benincasa hispida*. It’s also called a “wax gourd” because the green skin gets coated with a waxy material when it matures. It needs a hot climate and takes 150 days to mature. (Seed is available from Southern Seeds.) Use when young, like a zucchini squash. Just cut into slices, steam, and serve with soy sauce. Or, if left on the vine, this variety can get as heavy as 35 lb. and then is treated like a winter squash.

The Chinese sometimes scoop out the cavity of such a very large winter melon and serve soup in it. For special occasions, they may create ornate carvings from the outer skin. Harvest very late in the year; cure and store like a pumpkin or winter squash (hence its name, “winter melon”).

Recipe Ideas. Scoop out the winter melon’s flesh and cook it with black mushrooms to make a soy-flavored soup. Or bake sections. Or simmer flesh slowly with bamboo shoots, thicken with cornstarch, and serve. Or steam with other vegetables and mushrooms and serve with soy sauce. Or use as an ingredient in a chicken and shiitake mushroom stew.

Craft Gourds

“Bottle gourd” or “hard-shell” squashes (*Lagenaria siceraria*) are easy to grow and are quite durable, as vegetable products go. Grow as you would other squashes or pumpkins. If you love doing crafts, these are the melons for you! Except for cocozelle (discussed a bit later on), craft gourds are inedible; they’re simply gourds with interesting shapes and colored patterns that are dried whole to look at or make useful objects out of. People who live in the Southwest have the easiest time with gourds because they both grow and dry so well in that climate.

Archaeologists tell us that early human societies were making lagenaria gourd containers even before they had discovered how to turn clay into pottery or stems into baskets. They used the largest ones for storing grain and seeds, the smaller ones for dishes. The lagenaria "bottle gourd" is indeed of a suitable shape for a liquid container. The bowls and baskets aren't sturdy enough to be cooked in over a fire, but you can drop heated stones in them to cook. They make fine children's toys, little dishes, and doll bathtubs. A big burlap bag full of them makes marvelous winter entertainment for the children. You can hang them to display by punching a hole in the top and running string or leather through. And they can be flower vases.

You grow a lagenaria until the stem has dried, pick it, dry it, use a strong household disinfectant to wipe off all the dirt (including invisible fungi that otherwise could cause rotting), and then wax and polish it. A good wax car polish looks fine. These squashes can be made into bowls, skimmers, dippers, bottles, seed holders, and birdhouses.

MORE INFO: See *Traditional American Crafts* by Betsy B. Creekmore (New York: Hearthside Press, 1968), *Gourd Craft* by Carolyn Mordecai (New York: Crown, 1977), and *The Art of Drying Plants and Flowers* by Mabel Squires (New York: Bonanza Books, 1958).

VARIETIES: The lagenarias come in a delightful array of varieties, mainly named for their shapes or uses: ball, bottle (vase or liquid container), "canteen" or "bushel" (great bowls or "baskets," depending on size), club (good rattle), dipper (ladle, planter), dumbbell (small ones can be made into salt shakers with a wood plug in the center bottom), and penguin (bowls with interesting matching lids). They range widely not only in shape but also in size and color.

Garden catalogs generally list both small and large varieties. To start with, you could plant one of the "mixed" packets, which will give you an interesting assortment. Gourds come in an amazing array of sizes and styles. Stokes Seeds offers a good assortment of both large (Cave Man's Club, Giant Bottle, Dipper, and Birdhouse) and small (Miniature Bottle, Miniature Ball, etc.) gourds. Nichols also offers an outstanding collection: 10 small types and 9 large ones. Southern Seeds offers them as well.

Cocozelle. *Lagenaria longissima* is the exception among lagenarias: It's grown to eat rather than to carve. It's a variety of the Italian cocuzza squash. Seed is available from Southern Seeds. It produces like a zucchini, grows well in an area like southern Louisiana, and is great to eat when just 18 to 24 inches (that's immature for it!). Bake, steam, or add

to a casserole.

PLANTING: The lagenarias, like the luffas, are tropical plants that thrive in hot, humid weather and need a long growing season, at least 100 to 110 days. You can direct-seed them into the garden and harvest before frost only if you live in the southern United States. Plant seeds a foot apart if in rows; 2 to the hill, hills 6 feet apart, if in hills. In more northern zones, start them in peat pots (2 seeds per pot, $\frac{1}{2}$ inch deep) some weeks before your last frost date, and then transplant to the garden after the dirt has warmed up. In the coldest zones, they can only be grown in a greenhouse, where they will thrive and provide dense foliage as well as flowers and fruits.

Gourds are best grown as climbers—over a fence, for instance, to keep them out of the dirt—unless the growing instructions say otherwise. That's because the position in which they grow can affect the ultimate shape of the gourds. Lagenarias do best in soil that is light and only moderately provided with nitrogen, although humus is good for them. Excess nitrogen tends to make them produce more leaves and fewer gourds. Lagenarias need full sunlight and regular enough watering that their dirt never completely dries out.

CLIMBING: Inside or out, plant any lagenaria next to something the vines can climb: a fence, trellis, or sash. Strange but true: Experiments have shown that craft gourds produce much better—even 2 or 3 times as much—if their vines are tied up with string or in some fashion supported up off the ground. However, some of the lagenarias need to develop on the ground either to have the right shape or because of their weight. If having the melons sitting on the ground seems to be a problem, protect the fruits by slipping some clean dry mulch (such as straw) under them.

Large Bottle Gourd. This one grows 12 inches long, 8 to 10 inches in diameter, with a somewhat hourglass shape. In Mexico it's still used to make water bottles. It also makes a great birdhouse. To form a bottle with a flat, stable bottom, stand the gourd upright while young and still growing. Seeds are available from Southern Seeds. You can take off just the tip and discard it, clean out the seed cavity, and make a vase. If you do the same thing but keep the top for a lid, you have a nice bottle. If you cut about two-thirds of the way up and keep the top, you have a nice bowl with a lid.

Bushel Gourd. This one makes a large, round “bushel basket.” It is basically pumpkin-shaped but with smoother sides, and it grows from 12 to 18 inches in diameter. Mature fruits can weigh as much as 30 to 100 lb. Seeds are available from Southern Seeds. Its large vine needs lots of room. Let the fruits fully mature on the vine. Then pick, dry, and cure.

Dipper Gourd. This variety is also called “siphons.” Its fruit makes excellent ladles, planters, and vases as well as dippers. The gourd has a narrow neck, which becomes the dipper’s handle, and a wide but flattish body, 6 to 8 inches in diameter on that larger end. The plant does best when provided with something like a trellis to grow on.

SECRETS OF LAGENARIA HARVESTING AND CUTTING

1. Pick the gourds when completely ripe. Don’t let them frost. You can give them a little more time by protecting them with paper or cloth from the first light frosts. They’ll be ready to be picked any time after the stems have become dry and shriveled. Leave several inches of stem when cutting. Be careful not to injure or bruise them while

handling.

2. Let them dry several days to 2 weeks.
3. Dip into diluted bleach or alcohol, dry the gourd, and that's it. Or, if you want to decorate the gourd skin, remove the outer skin by rubbing it off with steel wool until all of that waxy outermost layer is off. Or wrap each gourd in a towel that has been soaked in liquid household cleanser, and let the gourd soak for at least 3 hours. That softens the outside skin layer. Take the gourd out of the towel. Scrape off the outer skin. Getting it off enables the rest of the gourd to quickly finish drying. (Or else skip this and wait until you've finished cleaning and scraping the gourd [see the next "Secrets" list]. Then take off the outer papery skin by giving it a quick scalding in boiling water. A light scraping then will take off the rest.)
4. Spread out the gourds to dry in a dry, well-ventilated place, making sure the gourds don't touch each other. Turn them regularly until the drying is completed—usually 3 or 4 weeks. (You can also hang them to dry, but don't let them touch each other.) As a gourd dries, the seeds get loose and rattle and the gourd gets light. A gourd rattle makes a fine toy or child's musical instrument.
5. Let the size and shape of the gourd suggest its use to you. Refer to one of the following cutting patterns. To cut a lagenaria, first draw a line on it with a pencil. Use something small and pointed to punch open a spot on the line. Finish the cut with a fine-toothed saw and steady pressure. Or, if you're like me, just brace the gourd and hammer the knife through it, or chop with a hatchet. They're hard to cut. For more precision, use a drill, saber saw, or keyhole saw. Make your first cut where you want it, because it's very difficult to trim, although some gourd varieties are softer than others.
6. Proceed to the next list of "Secrets" to finish your gourd.

For a Bowl. Choose a round gourd. Cut off one end, or cut the gourd across the middle, depending on whether you want a wide mouth or a tapered shape. To make yourself a "set," choose matching gourds.

Dipper. For a dipper, choose a gourd with a long, nicely shaped neck. The neck will be your handle. Lay the gourd on its side. Cut off the top half from the base of the neck to the other end of the gourd. If one side is flatter than the other, let that be the bottom of your dipper.

Skimmer. To make a skimmer, proceed as for a dipper. Then perforate the bottom and sides of the dipper with a nail in lots of places, creating a slotted-spoon effect. Finish drying. Then you can dip up scum from your stew pot with it, and the juice will flow back into the kettle through the holes. Or you can scoop vegetables out of a soup or use the gourd as a sieve.

Bottle or Vase. Choose a gourd with the appropriate shape. Test it to see if it can stand up on its bottom. Cut off the neck to make the shape you desire. Remove seeds, pulp, and fibers through the neck hole as it softens up. You can make another kind of vase by cutting a gourd in half lengthwise, hollowing it out, and putting flowers in it to use as a centerpiece. Some people waterproof the inside with paraffin.

Toys. Gourds make good toys: dolly bathtubs, cups for dolls to drink out of, and so on. You can make a lantern from a really big gourd by cutting out one whole side, leaving the neck and base intact so it will stand up. Hollow it out and then put a candle inside. Start

with a large gourd—if your gourd is too small, the sides will scorch and get kind of stinky.

Bird Feeder. To make a bird feeder, cut out an entry hole for the bird and let the gourd dry. Then hollow it out. Hang it up outside fairly securely and put some birdseed in it. Birds will climb in and eat.

Birdhouses. The big, round, pumpkin-sized gourds are good for these. Cut a hole that's big enough to let you hollow out the gourd. Hang it in a tree by punching a hole and putting leather through it. For a lot more detail and to learn which size the entrances should be to attract a certain type of bird, look up "Gourds Make Attractive Birdhouses" in *Organic Gardening* (Aug. 1971, p. 54).

SECRETS OF LAGENARIA DESEEDED AND FINISHING

1. Cutting has now enabled you to get at the inside seeds and pulp. If they're hard to scrape out, set the gourd in a warm place for another few days before removing the seeds. Don't scrape the inside of the gourd too hard at any particular point; otherwise the shell will become thin and may shrivel. After taking out the seeds, wash the inside of the gourd and stand it in a fairly warm place for a few days. If you're working down a long narrow neck to make a vase or bottle, it will help to fill the gourd with water for about 3 hours and then scrape with a suitable long instrument (such as a metal spoon). Then soak and repeat until it's all cleaned out.
2. Gourd makers recommend using steel wool to finish cleaning both the inside and the outside of the gourd.
3. To decorate a lagenaria, first pencil your pattern onto it. Then paint, stain, or carve with any engraving tool or just a sharp knife.
4. When gourds are finished and completely dry, polish them to ensure that they will keep well. Shellac, varnish, or spray with a clear cellulose lacquer.
5. How long will decorative gourds keep? Temperature and humidity are important factors, but gourds should keep at least several years, although as time passes they will lose some of their natural color. You can make them look nice if you wax them with floor wax and polish them with a soft cloth.

Squash Sponge: Luffa

The luffas are a totally different gourd species (*Luffa*) than the lagenarias. The luffa (sometimes spelled "loofa") originated in Asia and has as about as many names as there are seed catalogs. One of its most common names is "vegetable sponge" because the skeleton of this gourd is the "luffa sponge" you can buy from your health-food store. It's also known as "towel gourd" or "dishcloth gourd." Asian specialty catalogs may use its Chinese names.

Luffa sponges can be used as bathing sponges, boat or kitchen scrubbers, filters, insulation, and packing material. You can use them to make baskets, mats, and slippers. Luffa is also edible!—unlike the lagenarias. In fact, in much of the tropical world, luffas are grown not only for their summer squash-type fruits and the spongy skeletons of mature fruits left to dry on the vine but also for their edible flowers, leaves, and seeds!

LUFFA VARIETIES: There are 2 basic kinds of luffa: "ridged" and "smooth." You can tell their seeds apart by looking, because the seeds of ridged luffa are wrinkled and winged. The

seeds of smooth luffa are smooth and wingless.

Ridged Luffa. Its Latin name is *Luffa acutangula*. Its Chinese name is “Sze Kwa.” Some call ridged luffa “Chinese okra” because each fruit resembles a large, long, dark green, club-shaped (wider at one end) okra. It’s also known as “angled luffa” because of its odd, S-curved shape. Ridged luffa grows wild in Indonesia and India. In most of Asia, luffa is grown for both food and sponges. At full maturity, they’re about a foot long. Ridged or “angled” luffas grow long and slender, with leathery furrows down their length. To prepare them for eating, cut those long ridges off the sides, since they’re too stiff to eat.

Smooth Luffa. Its Latin name is *Luffa aegyptiaca*. But its scientific name is unclear because it’s also been called *L. cylindrica*, *L. macrocarpa*, and *L. marylandica*. The fruits are significantly bigger than the ridged kind. They’re light green and smooth-skinned, and they’re straight cylinders rather than S curves.

PLANTING AND GROWING: Luffas are grown much like lagenarias. Allowed a long growing season, they are easy to grow and produce as prolifically as zucchini. You can order luffa seed from Exotica, Gurney, Hudson, Johnny’s, Nichols, Redwood City, Shumway, and Thompson & Morgan.

Luffa seeds have unusually hard outer coats and thus are slow to germinate. It helps to start by soaking them at least 12 hours. If you plant them indoors, keep the pot in a dark place in a warm room. Even so, figure on waiting several weeks before seeing a sprout. As soon as the sprout shows, transfer the pot to a situation with good light. At the 2-inch point, cull the weaker-looking plant in a pot. At 3 inches, it’s ready to be transplanted outdoors (plant in the evening). It becomes an attractive plant with yellow flowers.

HARVESTING: Gather fruits when young and tender—*no more than 6 inches long*. Longer, older luffa rapidly develops a stringy quality. Luffa has a mild flavor and lots of vitamin B complex.

Recipe Ideas. You can substitute raw luffas in any recipe that calls for raw cucumbers. Or substitute cooked luffas in any recipe for cooked summer squash or okra. Or steam to cook and then add sugar, vinegar, sesame oil, and ginger to flavor. Or cut into strips and saute with other slivered or chopped Chinese vegetables in a little hot sesame oil. Or cut in half the long way; partly scoop out inside; stuff with a mixture of onions, cooked rice, marjoram, and thyme; and bake 40 minutes at 350°F. Or make into a soup by cooking chopped luffa together with sliced shiitake mushrooms, fresh peas, sliced bamboo, or other vegetables. Or cook cut-up chunks of luffa, tomato, onion, and basil in a casserole (sprinkle cheese on top). Or boil, puree, season with a bit of soy sauce, and serve. Or make a Chinese-style stew: Add luffa and other Asian veggies to a cooked pork soup, thicken the broth, and serve. The Japanese prepare chunks of luffa tempura-style.

Luffa Greens and Flowers. You can gather luffa leaves any time and use them raw in salads or cook them like spinach. Luffa bears large, yellow flowers. The plant will bear more fruit if you pick the first several flowers. Substitute them in any recipe for dandelion blossoms!

Luffa Sponges. To get the sponges, you really need to live in a southern zone or have the plants in a greenhouse. First you let the luffas grow past eating size, on to complete maturity on the vine. They will get from 1 to 2 feet long before they quit growing and will be several pounds in weight. To reap the very best sponges, let them stay undisturbed on

the vines, where they will first grow to that fully mature size, then ripen, and then dry. If possible, let them dry there until the stem turns yellow and the skin gets dry, paper-thin, and faded in color. Then peel them like an orange. Don't wait until they are fully yellow to peel. Greener skin means a more tender sponge. Yellower skin means a wiry, harsh sponge. (You can soften sponges by boiling them in water 5 minutes.)

When the time comes to harvest the luffas, cut them away from their vine using a keen-edged blade. Dry at least 10 days more, or until their outsides have gotten hard and turned to a brown color. Now open the big end of the luffa. Shake out all its seeds. Get rid of any remaining outer skin, strings, or seeds and rinse out the center of it. Immerse the luffa sponge in water and leave it there 12 hours. Now peel off the outside layer. Dry in the shade. If you need white sponges for some reason, soak your dried sponges for 30 minutes in water that has a little bleach added.

MELONS

This section includes cantaloupe, honeydew, and watermelon. Nichols, Seeds of Change, and Shumway all offer outstanding melon collections. Small cantaloupes can be as quick as 65 days to maturity; watermelons may take as long as 95 days. Good varieties for the north are honeydew and Persian melons.

HEAT: Melons grow best where the summer is hot, dry, and almost constantly sunny—the hotter, the better the flavor. (Cloudy, rainy weather literally stops melons' growth.) Squash are the hardiest cucurbits; cucumbers, a little less hardy; cantaloupes, less hardy; and watermelons, still less. Melons have deep taproots, so they're good at finding water on their own. And direct watering cools off this heat-needing plant and slows down its growth. So if you live in a marginal climate for melons and want to help them along, don't water them—or water only around the edge of the hill, not on the plants. If you don't have plenty of subsoil water, you do need to water them somehow when the weather is hot, at least 1 to 2 inches per week.

PLANTING: If you live in a northern temperate zone, plant your cantaloupe and watermelon seeds as early as you dare. If the seeds rot, plant them again. If those seeds rot, plant again. The longer the season you can manage to give your plants, the better your harvest will be. Allow plenty of room between plants. Keep out the weeds, and you'll get fine melon crops.

You can get a head start on the summer heat by starting plants from seed indoors, several weeks before your last frost date. Transplant after a week of hardening off or set out under a plastic cover, which will keep your ground warm. If you plant in succession every week, you might get a jump on the season if there's a warm spring. You can plant 1 or 2 cantaloupes or bush watermelons in a container the size of half a whiskey barrel; use 5 gal. soil per plant, 12 inches deep and 2 feet between plants. Near harvest time, when frost is coming, pick and discard any little melons that aren't going to make it. Then the plants can concentrate their energy on ripening the hardier melons.

Now on to more species-specific info ...

Cantaloupe

Cucumis melo is Latin for both the smooth-skinned muskmelons and the netted-skin cantaloupes, although those two are too distantly related to cross-pollinate. Cantaloupes

are raised on a truck-garden scale all up and down the bottom of our valley. The bottom is the warmest place of all. Plant 1 inch deep, 6 feet between hills and 6 feet between rows. Allow a week or two to germination and about 90 days to harvest.

HARVESTING CANTALOUPES AND MUSKMELONS: You may find wasps eating your melons. Wasps will nibble at the shell until they get a hole; then they'll eat out a chamber inside the hole, causing the melon to rot inside. If this happens, harvest any melons that are under attack; that minimizes the damage. These melons are ready to pick when the skin starts to get yellowish; they soften up a little and detach readily from the vine. American melons also usually crack away from the stem a little when they are ripe and ready. *Don't pick them green. Cantaloupes and muskmelons (and also watermelons) do not ripen any more after picking.* If the only cantaloupes you've eaten before are those from supermarkets, you've never enjoyed a genuinely ripe melon, since store melons are all picked green and stay that way. A cantaloupe picked green will keep 4 to 6 weeks if stored at 40 to 50°F, but a fully ripe cantaloupe keeps only a week or two. A melon picked green can get softer and can ultimately rot, but it can't get any sweeter.

➲ **CANTALOUPE SWEET PICKLES** *Cut 12 unripe melons into quarters. Peel the tough outer rind and the mushy, stringy inner surface of each melon. Place fruit in a jar in vinegar to cover, and leave overnight. In the morning, to each pint of vinegar, add ¾ lb. sugar, 1 T. cloves, ½ T. mace, and 4 large sticks of cinnamon, broken into small pieces. Boil the vinegar and spices, and remove the melons to jars. Boil the syrup 30 minutes longer. Pour it hot over the fruit in jars and seal.*

Watermelon

Watermelon, *Citrullus lanatus*, is the best fruit in the world if you're thirsty. It comes from Africa, where early farmers in semi-desert areas developed it as a source of water during droughts. People have lived with no other source of water but watermelon juice for as long as 6 weeks.

Seems like some people can grow watermelon and some can't. I have neighbors who grow fields of watermelon to sell on a truck-garden basis, but I can't seem to grow even one big one. (I've just about decided to quit wasting my time and stick to cantaloupes, which are much easier for me to grow.) Shumway has a great watermelon collection. There are even small watermelon varieties, such as Sugar Bush, that can be grown in a container.

PLANTING: Plant outdoors a week after last frost date, 1 inch deep, 8 feet between hills and 8 feet between rows. Allow a week or two for germination and about 100 days to harvest.

TESTING WATERMELON FOR RIPENESS: Using the thump test, rap the melon with your knuckles; if it sounds hollow, it's ready. The plug test is surer: With a pocketknife, cut a round cork-shaped plug from the side of the watermelon, pull it out, and have a look at what's inside. If it's white, you've been way overeager. If it's pink, it's coming but is not ready yet. If it's bright pink, you can eat the plug and harvest the melon, or slip the plug back in the melon and leave it until you're ready to serve it fresh off the vine for dinner. Another test is to look and see whether the place where the melon skin is lying on the ground has turned kind of white—then it's ripe.

FREEZING MELON: I think the best way to eat a watermelon is to cut it in pieces, start eating,

and continue until you're full. But Lane Morgan says mashed-up, frozen watermelon makes good kids' popsicles. And a new neighbor of mine who has lived entirely on raw food for many years freezes melon chunks. He cuts 1-inch chunks from the heart of melons like casabas and honeydews. He doesn't include any rind. If just dicing the melon hasn't given him enough juice for packaging, he mashes a little extra melon to give him juice to pour over the fruit. He packages it in plastic baggies. Here's the extension service's way: Cut the melon into slices, balls, or cubes. Pour cold, light syrup to cover. (Optional: Add 1 t. lemon juice per 1 c. syrup for flavor.) Cover and freeze.

➲ **WATERMELON SEEDS** *One thing they haven't put on the American market yet is watermelon seeds. But Alice Shattuck wrote me that when her grandmother (and Alice is a grandmother herself!) and her mother used to cook up a lot of watermelon for syrup, they would save all the seeds. They washed the seeds, boiled them a little, dried them off and spread them on wooden trays to dry in the sun.*

CUCUMBERS

Cucumis sativus, the cucumber genus (of which citron is a member), is easy to grow if you have a warm summer and can avoid insect and disease problems. Before World War II, especially in the South, people had simply given up trying to grow cucumbers because they suffered so from diseases. Then seed companies came out with disease-resistant hybrids that solved most problems—except the cucumber beetle. As with tomatoes, there are a jillion varieties: the familiar green salad cuke, various thin-skinned pickling kinds, little yellow-colored “lemon” cucumbers, long crooked ones from Asia, the Japanese “kyuri” (which they use unpeeled), citron, and so on.

CITRON: Citron looks like a small, round watermelon but is solid clean through, with uniformly green flesh and green seed. (Don't confuse it with the citrus fruit that resembles a large lemon and is also called citron.) Citron is eaten only pickled, preserved in sugar syrup, or candied. You can substitute citron-melon preserves for store-bought citron in fruit cakes, plum puddings, and mincemeat.

LEMON CUCUMBERS: This round, tennis-ball-sized fruit may have a few spines on the skin; just rub them off. Otherwise it's just another cuke.

Planting and Growing

WHEN TO PLANT: Cucumbers are less hardy than winter squashes but are more hardy than melons. Wait to plant or transplant into the garden until the weather is truly warm, after the corn, at the same time that you would plant watermelon—about a week after your last frost date. (A frost would be the end for them.) In a very hot climate like that of the Mississippi Gulf Coast, an early spring planting (February or March) and a late summer one do best. Cucumbers like a warm summer and lots of sunshine.

HOW TO PLANT: Cucumbers need well-manured, well-tilled ground and plenty of water all through their growing season. We plant from seed directly in the garden around June 1, which is when we can start to trust the weather to be and stay warm here. Cucumbers are only 55 to 65 days to maturity, so a late start still gives you time for a good crop if you have a reasonably long growing season.

It's possible to transplant cucumbers, but it's a little risky because they don't do well if

their root system is disturbed. So if you start them inside, do so using a system that lets you set them out in the garden in the same block of dirt in which they grew inside—little peat pots, for instance. Or plant in the garden under paper or plastic, which gives you a little extra safety as the weather is warming up.

Most people plant them in hills, 4 to 5 feet apart each way, 1 inch deep. Allow 7 to 10 days for germination, about 75 days to maturity. If you want to plant cucumbers in rows instead of hills, make the rows about 7 feet apart, and thin the plants to 12 to 18 inches apart in the row.

CONTAINER AND TRELLIS GROWING: Cucumbers do exceptionally well in containers, and they produce for city dwellers even in rooftop gardens. You can fit 3 bush cucumber plants into a container the size of half a whiskey barrel. Provide at least 3 gal. soil per plant, at least 1 foot deep, plants at least 6 inches apart. In the garden, you can crowd them more if you give the vines something to climb up. Lane Morgan says she usually uses trellises with hers “to save space and make life harder for the slugs.” There’s info on growing greenhouse cucumbers at www.lpl.arizona.edu/~bcohen/cucumbers/greenhouse.html.

THINNING AND WEEDING: In hills, thin to about 4 plants per hill if you have well-composted or manured soil, less if you don’t. But don’t thin until the plants are at least 3 weeks old, because they have a high fatality rate and you may end up with too few. Weeding in your cucumber patch can be done thoroughly and with a rototiller while the little plants are at home on cucumber hill. But when they start “running,” as it’s called, with long, leafy stems covering the ground every which way, that’s the end of the cultivating. You can still weed by hand, though.

WATERING: Cucumbers need plenty to drink, especially after they start making cucumbers. A cucumber is 95 percent water, which has to come from somewhere. Figure on a deep watering at least once a week. You don’t have to water every piece of ground the running vine is covering. If you’re short of water, concentrate it near the hill where the primary roots are. Once the cucumber vines start bearing fruit, as long as you keep watering, they will keep bearing cucumbers until the frost kills them. A few vines can produce a lot of cucumbers before the summer is over. But if you let your vines dry out badly, the cucumbers will taste so bitter that you won’t be able to eat them, and even the very little ones that have experienced such a drought will grow up with that bitter taste. So if they do dry out badly, it’s a good idea to pick off all the cucumbers, water the plant well, and let it start from scratch again.

BEETLES AND DISEASES: Cucumber beetles do their damage while the plant is young, before it starts to run. They attack the lower part of the stem and the underside of the leaves. Commercial farmers generally have more trouble with them than do home gardeners. It doesn’t take a whole lot of cucumber plants to give your family a good supply. If you live in cucumber-beetle country, you can protect the little plants by covering them with frames over which you have stretched fly screen or mosquito netting—wooden box-type frames set into the dirt, for instance, or wire frames with the edges of the netting held down by covering with dirt. When the plants have grown big enough to hold their own, you can store away the whole rigging for use next year. It helps control diseases if you destroy the old vines and cucumbers by burning at the end of each year and don’t plant cucumbers in the same place in your garden 2 years in a row. If you’ve never grown cucumbers before, the best way to find out what problems you will face is to simply plant some and see what

happens.

Saving Seed

The cucumber is a self-fertile, annual, fruited plant that makes its seed inside the fruit. In this it resembles the entire gourd family—pumpkin, squash, and so on—and also the nightshade fruits—tomatoes, green peppers, and eggplant. The “fruit” in this case is the cucumber itself.

CROSSES: Cucumbers are cross-pollinated, with the pollen being carried from one flower to another by insects. That means any one cucumber variety will easily cross with another. But cucumbers will not cross with watermelon, muskmelon, pumpkin, or squash—only with other cucumber varieties. So to avoid crosses, pick one open-pollinated cucumber variety and plant just that. Or separate varieties by $\frac{1}{4}$ mile (preferable) or by at least 100 feet, with some natural barrier like a house in between. That works if you have no gardening neighbors.

SELECTING: Choose your best-looking cucumber fruits from your best-looking vines; really pay attention to health. The cucumbers intended for seed must be left to ripen on the vine. Mark them with a stake or some kind of tag so that somebody doesn’t come along and accidentally pick them off.

HARVESTING AND STORING: After being green, your cucumbers for seed will turn yellow and then brown. The skin will become hard, almost like a gourd. Then it’s finally ready. You can store the hard brown fruits in a cool place for as long as several weeks at this stage. That enables you to wait until all your seed cukes are ready and then process them all at once.

GETTING OUT THE SEED: Cut each cucumber fruit in half, trying not to damage any more seeds than necessary as you do it. Spoon out the seed together with the surrounding pulp into a nonmetal container (glass or crockery). Let seeds and pulp sit and ferment at room temperature, stirring twice a day. After 2 to 4 days the jellylike pulp that had been clinging around the seeds will change into a thin liquid that lets them go. It’s ready for the next step when most of the seeds are at the bottom of the dish and the liquid above is pretty much clear. Don’t worry about the seeds that are still floating. They are doing that because they’re hollow, no good, and wouldn’t grow anyway. Skim and dump those. Don’t get in a rush and skip this fermentation procedure because it destroys seed-borne disease—a very important step in saving cucumber seeds.

RINSING AND DRYING SEEDS: Finish the seeds by filling your container with cool water, letting the seeds settle to the bottom and pouring off what’s left. Do that several times. Now spread out the seeds to dry, no more than 1 layer deep, in a place like a sunny window.

Don't use artificial heat like an oven or a heat lamp, because that could hurt or kill them. Figure on at least 2 days for them to dry, and then you can store.

STORING SEEDS: Label them with the year, their variety, and the characteristics you selected them for. It's a long time until next spring or the spring after that, and you're liable to forget if you don't record it. Store seeds in a cold, dry place. Don't panic if they freeze. If the seed is dry, freezing not only won't hurt but may even improve the crop. Cucumber seeds can easily germinate for 5 years and maybe more.

Harvesting

Keep picking to keep your vines producing. Pick cukes while they're green and small for the best taste. Pick according to the size of cucumber that your recipe calls for. In general, 3–9 inches long is about right. You can actually pickle or eat any size, but cucumbers that are getting yellow and seedy are not nearly as tasty. All you have to do once the cucumbers are big enough to suit you is gently pluck them off the vine and carry them into the house. Store extras in the refrigerator while you're figuring out what to do with them.

Very young, tender cucumbers can be used peel and all. "Midgets" are those up to 3 inches. They go into your midget crock—a glass gallon jar will do. "Dills" are those 3 to 6 inches long. Cucumbers over 6 inches long are "slicers" to be used fresh or to make cucumber sandwiches (slice peeled cucumbers and mayonnaise on homemade bread) or instant pickles (put thinly sliced, peeled cucumbers in a salt-vinegar-water brine). Great big cukes don't make good pickles anyway because they get too hollow in the middle.

If you've seen only store-bought cucumbers you may not know about yellow ones, but the life cycle of a cucumber goes like this: blossom, tiny green cucumber, big green cuke, real big green cuke, yellow cuke, brown cuke. Yellow/brown is the proper stage for saving seed or feeding to cows, pigs, or chickens. But some people cook the yellow ones or make pickles out of them.

STORING AND PRESERVING: Store green cukes in a basket in a cool, damp place such as your root cellar. Storing at 45–55°F, 80–90 percent humidity, will keep them fresh as long as is possible for cukes—which isn't all that long. Then you'll need to shift to another method.

Freezing. I've been told that if you wrap individual servings of sliced cucumbers in foil and freeze them, they make a delicious dish that winter served unwrapped, thawed, in individual dishes. Mix heavy cream with a little dollop of lemon juice and pour it over them.

Drying. I used to think pickling was the only way to preserve cucumbers. As on many other points, my readers have educated me. Jeanne Weston from Durango, CO, sent me a lot of advice about home-drying foods, and she says you can dry cucumbers. She has done it and says they make good salad flavorings. She thinly slices them, dries them until brittle, and stores them until needed. Then she breaks up the dried cucumber into small pieces and scatters them over her winter salad.

Recipe Ideas

RAW CUKES: Cucumbers are good raw in salads and sandwiches. Or peel and cut into sticks or chips and serve plain or with dip. Or make a gourmet salad: sharp cheese, Greek olives,

tomatoes, and cukes, all chunked and tossed with raw greens and salad dressing. Or serve cuke slices with chopped onion, tomato, raw greens, and blue cheese dressing.

Boats. If allowed to grow, cucumbers will get very large—as long as 10 inches or so. Such a fat cucumber makes a fine child’s boat for the bathtub. Cut in half lengthwise, scoop out the seeds, and there’s your boat. You can feed the other oversized, yellowed, or imperfect cucumbers to the chickens and pigs. When feeding them to chickens, first break cukes open. If the chickens aren’t hungry enough to stoop to cucumbers, the cukes will still make fine compost.

Sandwiches. In summer we eat lots of cucumber sandwiches, a quick lunch at a time of year when cucumbers are abundant and time is not. Peel and slice fresh cucumbers. Spread homemade bread with mayo, layer on sliced cucumbers—maybe add slices of fresh garden tomato—and top with another slice of bread.

Instant Pickles. I usually feel like I’m making oh-so-many of these and then discover that by the time the meal is on the table, they are already two-thirds gone, thanks to snitchers and big ones (my husband loves them too). I just peel and slice several cucumbers as for sandwiches. Put them in a bowl with salt, vinegar, and water. Now you are going to ask: “How much of each?” Sigh. I never measure, just taste my way to success, so I don’t know. It adds up to just barely enough liquid to cover. About half vinegar, half cold water, and maybe $\frac{1}{2}$ t. salt. It is a salty dish. The salt pulls the bitterness out of the cucumbers. It needs to be made at least 15 minutes ahead of the meal to let the salt work. The longer ahead you make it, the less salt you should use. It won’t keep; it gets too strong.

➲ **INSTANT SALAD** Wendy Czebotar, Kennewick, WA, slices cucumbers across in very thin slices, sprinkles them with salt in between, and then lets them set in the refrigerator an hour. Then she takes them out; squeezes out all the excess water to make the cukes limp; adds chopped onion, vinegar, oil, salt, and pepper; and serves.

➲ **SOUR CREAM CUCUMBERS** Peel 3 cucumbers. Mix with $\frac{1}{2}$ t. salt. While the cucumbers are being worked on by the salt, peel and slice 3 small-to-medium onions, and add. Make a dressing by beating together 1 c. sour cream, $1\frac{1}{2}$ T. vinegar, and 2 T. sugar or the equivalent in honey. Pour dressing over and serve.

➲ **YOGURT CUCUMBERS** Jan Franco, Hamden, CT, says cucumbers are also great in yogurt with a bit of dill weed and salt. She just slices them up and tosses them in the yogurt; there’s no need to soak them with salt. Or season them with fresh mint leaves and coriander.

➲ **CUCUMBER JUICE** Peel cukes, grate, and squeeze.

COOKED CUKES: Cukes can also be eaten cooked, as you might a summer squash, in soups and vegetable dishes. See summer squash recipes for more possibilities; you can often substitute cukes for zukes.

➲ **COOKED CUCUMBERS AND TOMATOES** Saute 2 peeled, chopped cucumbers with 4 chopped tomatoes. Season with salt, pepper, a few dill seeds, and a bit of lemon juice or vinegar. Or saute with tomatoes, onions, and bacon, and season with chiles.

➲ **FRIED CUCUMBERS** Edna Andrews wrote me from Ravensdale, WA, with this recipe—a new idea to me. She said, “I slice the cucumbers, take these thin slices, and salt, pepper, and flour them. I put a thin amount of butter in the skillet and fry them. They look like fried green tomatoes but taste somewhat different.”

➲ **STUFFED YELLOW CUKES** Lane Morgan told me she'd heard about "big yellow cuke blimps seeded; stuffed with a meat mixture; browned in bacon fat plus cucumber juice, vinegar, sugar, and salt; and then served with boiled potatoes. I tried a baked version of that, with burger and I forget what else, and it was pretty good."

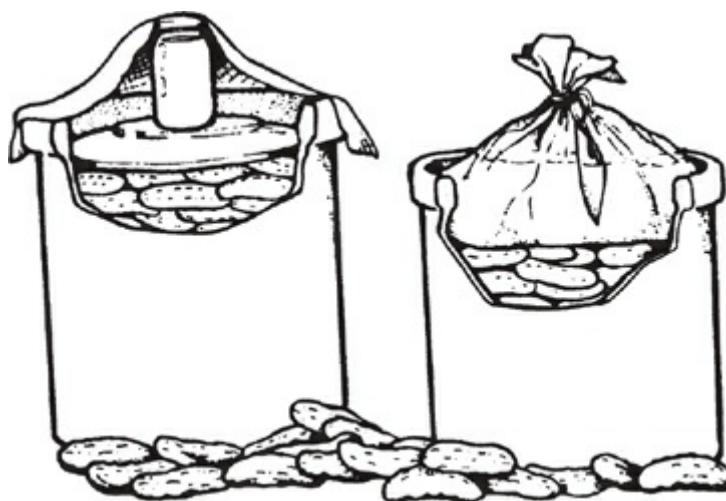

➲ **CUKE SOUP** Cook pork until done. Add turnip and cucumber chunks and brassica greens and cook until tender.

Pickles

Lots of vegetables get pickled (or made into a relish), including other cucurbits—citron, summer squash, unripe cantaloupe, and watermelon rind. But when I think "pickles," it's cucumbers that first come to mind. There are 2 basic pickle categories: "quick" pickles and "fermented" (crock) pickles. Fermented pickles are whole, but quicks can be either whole or cut.

SECRETS OF MAKING QUICK PICKLES

1. If you're planning to make both quick pickles and fermented pickles, make the quick (unfermented) pickles first. That way you make your crock pickles around September. This is best because it helps if they don't ferment at a warm temperatures. At 80°F or above they'll spoil.
2. Get the cucumbers into the brine quite soon after picking. If you have to hold them any time, refrigerate or at least keep them in the shade with a wet cloth over them. Cucumbers deteriorate rapidly, especially at warm temperatures.
3. Wash them well. Handle gently to avoid bruising, since bruised places decay easier. Remove any blossoms because they are a source of enzymes that cause unwanted softening during fermentation. Don't soak cucumbers in water before pickling. They will fill with water and won't soak up the brine.
4. Don't use zinc, copper, brass, galvanized metal, or iron containers or utensils. Don't use plastic containers that are not food-grade (such as a garbage can).

5. Use pure granulated salt ("pickling salt"), not iodized table salt, because the additive that keeps it free-flowing may make the brine cloudy. Don't use flake salt or rock salt.
6. For the best flavor, use fresh spices. Whole spices are best. Powdered spices may cause the pickles to darken and become cloudy. If you raise your own dill, by the time

your cucumbers are ready for pickling, the dill should have matured its seed heads and be ready for cutting. You use stems, heads, and seeds, either dried or fresh from the garden. Dill heads give better flavor than dill seeds; 1 t. seeds equals 1 dill head. To use dill oil, substitute 1 drop for each head of dill.

7. Don't make the pickles using heavily chlorinated water. Hard water may cause cloudiness and off-colors. If only hard water is available, boil and let sit for 24 hours. Skim off scum and use water from the top of the container without disturbing any sediment.
8. Vinegar is the most important ingredient in recipes for quick pickles. Without an adequate amount of water, the pickles won't be safe to eat. Use vinegar with 5 percent acidity. Don't reduce the amount of vinegar or increase the amount of water in a recipe. For a less sour taste, just add a small amount of sugar. You can use white or cider vinegar. Don't use homemade vinegar unless you're sure of its acidity.
9. Cucumber slices are sometimes soaked in a lime-water solution for 12 to 24 hours before pickling. Lime contains calcium, which improves pickle firmness. *The lime should be food-grade. Don't use lime sold at garden centers or lumber yards.*

LOWER-TEMPERATURE PASTEURIZATION

Here, for use in the recipes that call for it (and only those!), is a canning processing method that you can use for certain pickles to avoid a "cooked" quality. Processing at temperatures lower than the boiling point of water can give you crunchier, nicer pickles. But follow directions carefully to avoid spoilage.

1. Place jars in a canner half-filled with warm water (120–140°F). Add hot water to a level of 1 inch above jars.
2. Heat the water to 180–185°F and start a timer. Process for 30 minutes, checking with a candy or jelly thermometer to be certain that the water temperature is at least 180°F but not much higher (temperatures higher than 185°F may cause softening of pickles).
3. Immediately remove jars from canner at end of processing time.
4. Put jars on a rack or cloth so air can move freely around them.

You may can your cucumber pickles whole or slice them into fourths, sixths, or eighths—depending on how big the cucumber is. Dill pickles are sliced lengthwise; bread-and-butter pickles are sliced crosswise.

The following recipes are courtesy of Pacific Northwest Cooperative Extension.

QUICK KOSHER DILLS: You'll need 4 lb. pickling cucumbers (4 inches long), 14 split garlic cloves, $\frac{1}{4}$ c. pickling salt, $2\frac{3}{4}$ c. vinegar (5 percent), 3 c. water, 14 heads fresh dill, and 28 peppercorns. Yield: 6 to 7 pints. Wash cucumbers and cut in half lengthwise. Heat garlic, salt, vinegar, and water to boiling. Remove garlic and place 4 halves into each pint or quart jar. Pack cucumbers into jars, adding 2 heads dill and 4 peppercorns. Pour hot vinegar solution over cucumbers to within $\frac{1}{2}$ inch of top. Adjust lids; use water-bath processing and the "raw pack" times in the "Processing Times for Water-Bath-Canning Quick Pickles" table. Or use lower-temperature pasteurization.

**PROCESSING TIMES FOR WATER-BATH-CANNING
QUICK PICKLES**

		Altitude (feet)			
Style	Pack	Jar Size	1-1,000	1,001-6,000	Over 6,000
Hot		Pints/quarts	5 min.	10 min.	15 min.
Raw		Pints	10	15	20
Raw		Quarts	15	20	25

QUICK SWEET PICKLES: You'll need 4 lb. pickling cucumbers (3 to 4 inches long), $\frac{1}{3}$ c. canning or pickling salt, $4\frac{1}{2}$ c. sugar, $3\frac{1}{2}$ c. vinegar (5 percent), 2 t. celery seed, 1 T. whole allspice, and 2 T. mustard seed. Yield will be 7 to 9 pints. Wash the cucumbers. Cut tip off blossom end, but leave $\frac{1}{4}$ inch of stem at other end. Slice or cut into strips. Place in bowl and sprinkle with $\frac{1}{3}$ c. salt. Cover with 2 inches of crushed or cubed ice. Refrigerate 3 to 4 hours. Add more ice as needed. Drain well. Combine sugar, vinegar, celery seed, allspice, and mustard seed in 6-qt. kettle. Heat to boiling.

Hot Pack. Add cucumbers and heat slowly until vinegar solution returns to a boil. Stir occasionally to make sure mixture heats evenly. Then fill pint or quart jars, leaving $\frac{1}{2}$ inch headspace.

Raw Pack. Fill pint or quart jars with cucumbers, leaving $\frac{1}{2}$ inch headspace. Then add hot pickling syrup, leaving $\frac{1}{2}$ inch headspace.

Processing. Adjust lids and process in a water-bath canner for the time appropriate to your altitude, as listed in the "Processing Times for Water-Bath-Canning Quick Pickles" table. Or use lower-temperature pasteurization. For the best flavor, store 4 to 5 weeks.

FIRMER (LIME-TREATED) QUICK SWEET PICKLES: Use liming solution and procedure for Firm Bread-and-Butter Pickles. For the rest of the procedure, use the preceding Quick Sweet Pickle recipe.

ONION-FLAVORED QUICK SWEET PICKLES: Add 2 slices raw whole onion to each jar of Quick Sweet Pickles before filling with cucumbers.

REDUCED-SODIUM SLICED SWEET PICKLES: You'll need 3 lb. cucumbers (3 to 4 inches long). Wash

cucumbers and cut off blossom end. Cut cucumbers into $\frac{1}{4}$ -inch slices. You'll need a canning syrup: Combine $1\frac{2}{3}$ c. distilled white vinegar (5 percent), 3 c. sugar, 1 T. whole allspice, and $2\frac{1}{4}$ t. celery seed in a pan. Bring to a boil and keep hot until used. And you need a brining solution: In a large kettle, combine 1 qt. distilled white vinegar (5 percent), 1 T. canning or pickling salt, 1 T. mustard seed, and $\frac{1}{2}$ c. sugar.

Now add the sliced cucumbers to your brining solution, cover, and simmer until the cucumbers change color from bright to dull green (5 to 7 minutes). Drain the cucumber slices. Fill *pint jars only*. Cover the slices with hot canning syrup, leaving $\frac{1}{2}$ inch headspace. Adjust lids.

Use water-bath processing and the "raw pack" times in the "Processing Times for Water-Bath-Canning Quick Pickles" table. Or use lower-temperature pasteurization. Yields 4–5 pt.

BREAD-AND-BUTTER PICKLES: You'll need 6 lb. pickling cucumbers (4–5 inches long), 8 c. thinly sliced onions (about 3 lb.), $\frac{1}{2}$ c. canning or pickling salt, 4 c. vinegar (5 percent), $4\frac{1}{2}$ c. sugar, 2 T. mustard seed, $1\frac{1}{2}$ T. celery seed, and 1 T. ground turmeric. Yield will be about 8 pt. Wash the cucumbers. Cut $\frac{1}{16}$ inch off the blossom end and discard that. Cut into very thin slices (" $\frac{3}{16}$ inches"—those extension folks are so precise!). Combine cucumbers and sliced onions in a large bowl. Add salt. Cover with 2 inches crushed or cubed ice. Refrigerate 3 to 4 hours, adding more ice as needed. Drain. Combine remaining ingredients in a large pot. Boil 10 minutes. Add cucumbers and onions and slowly reheat to boiling. Fill pint or quart jars with slices and cooking syrup, leaving $\frac{1}{2}$ inch headspace. Adjust lids.

You can use water-bath processing or lower-temperature pasteurization. For water-bath processing, process either pints or quarts 10 minutes at 1–1,000 feet, 15 minutes at 1,001–6,000 feet, 20 minutes above 6,000 feet. After processing and cooling, store your jars 4 to 5 weeks before serving to let them develop the best flavor.

FIRM (LIME-TREATED) BREAD-AND-BUTTER PICKLES. Use preceding Bread-and-Butter Pickle recipe, except after your cucumbers are sliced, soak them in lime water. To make the lime water, mix 1 c. pickling lime and $\frac{1}{2}$ c. salt per 1 gal. water. Use a 2-to 3-gal. crock or enamelware container. Avoid inhaling lime dust while mixing the lime-water solution. Soak the cucumber slices in the lime water for 12 to 24 hours, stirring occasionally. Then remove from the lime solution, rinse, and resoak 1 hour in fresh cold water. Repeat the rinsing and soaking 2 more times in fresh water. Handle carefully—slices will be brittle. Drain well. Proceed with the remainder of the Bread-and-Butter Pickle recipe steps.

SWEET GHERKIN (4-DAY) PICKLES: You'll need 7 lb. of cucumbers (1 $\frac{1}{2}$ inch long or less), $\frac{1}{2}$ c. canning or pickling salt, 6 c. vinegar (5 percent), 8 c. sugar, $\frac{3}{4}$ t. turmeric, 2 t. celery seeds, and 2 cinnamon sticks. Optional spices: 2 t. whole mixed pickling spice, $\frac{1}{2}$ t. fennel, and 2 t. vanilla. Yield will be 6–7 pt. Wash cucumbers. Cut off blossom end and discard, but leave $\frac{1}{4}$ inch of stem attached.

Place cucumbers in large container and cover with boiling water. After 6–8 hours, drain and cover with 6 qt. fresh boiling water containing $\frac{1}{4}$ c. salt. Repeat on the second day. On the third day, drain and prick cucumbers with a table fork. Combine and bring to a boil 3 c. vinegar, 3 c. sugar, and spices. Pour over cucumbers. After 6–8 hours, drain and save the pickling syrup. Add another 2 c. each of sugar and vinegar to the syrup and reheat to boiling. Pour over pickles. On the fourth day, drain and save syrup. Add another

2 c. sugar and 1 c. vinegar. Heat syrup to boiling and pour over pickles. Let sit and then drain 6 to 8 hours later, saving the pickling syrup. Add 1 c. sugar and 2 t. vanilla and heat to boiling.

Fill *pint* jars with pickles and cover with hot syrup, leaving $\frac{1}{2}$ inch headspace. Adjust lids and process in water-bath canner using the “hot pack” times in the “Processing Times for Water-Bath-Canning Quick Pickles” table. Or use lower-temperature pasteurization. Or process using lower-temperature pasteurization.

FERMENTED (“BRINED”) CUCUMBER PICKLES: Not very many people make crock pickles nowadays—not because it’s hard to do, but mainly because people are suspicious of the yucky-looking stuff on top that I will hereafter refer to as “scum.” The scum is lactic acid bacteria that grow, change the pickle color and flavor, and produce a desirable acid. Old-fashioned crock pickles are cured by fermentation, and the scum is the fermentation agent. The bacteria have to be in the crock at least 3 weeks (longer if temperatures are cooler) to complete the process of fermentation. During that time, they will change in color from bright green to an olive or yellow green, and the white inside will become translucent.

To keep them in the crock all winter, which is what Great-Grandmother did and also the way they were stored in the pickle barrel down at the general store, they must be very acid and salty so as not to spoil. But that hasn’t been necessary since canning was invented.

SECRETS OF MAKING FERMENTED PICKLES

1. You can’t make crock pickles from waxed grocery-store cucumbers. The brine cannot penetrate the wax. So you’ll be using cucumbers from your own or a friend’s garden.
2. Don’t let dirt in the pickle crock. The more beasties there are in the food at the moment you put it into the pickling solution, the greater your risk.

3. You’ll need 1 gal. of container for each 5 lb. of pickles. A 5-gal. crock will hold 25 lb.

of cukes. Or use glass or food-grade plastic. *But it's not safe to use garbage cans or other containers that are not made to come into contact with food that will be eaten.* For the container, a “crock” is traditional, but glass jars (gallon or larger) and unchipped enamel, plastic, or wood containers work fine.

4. Don't use a reduced-sodium salt. Fermented pickles need a specific amount of sodium to control bacterial growth and have a firm texture.
5. Alum is sometimes used to firm fermented cucumbers. But it isn't necessary. (Alum doesn't do anything useful for quick pickles.) I don't use it because I have a general principle of avoiding aluminum.
6. You need a weight to keep fermenting food under the brine. When using a crock, choose a dinner plate or glass pie plate that is slightly smaller than the crock. Weight it down with 2-or 3-qt. jars (with lids) filled with water. For a different kind of weight, fill a large food-grade plastic bag (either heavyweight or double-bagged) with brine (in case it breaks). The plate should be well below the top of the fluid so that your pickles are under 2 inches of brine. Your pickled food must always be kept completely covered by the protective brine, preferably by a safety margin of at least 2 inches.
7. Don't let the fluid get too low. The water will slowly evaporate. Keep a cloth over the top to keep bugs out.
8. *It's extremely important to wait until fermented pickles taste tart before canning them.* Use either water-bath processing or lower-temperature pasteurization.

Fermented Dill Pickles. For each gallon you want to make, you'll need 4 lb. cucumbers (about 4 inches long), 2 T. dill seed or 4 to 5 heads fresh or dried dill weed, 2 cloves garlic (optional), 2 dried red peppers (optional), 2 t. whole mixed pickling spices (optional), $\frac{1}{2}$ c. salt, $\frac{1}{4}$ c. vinegar (5 percent), and 8 c. water.

Wash cucumbers. Trim off blossom end, but leave $\frac{1}{4}$ inch of stem at the other end. Place half of dill and half of the other flavorings on the bottom of a clean, suitable container (see “Secrets of Making Fermented Pickles”). Add cucumbers, remaining dill, and flavorings. Dissolve salt in vinegar and water. Pour over cucumbers. Cover and weight down cover. Store where temperature is 70–75°F for about 3 to 4 weeks. Temperatures of 55–65°F are acceptable, but the fermentation will take 5 to 6 weeks in that case. Your pickles will get too soft if temperatures are above 80°F during fermentation. Check the container several times a week. Skim off surface scum or mold. *If pickles become soft or slimy or develop a disagreeable odor, discard them.*

Fully fermented pickles may be stored in the original container for 4 to 6 months, provided you refrigerate them and remove surface scum and molds regularly. But canning is a better way to store fully fermented pickles. To can them, pour the brine into a pan, heat slowly to a boil, and simmer 5 minutes. Filter brine through clean cloth or paper coffee filters to reduce cloudiness, if desired. Fill pint or quart jars with pickles and hot brine. Leave $\frac{1}{2}$ inch headspace. Put on lids. This is a raw pack. Process pints in boiling water bath 15 minutes at 1–6,000 feet above sea level, 20 minutes above 6,000 feet. Process quarts an extra 5 minutes.

NIGHTSHADES

Eggplant, peppers, and tomatoes (as well as husk tomatoes, ground cherries, and tomatillos) are all related. They're members of the big nightshade family (Solanaceae) and are also called “solanums.” (I talk about potatoes and huckleberry, which are nightshades

too, elsewhere in this book.) Martynia and okra are not solanums but are grown and bear fruit so similarly, and are so different from other plants, that I squeezed them in here too.

GENERAL INFO ON RAISING SOLANUMS: Eggplant, okra, peppers, and tomatoes share the same basic nature: All are tropical natives grown as annuals in the temperate zone. All refuse to germinate unless their ground is warm, grow slowly in cool weather, and may be badly and permanently stunted by exposure to a temperature below 45°F, so they're often protected by a cloche for the first part of their garden time. All take a long time to bear fruit, so northern growers must start them indoors. All do best of all when soil and air temperatures stay very warm. Try out species and varieties until you find the one that suits your climate and cooking best. But there is one group of nightshades that is easy to grow: the Physalis group (ground cherries and tomatillos). See "Planting" in the "Tomato" section for much more info on starting nightshades.

Soil. A good soil combination is 1 part each peat, sand, and garden dirt. If you are worried about disease or bug problems in the dirt, sterilize it in the oven at 180°F for 45 minutes. Put your seedbed dirt into shallow boxes, small growing pots, or big tin cans with drainage holes in the bottom. The dirt should come up to about $\frac{1}{4}$ inch below the rim of the container. (See "Planting" in the "Tomatoes" section for more information useful for planting any nightshade.) About 2 hours before planting, moisten your seedbed dirt well. Then plant, and let them grow. They'll do best in a really warm place, such as near your furnace. Water as needed. Before transplanting them to the garden, harden them off.

Hardening Off. Most nightshades, especially peppers and eggplant, should be "hardened off" before transplanting from house to garden. Start 10 days before they will be set out by taking them outside on warm days, bringing them in each night. Leave them outside (unless the weather gets unseasonably cold) the last 2 or 3 nights. Then plant them in the garden—in the evening if possible. Make sure they aren't shocked by cold soil or cold air. They can't go out if nighttime temps are below 50°F. Keep them growing inside until then.

Keep them well watered their first few days. After that, water when they're dry. In

blistering hot weather, protect them from the worst of the sun. After the soil gets good and warm, you can mulch to help keep it damp, but don't mulch prematurely, because that delays the warming of the soil—and your harvest.

Storing. Don't cram fruit into airtight plastic bags. That will make them spoil sooner rather than later.

Eggplant

Eggplant (*Solanum melongena*) is a tropical perennial grown for thousands of years in China and India and since the 16th century in Europe. Technically and botanically, the eggplant is a “berry” (so is a pumpkin!). It takes up space and doesn't bear heavily, so it's not practical for a small garden. Most eggplant varieties are grown as an annual in temperate zones; to bear fruit, they need a growing season of at least 90 days, with hot days and warm nights. (Eggplant is the most temperature-sensitive solanum.) Disease or bugs may get it. On the good side, eggplants are pretty, they're in their element and produce well in both heat and drought, and garden-fresh eggplants are wonderful.

VARIETIES: Glecklers sells Louisiana Green Oval, which bears large (up to 4 lb.), light green, mild-flavored fruits; Snake-Eye mini-eggplant, which bears ½-inch fruits that can be mashed into a sauce; Small Ruffled Red, which bears 2-inch red fruits; and white Italian types. The familiar big, oval, purple variety is *Solanum melongena* var. *esculentum*, also called “aubergine” (especially outside the United States). It is the best keeper, and that's why you see it in supermarkets. However, aubergine needs a growing season of about 120 days, and it usually ripens a total of only 2 to 6 fruits, each weighing 1–5 lb. depending on climate, soil, care, and the plant itself. You can get hybrids and Orientals that fruit as soon as 55 days. Black Beauty, a disease-resistant non-hybrid, bears aubergine-like fruit in only 80 days.

Orientals. These are hardier and quicker to harvest than the aubergine. They produce about twice as many fruits and do so earlier, and they produce several fruits at a time. Lane Morgan says, “Short-season and cool-season growers should stick with the Oriental kinds if my experience is any guide.” You can order Orientals from Burpee, Gurney's, Hudson, Johnny's, Kitazawa, Le Jardin, Nichols, Park, and Redwood City. But the seed companies are liable to call them anything, making the Oriental connection hard to recognize at times.

One Thai eggplant is round, white, and baseball-sized. Another Thai is tiny with purple streaks near its stem. The Japanese have a purplish black, cucumber-shaped, foot-long one called “black eggplant” or “nasubi.” Nasubi has a delicate, edible skin, so it doesn’t keep well and is more vulnerable to flea beetles. It doesn’t cook up mushy like the aubergine, instead keeping a pleasant, crunchy texture. Chinese eggplant, grown there for millennia, is long, thin, and lavender/violet. The Indian type is long, deep purple, and club-shaped. Bitter Orange is the strangest Oriental eggplant, so bitter it spices up bland dishes. It resembles a small, flat green pepper.

PLANTING: Eggplants thrive in well-drained, sandy, really rich soil (2 or 3 inches of manure or compost worked in well). If bacterial wilt is a risk, make sure the soil hasn’t been previously used to grow eggplant, peppers, or tomatoes. Plant in a seed flat in March or April. The best germination temperature is 75 to 90°F. Allow 12 to 15 days for sprouting. Transplant to peat pots after they get 2 inches tall. (Or you can buy plants at setting-out time.)

Transplanting and Garden Growing. Transplant 6 to 8 weeks later but not until at least 2 weeks after the last frost date; even then, they’ll do best starting under plastic. A late frost will kill them, and they won’t do anything in cold soil anyway except stand there weak and vulnerable to bugs and disease. (If you do get disease in your garden, pull out and burn affected plants.) Plant where sheltered from cold winds, $\frac{1}{4}$ to $\frac{1}{2}$ inch deep, 18 to 30 inches apart, rows 2 to 3 feet apart (wider for longer, hotter growing seasons or bigger varieties). They produce better if you add more manure during their growing. The water supply needs to be moderate but regular—about once a week at the most. In drought they seal up their pores like a cactus to save water, and they thrive anyway, but too much watering causes watery, bland-tasting fruit. Eggplants also do better if their roots aren’t walked on.

Container Growing. Put 1 plant in each 12-inch pot (3 gal. soil). The container’s dirt should be at least a foot deep. If multiple plants are in a large container, leave at least 18 inches between them. Eggplant does well in a tub on a patio and is easy to bring in before a chill. You can grow a lot of eggplant in a tub indoors because eggplant is self-pollinating and doesn’t need insects to help it bear fruit. If you live in a subtropical zone or keep your eggplant warm year-round, it can live 6 years and get as tall as 8 feet!

SAVING SEED: Eggplant is a fruited, self-fertile (self-pollinated) annual. Its flowers have both male and female parts and its flowers can attract insects, so crossing with other eggplant varieties is technically possible but likely only if there’s another variety within 20 feet. Select the best fruits on your best plants and identify them. Leave on the bush the eggplants destined to make seed—until they fall off, if possible, because that means the seeds inside are fully mature. But if frost is a risk and the fruit is ripe enough to be eaten, you can pick them and store them indoors. After about 2 more weeks, the seeds should be mature. Clean the seeds then, because if you wait too long, the fruit will rot—seeds and all.

Cut the fruit in half, and scoop out the seeds and the pulp that contains them into a glass bowl. Add water until you can easily work the seeds and their pulp around with your fingers. Knead and squish them around until the seeds have all been freed and have sunk to the bottom. Pour off the water. (You may have to squish and pour several times.) Now spread out the seeds to dry in a sunny spot at room temperature, gently separating them if they stick together. Eggplant seeds live about 5 years.

HARVESTING: Eggplants produce most in hot, sunny weather. Cool, rainy weather cuts your harvest to a fraction of that. Aubergines typically bloom in early July but don't have mature fruits until the end of August or even early September. You can start harvesting as soon as the fruits are shiny and as big as a large egg. If not picked, they'll continue growing slowly to their variety's size. Be sure to get aubergines before they get overmature—before the skin loses its gloss and the fruit is longer than 8 inches. These are signs the fruit has gotten bitter. The younger ones are more tender and have smaller seeds and no bitterness. And picking early results in more fruit being set. Cut fruit off using a sharp blade because the stem is tough and pulling can cause damage.

STORING AND PRESERVING: Eggplants store better on the vine than anywhere else, so it makes sense to leave them there until your menu calls for eggplant. Off the vine they store best if part of the stem is still attached. Or you can preserve by drying or freezing.

Drying. Peel and slice $\frac{1}{8}$ to $\frac{1}{4}$ inch thick. You can dry those whole slices or further cut them down into $\frac{1}{2}$ -inch strips or 1-inch squares. *Steam-blanch* about 4 minutes for full-sized slices, 3 minutes for little ones. In a dehydrator or oven, dry at 120°F for about 18 hours. They're done when leathery and dry all the way to the middle. Or dry in a single layer in full sun and freely moving air. Takes 2 to 3 days. (Take trays inside at night.)

ABOUT PHYSALIS SPECIES

There are several edible *Physalis* species within the solanum category: *Physalis peruviana*, the ground cherry; *P. alkekengi*, the lantern plant (one of the few edible plants not covered in this book; you can read about it in Deep Diversity's catalog); and *Physalis ixocarpa*, the tomatillo (discussed a bit later).

For more info order "Ground Cherries, Husk Tomatoes, and Tomatillos," a 22-page booklet by C. Dremann, from Redwood City. For more on the ground cherry and tomatillo, also see *Unusual Vegetables: Something New for This Year's Garden* by the editors at Rodale Press.

Using Dried Eggplant. Start by soaking dried slices or pieces in water for several hours or even overnight. Then use them in recipes as you would fresh eggplant. You can use dried pieces in long-cooking recipes without presoaking. Just add some extra liquid.

Freezing. Peel; slice or dice. Add 1 T. lemon juice per 1 qt. water, and put eggplant pieces in water to protect their color while they're waiting to blanch. Steam-blanch, or scald 2 to 4 minutes. Cool. Dip again into the lemon-juice solution, drain well, and freeze. Or precook eggplant, put wax paper between slices, and freeze.

Canning. Eggplant doesn't can well.

PREPARING: You can peel or not peel. *If you're not peeling supermarket eggplant, wash them well. They've been sprayed a lot!* Home-grown, freshly harvested fruits have a tender peel that you can remove with a potato peeler. White fruits generally are eaten skins and all.

Some people salt eggplant before cooking, no matter what the recipe (except if they're going to split it down the middle, scoop out the insides, stuff the halves, and bake). If you want to salt, slice your eggplant (peeled or unpeeled), sprinkle each slice with salt, stack them on top of each other, weight them down, and leave them for about 30 minutes. Then they pour off the liquid that has seeped out, rinse the slices, and proceed with the recipe.

Bitter Orange Recipe Ideas. This strong-tasting Oriental can be presoaked and then stewed Chinese-style with pork shreds, greens, and hot peppers. Or saute slowly with hot peppers and greens until soft. Or marinate in vinegar to pickle it. Or presoak and cook with tofu, vegetables, and hot peppers to make a soup.

Eggplant Recipe Ideas. Eggplant has only 19 calories per cup. Here are some ways to fry it: Dip thinly sliced eggplant into buttermilk and then in seasoned flour; fry coated pieces. Or dip into an egg-and-milk mixture and then into fine homemade bread crumbs; fry in oil, first on one side and then the other. Or (from reader Mary Debonis's Italian friend) dip into beaten eggs and then into flour; fry until brown, turning once; layer the fried slices in a casserole, alternating them with grated Italian cheese and Italian Gravy (see "Cooked Tomato Recipe Ideas" in the "Tomato" section); and bake 20 minutes at 350°F. Ruth's vegan "fried" eggplant: Marinate unsalted slices in lemon juice or tamari (and your choice of herbs), roll in bread crumbs, and cook in tomato sauce, covered, until tender.

➲ **BABA GANOUJ ("EGGPLANT CAVIAR")** This is a Middle Eastern eggplant dip or sandwich spread. Cut off stem ends of 1 large or several smaller eggplants. Bake them whole on a cookie sheet at 400°F for 45 minutes—until they're sagging, wrinkled, and quite soft. Cool. Scoop out the flesh from the peel, and blend or mash with a fork with one or more of the following: $\frac{1}{2}$ c. finely chopped onion, 2 crushed garlic cloves, 3 T. lemon juice, salt to taste, 1 T. minced parsley, and 1 T. olive oil. Vegan Ruth makes it with only eggplant, garlic, and enough lemon juice for consistency and flavor. Or she may add parsley or onion, or a scoop of tahini. She and her family use baba ganouj as a thick salad dressing or sandwich spread, and they also spoon it over baked potatoes. You can also blend it with $\frac{1}{2}$ c. yogurt or sour cream. It's also good with dark bread or chips.

➲ **VEGAN GRILLED EGGPLANT STEAKS** Remove stem end from a large eggplant and slice lengthwise into 4 equal slabs. Trim peel off each slab. Crush 2 or 3 garlic cloves and mix with $\frac{1}{4}$ t. oregano, 1 t. tamari, 2 T. lemon juice, and 2 T. water (or tomato juice). Poke a few shallow holes in each steak with a fork. Then drizzle on the marinade. Grill for 15 to 20 minutes over slow coals, turning and basting frequently. Place a slice of ripe red tomato on each "steak." Drizzle on more marinade, and cover with grill hood for a few minutes.

➲ **EGGPLANT AND PASTA** Slice an unpeeled, large eggplant the long way into French fry-size strips. Saute them in a little olive oil about 15 minutes. Add a dozen sliced fresh mushrooms and fry 10 more minutes. Pour 4 c. of any kind of warm tomatoey sauce over 1 lb. of cooked pasta (penne is traditional). Now mix in the eggplant and mushrooms. Season with a little salt, pepper, and Parmesan cheese.

Ground Cherry

The ground cherry (*Physalis pruinosa* or *P. peruviana*) is also called the "strawberry tomato" and "husk tomato," but it's not a true tomato. This low, bushy plant bears fruit about the size of a small cherry. The fruit is round and yellow, and it grows inside a thin, paperlike husk.

VARIETIES: The ground cherry is a native of the Central and South American tropics; there are many wild and domestic species of it there. Deep Diversity's seed catalog divides the ground cherry into these varieties: *P. peruviana*, the basic 3-to 5-foot rambling plant with 1-inch berries, the most flavorful of all; the giant ground cherry, which is from Guatemala and is the biggest; and the Goldenberry (cape gooseberry), which is bigger than *P. peruviana* and matures earliest.

PLANTING AND GROWING: Seeds are available from Burgess, DeGiorgi, Henry Field, Hudson, Nichols, Shumway, and Thompson & Morgan. Follow procedures for planting and growing tomatoes. Plant ½ inch deep in full sun. The ground cherry will grow in poor soil and needs little care. In northern zones, you can start seed inside, harden off young plants, and transplant to the garden at 6 weeks or later, at least a week after the last spring frost. These plants grow across the ground like tomatoes, 1 or 2 feet high and off in every direction. So plant 3 feet apart. Water if the ground gets dry. Keep the ground weeded and cultivated so it doesn't pack around the plants. To grow in a greenhouse or container, start in peat pots; at 2 inches, transplant to 12-inch pots. You can squeeze 2 into a 10-inch pot. In a window box, space plants 18 inches apart. The trailing vines are nice in hanging baskets.

SAVING SEED: Even though the plants perish in the chilly weather of fall, seeds self-sown by the plants may survive and sprout spontaneously in the spring, providing an early crop. You may find wild ground cherries that migrated from somebody's garden and self-seeded. In a subtropical climate zone like southern California, the ground cherry grows easily and self-sows enthusiastically. To save seed, select the best plants and use the procedure for saving tomato seed.

HARVESTING: Figure about 75 days to fruit. Harvest your ground cherries when they have turned yellow and become a little soft. If any fruit has fallen onto the ground, it was dead-ripe. If you pick once a week, you'll have a good chance of staying ahead of them. Even if they do get onto the ground, they'll be good for several more days. You'll be able to harvest an average 2 lb. of ground cherries from each plant.

PRESERVING: If you spread them out in a cool, airy, dry place, they might last a couple of weeks, but the best way to preserve them is to cook and can, or freeze, or dry.

Ground Cherry "Citron." Cut the ground cherry into chunks, roll chunks in sugar, and dry in full sun or a dehydrator until thoroughly dried. Substitute for another dried fruit, such as raisins or citron, in baked goods or fruit cake.

Freezing. Peel off husk, scald 2 minutes, chill, pour a syrup over, package, and freeze.

RECIPE IDEAS: This veggie has a fruity taste that's tart and acidic yet sweet. Eat raw, dehusked and plain, or add whole to any salad with a sweet dressing. Or add to a stew, bean chili, or vegetable soup. Or cook with onions, garlic, parsley, and peppers; add vinegar and use as a sauce. Or boil in water; add mushrooms, onions, cilantro, and ginger; and add tofu at the last moment. Or treat like a fruit and substitute in any basic fruit sauce, fruit pie, or fruit preserve recipe. Or cook, sweeten, and serve as an ice cream topping.

Martynia

Martynia (or *Proboscidea*), of the botanical family martynacia, is a native of the southwestern United States. There are more than half a dozen types of this desert and plains species, which has bristly leaves and an edible seed pod. They are found in an area ranging from the United States south to Brazil.

VARIETIES: *Proboscidea fragrans*, a common Mexican type of martynia, has bright red flowers whose pods pickle especially well. *P. lutea* has yellow blooms and is from Brazil. *P. annua*, *P. parviflora*, and *P. louisianica* (a.k.a. *P. jussieus*) all also have edible pods. *P. louisianica* is considered the best risk for northern gardeners. Martynia seed is available from DeGiorgi, Park, and Shumway.

You need 120 warm days to get martynia from seed to a pod harvest. This is easy if you're gardening in the south. Northern gardeners must start martynia like a nightshade. In the garden, plant 1 inch deep, rows 3 feet apart. Plant near the end of February or early in March. Set out your started plants in peat pots at the same time as the nightshades. Plant 4 feet apart in the garden, rows 3 or more feet apart. They need to be that far apart because, although they get only a few feet tall, they spread out widely. Plant in full sun and fertile soil.

HARVESTING: Martynia will start flowering about 6 weeks after germination. Its large (2-inch), lovely flowers grow in clusters of up to a dozen at the end of each stem. Each is followed by the edible seed pod, which somewhat resembles an okra pod (fuzzy and green) but has a curving rather than a straight shape. Harvest while still tender and green.

RECIPE IDEAS: Include either whole or sliced in soups and stews. Or pickle using a dill recipe. Or cook, chill, and serve with a vinegar-oil dressing. Or dry on the plant and then include that unusual double-forked tip in dried flower arrangements.

Okra

Okra (*Abelmoschus esculentus* or *Hibiscus esculentus*) is not a member of the nightshade family. But since it most resembles the nightshades in its growing requirements, I added it to this section. (Along with roselle and hollyhocks, okra belongs to the cotton family.) Okra grows wild in Egypt and Ethiopia and has been cultivated since prehistoric times. Ruth wrote me from her Caribbean desert isle of Bonaire: "Okra is one thing that will grow in this awful soil and horrendous heat." It's a famous Deep South garden annual and a beautiful plant. But it doesn't store or preserve very well. It's possible to grow okra outside the South if you have a hot summer.

VARIETIES: Many okra growers plant it in their flower rather than their vegetable area because the leaves can be as much as a foot wide. Okra grows from 2 to 9 feet high depending on the variety. There is a Red Okra variety that has yellow and red blooms, red stems, and red okra pods. Geneva Travis wrote me from Kell, IL: "Red okra is a beautiful red-maroon color. It bears more quickly, tastes better, and isn't nearly as slimy. I win a blue ribbon at the fair every year I enter it."

PLANTING: Okra will grow in any soil as long as the soil temperature is at least 60°F before planting, but it does better if the soil is fertile. If you live in an area with a hot summer but a short growing season, plant okra indoors a month before setting-out time. Start okra

only in a pot that can be planted out in the garden as is; otherwise it won't survive transplanting. Four or five plants can produce enough for a small family. Soak the seeds in tepid water several hours before you plant them; otherwise they will be slow to sprout. For permanent container planting, choose a dwarf variety (dwarf okra pods are the same size as standards) and plant in a tub or box. A dozen plants will supply an average family.

Don't plant outside until you have dependably warm weather, for okra is very cold-sensitive. In a northern garden, plant in as much wind shelter as you can—but always in full sun. Set out or plant seed about the same time you would watermelon or squash, when you're sure the last frost has taken place and the soil has warmed up. Plant seed directly into the garden $\frac{1}{2}$ to 1 inch deep, 3 inches apart (because okra germination rate is poor), rows about 30 inches apart, closer for a dwarf variety. Later thin to 12–20 inches apart. While the plants are young, keep them weeded but don't till deeply, because that messes up their root systems. Once they start to cover the ground, don't cultivate at all. Okra usually doesn't have pest or pestilence problems.

SAVING SEED: Okra is a self-fertile, insect-pollinated annual. Cross-pollination is possible if any other okra species is within a mile, but it's unlikely because of okra's self-fertilization. Let the pods stay on your chosen plant until they become completely mature: brittle, brown, and up to a foot long. In the late fall, gather the pods, break them open, and shell out the seeds like beans. Dry and store.

HARVESTING: Varieties differ, but in general you begin harvesting 50 to 60 days after planting. Before making fruit, okra bears lots of pretty blossoms that are either all yellow or yellow with red centers. A few days after the flowers come the edible seed pods. Severely hot, dry weather, a harsh change in temperature, or poor drainage can cause bud drop. But if growing conditions are halfway right, you'll be loaded with green, fuzzy, finger-shaped okra pods. Some varieties start bearing pods when only a foot high and will keep on from then until frost.

Okra leaves have spines that are almost invisible but can get into your skin and cause a miserable burning itch. So if you're going to be picking much okra, wear gloves and long sleeves, and don't pick unless the plants are completely dry.

Pick the long, green seed pods when they are 2 to $3\frac{1}{2}$ inches long—not longer! Bigger ones are getting old and can be bitter and tough. Go through and collect pods at least every other day if possible, not only to get pods at their prime but also to keep the plants producing, because if you let pods mature on the plant, it will stop producing new ones. Cutting off the pods rather than pulling them off protects the plant roots from tugging. If you keep on picking, the plant will keep on making fruit until it's killed by frost, but the first part of the crop is the best. In the South, in midsummer when okra gets too tall to harvest, growers cut the plants down to about 18 inches. The plants quickly grow up again and provide another crop!

PRESERVING: Fresh okra will keep only 1 or 2 days. It does best if you occasionally sprinkle water on it and keep it where air can circulate. So preserve or eat the okra as soon as possible, because the pods will toughen quickly, turning woody the same way they do if left on the plant. Okra can be frozen, dried, or canned.

Freezing. If you start with young, tender pods, okra freezes well. Trim off the stems—but don't cut into the pods. Steam-blanch 2 or 3 minutes; chill. Leave whole or slice them.

Package and freeze.

Frozen Half-Fried Okra. This tastes even more like fresh okra. Wash, trim off tips, slice, season with salt and pepper, and shake in a sack with cornmeal until all covered. (Or use in fried eggplant recipe ideas; see “Eggplant Recipe Ideas” in the “Eggplant” section.) Then fry only until barely half-fried. Cool to room temperature. Then package and freeze. To use, thaw and cook in the oven, or thaw and then finish browning in a skillet (with little or no oil).

Drying. The old-timers dried okra by stringing small, tender pods on a thread, hanging them over the stove to dry, and then giving them one last good heating in the oven before putting them into long-term storage. You can string up larger pods the same way. First wash them, cut off stem ends, and slice. Then string, and hang the strings in an airy but shady place until dried. No need to blanch okra. Or slice okra and spread out it thinly on your drying tray in the full sun (take in at night). It takes only a day or two to sun-dry. Or dry inside: cut young, tender pods crosswise or lengthwise, $\frac{1}{4}$ inch thick, and spread thinly on trays. It takes up to 12 hours in a dehydrator at 120°F to dry them. They’re done when brittle. To cook dried okra, add 2 c. boiling water per 1 c. dried okra and simmer. It’s tastiest if you add onion, tomato, and seasoning.

COOKING: “Gumbo” means okra. A gumbo recipe means okra soup, a Creole specialty. Inside the okra pod there is a kind of “slimy” stuff. If you like okra but not the slimy part, cook it with tomatoes or in soups to cut it. Geneva Travis, Kell, IL, says boiled okra is less slimy if you “kinda steam it till barely fork-tender, drain, and then set it back on the turned-off burner till ready to serve. This dries it out a little. I fry okra kinda fast—no lid, stir often, and watch carefully.” Trim off both ends of the pods before cooking. Very young and tender pods can be cooked whole. With pods of middling age and tenderness, slice them into about $\frac{1}{2}$ -inch lengths.

Woody Okra. To get some food value out of woody okra, add it to your soup or stockpot. The soft part will cook into the mix and add flavor and vitamins. After the cooking, fish out the woody part that’s left so you don’t have to eat it.

Okra Peas. The best okra is picked when its seeds are no more than half grown. But if the seed is still tender but fully grown, you can shell it out separately, discard the too-tough pod, and cook like peas. Okra peas combined with whole wheat flour or sesame seeds make a perfect protein.

Recipe Ideas. Okra is good with peas, tomatoes, onions, peppers, corn, squash, and eggplant—any or all. It’s a natural thickening agent. Stew it with tomatoes and rice, and add filé powder at the last minute. Or cook over low heat in a spicy sweet-and-sour sauce. Or blanch and served with chopped tomatoes, green onions, greens, and a vinegar-oil dressing. Or cook and then soak in the liquid left from dill pickles, or use in a dill pickle recipe. Or dip in tempura batter and fry in deep fat. Or boil pods in salted water until tender; drain and add butter, seasoning, and a dash of vinegar, and simmer until butter is absorbed. Or cover sliced pods with hot water and simmer 20 minutes; add peeled, cut-up garden tomatoes and cook 10 minutes more; add butter, salt, and pepper, and serve.

Julia Reynolds, Galvin, WA, likes okra cooked, sliced, and fried with potatoes. Reader Ruth Miller cooks sliced okras in a mixture of tomato juice and water with chopped green pepper and onion; adds chopped tomatoes, frozen corn kernels (or sliced green beans), and a dash of cumin; and serves it over rice. Also see gumbo recipes under “Sassafras” in Chapter 5.

➲ **RUTH'S BONAIREAN GUMBO** "Here's how to make Bonairean-style gumbo, 'sopi di giombo.' Cube ½ lb. salt pork, beef, or goat. Cover with water and simmer until tender. Add 1 lb. of fish like red snapper, and cook till the fish flakes easily. Remove meat and fish, and chunk them into bite-sized pieces. Cut about 4 c. of okra rounds and add to broth, along with sprigs of fresh oregano and/or basil and a bit of hot pepper. Simmer till okra is tender. Then use a whisk to break okra into tiny pieces, and simmer on till broth is thick. Return meat and fish; test for seasoning. (Bonairean cooks always taste and season!) Serve with funchi [cornmeal cooked in water to a mush, molded, and chilled]."

Pepper (Hot)

The pepper family (the many species of the genus *Capsicum*) is huge and varied, ranging from mild green peppers to burning "hot" ones. Peppers have all sorts of shapes, colors, uses, and Latin names. Most are *Capsicum annum* varieties, subdivided into the Grossum group (mild-flavored sweets) and the Longum group (hots, which range from a little hot to very hot). The hottest ones of all come from related species: *C. chinense* (Habanero) and *C. frutescens* varieties (Tabasco, Red Chili, Thai). Peppers come from the Americas, where they've been domesticated for at least 7,000 years. They're perennial shrubs in the tropics (some grow as tall as 10 feet!), grown as annuals in temperate zones. Special info on hots is covered in the following text; sweets come after that, and growing info for both kinds is in the "Sweet Pepper" section.

Hot peppers, natives of the American tropics, are also called "chili" or "chile" peppers or "pequins" because they're all relatively small in size compared to the sweets. Compared to the sweet peppers, the hot peppers generally are easier to grow and give bigger harvests. They are usually larger plants with smaller leaves. Most are green at first, some have a yellow stage, and most end up red. Some get brown. Because of the bright colors, they are often grown as ornamentals as well as for their fruit. All the peppers are tropical perennials that must be grown as annuals except in subtropical climate zones. The smallest chilies generally like the hottest climates. New Mexico is where the most U.S. chili peppers are grown. And the farther north they grow, the less hot even the same variety tends to be.

Hot Topics: For more info, read *Peppers: The Domesticated Capsicums* by Dr. Jean Andrews (U. of Texas Press, 1984); "Taste Bud Burnout" by Jake Page in *Hippocrates*, May/June 1987; and the article in *National Gardening*, May 1988.

What Hot Peppers Are Good For. Peppers are high in vitamins: They have more C than citrus, more A than carrots, and contain E and B1 too. But the quality of hots that you notice most is their heat. Is that good for anything? Well, hot peppers and other spicy foods raise the body's metabolic rate, for some reason, causing the eaters to burn as much as 25 percent more calories. Perhaps that's why a bowl of chili is great on a wintry day. It literally warms you. Chilies also stimulate saliva and gastric juice production, so in that way they aid digestion. Researchers have also discovered that a diet of blazing hot peppers helps dissolve blood clots and thus protects against stroke and heart attack. Hot peppers are also a medically sound home remedy for colds because they help relieve lung congestion and stuffy noses. The chemical that makes hot peppers hot is capsaicin, an alkaloid, and its presence is measured by the Scoville heat scale.

Scoville Heat Scale. Food scientists and commercial food processors use the Scoville heat scale (created in 1912 by Wilbur L. Scoville) to measure the comparative spicy-hotness of

foods: the more Scoville units, the hotter it is. The scale ranges from 0, or no heat units (for sweet peppers of every kind) up to 600,000 of them (for the Tepin, the hottest pepper of them all). What the scale is actually measuring is the amount of the capsaicin: the more capsaicin, the more heat units.

Capsaicin. Your regular taste buds register sweet, sour, salty, and bitter—but not capsaicin. When chili lovers speak of the “burn,” they’re being precise. The way you “taste” capsaicin is that it literally burns the place on your body that it touches, and the pain receptors tell you it’s there. You “taste” hot peppers via the pain receptors in your mouth rather than via taste buds. It’s called a “nerve-irritating chemical” because it irritates nerve cells—on the skin and in the eyes as well as in the mouth.

Capsaicin Damage. In large enough amounts, capsaicin causes irritation and even bleeding in your stomach. If you have an ulcer, even smaller quantities will make the ulcer worse. The condition of large intestine irritation caused by capsaicin (epidemic among participants in jalapeno pepper-consumption contests) is called “jalaproctitis” by doctors. Long-term, heavy consumption of very hot peppers significantly increases your risk of colon cancer. It also results in some permanent nerve loss. Even though those organs are merely innocent bystanders and can’t taste the capsaicin, they can get burned by it. When you eat spicy-hot food, the capsaicin literally causes a chemical burn of the inside of your mouth and on down your digestive tract. To a doctor, the results of Chinese red oil taken in a soup, for example, look like second-degree burns. Burned taste buds usually heal within a couple of weeks, but the nerve cells that actually register the presence of capsaicin don’t always manage to recover from the damage they suffer. In fact, people who chronically consume capsaicin don’t even taste it any more at low levels because some of their nerve endings have already been destroyed.

In effect, it works like a kind of addiction. The more you consume, the more you have to consume to taste the same amount because of the numbness caused by nerve destruction. So why do people eat it? Is it bravado, a sense of contest, the thrill of going to the brink of endurance? Researchers have noted that the pain receptors stimulated by capsaicin cause the brain to secrete endorphins, which are morphine-type natural chemicals that also cause the familiar “runner’s high.” They theorize that heavy-duty hot-pepper eaters are actually after those endorphins.

VARIETIES: Hot peppers can be classified according to “hotness.” (You can mail-order a “Pepper Hotness Test” from Redwood City that tells you how, with simple equipment (gram scale, blender, etc.), you too can accurately measure hotness.)

Mild Hots. These are semisweet, semihot, or “mild” peppers. The banana pepper is mild, longish, and yellow. The Japanese mildly hot pepper, also called fushimi or long Asian, resembles a green bean with its long, wrinkled shape and curved tail. It dries well because of its very thin skin. It can be used in sweet pepper recipes or substituted for the hot chilies in Mexican and Cajun recipes; they’ll give you some of the effect without so much of the punishment. Numex Big Jim is a foot-long mild from New Mexico State U. Anaheims range from mild to medium-hot, depending on the variety, averaging 1,000 Scovilles. They are long and pointed at one end. They are first green and then turn red, and they’re popular in California and the Southwest. Anaheims are used to make chili powder and chiles rellenos and to string into ristras.

Hotter Hots. In this group, there is Chamayo (shaped like a green bean and smaller than most of the others), Hungarian wax (ranging from medium to hot), Negros/Pasilla (black

when dried, used in mole sauce), and Poblano (hot; wide rather than long). Jalapeno peppers are small (about 1½ to 3 inches long) and very hot, rated at 3,500 to 4,500 Scovilles. Jalapenos are first green and then turn red, and they are often used to make salsa. Both Caribe and Guero are yellow, very hot, and the same size and shape as jalapenos. Fresno peppers, also jalapeno-sized, are red in color. Ancho may be mild or hotter-hot, depending on which type of “ancho” it is.

Hottest Hots. *When preparing peppers this hot or hotter, use rubber or plastic gloves.* Cayenne is first green and then turns red. It’s thin, measures 3–12 inches long, and is much hotter than jalapeno—20,000 Scovilles—and is dried and ground to make cayenne pepper. Serrano, pale green and 1 to 1½ inches in length, may or may not be hotter than cayenne. Fresh serranos score at 7,000–25,000 Scovilles. Serranos are a traditional ingredient in Southwestern guacamole and tomato sauces. Other very hot peppers are de Arbol, pequin, and Pasilla.

Hottest of All! *Remember, use rubber or plastic gloves when preparing these peppers!* Tabasco peppers rate at 70,000. (Tabasco sauce is made from either serrano or Tabasco peppers; dry the peppers when they’re yellow but turning orange-scarlet, and then grind them.) In this category are the Thai pepper (a *C. frutescens* variety at 70,000–80,000 Scovilles) and other very hot Asian peppers used in traditional Szechuan and Thai cuisines. Habanero peppers are native to the Yucatan peninsula but are now being grown all over the United States. These pale green, small (1-inch) peppers come in at an incredible 80,000–300,000 Scovilles. Red Chili is even hotter than that, however; it’s a *C. frutescens* variety with small, bright red fruits that are 2 inches long and ½ inch wide. And the “Hottest of All!” title belongs to the Tepin pepper (*C. annum* var. *aviculare*, or “Chiltepin”), which is round, red, ¼ inch thick, as tiny as a fingernail, and twice as hot as a Habanero!

PLANTING: Burpee, Native Seeds, Nichols, Redwood City, Seeds of Change, Shepherd’s, and Territorial all offer a good selection. The Pepper Gal, Betty Payton, offers 250 varieties! Contact her at 954-537-5540; fax 954-566-2208; PO Box 23006, Ft. Lauderdale, FL 33307; peppergal@mindspring.com; www.peppergal.com. If you live well north of the Mason-Dixon Line, look for varieties bred to produce even in northern zones. Lane Morgan says that at her home on the western Canadian border, hots grow more easily than sweets.

Plant like sweet peppers. Hot peppers usually do well in containers and in the house, where some, such as cayenne, will produce all winter. You can grow 1 of these small pepper plants per 8-inch pot if it has at least ½ gal. soil, 8 inches deep. In a larger container, space plants 6 to 8 inches apart.

HARVESTING AND PROCESSING

NOTE: *Wear gloves when harvesting or processing hot peppers. Whenever working with cut chilies, keep your hands away from your face, especially your eyes. Keep all chilies—whole, cut, or ground—out of reach of small children!!!*

NOTE: *A child with chili in his or her eyes is having an unforgettablely traumatic experience. For first aid, rinse and rinse and rinse with whole milk or a mild alcoholic beverage. Rinsing with water or drinking water won’t help, because capsaicin does dissolve easily in fat or alcohol—but not in water.*

The chili fruits start to get hot when they’re about 4 weeks old; they make more and more alkaloid from then to full maturity. Ordinarily, you let them ripen completely before

gathering—about 65 to 75 days to first harvest for most. *To prevent damage to the plants, cut off the pods, leaving 1 inch of stem on them. Don't pull them.* Keep the pods picked if you want the plant to keep producing at full capacity. There's no hurry about the final harvest. If a frost occurs, the peppers will probably still be all right because most chilies can survive even several light frosts.

STORING: Keep in a plastic bag in your fridge. They store best at 40–45°F. Green peppers will last in storage 3 times as long as red ones, which are fully ripe and ready to deteriorate.

DRYING: You can pull up whole plants by hanging them upside down in an airy place. To dry small individual chilies, wash them, remove stems, and slit with a knife; cut in half lengthwise; or cut into thin slices. Spread out and dry in an airy place in full sun, or in an oven or dehydrator at 120°F. Sun drying works best if day temps are at least 85°F. If night temps drop to the dew point, bring them in. They shrink and darken as they dry, eventually getting leathery or brittle and hard.

Ristas. These strings of dried chilies are best made from the most thin-skinned varieties: cayenne, ancho, Red Chili, pepperoncini, etc. String the pods on a thread by piercing them through the stem end with the needle. Hang by those strings in the sun or a sunny window to dry.

Chili Powder Recipe Ideas. Plain cayenne powder is made by removing the seeds and grinding dried shells of red cayenne or “chili” peppers. Or mix dried, ground cayenne peppers, cumin seed, and oregano in the proportions you prefer. Or combine 3 dried ancho chilies and 3 or 4 dried pequin chilies (stems removed, seeded, and crumbed), 1½ t. cumin seed, 1 t. oregano, and ½ t. garlic powder. Pulverize the mixture and store the powder airtight (in a non-metal container). Use to season chili sauces and beef, hamburger, or meatloaf recipes.

FREEZING FOOD THAT CONTAINS CHILI PEPPERS: Remove the chilies before freezing, or the stuff will get hotter and hotter! To freeze chilies by themselves, chop them up first. The thick and fleshy varieties are best preserved by freezing rather than drying.

CANNING CHILIES: Wash; remove cores and seeds. Slash 2 or 4 slits in each pepper, and either blanch in boiling water or blister outer skin with heat. Pack loosely. Add salt as desired. Cover with boiling water, leaving 1 inch headspace. Pack in half-pint or pint jars only. Process half-pints for the same time as pints. Process in a pressure canner only for 35 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Pickled Hot Peppers. You'll need 4 lb. of hot, long red, green, or yellow peppers (Hungarian, banana, chili, or jalapeno), 3 lb. sweet red and green peppers (mixed), 5 c. vinegar (5 percent), 1 c. water, 4 t. canning or pickling salt, 2 T. sugar, and 2 garlic cloves. Wash peppers. If small peppers are left whole, slash 2 to 4 slits in each. Quarter large peppers. Blanch in boiling water or blister skin to peel. Allow peppers to cool by placing in a pan and covering with a damp cloth. Peel after several minutes. Flatten small peppers. Fill half-pint or pint jars, leaving ½ inch headspace. Combine and heat other

ingredients to boiling, and simmer 10 minutes. Remove garlic. Add hot pickling solution over peppers, leaving $\frac{1}{2}$ inch headspace. Adjust lids and use boiling-water processing. At up to 1,000 feet above sea level, process 10 minutes; at 1,001–6,000 feet, 15 minutes; and above 6,000 feet, 20 minutes. Or use lower-temperature pasteurization, detailed in “Pickles” section under “Cucumbers.”

Canned Mexican Tomato Sauce

CAUTION: Wear rubber gloves while handling chilies, or wash hands thoroughly with soap and water before touching your face. Wash and dry 2 $\frac{1}{2}$ to 3 lb. chopped chili peppers. Slit each pepper along the side to allow steam to escape. Peel using one of the above methods. Discard seeds and chop. Wash tomatoes and dip in boiling water for 30 to 60 seconds or until skins split. Dip in cold water, slip off skins, and remove cores. Coarsely chop 18 lb. tomatoes. In a large pan, combine chopped peppers, tomatoes, 3 c. chopped onions, 1 T. salt, 1 T. oregano, and $\frac{1}{2}$ c. vinegar (5 percent). Bring to a boil. Cover and simmer 1 hour. Fill jars, leaving 1 inch headspace. Adjust lids and process in a pressure canner: 20 minutes for pints, 25 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

CHILI OIL: Heat 1 c. cooking oil until hot (but not until smoking hot!). Add 24 small (dried) red chili peppers. Cover and let cool gradually. When it is cooled to room temperature, strain out the solids. Chili oil is used in Asian recipes to add *heat!*

USING: Capsaicin is created in the fleshy white “placenta” that is the inner lining of the pod, but it can seep into the flesh and seeds too. So when you remove seeds and inner parts of the pepper, you cool it some. When you grind any hot pepper in a mortar, be sure you crush it really fine. Otherwise, if somebody gets an oversized chunk of that stuff in his food, it’ll take off the top of his head!

Skinning Peppers

1. Place peppers in a 350–400°F oven and roast for 20 minutes or until you see even browning. Or place chilies under a broiler for 6 to 8 minutes until skins blister.
2. Put peppers inside a food-grade plastic bag for 5 minutes, or put them in a pan and cover with a damp cloth. This step makes peeling easier.
3. After several minutes of cooling, slip off skins.

⇒ **HOMEMADE SALSA #1** Chop 3 fresh jalapeno or serrano chilies, 4 ripe big tomatoes, 1 globe (or 6 green) onion, 2 garlic cloves, and $\frac{1}{4}$ c. fresh parsley (or cilantro) leaves. Mix together. Stir in $\frac{1}{2}$ t. salt.

⇒ **HOMEMADE SALSA #2** Combine 4 fresh (split and seeded) red chilies, 2 c. boiling-hot vinegar, and 2 peeled garlic cloves. Cover and let steep 2 days. Add 1 c. chopped tomatoes and blend thoroughly. Add 2 dried chilies. Cook half hour in double boiler. Strain out solids. Store in refrigerator.

⇒ **CHILES RELLENOS** Use 1 or 2 mild, big peppers, such as Anaheim or Numex, per person. Roast, skin, and deseed the chilies. Cut a 2-inch opening at the top of each one, and remove the seeds and inner fibers. (At this stage you could flatten the whole chilies to remove air, package them with waxed paper between, and freeze for later use.) Rub the sides of a casserole dish

with butter. For proper *rellenos*, the chilies are stuffed with cheese, but in this quick and easy version, you cover the sides of the casserole with the chilies and then cover all with about $\frac{1}{2}$ lb. grated Cheddar cheese. Beat together 2 eggs, $\frac{1}{2}$ c. flour, and 2 c. milk, and pour that mixture on top. Bake about 1 hour at 350°F. Serve with beans and guacamole.

⇒ **CHILI VINEGAR** Add chilies (your choice of kind and amount) to white vinegar in a glass container. Optional: Add garlic cloves. Soak in dark, cool room for at least 2 weeks. Use to make salad dressing, guacamole, or salsa.

Chili Insecticide. The best use for the real hot stuff, I think, is as an ingredient in garden spray. Mix hot chili with soap powder and water. The spray works against a wide variety of insect varmints, including the tomato worm. Or dust your invaded plants (when wet with dew) with dry, ground chili pepper. Or spray plants with a 3-way punch: hot pepper, onion, and garlic!

Pepper (Sweet)

VARIETIES: The sweet peppers (*Capsicum frutescens grossum*) are basically bigger than the hots and come in many types: blocky bell peppers; heart-shaped pimentos; tomato-shaped “cherry” varieties; long banana-shaped peppers that are only 2 inches wide at the top but 6 to 8 inches long and produce heavily (30 or more fruits per plant); the long, curved, green Italian bull’s horn pepper; Japanese sweet peppers; Lamuyo, the European sweet pepper; and yellow-green, thick-walled, 4-to 5-inch-long cubanelles that set fruit continuously once mature. You can grow the pimento (also spelled “pimiento”), an exceptionally sweet pepper when red-ripe, for salads or to make red strips for stuffing olive centers (see “Canning Pimentos”). In my opinion, bell peppers are for folks who’ve never tried the others. Sweets do well where there’s a long, warm growing season; they’re also a possibility if you have a hot summer and give them an early start indoors. Redwood City, Territorial, Shumway, and Nichols all have good sweet-pepper offerings.

PLANTING: Sweets like a light soil. (I have the heaviest clay imaginable. Our valley used to have a brick factory, and all the really old buildings on Main Street are made of Kendrick mud.) *Too much nitrogen in the soil makes tall, dark green plants that don’t grow any peppers.* Small plants will set more peppers. In temperate zones, start peppers from seed indoors, about 50 to 70 days before your frost-free date. Plant between February and April, $\frac{1}{8}$ to $\frac{1}{4}$ inch deep and 1 inch apart, more or less. During germination, keep them at 75 to 95°F; a soil temperature of 85°F is ideal. Keep moist until they’ve sprouted. *Water with warm water to avoid a possibly fatal cold shock.* After germination they can handle 70°F day temps and night temps as low as 60°F, but they’ll grow faster if warmer. Below 55°F, they stop growing.

When peppers are about 2 inches tall, transplant to 2 inches apart. They need plenty of dirt for their roots! If you buy plants, be careful: Sweets and hots look exactly the same when young. To grow in a container, put 1 pepper plant in each 12-inch pot; to grow in a larger box, space 18 inches apart, soil at least 1 foot deep, 3 gal. soil per plant.

Wait to transplant peppers to the garden outside until they are at least 5–6 inches tall, 6 to 8 weeks old, and last frost date is at least a week past (2 weeks is better). (They grow best when days are 70 to 75°F.) Plant 1–2 feet apart, rows 2 or 3 feet apart. Don’t mulch cold ground.

SAVING SEED: Sweet peppers are self-fertile and bee-pollinated. They will cross with nearby

plants, so don't grow another variety within 20 feet. Remove inferior plants before flowering happens so that any marrying that occurs is between your best. Thoroughly ripen before picking—until they actually begin to shrivel. If frost is a risk, gather just before frost and finish ripening inside. Then cut in half and remove seeds. Not much pulp will come along, so you can just dry and store them. You'll get hundreds of seeds per fruit. They live about 4 years.

HARVESTING AND PRESERVING: Night temps below 60°F and day temps above 90°F can cause blossoms to die and drop off. But with good weather, you'll harvest maybe 10 weeks after transplanting to the garden. Each bell plant ripens only 1 fruit at a time. You'll get 8 to 10 fruits per bell under ideal growing conditions, with steady picking and no frost. Be sure to harvest before frost. You can use the small peppers too (they're great stuffed). To pick, cut the stem an inch above the fruit. "Green" peppers start out green-colored and are generally picked green if they're to be shipped to market. But you can wait until they are ripe and truly sweet (the darker the color, the sweeter the flavor). They change in color to red (or yellow, dark purple, white, or brown for unusual varieties). When a frost is imminent, pull up the whole plant, hang it upside down somewhere, and the fruit will continue to ripen! Sweets will keep a while more off the plant and in the house, if it's cool and the air is not too dry.

Freezing Sweets. Cut in half; remove seeds and pulp. Freeze your nicest ones in halves for later stuffing. Dice or slice the others. No need to blanch. Package in small plastic bags, since you may want only a little at a time. To freeze pimentos, roast and skin as described under "Canning Pimentos," and then freeze. Frozen pepper strips of various colors make visually appealing dishes. Never thaw pepper before using. Use in strips in winter salads when only partly thawed and still crisp. Or add to soups, casseroles, and macaroni or chicken dishes.

Drying Sweets. Cut in $\frac{1}{2}$ -inch strips or rings. Remove seeds. Spread on drying frames or thread on a string. Spread rings no more than 2 layers deep, strips no more than $\frac{1}{2}$ inch deep. Dry until crisp and brittle.

Canning Sweets. Cut out stem ends and remove seeds and cores as above. You can leave them whole or cut into any number or shape of pieces you fancy. Preboil 5 minutes. Then pack hot with hot liquid. Use procedure and times for canning chilies (in "Pepper (Hot)" section).

Canning Pimentos. First roast in a 450°F oven 5 minutes or until the skins blister. Then drop them into cold water. Then peel. Cut out stem ends; remove seeds and cores. Pack them flat in pint jars. Sprinkle in about $\frac{1}{2}$ t. salt. Put on your jar lid. Pimentos make their own liquid—don't add any. Use procedure and times for canning chilies (in "Pepper (Hot)" section).

Sweet Red Pepper "Pimentos." Halve sweet red peppers. Take out seeds and pith. Cut into strips; steep in boiling water 5 minutes. Drain. Put into canning jars. Pour over a boiling-hot mix of 1 c. cider vinegar, 1 c. water, $\frac{1}{2}$ c. sugar, 1 t. salt, and 2 t. olive oil. Cover and let soak like that 2 weeks in the fridge. Then either repackage into small bags and freeze, or use procedure and times for canning chilies (in "Pepper (Hot)" section).

➲ **RED AND GREEN PEPPER RELISH** You'll need 3 qt. chopped cucumbers, 3 c. chopped sweet green peppers, 3 c. chopped sweet red peppers, 1 c. chopped onions, $\frac{3}{4}$ c. canning or pickling salt, 4 c. ice, 8 c. water, 2 c. sugar, 4 t. each of mustard seed, turmeric, whole allspice,

and whole cloves, and 6 c. white vinegar (5 percent). Add cucumbers, peppers, onions, salt, and ice to water. Let stand 4 hours. Drain. Recover vegetables with fresh ice water for another hour. Drain again. Combine spices in a spice or cheesecloth bag. Add spices to sugar and vinegar. Heat to boiling and pour mixture over vegetables. Cover and refrigerate 24 hours.

Heat mixture to boiling and fill hot half-pint or pint jars, leaving $\frac{1}{2}$ inch headspace. Adjust lids and use conventional boiling-water processing. For either half-pints or pints: At up to 1,000 feet above sea level, process 10 minutes; at 1,001–6,000 feet, 15 minutes; and above 6,000 feet, 20 minutes. Or use lower-temperature pasteurization, detailed in “Pickles” section under “Cucumbers.”

Recipe Ideas. Whether using raw or cooked sweet peppers, always get rid of the seeds and white pulp inside. There’s really no need to skin a pepper except with pimentos, but if you want to, see “Canning Pimentos.” Serve them raw, chopped in a green salad, or as strips with or without dip. Or add to casseroles, lay strips on pizza, skewer as part of a shish kebab, add to omelets, fry with just garlic, or stir-fry with other veggies and maybe meat too. Or saute with garlic and onion, adding tofu chunks at last moment. Or stuff with cheese and rice (see the following recipe). Or precook with onions and green beans, and serve mixed with melted cheese. Or chop small and add to any stew or soup. Or dip in batter and fry.

⇒ **RUTH’S VEGAN STUFFED PEPPERS** Cut around the top stem with a sharp small knife as if you were going to make a lid for a jack-o’-lantern. Lift it out, and scoop out seeds and pulp. “Plunge 4 large, deseeded green peppers into boiling water. Return to boil, remove peppers, and drain. Combine 2 c. corn kernels, 1 c. cooked dried beans, and $\frac{1}{2}$ c. tomato sauce. (Actually, peppers can be stuffed with almost any bean or rice mixture.) Stuff into peppers, and sprinkle liberally with cumin. Place peppers in baking dish with a little water for moisture. Bake 20 minutes in a preheated 375°F oven.”

⇒ **PIMENTO CHEESE** From Judy Hohstadt, Cove, OR: “I’ve been trying to raise pimentos. They grow great except for turning red; that they will not do for me until after they’re picked. By the time they’re red there is not much meat left in them to can. We use them in this Pimento Cheese recipe—great in sandwiches or as a dip. Grate $\frac{3}{4}$ lb. medium sharp cheese. Add $\frac{1}{4}$ c. (or more) mashed, canned pimentos with juice, 1 t. onion juice, and a pinch pepper. Mix with enough mayo to be spreadable.”

⇒ **RUTH’S PIMENTO PEPPER PASTA SAUCE** “Cook a large chopped onion and 2 c. (firmly packed) chopped red pimento pepper in $\frac{1}{4}$ c. water until soft. Puree in blender with $\frac{3}{4}$ c. water until pulpy. Pour the puree back into a pot and add 1 T. lemon juice, 3 T. parsley (1 T. dried), and 1 t. each of oregano and basil (dried). Simmer 5 minutes and then serve over warm pasta.”

⇒ **PAPRIKA** Dry and grind the outer shell of the sweet red pepper. It’s good sprinkled on a white sauce or white vegetables (such as mashed potatoes, cauliflower, or parsnips) to add color as well as taste. Or use in any meat, gravy, sauce, or veggie dishes. If made from sweet peppers, paprika rates 0 on the Scoville scale.

Tomatillo

Tomatillo (*Physalis ixocarpa*), also called the “Mexican husk tomato,” is closely related to the ground cherry (see “Ground Cherry”). You can get tomatillo seed (green or purple) from Nichols, Redwood City, Seeds of Change, and Shepherd’s. Greens bear bigger fruit (2 to $2\frac{1}{2}$ inches across), but the purples, although only 1 to $1\frac{1}{2}$ inches across, taste and store

better. This solanum grows anywhere, unlike its less hardy cousins. This sprawling plant can grow to 4 feet in diameter, so plant far apart. Jana Dean, Olympia, WA, says, "They grow like weeds and don't need water. They volunteer themselves."

HARVESTING: Tomatillos take 68 days to produce, and then they bear prolifically. They're ready more quickly than tomatoes and don't mind cooler weather. Tomatillos grow encased in a papery outer husk that looks like a Chinese lantern and splits when the fruit is ready for picking. Pick when the fruit is the size of walnuts. They may be sticky to touch. If left on the vine to continue ripening, they'll turn from green to purple or yellow (depending on variety) and get milder and sweeter in taste. Jana advises that to make great tomatillo green salsa, pick only green tomatillos, not yellow ones: "Harvest as soon as they nearly fill their husks." People usually get about 1 lb. fruit per plant.

Storing. To store, leave them in their husks and set only 1 layer deep in a cool and airy room, or keep them in the refrigerator. But don't seal or wrap in plastic or anything similar. They store better than ground cherries. The purple kind stores better than the green. If you pull back the husks of purples and string them like garlic, they'll keep for months.

Canning. Remove the husks. Rinse fruit. Boil uncut tomatillos in a covered pan for 10 minutes (or until tender). Drain. Pack hot into hot pint jars. Pour in boiling water, leaving at least $\frac{1}{2}$ inch headspace. Add $\frac{1}{2}$ t. salt and 1 t. lemon juice or vinegar. Put lids on and tighten. Follow instructions for canning tomatoes.

Freezing. Cook first; then freeze. You can use frozen tomatillos to make salsa verde or any other cooked tomatillo dish.

Recipe Ideas. Tomatillos are a south-of-the-border favorite, the basis for genuine Mexican salsa verde, the green mild-hot sauce used on tacos and chiles rellenos. Green tomatillos taste something like green tomatoes and can be substituted for them in recipes if you compensate for tomatillos being solid rather than open and juice-filled inside. You can substitute fully ripe (purple or yellow) ones in ground cherry recipes, but cooks generally prefer using tomatillos when they're green, because dead-ripe tomatillos taste so bland. Serve sliced raw tomatillo in a mixed green salad, sliced plain, or with dip as finger food. Or use to make salsa verde or dip. Or cook and add to dishes (tomatillos add an herb-lemon flavor). Or slice and add to a veggie soup or bean casserole.

⇒ **TOMATILLO DIP** Combine 2 c. chunked, uncooked tomatillo, 1 c. chunked onion, $\frac{1}{4}$ c. dried epazote, maybe a little minced hot pepper, and 1 t. garlic salt. Churn in a blender until smooth. Add 1 c. sour cream. Serve chilled.

⇒ **TOMATILLO SALSA VERDE** Make the above dip, but leave out the sour cream and add 1 T. lemon juice and 3 cloves garlic.

Tomato

This tropical perennial, grown as an annual in temperate zones, is from South America. Natural tomatoes do best if they have a long, hot time to grow, but rigorous selection has developed early, more hardy varieties. Tomatoes have both fruit and veggie uses. Botanically they are fruits. In 1893 the U.S. Supreme Court applied its solemn expertise to the problem of tomato classification and decided that henceforth the tomato, *Lycopersicon lycopersicum* (a.k.a. *L. esculentum*), would legally be a vegetable rather than a fruit.

TOMATO INFO AND RESOURCES: You'll enjoy J. W. Jung's *Totally Tomatoes* (and peppers!), an 80-pg catalog: 800-345-5977; fax 888-437-2733; 334 W. Stroud St., Randolph, WI 53956-1274; www.totallytomato.com. Tomato Growers Supply Co. carries 200 varieties, and everything else for the tomato grower in its catalog: 941-768-1119; 888-478-7333; PO Box 2237, Fort Myers, FL 33902; www.tomatogrowers.com. *The National Gardening Book of Tomatoes* shares tomatogrowing expertise from the National Gardening Association; 802-863-5251; 1100 Dorset St., So. Burlington, VT 05403; www.garden.org. You can look up greenhouse tomato production at nwrec.hort.oregonstate.edu/tomatogh.html and get help with tomato disorders at aggie-horticulture.tamu.edu/publications/tomatoproblemsolver/index.html.

VARIETIES: Tomatoes are big business for the seedsman, the most popular garden vegetable in the United States (beans are the next most popular). New varieties and hybrids are easy to develop, so there are many, many kinds to choose from.

How MANY TOMATOES?

It's easy to raise tomato plants from seed, and they transplant without difficulty. One ounce of tomato seed might produce 3,500 to 4,500 plants. (I didn't count 'em. I read that in a book—like a good share of the stuff in this book.) It's easy to accidentally get far too many started. If you can't bear to throw out the extras, you'll have to hit up your friends to please take a few dozen plants, or maybe a few hundred. Even 25 plants would give you a big crop of tomatoes, with lots to put up for the winter and some for the neighbors too—if you give them room, fertile soil, and plenty of water. With 100 plants, you can become a truck gardener and sell tomatoes. Just half a dozen plants gives you a good summer's eating.

Ricki Witz, Armstrong, IL, wrote me, "For the first 26 years of my life, I lived in the northwest suburbs of Chicago. The first time I saw a cow was in the petting zoo when I was 11! I had never even planted a seed when I married my husband. I thought I would go crazy living in his small country town ... a nice house on 5 acres, small but

affordable. When we moved in, I found that the previous owner had planted 21 tomato plants. I had never seen a tomato plant in my life. I couldn't imagine why there was horse manure all over the garden and ick! around the tomato plants.

"Well, they grew and grew with no attention from me until my husband started bringing in 40 or 50 lb. of tomatoes every 2 or 3 days. Soon my sink was full of rotting tomatoes. I made up my mind then ... it was throw away food or learn to can it, so I bought a canner and jars and made taco sauce, spaghetti sauce, and tomato juice. Then our apple tree (that I didn't know was really an apple tree) started to do its thing too. After supplying my 'city' friends with crates of apples, I made the plunge there too and canned apple sauce (80 pints) and apple butter. I was glad when it was all over."

Ricki told me the next year she planted only 10 tomato plants! Just exactly how many is right for you depends on how much room you have in your garden, how large your family is, how well your variety will produce, and how hard you're willing to work at putting them up for winter. After growing them a few summers, you'll know the answer.

The original tomatoes were yellow; now you can have them in red, orange, pink, green, or white, with fuzzy or smooth skin. They range in size from supersized 1½ lb. tomatoes to the cherry (earliest to mature) and dwarf kinds, some of which are as small as a marble. They can be sweet or sour; round or oval; open-pollinated heirloom standards that you can save seed from or heavy-yielding hybrids; vines or bushes. The plants can grow anywhere from 18 inches to 6 feet tall. You can get early (sets fruit well even in cool weather; matures quickly), mid-season, or late-maturing (biggest individual fruits; 80 to 90 days) varieties. It may be 120 days before you have a big harvest from a late variety, but you can get 200 lb. of tomatoes from 1 packet of seeds or a 50-foot row, and that is worth the wait.

You can choose a variety that's resistant to verticillium wilt, fusarium wilt, or nematodes. Those resistances are coded in seed catalogs as V, F, or N. Other varieties resist cracking or tobacco mosaic (spread by people smoking in the garden or smokers who handle tomato plants). A tomato variety has either "determinate vines" that are bushy, stay short, and are probably best for container growing; or "indeterminate vines," the usual garden kind, which grow and bear until frost, sprawling across the ground and growing bigger and bigger unless staked, caged, or trellised. We just let that kind run.

You can choose juicy types, more solid types for making tomato paste and sauce, or even the hollow Burgess Stuffing tomato. You can get them seeded or seedless. Commercial gardeners grow varieties that ship better than they taste; gardeners can go for the most flavorful kinds. Florida growers, plagued with nematodes and blight, may get the best tomato crop by growing Celebrity or 5000 and remembering that tomatoes will produce best there if in a shady area. If you live in the cool, cloudy weather of the maritime Northwest, pass up the beefsteaks (which require heat) in favor of very early kinds such as Oregon Spring Tomato (Nichols) and cherry tomatoes. Your extension agent probably has a list of varieties recommended for your area. Or ask a gardening neighbor. My choice is a standard, red, average-sized, usual-shaped, high-acid type. But it's fun and good insurance to try 2 or 3 kinds unless you're saving seed.

PLANTING: Move your tomatoes around in the garden. To avoid disease, wait 3 years before planting tomatoes in the same place or in a place where potatoes or eggplants have grown. If you live in the southern part of Florida or Texas, you can plant tomatoes outside, right where you want them to grow. They need a soil temperature of 60 to 85°F for best germination. In the garden, plant ½ inch deep. Plant generously and thin later to the best ones for your crop. It will be 7 to 12 days before the seeds germinate. Thin to as much as 4 feet between plants and between rows unless you need to cram tighter.

Sheltered Starts. In somewhat more northerly but still mild-wintered areas of the South, start the plants outdoors in cold frames during cool weather, and then transplant to your garden proper from there. In colder climates than that, plant indoors or in a hot frame 10 to 12 weeks or longer before your average last spring frost date. Plant ¼ inch deep; cover with newspaper, plastic, or glass, leaving a small opening on a corner; and keep at least 70°F. Keep the dirt moist with a fine spray. When you can see seedlings, take off that cover and provide lots of light. Try not to wet the leaves while you're watering.

When the plants are 3 to 4 inches tall, repot into a deeper container, setting them down in the dirt right up to the leaves. When they've grown to about 10 inches high, repot again into a yet deeper container (such as a milk carton), again setting them as deep in the dirt as you can—right up to the leaves (you can pinch off the lower ones). Harden plants for at least 10 days just before transplanting.

Lazy Person's Indoor Start. If you don't want to bother with all that transplanting and covering in the garden, plant in March or April and transplant to the garden in 6 to 8 weeks—after last frost. You'll harvest in July and August.

Transplanting to Garden. Move the first few to your garden 3 weeks before last frost date; then move a few more each week after that until all danger of frost is over. If the day isn't cloudy, wait to transplant until evening. Plant in a full-sun site with fertile soil. Water your tomato plants before transplanting. Their dirt should be wet enough to cling to the roots. Before you take the plant out of its former home, dig the hole or trench you're going to plant it in. Put plenty of water into the new hole.

Trench Planting. The best way to set the plant in is with its stem laid down under the dirt horizontally instead of vertically, until you come to the leafy part, which you should let stick up out of the dirt. Set the plant in right up to its leaves. You can pinch off the lower ones. It will grow new roots along the part of the stem that is underground. Tomatoes do better in trench than in vertical planting because the upper soil is warmer, and solanums need that warmth. Set the plants 2 to 6 feet apart depending on the variety and garden space available, in rows 3 feet or farther apart. But crowded tomato plants are no bargain—they produce less fruit. Once the plants are in the holes, firm up the dirt over them by gently stepping on it. Then give the area a good wetting. Don't mulch unless you use black plastic. Use a cover for windbreak, frost protection, and heat-gathering until the weather seriously warms up.

Cutworms. What to do? You set out your plants, you come back the next day, and all that's left is a little stem sticking out of the ground. Mae Wallace, Berwyn, IL, says she uses cornflake boxes or other similar boxes, cutting around them to make narrow cardboard collars for each plant. She makes the collars about 3 inches tall and pushes them down into the soil until the dirt comes to within an inch of the top of the band. The cutworms don't crawl over, and her plants are spared.

Container Growing. Tomatoes are great container plants and do well on a window sill

or in a hanging basket. Cherry or dwarf bush types are good for small containers. When the seedlings have made it to 2 inches tall, transplant them to individual pots. To raise full-size tomato plants in a container, place only 1 in a container the size of half a whiskey barrel. You need 3 to 5 gal. of soil per tomato plant, and it should be at least 12 inches deep. In larger or longer containers, space plants at least 18 to 24 inches apart. With dwarf tomato varieties, you can squeeze one into a 12-inch pot and need 1 to 2 gallons of soil per plant, 8 to 10 inches deep. Plant small ones at least 12 inches apart.

OF STAKES AND CAGES: There are different varieties of tomatoes, but the typical one can be allowed to run over the ground like any vine plant. Or it can be staked up or caged to save room. Caged tomatoes produce up to twice as much as staked ones (which in turn may produce less than vines allowed to run free). I let mine run, but lots of people stake or cage. To stake them, plant a stake as high as your variety is expected to grow. Using an old stocking or rag or some such, tie a strip firmly to your stake and then make a loose loop with the cloth around the stem of the tomato plant. If you squeeze the stem, you'll really hurt the plant. To cage, buy a ready-made cage, or put a circle of woven wire fencing or something similar around your plant. You can fasten it down to the ground on each side with stakes.

WEEDS: One way or another you've got to fight weeds. You can put down a good 2-inch mulch or come through regularly tilling the ground between plants until the vines cover the ground and prevent weeds.

TOMATO WORMS: You may have to cope with tomato worms. I haven't ever had them, but I've had neighbors all around who did. I credit my chickens for allowing me to be spared. Chickens also like tomatoes, though, so I have a struggle either way. Shutting up the chickens from midsummer on seems to work fine. A tomato worm is about 1½ inches long; it's a very fat, hairless green grub with one horn sticking out of its tail. They can't sting with the horn, although folklore says they do; and they can't bite, but they are revolting to pick up with your bare hands. You find them deep in the plant and have to pick them off by hand, going out early each morning with gloves and a can. Personally, I'd rather cope with the chickens. A reader in Berwyn, IL, says she takes a green twig that will bend but not break and uses it as pincers to pick off the green tomato worms.

SAVING SEED: Don't save hybrid seed. Tomatoes are a self-fertile, insect-pollinated, temperate-zone annual. Although the chance of crossing is slight, it is possible if you have different varieties flowering, so plant them as far apart in your garden as possible. Choose the best fruits from the best plants—at least 3 of each variety you're saving from. Let the fruits stay on the plant until well past what you would consider overripe for table use. Then gather and follow the fermentation directions under "Saving Seed" in the "Cucumber" section. Tomato seeds will live 4 years or more.

HARVESTING: Your tomatoes will probably begin to ripen sometime in August. Pick them as fast as they get ready. Green, yellow, and red are the stages of ripeness for ordinary tomatoes. Vine-ripened tomatoes are so good! Pick them when red and ripe, when their taste is at its perfection. (Don't pick them early to ripen later yet. They have to do it that way in the commercial world, where picking green tomatoes is serious science and big business. Those tomatoes are picked once they're mature enough to finish turning red off

the vine. Then they're treated with ethylene gas to help get them going and are shipped to supermarkets.) The time you do have to pick green tomatoes is frost time. Your tomato vines will keep bearing until frost kills them, so you should keep picking to eat, can, freeze, sell, give away ...

GREEN TOMATOES: Green tomatoes extend your tomato season as well as become tasty dishes in their own right. Before you expect the first frost, either cover your tomatoes with plastic, old sheets, shower curtains, or rugs—anything to protect them—or give up and pick all the nice big green ones as well as the ripe red ones and bring them in the house for storage.

If you slice a green tomato with a sharp knife and you can cut one of its seeds in two, it isn't mature enough to make it off the vine. Tomatoes that are mature enough have seeds suspended in a jelly-like juice that will shift away from the knife so the seeds don't get cut. Once the fruit is at that stage, it's worth picking.

If a frost doesn't actually occur that night, wait until you fear one again. Then go through the same routine of covering or picking again. If you pick, you'll get all the ripe-enough tomatoes that have matured since you last picked. The day after a vine-killing frost finally does occur, harvest every tomato left on the vines—whether developed or not, frosted or not. Tomatoes that got touched by frost will have translucent spots. But deep inside the vines, if the frost wasn't too heavy, there will be lots of unharmed ones. The undeveloped ones can be used in green-tomato recipes, and both frosted and undeveloped tomatoes are good food for pigs or chickens.

Storing Greens. You are either going to eat them green, try to store them green until you want them to ripen, or try to get them to ripen. Green tomatoes stay green best around 45°F. They ripen best at around 70°F. Either way, store where the light is dim.

Storing on the Vine. Trudy Dorr, Lynden, WA, wrote me: "When freezing weather comes, I pull up the whole plant, root and all, and hang in porch, shed, attic, etc., and the tomatoes will ripen. This way I have tomatoes until at least Thanksgiving, and they taste the same as summer vine-ripened ones." Another reader has a similar system: "I cut the vines off at the ground and haul them indoors, cages and all, and pile them on a drop cloth on my basement floor. I pick them there in my basement until November or December, when they're gone. Then I clean up the mess. Even small ones ripen. I make these late ones into sauce."

Storing Off the Vine. You can also pull them off the vines to bring in. Anything that is big enough to have gotten to the glistening stage will eventually ripen. Spread them out in a place where they won't freeze and won't be damp. You can lay them on straw in cold frames (cover if needed) or on shelves. Tomatoes in storage will gradually ripen. They will taste like store-bought tomatoes rather than vine-ripened ones. But you'll have home-grown tomatoes for Thanksgiving dinner and fresh-sliced ones on the table, and that's worth a lot too. *To hurry ripening, put an apple in with the tomatoes.*

Checking on Them. Check the tomatoes every couple of days, especially at first. The reason you don't want to pile your green tomatoes in a box is that when they go bad, they do so suddenly and make a repulsive, slimy mess. A bad apple in a box just quietly shrivels and gets fuzzy. A bad tomato collapses all over its neighbors, spreading the infection. Spread them out so they don't touch each other; that way you can quickly remove any bad ones, and the rest will be unaffected. If a tomato has a translucent spot on it, that is where it got a touch of frost, and it will rot first from that spot. If you catch it

soon enough, you can just trim out the spot and use the tomato in a green-tomato dish.

Recipe Ideas. For more green-tomato recipes, check out *The Green Tomato Cookbook* by Paula Simmons. Storey Communications offers a booklet, "52 Great Green Tomato Recipes!" Green tomatoes can be sliced and dried the same way as ripe ones.

⇒ **FRIED GREEN TOMATOES** *I like these, and this is the easiest way to fix green tomatoes. Slice your green tomatoes into about ½-inch slices. Combine flour, salt, and pepper in a pie tin. Dip the tomato slices in the mix to get both sides well coated. Fry them in hot shortening on one side and then the other. Serve hot and right away. Or you can use an egg-and-flour coating. A little basil in the flour is also good.*

⇒ **BAKED GREEN TOMATOES** *Cut your tomatoes in about ½-inch slices and arrange half of them in the bottom of a greased baking dish. Over that make a layer of small toasted bread cubes (use homemade bread), salt, pepper, and butter dots. Add a second layer of green tomatoes and then a second layer of everything else. Finally, sprinkle grated Parmesan cheese on top. Bake at 350°F until tender.*

⇒ **GREEN TOMATO PIE** *This is a classic green-tomato dish. Cover 2 c. chopped green tomatoes with water, and bring to a boil. Drain. Add ½ c. brown sugar, 2 T. vinegar, ½ t. cinnamon, ½ c. chopped raisins, 3 T. melted butter, ½ t. salt, 3 cloves, and ¼ t. This makes a mock mince filling. Use a pie plate lined with a bottom crust. Add your mock mince. Put on a top crust, and slash to let steam escape. Crimp crust edge. Bake at 375°F about 40 minutes.*

PRESERVING

NOTE: *Don't refrigerate vine-ripened tomatoes unless you have to. Cold destroys their wonderful fresh flavor.*

Speeding Up Sauce-Making. Marie Oesting, Ocean Park, WA, says, "When making spaghetti sauce, paste, ketchup, etc.: Scale and peel, take out bad spots, slice or 'whunk' them up, and then let them set in a strainer, colander, jelly bag, or anything like that overnight. You'll be surprised at the amount of water you separate out—it's clear liquid, not at all red, and you save about half the cooking time. Incidentally, the quickest jelly bag is a kid's short-sleeve or sleeveless pajama top or a man's undershirt. Sew the waist shut and stick a broomstick through the arms to hang it up with, or put a string through the arms. I did this with one of my husband's old undershirts, rinsed it out, and put it in the laundry. I forgot about it and put it back into his undershirt pile. Boy, was he frustrated one morning trying to put that jelly bag on!"

Lane Morgan has a different system for the same purpose. She says, "Put your washed, stemmed tomatoes in a steamer with just a little water in the bottom. Heat slowly until the tomatoes start to give up some liquid, and then turn up the heat. Keep steaming until tomatoes are cooked. Then you pull out the basket, puree your cooked tomatoes however you like, add whatever else you like to put in tomato sauce, and cook until thick enough—maybe half an hour. Then can or freeze as usual. The watery juice that takes hours to evaporate by other methods is right there in the bottom of the steamer pot. And better yet, although it looks thin, it tastes great. I drink it straight or with a dash of salt and Tabasco sauce. Or else I put it in soup stock or bread dough. If you want to use it as a regular-looking tomato juice, mix in a bit of the puree. Leave a little liquid in the pot after the first batch of tomatoes to get the next one started."

FREEZING: Freeze tomatoes raw or cooked. To use, just drop the frozen chunk into the stew

or whatever. That way it cooks up so quickly it can't spoil.

Frozen Whole. Lane Morgan says, "I freeze whole tomatoes. They thaw into mush, but it's great, fresh-tasting mush. It's good for salsa. Just put them straight into the freezer and bag them up later when they are hard. In my garden I seldom get enough tomatoes at a time to can, so this lets me build up a supply slowly. I leave the skin on—it peels right off as the tomato begins to thaw." For a salad, take them out just before mealtime, cut in pieces, and mix with your lettuce. They will be just right by the time you're ready to eat.

Frozen Stewed. Peel tomatoes and cut into quarters. Boil them 5 or 10 minutes. Cool, package, and freeze. You can freeze them in jars; I've done it and it works all right, but I like canned tomatoes better because you don't have to bother thawing them, and I think they taste better.

Frozen Tomato Mix. Liz Zellhoefer, Albany, CA, grew over 300 lb. of tomatoes in a 12 × 16-foot plot. She wrote me: "Well, I caught on real quick that if I canned all those tomatoes, I might go bananas. So I looked around for recipes and came up with this way to put up many pounds of tomatoes as easily as possible. In a huge kettle put 30–40 lb. of washed, halved tomatoes. Add 3 chopped celery stalks, 3 carrots, 3 onions, and a bunch of parsley, and boil. Boil hard until everything is mushy. Drain off water; puree through a ricer. Bring to boil and cook until thick. Pour into containers and freeze. I had so many containers that for 1½ years I didn't have to buy any tomatoes or tomato sauce!"

Frozen Tomato Juice. Low-acid tomato varieties and sound, well-ripened tomatoes will freeze best. Quarter them. Place in a covered pan. Crush lightly to provide enough juice to cover the bottom of the pan. Heat rapidly to 185–195°F (below boiling). Then put them through something to get the juice—a food press or a rotary colander, for instance. If you want seeds in your juice, use something with large holes. Then cool the juice quickly by setting the pan in ice water. Add 1 t. salt per 1 qt. juice. Pack in your containers and freeze immediately.

Frozen Tomato-8 Juice. This makes lots. Cook until soft ½ bushel of tomatoes, 10 large carrots, 4 green peppers, 4 large onions, ½ lb. green beans, 3 kohlrabies, a bunch of celery, and a bunch of parsley. Rub it all through a colander. Season with salt and pepper. Cool as quickly as possible, package, and freeze.

Frozen Green Tomatoes. Edna Andrews, Ravensdale, WA, wrote me: "I slice them thin, package, don't add anything to them, and freeze. Sometimes a few on top look dark when the package is opened, but they still taste good. Because of freezing, we can have fried green tomatoes all winter. They lose some of their hardness from the freezing, but when fried crisp they taste just like fresh ones."

DRYING: Drying tomatoes is harder than drying most other vegetables because tomatoes are mostly water. They're so wet that a dehydrator may not be able to release moisture fast enough, increasing the risk of mold. Yet it's easier to dry them in a dehydrator than in the oven or sun, unless you live where the humidity is very low and the sun's heat is very high. Starting with paste-type tomatoes helps a lot, because they're low-moisture types. The tomatoes must not be overripe, or they'll have an even greater tendency to mold. (You can make a leather from overripe ones.) Choose firm ones that are just at the peak of maturity. Peel and slice as thin as possible— $\frac{1}{8}$ inch thick. Drain off juice and seeds (which may cause a bitter taste). Optional: Sprinkle with salt.

Lay the sliced pieces directly on your drying tray, no more than one layer high, with a

little room between slices for air circulation. Use only part of a commercial dehydrator so that it isn't overloaded with moisture. Gen MacManiman says to dry them at 110°F (it takes up to 30 hours). Some people who dry tomatoes dehydrate them at up to 140°F in a homemade dehydrator or at 120–200°F in an oven—with either dehydrator or oven door propped open several inches. If using the higher temperatures, check every 15 to 30 minutes because tomatoes scorch easily in the last stage. With care they can dry very nicely, keeping their flavor and color. Dry until shriveled and slightly flexible yet not brittle. To make tomato leather, use the basic directions for making food leathers in [Chapter 7](#).

Tomato Paste. Start with a paste-type tomato variety. Cook to softness, blend or process into a puree, and simmer until reduced in volume by 50 percent. (Stir often and don't let it scorch!) Now can in pint jars in a pressure canner using the times and directions for canning pumpkin (see "Winter Squashes"). Or spread a ½-inch layer of the thick puree onto a cookie sheet. Dry in dehydrator or sun until no longer sticky (maybe 2 days). Then make into balls, dip in oil, and store in a tightly lidded jar in a very cool place. Optional: Add basil, parsley, oregano ...

Dried Tomato Recipe Ideas. Season with salt, basil, and oregano and marinate in olive oil in a dark place for at least 4 weeks. Or add to soup, stew, chili, or lasagna. Or pour boiling water over, simmer until tender, season as you would stewed tomatoes, and serve. Or grind to a powder and add that to meat loaf, casseroles, etc.

CANNING: I can tomato juice, sauce, and stewed tomatoes while they are in season. Literally bushels of tomatoes go through my canner. Then we have the green tomatoes all fall. The following tomato information and recipes are from Pacific Northwest Cooperative Extension and represent the state of the art:

BIG CHANGES IN TOMATO CANNING: Recent research has caused more changes in the tomato-canning process than in the process for canning any other kind of food:

1. Because tomatoes are the least acidic of all the foods defined as "high-acid," and because acidity varies so much, canners are now urged to *always* add citric acid or lemon juice to all water-bath-canned tomatoes in order to raise their acidity. Water-bath canning is okay for plain tomatoes, but they *must* be acidified.
2. Processing times have been lengthened.
3. Pressure canning can be used as an alternative to water-bath canning.
4. Recommended pressures now differ for dial and weighted-gauge canners. (This is true of canning *anything*!)
5. Altitude adjustments for both boiling-water canners and pressure canners have been revised. (This is also true for *all canning recipes*.)

Adding Acid, Sugar, and Salt to Canned Tomatoes. Add 1 T. bottled lemon juice per pint or 2 T. per quart. Or add ¼ tsp. USP citric acid per pint, ½ t. per quart. Some people add a little sugar to mask any sour flavor: 1 t. sugar per pint, 2 t. per quart. You can add salt to taste; it doesn't help preserve the tomatoes. On average, people add ½ t. salt per pint, 1 t. per quart.

Choosing and Preparing the Tomatoes. The amount of tomatoes it takes to make a canned quart ranges from as little as 2¾ lb. for crushed tomatoes to 3¼ lb. for tomato

juice, on up to 5–6½ lb. for tomato sauce. Select firm, underripe-to-ripe tomatoes. Never use decayed or overripe ones because their presence can significantly lower the acidity. Don't can tomatoes from dead or frost-killed vines. Wash tomatoes in cool running water. Skinning is optional. To skin, dip into boiling water for 30 to 60 seconds or until skins split. Dip in cold water; slip off skins.

NOTE FOR RECIPES

1 lb. mushrooms = 2½ c. sliced mushrooms

1 lb. onions = 2½ c. chopped onions

1 lb. peppers = 10 large peppers

1 lb. tomatoes = 3–4 small tomatoes

Crushed Tomatoes. To pack them hot without any added liquid, cut your prepared tomatoes into quarters. Heat them quickly in a large pot, crushing the first layers with a wooden spoon to press out juice. Continue heating to a boil, stirring to prevent burning. Boil gently for 5 minutes after adding all tomatoes. Fill pint or quart jars immediately with hot tomatoes, leaving ½ inch headspace. *Add acid.* Adjust lids and process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 45 minutes; at 1,001–3,000 feet, 50 minutes; 3,001–6,000 feet, 55 minutes; and above 6,000 feet, 60 minutes. Process pints for 10 minutes less than the time given for your altitude.

To use a pressure canner, process for 15 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Whole/Halved Tomatoes Packed in Water. Prepare as above, but leave whole or cut in halves. To raw-pack, fill jars with raw, peeled tomatoes. Cover with hot water, leaving ½ inch headspace. To hot-pack, add enough water to cover tomatoes in a large pan. Boil gently for 5 minutes. Fill jars with hot tomatoes. Cover with hot cooking liquid, leaving ½ inch headspace. *Add acid* to both hot-and raw-packed tomatoes. Adjust lids and process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 45 minutes; at 1,001–3,000 feet, 50 minutes; 3,001–6,000 feet, 55 minutes; and above 6,000 feet, 60 minutes. Process pints for 5 minutes less than the time given for your altitude. Process pints or quarts in a pressure canner for 10 minutes at the correct pressure for your altitude, as indicated in the preceding Crushed Tomatoes recipe.

Whole/Halved Tomatoes Packed in Tomato Juice. Prepare tomatoes as in the preceding recipe and tomato juice as in the following Canned Tomato Juice recipe. To raw-pack, heat the tomato juice in a pan. Fill jars with raw tomatoes. Cover with hot tomato juice. Leave ½ inch headspace. To hot-pack, completely cover tomatoes with tomato juice in large pan. Boil gently for 5 minutes. Fill jars with hot tomatoes and cover with hot tomato juice, leaving ½ inch headspace. *Add acid* to jars of either hot-or raw-packed tomatoes. Adjust lids. Process pints or quarts in a pressure canner for 25 minutes

at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. To process pints or quarts using a boiling-water bath: At up to 1,000 feet above sea level, process 85 minutes; at 1,001–3,000 feet, 90 minutes; 3,001–6,000 feet, 95 minutes; and above 6,000 feet, 100 minutes.

Whole/Halved Tomatoes Packed Raw Without Added Liquid. Prepare tomatoes as above. Leave whole or halved. Loosely fill jars with raw tomatoes, pressing until spaces fill with juice. Leave $\frac{1}{2}$ inch headspace. *Add acid.* Adjust lids and pressure-can pints or quarts for 25 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. Or process pints or quarts using a boiling-water bath for the times indicated in the Whole/Halved Tomatoes Packed in Tomato Juice recipe.

Canned Tomato Juice. Wash, remove stems, and trim off bruised or discolored portions. Slice or quarter tomatoes into a large pan. Crush, heat, and simmer for 5 minutes before juicing. Press the heated, crushed tomatoes through a sieve or food mill to remove skins and seeds. Heat juice again to boiling. (If you made the juice in a blender or Squeezo strainer, cook it 5 minutes more to get out the bubbles so they don't pop off the jar lid.) Fill jars with hot juice, leaving $\frac{1}{2}$ inch headspace. *Add acid*—especially if you used overripe tomatoes. Adjust lids and process pints or quarts in a pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. Or process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 40 minutes; at 1,001–3,000 feet, 45 minutes; 3,001–6,000 feet, 50 minutes; and above 6,000 feet, 55 minutes. Process pints for 5 minutes less than the time given for your altitude.

Tomato/Vegetable Juice Blend. Prepare, crush, and simmer tomatoes as for making tomato juice. An average of 22 lb. of tomatoes is needed per 7-qt. canner load. Add no more than 3 c. of any combination of finely chopped celery, onions, carrots, and peppers to each 22 lb. of tomatoes. Simmer mixture 20 minutes. Press hot, cooked tomatoes and vegetables through a sieve or food mill to remove skins and seeds. Reheat tomato-vegetable juice blend to boiling and fill jars immediately, leaving $\frac{1}{2}$ inch headspace. *Add acid.* Adjust lids. Process pints or quarts in a pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe.

Canned Tomato Sauce. Prepare tomatoes, heat, and press as for making tomato juice. Simmer in large-diameter pan until sauce reaches desired consistency. Simmer until volume has been reduced by about a third for thin sauce or by about a half for thick sauce. Fill jars, leaving $\frac{1}{2}$ inch headspace. *Add acid.* Adjust lids. Process pints or quarts in pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the preceding Crushed Tomatoes recipe. Or process in a boiling-water bath using the times given in the Tomato Juice recipe.

Spaghetti Sauce Without Meat

NOTE: It is not safe to increase the proportion of onions, peppers, celery, or mushrooms in this recipe if you are planning to can the sauce!

Wash 30 lb. tomatoes and dip in boiling water for 30 to 60 seconds or until skins split. Dip in cold water and slip off skins. Remove cores and quarter tomatoes. Boil 20 minutes, uncovered, in large pan. Put through food mill or sieve. Saute in $\frac{1}{4}$ c. vegetable oil until tender: 1 c. chopped onions, 5 minced garlic cloves, 1 c. celery or green pepper (chopped), and (optional) 1 lb. sliced mushrooms. Combine sauteed vegetables and tomatoes. Add 2 T. salt (or to taste), 2 t. black pepper, 2 T. oregano, $\frac{1}{4}$ c. minced parsley, and $\frac{1}{4}$ c. brown sugar. Bring to a boil. Simmer, uncovered, until thick enough for serving.

(The volume should be reduced by nearly half.) Stir frequently to avoid burning.

Fill jars, leaving 1 inch headspace. Adjust lids. Process in a pressure canner 20 minutes for pints, 25 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Spaghetti Sauce with Meat. Prepare 30 lb. tomatoes as in preceding Spaghetti Sauce Without Meat recipe. Sauté 2½ lb. ground beef or sausage until brown. Drain off fat. Add 5 minced garlic cloves, 1 c. chopped onion, 1 c. chopped celery or green peppers, and 1 lb. sliced mushrooms (optional). Cook until vegetables are tender. Combine vegetables with tomato pulp in a large pan. Add 2 T. salt (or to taste), 2 t. black pepper, 2 T. oregano, ¼ c. minced parsley, and ¼ c. brown sugar. Bring to a boil. Simmer uncovered until thick enough for serving (till volume is reduced by nearly half). Stir frequently to avoid burning. Fill jars, leaving 1 inch headspace. Adjust lids and process in a pressure canner 60 minutes for pints, 70 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Stewed Tomatoes. You'll need 1 gal. peeled, cored, chopped tomatoes, 1 c. chopped onion, ½ c. chopped green pepper, and 2 t. salt. Combine those in a pan, cover, and cook over gentle heat for about 10 minutes. Then ladle hot mix into hot jars. Allow ½ inch headspace. Put lids on and tighten. Process in pressure canner: pints 15 minutes, quarts 20 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Basic Garden Vegetable Soup for Canning. Prepare 1 gal. peeled, chopped tomatoes 3 qt. peeled, chunked potatoes, 2 qt. snapped green beans, 2 qt. corn cut off the cob (about 20 ears), 3 qt. carrot chunks (about ½-inch), 1 qt. onion chunks, 8 crushed garlic cloves, 1 T. black pepper, and salt and other spices according to your taste and preference. Combine vegetables in a big pan; add 3 qt. water. Bring to a boil and cook 5 minutes. Dip hot into clean pint or quart jars. Leave 1 inch headspace. Put on lids. Process in *pressure canner only* for 95 minutes for pints or quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

RAW TOMATO RECIPE IDEAS: Our summer tomatoes are usually eaten fresh, mouthful by mouthful, juice running down grinning, happy chins. For meals, I serve the tomato cut in thick slices, skin and all. But if you dip the tomato in boiling water for 1 minute and then into cold water, you can easily slip off the skin. We also like tomatoes in sandwiches and salads.

Making Tomato Flowerets for Salads. Choose small tomatoes of equal size. Cut across 3 or 4 times not quite to the base. The tomato should open up like a water lily. You can put a little blob of mayonnaise in the center with a pinch of chopped parsley on top.

TOMATO JUICE RECIPE IDEAS: Tomato juice can be drunk plain from fresh, canned, or frozen sources. Or to 2½ c. tomato juice, add a trace of pepper, a pinch of salt, 1 T. lemon juice, ½ t. horseradish, and a pinch of celery salt. Or combine 1 part each celery juice and tomato juice, and season to taste. Or combine 1 part each grapefruit juice and tomato juice; then add a squeeze of lemon juice and a dash of salt. Or combine 1 part each sauerkraut juice and tomato juice; then add a squeeze of lemon juice, and spice it up with Tabasco and Worcestershire if you have an iron stomach.

➲ **GAZPACHO** *From Ruth of Bonaire: Combine in blender 4 c. tomato juice, 2 tomatoes, juice of ½ lemon, 1 peeled cucumber, 2 green onions, 1 celery stalk, 1 T. tamari, and basil, oregano, and/or parsley. Serve well-chilled.”*

➲ **RAW-TOMATO SPAGHETTI SAUCE** *Make the sauce at least 1½ hours before you’re going serve it. After you have your sauce all made and it has rested 1½ hours to get the flavors well-merged, add your cooked spaghetti (well-drained), mix it up with the sauce, and serve right away. To make the sauce: Combine ½ c. olive oil, about a dozen medium-sized fresh tomatoes (sliced very thin), 20 leaves of fresh basil (torn across), 3 mashed garlic cloves, 1 t. salt, and a pinch or two of freshly ground pepper.*

COOKED TOMATO RECIPE IDEAS: Briefly saute chopped tomatoes and stir into a pasta dish together with melted cheese. Or add to any vegetable and/or meat soup. Or saute with onion and cooked chicken strips; then toss with cooked noodles. Or saute chopped tomatoes with garlic, basil, chopped sweet peppers, and onions; simmer a bit and serve as a sauce over pasta or bread.

➲ **ITALIAN GRAVY** *Fry 1 medium chopped onion, 1 chopped garlic clove, and 2 T. chopped parsley in 4 T. olive oil until light brown. Add ½ lb. ground beef, 1½ t. salt, and a pinch of pepper, and cook until the meat loses its redness. Blend in 1 can tomato paste and 1 small can of tomatoes or puree. Simmer for 1 to 1½ hours (longer tastes better), stirring occasionally. Add chicken, sausage, meatballs, pork chops, steak, or wieners to the gravy while simmering.*

➲ **STEWED TOMATOES** *Slice and peel into a cooking pan. Cook for 5 minutes and season with salt and pepper. Serve plain or on slices or cubes of toasted homemade bread.*

➲ **INSTANT KETCHUP** *Put 3 t. cornstarch in pan over medium heat and make a paste by gradually adding 2 c. tomato juice. Flavor with ½ t. salt, 1 t. honey, a little onion, and garlic salt. Optional: Add a pinch of red pepper.*

Seventh edition. Four days ago I had a baby, my sixth! On Monday I wrote the new version of the pepper section, which is mostly like writing from scratch because I've been expanding it so much. Tuesday morning I woke up and my water broke (in exactly that sequence—I was still lying in bed). My labor didn't start, but after a while Mike took me to the hospital anyway, because once before, with Rebecca, I had had the baby about 3 hours after the water had broken, which is fast as these things go. Even though Mike has tested a cow for pregnancy and delivered umpteen farm-animal babies, he doesn't want to get stuck delivering one of ours.

So he took me to the hospital labor room. I lay there all day wishing I could get to work on the potato section of this book. I felt very bored and sort of guilty because Mike had work to do too, and there we were and nothing was happening. Then at 5pm I had a contraction, at 5:15 another, at 5:20 another, and at 5:25 another. The nurse came in and I told her that I thought something might be happening. She said I'd have to be more

regular than that, and then she left. Then everything stopped for 30 minutes. Then I had contractions for another half hour, then nothing for the next half hour. From 7 to 8pm the labor ambled along in a semiserious way. The nurse checked me and said I was 3 centimeters dilated. (I had been 2 cm that morning, when I had checked in.)

At this point, I asked her to call my doctor, Dr. Drury. He had repeatedly made me promise that I'd let him know when "labor started" because, he said, "I have a feeling it might go pretty fast once you get started."

The nurse thought the call was premature. "It's too early," she said. But I humbly requested again, and she made the call.

In the meantime, nothing happened: still no serious contractions, still no good dilation. At 8:30 Mike was seriously considering going for a walk. But then I had some harder contractions, and he decided to stick around. At 8:45 I asked him to please tell the nurse it was feeling more serious. She came in and checked me and said, sounding kind of disgusted by the nuisance of having to measure somebody who wasn't doing much, that I was dilated 5 centimeters. That was at 8:48.

Just as her shoulders were disappearing out the door, I said, "Mike, you better tell her I feel like I'm getting ready to bear down!"

Mike took me absolutely seriously. He jumped up and dashed out into the hall after the nurse. The two of them came racing back with a cart, got me loaded onto it almost as fast as I could say it, and wheeled me into the delivery room, which was directly across the hall. They moved me off the cart and onto the delivery table, getting me in place before that predicted next contraction hit me at about 8:55.

For as soon as I was on the delivery table, here it came. I was bearing down all right! That one contraction moved the baby out of the womb and well down the birth canal. The nurse was running around getting things ready and paging Dr. Drury over the intercom system in case he had already arrived at the hospital, telling him to come to the delivery room immediately. In the meantime she was also yelling at me, "Don't push! Don't push!"

But a few minutes later, I had another powerful bearing-down contraction. I pushed for all I was worth because that was what was happening. Just then Dr. Drury came in the door at a dead run. He threw his coat off onto the floor as he passed through it—just as the baby crowned, because the second bearing-down contraction had moved its head all the way to the opening of the vagina. The others could see the top "crown" and almost to the baby's shoulders—out far enough so that Mike could see that it was as blue as blue ink. It was asphyxiating!

"Push! Push!" screamed the nurse.

I tried to push. With a bit of effort came a third, huge, involuntary bearing-down contraction. It brought the baby out all the way. As it came out, Mike, the nurse, and Dr. Drury could all see why it was blue. The baby had a loop of umbilical cord tightly wound around its neck and another around its chest. But Dr. Drury had the expertise that comes from having helped with hundreds of births. He expertly caught the baby as it slipped out, and in an instant, fluid motion as fast as the wink of an eye, he slipped his fingers under that loop of cord around the baby's neck, gently loosened it, and lifted it over the baby's head. Then he did the same for the other loop around its chest.

The baby gasped its first breath, coughed, cried, and turned a healthy pink!

I was sitting up, sobbing with joy and trying to see every part of the baby at once, trying to comprehend that the baby I had carried unseen for so many months really was, in every part and way, a fine healthy boy. And he was! It makes you believe in miracles.

Today is Saturday, 4 days later. I got home from the hospital on Thursday.

January 12, 1992. That baby—Jacob—is 15 now, almost 16. His brains are fine. He's graduating from high school in a few more months (yes, he's been accelerated 2 years), and he's eagerly awaiting the results of his applications to various colleges. It could so easily have been different. I still ponder that mysterious birth of his, so unlike those of my other children. Jacob was delivered in just 3 huge bearing-down contractions. The delivery time was 9pm on February 15, 1977—exactly 12 minutes after the moment the nurse had said I was merely 5 centimeters dilated. Jacob spent only about 5 minutes in his transit down the passage between the womb and the outside world. That's as long as you can hold your breath without brain damage.

Because of the cord around his neck and chest, if I had delivered that baby any more slowly, he surely would have been born permanently brain-damaged from lack of oxygen—or dead. He was fine as long as he was in the womb, but the moment the womb opened and he entered the birth canal, that cord tightened around his neck and chest; he then ceased to receive oxygen and began strangulation. The unique way that particular birth happened couldn't have been an accident. How did my body know exactly what had to be accomplished? Is there more capacity for communication with and inner direction of one's physiology than we consciously or scientifically understand? I'm so glad I didn't have any anesthetic in my system to mess up that subtle capacity for inner-directed birthing, if such was the case ...

WILD FOOD FORAGING

INTRODUCTION

An herb lady once told me, “I used to think anybody who grew flowers in their garden was wasting space. Now I don’t grow food any more—just herbs, mostly the herbs I use in my work. Herbs are ornamental, fragrant, and a pleasure to use.” So herbs can be a necessity of life, depending on your convictions. For sure they’re a pleasant luxury, a comfort so natural to country living that I’m including them in this book.

“Herbs” are the leaves or other parts of aromatic plants grown in the temperate zone. “Spices” are the stems, leaves, roots, seeds, flowers, buds, or bark of aromatic plants grown in the tropics. Here are some of the possible directions for your collection:

- Culinary herbs: basil, bay leaf, caraway, chives, mint, parsley, rosemary, sage, tarragon
- Stronger seasoning herbs: capers, dandelion, garlic, horseradish, hot pepper, mustard, nasturtium
- Decorative herbs: bergamot, lovage, rose, rosemary, tansy
- Scented herbs: chamomile, scented geranium, lavender, marigold, mint, patchouli, rose, rue, thyme
- Medicinal herbs: anise, horehound, hyssop, feverfew
- Herbs that are natural pesticides: pennyroyal, pyrethrum
- Herbs that thrive in containers: garlic, parsley, thyme, tarragon, marjoram, oregano, chives, mint, winter savory, geranium, bay leaf
- Edible flowers: marigold, lemon mint, borage, nasturtium, bean, chrysanthemum, cucumber, rose, squash, violet

You can also grow herbs for dyeing, making cosmetics, or attracting bees that make exotic flavors of honey.

Some people doctor with herbs, but not all herbs are as safe or effective as you might think. If you wish you knew what has been scientifically verified about healing herbs, what’s hocus, and what’s dangerous, read *The New Honest Herbal* (especially the “Remedies” section by Dr. Varro E. Tyler, a plant drug specialist at Purdue University).

Healthwise, I recommend a Seventh-Day Adventist doctor as providing the best of both worlds. On one visit to my Adventist doctor, Dr. Drury, when I was full of mysterious problems, he first wrote me a couple of prescriptions, then gave me some marital advice, and finally prayed for me. Now that’s doctoring! The gist of his advice was that I should quit trying to write this book. He has continued to offer that same advice at every visit. I almost always throw away his paper prescriptions (I just want to hear what he thinks, not

get pills) and, as you see, I didn't obey his advice about the book, so any health problems I end up with are no fault of his! Fact is, though, I feel great.

Dr. Drury was, I think, the last of the old-time country doctors. If you wanted to give birth in his office examining room with only him and his wife (a nurse) to help, he'd let you. Then he'd move you and baby to a waiting room. Some of his waiting rooms had real beds, so sick people or women who'd just given birth could be genuinely comfortable. My daughter Esther was born that way about 2:30am (she was my seventh). After Dr. Drury got her and me all fixed up, he and his wife went back to their home, just a little way up the road. We stayed there for a while, my husband Mike sleeping on one bed in the room, precious baby Esther and me on the other. Mike woke up at about 6:00am and said, "Well, are you ready to go home?" I answered, "Yes." We took our new baby, let ourselves out the back door of the silent building, got in our pickup (which was parked out back), and drove home. We loved it—no hospital bill, no hassle! And the expertise of a doctor who had delivered hundreds of babies available if needed.

Dr. Drury had delivered most of the local babies for thirty-some years when the insurance company forced him to quit. Doc explained that they'd made a new rule: the more babies a doctor had delivered (so the more experience he had and the more women trusted him, went to him for their birthings, and told other women about him), the higher his insurance rates soared. Dr. Drury had delivered so many babies that his rates became absolutely unaffordable. He had to start telling women to go to a young city doc who had only delivered a few and thus could afford insurance.

HERBS

YOUR HERB GARDEN: Unlike spices, herbs can be used fresh from the garden because we temperate-zone dwellers can grow them ourselves. You can plant herbs in a border around your vegetable garden or give them a plot of their own. Kitchen herbs fit nicely into about a 3 × 5-foot area, ideally outside near your back, or kitchen, door! Herbs are grown in solid patches jammed up against each other rather than in rows like a vegetable garden, so you get lots for your space. Some herbs are enthusiastic self-spreading, but wood, stone, or metal edging keeps them within your chosen bounds and can also serve as little footpaths of stones or slate. Some herbs you can start from seed, but many are propagated by division or layering. Some are temperate-zone perennials, but many do best if you bring them in for the winter. Some do fine in an ongoing window box or container setting. For herbs in the house, a southern-facing window in a coolish room is ideal.

PUBLIC HERB GARDENS

Brooklyn Botanic Garden offers herbs in their store, books on herbs and growing them, and videos ("Dyeing with Plants," 10 minutes); classes on herbs; and more: 718-623-7200; 1000 Washington, Brooklyn, NY 11225; www.bbg.org.

Lady Cathrynn's Garden, previously known as Lady Cathrynn's Herb & Wildflower Garden, features medicinal and period gardens (Biblical, Shakespearean, etc.): 903-639-2254; 1487 County Rd. 2924, Hughes Springs, TX 75656.

Medicinal Herb Garden, founded in 1911, is run by the U. of Washington's Botany Department (Box 355325, Seattle, WA 98195; <http://nnlm.gov/pnr/uwmhg>). It's on the main campus, open to the public seven days a week, and admission is free. For \$25/yr, you get their quarterly newsletter.

The National Herb Garden of the U.S. National Arboretum is the largest herb garden in the world. Founded by the Herb Society of America, it regularly offers teaching workshops: 202-245-2726; 3501 New York Ave. NE, Washington, DC 20002; www.usna.usda.gov.

Our Grandmother's Garden welcomes visitors to their greenhouses and gardens, which display culinary, decorative, aromatic, and medicinal herbs. These include a scented geranium garden and a 17th-century Elizabethan knot garden. Shop offers 450 varieties of herbs: 67 Christian St., Oxford, CT 06478.

Ozark Folk Center State Park offers herb vacations at the Ozark Folk Center's Lodge. Its Heritage Herb Garden does a yearly Spring Extravaganza with lavish herbal feast and various seminars: 800-264-3655; Box 500, Mountain View, AR 72560; ozarkfolkcenter@arkansas.com; www.ozarkfolkcenter.com.

WellSweep Herb Farm, an old-time family outfit, has one of the largest collections of herbs and perennials in the U.S. They have more than 5 acres of display gardens, featuring common and unusual herbs, scented geraniums, and flowering perennials. They offer special events, courses, and lectures throughout the year. Free catalog. Contact: 908-852-5390; fax 908-852-1649; 205 Mt. Bethel Rd., Port Murray, NJ 07865; herbs@goes.com; www.wellsweep.com.

INFO AND NETWORKING: Online, try www.herbworld.com, www.herbnet.com, and www.herbsociety.org. The latter is a great site maintained by The Herb Society of America: 440-256-0514; fax 440-256-0541; 9019 Kirtland Chardon Rd., Kirtland, OH 44094; herbs@herbsociety.org. You can e-mail herbworld@aol.com with herb-related questions.

The Herb Growing and Marketing Network publishes *The Business of Herbs: International News and Resource Service for Herb Businesses* 6 times/yr.; PO Box 245, Silver Spring, PA 17575; 717-393-3295; fax 717-393-9261; www.herbworld.com; www.herbnet.com. It also publishes (*The*) *Herbal Connection*, a bimonthly that provides info on growing and using herbs. Their \$95/yr membership fee gets you a newsletter, their industry herb directory, *The Herbal Green Pages*, listing hundreds of small growers with herbs to sell, and a cooperative herb buying program: www.herbworld.com; 717-393-3295; PO Box 245, Silver Spring, PA 17575-0245; herbworld@aol.com; www.herbnet.com. They're an "herb world" indeed!

Rodale's *Illustrated Encyclopedia of Herbs* (1987) is a print overview of kitchen and medical herbs. *Herbs: Partners in Life* by Adele G. Dawson is a guide to cooking, gardening, and healing with 70 wild and cultivated plants, written by a 76-year-old Vermont herbalist (available from Southern Exposure Seed Exchange). *The Harrowsmith Illustrated Book of Herbs*, by Patrick Lima, is helpful for northern gardeners. Storey Books offers many herb books, such as *The Art and Skill of Teaching about Herbs*, a teaching packet by Portia Meares.

OTHER HERB PERIODICALS

(*The*) *Country Shepherd Herb News: Herbal News and Information for the Southeast* provides a calendar of herbal events, listing of nurseries, etc.: 706-788-3116; Rt. 1, Box 107, Comer, GA 30629; \$15/6 issues/yr.

Herbalgram is a sophisticated, fascinating quarterly collection of articles on the medicinal uses of herbs and other topics of interest to serious and well-educated students of

materia medica. They sell a goldenseal data and grow packet. The magazine costs \$25/yr: 512-926-4900; 800-373-7105; American Botanical Council, PO Box 144345, Austin, TX 78714-4345; www.herbalgram.com.

MEDICINAL PLANT INFO: To research medicinal herbs, you might attend the Southern Appalachian School for Growing Medicinal Plants: 828-649-3536; 300 Indigo Bunting Lane, Marshall, NC 28753; robert@ncgoldenseal.com; www.ncgoldenseal.com. Or read *The Encyclopedia of Medicinal Plants* (1996) by Andrew Chevallier; *Cunningham's Encyclopedia of Magical Herbs* (1985) by Scott Cunningham; *The Herbal Medicine Makers Handbook* by James Green; *The New Age Herbalist* (1988) by Richard Mabey, et al.; *The Complete Medicinal Herbal* (1993) by Penelope Ody; and *Jude's Herbal Home Remedies* (1992) by Jude C. Williams. For an establishment medical view on what is scientifically verified about healing herbs, what's hocus, and what's dangerous, read *The New Honest Herbal* (especially the "Remedies" section), by Dr. Varro E. Tyler, a plant drug specialist at Purdue University. On the web, look up "Medical Plant Database," "Native American Ethnobotany," and the Southwest School of Botanical Medicine. More online info and a bibliography for medicinal herbs are in the ATTRA publication "Herb Overview" (800-346-9140; www.attra.org/ncat.org and search for herb). You'll find Steven Foster, author of *Herbal Renaissance* (1992), at photography@stevenfoster.com; www.stevenfoster.com.

The Business of Herbs

BUYING HERBS AND HERB PRODUCTS: Herb growing and use are enjoying renewed popularity both with builders of beautiful cuisines and fragrant potpourris, and with seekers after kinder, gentler, cheaper cures for what ails them.

Here's a list of places to buy herbs. Later in this chapter, as I discuss specific herbs, I'll note the firms that sell them. If you don't find their addresses below, look in the introduction to [Chapter 2](#) (for firms that also carry vegetables) or the source list in [Chapter 6](#) (for those that specialize in trees and fruits).

HERB PRODUCTS

Frontier Natural Products Co-op offers a wide selection of natural and organic foods and personal care products, plus bulk and bottled herbs, spices, and baking flavors, etc.: 800-669-3275; PO Box 299, Norway, IA 52318; www.frontiercoop.com.

Indiana Botanic Gardens sells by mail-order dried herbs, essential oils, floral scents, potpourri, spices, etc. Free catalog: orders 800-644-8327; 3401 W. 37th Ave., Hobart, IN 46342-1751; www.botanicchoice.com.

LorAnn Oils sells essential oils, flavorings, and specialty ingredients for soap-, candle-, and food-crafters: 4518 Aurelius Rd., Lansing, MI 48909; 888-456-7266; 517-882-0215; fax 517-882-0507; customercare@lorannoils.com; www.lorannoils.com.

Penzeys Spices offers 250+ spices and spice blends for gourmet cooks including arrowroot, vanilla beans, ajwain seed, annatto seeds, cassia buds, and gumbo filé: 262-785-7676; 800-741-7787; PO Box 924, Brookfield, WI 53008-0924; www.Penzeys.com.

HERB PLANT SOURCES: Herbs are sought after by cooks, decorators, and healers. For hard-to-find sources of seeds and growing info, order the 96-pg encyclopedic *Ethnobotanical Catalog of Seeds*. It's \$1 from J. L. Hudson (see below). In the detailed description of each

herb (alphabetical, later in this chapter), I usually name places to buy seeds or starts in addition to this general list. (Also see the list of seed companies in [Chapter 2](#).)

Abundant Life Seed Foundation sells herb seeds and books, etc. PO Box 279, Cottage Grove, OR 97474; 541-767-9606; fax 866-514-7333; www.abundantlifeseeds.com.

Burnt Ridge Nursery specializes in unusual trees, shrubs, and vines that grow edible nuts or fruit: 360-985-2873; 432 Burnt Ridge Rd., Onalaska, WA 98570; mail@burntridgenursery.com; www.burntridgenursery.com.

Cricket Hill Herb Farm, Ltd.: 978-948-2818; 74 Glen St., Rowley, MA 01969.

Dabney Herbs sells herbs, native Midwestern plants, books, etc.: 502-893-5198; Box 22061, Louisville, KY 40252; info@dabneyherbs.com; www.dabneyherbs.com.

Garden Medicinals and Culinaries offers 170 varieties of herb seeds, roots, tubers, and specialty garlics, herb books, and supplies/equipment for herb growers and herbalists. Many links to herb-related and phytotherapeutic sites from their website: www.gardenmedicinals.com. Catalog, \$2: 540-872-8351; PO Box 460, Mineral, VA 23117.

Herbal Advantage, 131 Bobwhite Rd., Rogersville, MO 65742; 800-753-9199; www.herbaladvantage.com.

Horizon Herbs Seed Farm: 541-846-6704; fax 541-846-6233; hhcusrserv@budget.net; PO Box 69, Williams, OR 97544; www.horizonherbs.com.

J. L. Hudson, Seedsman, sells medicinal plants and herbs. No phone. Catalog \$1: Star Rte. 2, Box 337, La Honda, CA 94020; www.jlhudsonseeds.net.

Le Jardin du Gourmet sells herbs and seeds: 802-748-1446; PO Box 75, St. Johnsbury Center, VT 05863-0075; www.ArtisticGardens.com/.

Linda's Garden offers a complete herb and herb line. 1436 Campbells Landing Rd., Virginia Beach, VA 23457, 888-419-6496; 757-426-6488; fax 757-426-6488; herbs@lindasgarden.com; www.lindasgarden.com.

Long Creek Herbs: Call/fax 417-779-5450; PO Box 127, Blue Eye, MO 65611; www.longcreekherbs.com.

Mulberry Creek's Herb Farm offers a very large selection of certified organic herbs, stevia plants, etc. Free catalog: 419-433-6126; 3312 Bogart Rd., Huron, OH 44839; www.mulberrycreek.com.

Nichols Garden Nursery is an herb specialist that's been around longer than this book, selling a wide variety of herb plants and seeds; 1190 N. Pacific Hwy., Albany, OR 97321; www.nicholsgardennursery.com; 800-422-3985; fax 800-231-5306.

Redwood City Seed has a great herb collection: 650-325-7333; PO Box 361, Redwood City, CA 94064; www.ecoseeds.com.

Richter's is an herb specialist offering 900+ culinary, medicinal, and ornamental varieties including stevia and yucca. Free catalog: 905-640-6677; fax 905-620-6641; 357 Hwy. 47, Goodwood, Ontario, L0C 1A0, CANADA; info@richters.com; www.richters.com.

Sandy Mush Herb Nursery offers 1,850 varieties of culinary and tea herbs; decorative, scented geraniums; dye plants, etc. Their \$5 catalog fully describes all those plants, their growing conditions, and uses; plants for various purposes and places; growing and using herbs; recipes; herb books; and sample plans for kitchen, bee, butterfly, fragrant, and geometric culinary gardens: 828-683-2014; 316 Surrett Cove Rd, Leicester, NC

28748-2014; www.sandymushherbs.com.

Southern Exposure Seed Exchange uses organic/sustainable methods and has an extensive online catalog: PO Box 460, Mineral, VA 23117; 540-894-9480; www.southernexposure.com.

SELLING HERBS: This isn't necessarily easy. But you might do well selling herbs at a farmer's market, either in peat pots, in hanging pots, or cut for culinary use. Develop a personal clientele. Herb growers, by definition, are supposed to be 100% organic, because the Environmental Protection Agency has not authorized any pesticides for use on herbs. And wholesalers won't buy herbal products unless growers can certify they are chemical free. (However, spot checks have found poison residues in some commercial herb products.)

For good information from a pro herb wholesaler for both beginners and other pros, see *The Potential of Herbs as a Cash Crop* by Richard Alan Miller or *Profitable Herb Growing* by N. P. Nichols. *Growing and Selling FreshCut Herbs* (1999) by Sandie Shores covers crop production methods, including in a greenhouse (www.freshcutherbs.com). Lee Sturdivant's *Herbs for Sale* focuses on small-scale growers selling herbs. The ATTRA brochure "Herb Overview," including an extensive resource list, is available free (800-346-9140; www.attra.ncat.org and search for herb). The American Herbal Products Ass'n (AHPA) is at 301-588-1171; fax 301-588-1174; 8630 Fenton St., Ste. 918, Silver Spring, MD 20910; ahpa@apha.org. Their website posts news such as "German health authority has cancelled all registrations for products containing kava," and "New bill limits the use of the name 'ginseng' ... to ingredients derived from the genus Panax" at their great website: www.apha.org.

If you're interested in the flower market, a valuable article on "Cut Flower Production" is at www.attra.org/attra-pub/cutflower.html. And read Lynn Byczynski's 1997 book, *The Flower Farmer: An Organic Grower's Guide to Raising and Selling Cut Flowers* (Chelsea Green). It has info on varieties to grow, picking a site, harvesting, marketing, and arranging. Join the Association of Specialty Cut Flower Growers: 440-774-2887; fax 440-774-2435; P.O. Box 268, Oberlin, OH 44074; www.ascfg.org. Also, network with and learn from other herb sellers by joining the Herb Growing and Marketing Network www.herbworld.com. For local networking, just look in your Yellow Pages under "Herbs."

Harvesting Herbs

NOTE: If you want to gather wild herbs, keep in mind that roadsides, fields, and even forests can get unannounced and unrecorded but heavy doses of herbicide or insecticide. Be cautious.

WHEN TO HARVEST: Gather herbs on a dry day, early in the morning but after the dew is off. The season to harvest varies with the species. Parsley and chervil are dried in May, June, and July; burnet and tarragon in June, July, and August; marjoram and mint in July; summer savory and lemon thyme at the end of July and August. The tender young leaves that appear before the flowering are usually best. Get leaves before the plants show signs of going to seed. That happens after they blossom, when the blossoms turn into seed clusters and their energy goes into making seed. At best the plant is not at its prime; at worst it gets bitter.

How to Harvest: Cut the herbs with pruning shears or scissors and put them into clean pillowcases or some such. Don't cut to the ground; leave at least a 4-inch stem if you're

topping an annual. If it's a perennial, leave at least two-thirds of the plant unharmed. Then take the herbs home and carefully pick them over. Rinse in cool water and drain.

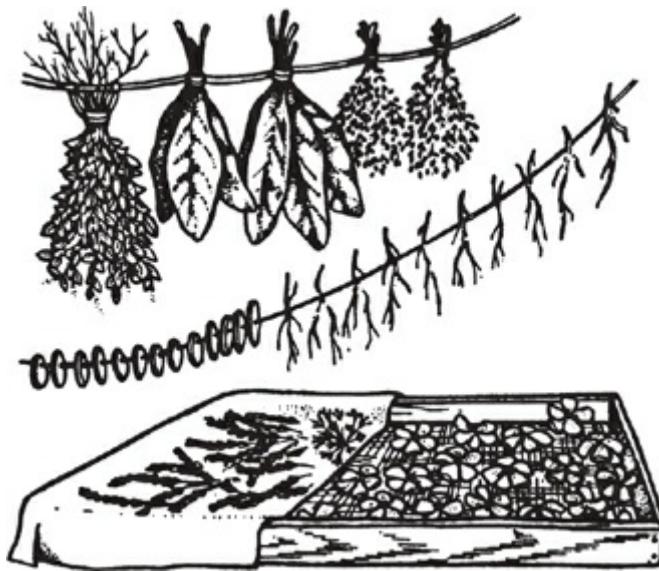

Preserving Herbs

If you can't pick from your herb plants all winter long or bring some into the house in pots, you can either freeze or dry your herbs for winter use. Whether freezing or drying, label all containers. Frozen and dried herbs tend to look alike, and you may not be able to smell the difference.

FREEZING: Wash if needed, shake off excess water, package in small amounts in baggies or boxes, and freeze right away. Herbs that freeze well are anise, basil, chives, coriander, dill, lovage, marigold, mint, oregano, parsley, rosemary, sage, savory, sorrel, sweet marjoram, tarragon, and thyme. Take out of the freezer only the amount you intend to use.

DRYING

Outside. Spread individual leaves or leaves still on the stem (they'll be easier to get off once dried) on sheets of clean cloth to dry in the shade in an airy place, or dry in a very slow oven or dehydrator. Or put them in an outdoor dryer covered with cheesecloth and place where there's good air circulation all around. Direct hot sunlight ruins leaves by burning or browning; a little sun early or late in the day is OK. The aromatic herbs shouldn't be exposed to too much heat, and don't let them get rained or dewed on.

Hanging Bunches. Cut off the top 6 inches of the plant, or use whole plants, bunch them, tie the bundles with string, and hang them up with the root end upward in a shady, airy place. (They hold the flavor better when not powdered.) Allow at least 2 weeks for drying. Hanging works well with anise, basil, marigold, marjoram, mint, oregano, parsley, rosemary, sage, savory, tarragon, and thyme. If you dry your herbs whole like this, crumble them or rub them through a sieve to remove the stems and midribs when you're ready to use them.

In an Oven or Dehydrator. Spread in shallow pans at 110°F, with the door ajar if you're using an oven. Don't mix different kinds of herbs. It takes an average of 8 hours.

Big Leaf/Small Leaf. Some herbs are huge plants (as tall as 6 feet high) with real big

leaves. Drying big, moist-leaved plants is harder than doing small ones. With comfrey, borage, and costmary, you can tear the midrib away from the rest of the leaf and then tear the rest of the leaf into smaller pieces. That helps the leaves dry better and prevents mold. Or hang these big leaves individually to dry.

Mint, lemon balm, and most other small-leaved kitchen herbs easily dry in the shade within 3 days. Tearing the small leaves away from the stem (which can then be discarded) speeds up the process. The problem with tearing the leaves is that they don't hold their flavor as well.

Turn all drying leaves once or twice a day. Keep good air circulation. Thick leaves tend to be better frozen than dried.

Roots. Herb roots are generally better fresh rather than dried. Dig in the fall after the leaves are dead and the roots are mature, or before they start growing again in the spring. Wash in cool water. Dry in a place that's warm enough to dry them soon but that's not exposed to the sun, such as an attic. Or slice and dry in a shady place where air circulation is good. Dry in the sun or oven only if you can't dry them completely the first way. Store when thoroughly dry and brittle. If protected from extremes of heat and cold, the roots will keep fine for years. Store so as to protect them from the air as much as possible.

Seeds. To save herb seeds, pick the entire stalk when the seedpods are fully formed but have not yet burst. Spread the pods on a cloth in the sun to dry. If it takes more than one day, stir occasionally while they are outside and bring them in at night. When your seeds are dry, shell and store them in a tightly covered container in a cool, dry place.

Flowers. Don't bruise or overheat. Collect just after they have bloomed. Don't pile them up; dry on a screen if possible. Harvest orange flowers and elderberry flowers in May, June, and July.

Storing Dried Herbs. To store leaves, seeds, or roots, I use baby food jars, cleaned, dried, filled, and with the lid on tightly. Keeping herbs in airtight containers helps prevent flavor deterioration. The fewer times you open the lid, the better they keep their strength. And try to keep them in a cool, dark, dry place away from heat—not on a shelf over or beside your stove! The cool storage inhibits evaporation of the flavoring oil in the herb, and the darkness protects the color, which fades when exposed to light.

Cooking with Dried Herbs. They are at least 3 times as strong as fresh. So figure 1 t. dried herb equals 1 T. chopped fresh herb. Another way to figure it is about 1 t. dried herb in a dish for four.

My head just does not want to work this morning. I have so many things to do, and my brains are moving like molasses in January. Mike said an angry word as he went out the door to work, and I'm not going to be right all day. Dear God, make that be a lesson to me to really watch my tongue and speak only kind and loving things. God, if I deserve it, make me a better person. Guide me, Lord. Sometimes things get so confusing. Sometimes I'm not sure what it is You really do want me to do. Help me to get everything done that I've got to do. Thank You for the joy to come.

PRODUCTS AND PROCESSES

BUTTER: To make herb butters, start with either salted or unsalted butter, as you prefer.

Softens the butter and cream into it finely chopped herbs to your taste. Chives, minced garlic, or watercress are fine additions. You may want to add a little lemon juice. Use 1–2 T. (well-packed) fresh herbs or 1–2 t. dried ones per $\frac{1}{4}$ c. butter. Use the herb butter on bread or hot meats, or with eggs. Unsalted butter won't keep as well as salted, but it's best for people who are watching their blood pressure.

CANDYING LEAVES AND FLOWERS: Mint leaves, rose petals, and the blossoms of borage, orange, lemon, lilac, sweet pea, and violet can all be candied. Dip in an egg white that's been stiffly beaten, flavored, and colored to suit. Coat with sugar. Then dry in a 110°F oven (door ajar) or dehydrator.

CANDY, HERB-FLAVORED: For a basic recipe, see "Horehound" under "Alfalfa to Yucca—Garden to Table."

CRYSTALLIZING: To crystallize angelica stems, very thin slices of fresh ginger root, rose petals (damask and cabbage roses are especially good), etc.: Cover the item to be crystallized with water. Boil 5 minutes. Drain. Repeat that process 3 more times. Save the liquid used to boil the item the fourth time. After cooling, measure the liquid and its herb contents by volume and add sugar equal to its volume plus a half more. Boil the herb/water/sugar until the herb gets a translucent quality. Drain the herb, dry it, and roll in white sugar. This keeps well if stored in sealed jars. (For another recipe, see "Angelica" under "Alfalfa to Yucca—Garden to Table."

DYE: Homemade colorings from herbs and other food products are more soft and subtle than artificial ones. Here's what you can use to make different colors:

- Black: barberry leaves
- Blue: blueberries
- Brown: nut hulls (walnuts are best), tea, coffee, rose hips, tobacco, hickory chips
- Green: beet tops, sunflower seeds, birch leaves, Spanish onion skins (outer leaves only), elderberry leaves, spinach, cabbage, rhubarb leaves
- Orange: orange juice
- Pink: cherries; beet and sassafras roots
- Purple: blackberries, cherries, huckleberries, cranberries, raspberries, grapes, purple cabbage
- Red: red onion skins, bloodroot, fresh beet juice, madder root, and logwood
- Yellow: the stem, leaves, and flowers of apple bark; barberry stems and roots; cinnamon; curry; ginger; the stems, leaves, and flowers of goldenrod; hickory bark; mustard; paprika; pear leaves; saffron; tanglewood stems; turmeric

For more information about dye plants, see *Weeds: A Guide for Dyers and North American Dye Plants* by Ann Bliss. There's also *The New Dyer* by Vinroot and Crowder, *I'd Rather Dye Laughing* by Jean M. Neal, *Hands-On Dyeing* by Blumenthal and Kreider, *The Dye Pot* by Mary Francis Davidson, and *California Dye Plants* by Marilyn Wilkins.

Natural Food Coloring. For a brown color, use a little browned flour, a little burnt sugar, or caramel. Pounded, uncooked spinach leaves make a rich green. Adding some spinach

leaf puree makes a lovely deeper green. This green can also be used to tint icings, desserts, etc. Another way to make a cooked-spinach green coloring is by washing some spinach, boiling it until tender, and pouring off the juice for your coloring extract. For a stronger green, let the spinach cool, squeeze dry, mash by pounding, and then put through a sieve. Cooked green peas make a lighter shade of green; split pea soup makes a very pale green color. The coral of a lobster pounded and put through a sieve yields red, as does vinegar or water that has stood on sliced boiled beets. See “Easter Eggs” in [Chapter 9](#) for more information.

Color Blending Chart. Commercial vegetable colorings can be varied like this:

- 2 drops yellow, 1 drop green, and 1 drop red = blue
- 1 drop red, 2 drops green, and 1 drop blue = gray
- 2 drops blue + 1 drop green = dark green
- 3 drops yellow + 1 drop blue = light green
- 12 drops yellow and 1 drop green = olive
- 2 drops red + 1 drop blue = orchid
- 3 drops red + 1 drop yellow = orange
- 3 drops red, 4 drops yellow, and 1 drop green = tangerine

Secrets of Dyeing Fabric with Herbs

NOTE: Dyes and mordants (substances used to set the dyes) are often poisonous. Keep them out of the reach of children. Don't use them in regular cookware.

1. Use an enamel kettle for dyeing. Don't dye in aluminum, iron, or tin pans; these metals can affect the mordant chemistry and color.
2. Herb dyeing is not an exact science. Plant colors can vary, even between one batch and the next. The soil the plants grew in, the amount of rainfall, the light intensity, and the time of year all can affect the color yield.
3. Flowers are the best bet for getting color from a plant, but stems, roots, leaves, fruits, and vegetables may make color too. In general, start with a weight of plant product equal to the weight of fabric you plan to dye.
4. Steep, heat, or even boil the plant until you have a heavily colored liquid; that is your dye. Experiment with a small amount to see if boiling improves extraction or if it makes the color dull.
5. A mordant sets the dye into the dyed substance, making it permanent and often brighter, even under the stress of machine-washing. Alum, acetic acid (from vinegar), and ammonia are mordants. Different mordants can give you completely different colors. Coreopsis plus alum results in a beautiful yellow. Coreopsis plus potassium dichromate (another common mordant) gives brick red. In a pinch you can use lemon juice, salt, or white vinegar as mordants.
6. Natural fabrics like linen, wool, and cotton, jute, silk, and rayon (which is cellulose-based) take herb dyes best.
7. Make your dye first and have it ready. Then wash the material to be dyed, soak it with the mordant, and finally dye it.
8. To dye fabric, heat it very gradually in the colored water up to almost the boiling

point, and then cool it down equally gradually. *Don't actually boil it.* Or soak in the color for at least 1 hour. *In the case of silk, keep below 160°F.*

EXTRACT: An herbal extract is an herb's essence or oil in a solution, usually with alcohol. Extracts and pure oils are used to make scented candles, soaps, and cosmetics like peppermint-flavored toothpaste, and to flavor candies and baked goods. Certain ones are also used in mixtures to repel insects from people and plants. Gather fresh herbs and pound to a pulp with a mortar and pestle. Let the plant parts concerned stand in pure distilled vinegar, alcohol, or corn, sunflower, or olive oil. Getting 180-proof edible alcohol to make an alcohol-based extract isn't as simple for us as it was for Great-Grandmother, but you can substitute vodka—it's half water and half alcohol, equal volumes in 100 proof. Use 2 T. pounded herb to $\frac{3}{4}$ c. liquid. Or put your herbs, berries, etc. into a bottle and cover with liquid. The liquid then gradually absorbs the soluble parts of the plant. Shake daily for 3 weeks. Keep at a warmish temperature—in the sun, for instance.

NOTE: Never use rubbing/isopropyl alcohol.

➲ **CITRUS EXTRACT** Peel away the fruit's outermost skin, called the zest. (There's a special tool for this at kitchen stores.) Don't use any of the white pith. Fill a wide-mouthed bottle one-third of the way up with zest. Pour in vodka for the other two-thirds. Soak 2 weeks, shaking twice daily. Strain and bottle your extract.

FLOWERS: Edible flowers are fun. Learn more in the brochure "Edible Flowers," free from ATTRA (800-346-9140). You'll find recipes in Cathy Wilkinson Barash's 1993 book *Edible Flowers from Garden to Palate* and Coralie Castle's 1994 *Cooking from the Gourmet's Garden: Edible Ornamentals, Herbs, and Flowers*.

➲ **CLOVER-ROSE "HONEY"** For this old-time homemade honey substitute, in the summer gather and dry about 90 white and 90 purple clover blossoms, plus 25 sweetbriar rose leaves. Add 10 c. sugar, 5 c. water, and cook together. Sieve out solids. Cook to a syrup consistency.

GROUND HERB OR SPICE: Ginger root was once invariably sold intact, and people grated their own. The same cooks also crushed their cinnamon bark and ground their cloves. Now you can take your choice, but the more freshly ground, the better tasting. So when buying, figure the more whole the better, and grind it yourself at home as needed. Whole spices store well and keep their strength a long time. Once they're ground, though, they start to weaken. It's best to grind no more than a 6-month supply of spices at a time, preferably far less. If you don't believe me, I suggest the sniff test: Grind some whole allspice or peppercorns. Sniff. Then sniff your kitchen container of preground spice.

So equip yourself with an old-fashioned mortar and pestle, "spice mill," or pepper or salt grinder; or grind herbs in your blender or juicer. With those you can also mash seeds, crush dried herbs, and so forth. You grind in your mortar by crushing with the pestle—just pure elbow grease (available from 719-962-3228; www.cfamlyresources.com). The old-time spice mill was a little hand-cranked grinder with a box to catch the ground spice.

HAND LOTION: Immerse $\frac{1}{4}$ oz. gum tragacanth (from Indiana Botanic Gardens) in water and soak for several days. Combine 2 oz. glycerine and 1 oz. alcohol. Strain the gum tragacanth solution and add the liquid to the glycerine/alcohol solution. Scent with herbal or floral extract (rose, lavender, rosemary, etc.). Add enough distilled water to make it the thickness you want; 2 cups is about right. See also "Quince" in [Chapter 6](#) and "Sheep, Lanolin" in [Chapter 11](#).

JELLY: Basically you combine a juice (grape, orange, cranberry, etc.) with an herb or spice (or both). Tarragon, mint, sage, rosemary, and thyme are good for this; allspice, ground and whole cloves, ginger root, and stick cinnamon are good spices.

➲ **MODERN** Prepare 4 half-pint jars. Heat 1 cup of your juice to boiling. Then pour it over $\frac{1}{4}$ c. fresh herb (or $1\frac{1}{2}$ T. dried herb) or 2 T. whole spice. Let soak for half hour. Strain into nonaluminum pan. Add 2 more cups of juice, 2 T. vinegar, and 3 c. sugar. Mix and boil, stirring constantly. Now mix in $\frac{1}{2}$ bottle pectin; boil another minute, still stirring. Remove from heat. Stir in food coloring at this point if you want it. Pour immediately into $\frac{1}{2}$ pint canning jars. Put on lids. Process 10 minutes in boiling-water bath.

➲ **OLD-TIME** Prepare jars to hold 10 cups. Coarsely chop 6 lb. tart apples, put into nonaluminum pan, add just enough water to cover, and cook half hour or to softness. Then pour into jelly bag over bowl and let drain overnight. On the next day, measure the juice. Add 2 c. sugar for each $2\frac{1}{2}$ c. of juice. Stir sugar into solution over low heat. Add herbs or spices, or a mix of them, tied into porous bag, and simmer until jelling point is reached. Remove bag and pour into jars. Process 10 minutes in boiling-water bath.

OIL: Herbs get their flavors from their natural oils. When herbs are dried the oil is still in there, but it's concentrated, which is why it takes less in volume of dried herb to give the same amount of flavor. In general, one drop of an "essential oil" is comparable to one handful of fresh dried herbs. Rose, lavender, violet, and lemon balm make good oils. If you do it right, the oil will have a strong scent of the plant, and you can use it like perfume or add a drop to your potpourri or homemade cosmetics. To make an herbal "oil" or "essence," there are several methods. For any particular plant, one works better than another, so experiment. Best of all, read *Potpourri, Incense and Other Fragrant Concoctions* by Ann Tucker Fettner, a thorough, accurate collection of everything you need to know about perfume ingredients and the extraction of scents, including recipes.

➲ **SUN-EXTRACTED OIL** Start with as much as possible of your fresh herb or flower. Lavender or lilac flowers, mint leaves, rose petals, rosemary, thyme, and basil all work well. Press them into a crock, using enough pressure to slightly bruise them. Carefully pour rain or distilled water over them until they are covered. Set the crock outside in full sun, in a place where it will be undisturbed. (Bring inside only to avoid rain.) It takes around a week for oily scum to develop on the water's surface. Using a small bit of cotton to absorb it, get that oil out of the crock. Squeeze it out into an appropriately small, dark-colored glass bottle. Don't put the lid on yet. The next step is to cover that container with cheesecloth to keep dust from getting in but allow all the water to evaporate. After a few days, you can go ahead and seal the bottle tightly.

➲ **COOKED-OUT OIL** Put your crushed ("bruised") plant materials—flowers, leaves, bark, or roots—into a bag. Put the bag into a kettle of water and simmer about 24 hours over a slow fire. Then slowly cool. Skim the oil that rises to the top of the water. The bag is used because it almost invariably floats, and it's easier to get the oil separated that way. Squeeze the bag to help get the oil out. You can even put it through a clothes wringer or use a cider press. For pine oil use pieces of wood cut fine. For birch oil, use the inner part of the tree; for cedar oil, use the tips of the branches. To make sunflower seed oil, throw seeds in premashed to help the oil come out.

➲ **OIL BY EVAPORATION** Boil your materials in a tea kettle. Strain. Boil more. The principle is that you are separating out substances that vaporize at a higher temperature than

water; that's the oil. After the water evaporates, the oil is left behind because it hasn't yet vaporized.

⇒ **ALCOHOL-EXTRACTED OIL** *Soak the herbs in a capped bottle of pure alcohol for 10 days or so. Strain. Leave the alcohol and its contents in a wide, open container in a warm place. Put a cheesecloth over it to keep the contents clean. After the alcohol evaporates, your oil remains.*

⇒ **CITRUS OIL** *You can collect citrus oil by turning rinds inside out to squeeze them just a little and then wiping the outside (now inside) surface with a bit of absorbent cotton.*

⇒ **OIL INTO OIL** *Because the essential oil can be so minute in volume, here's another option if you have only a small quantity of herb to start with. Pulp your fresh herb thoroughly using a mortar and pestle or some such. Place it in a small bottle—about 2 T. herb for a 1-cup bottle. Pour a quality cooking oil over the pounded herb until the bottle is nearly full. Add 1 t. distilled vinegar. Cover tightly. Place where it will be in hot sunshine every day. Shake twice a day for 3 weeks. Strain and it is ready to use.*

OIL, HERB-FLAVORED FOR COOKING: Make the above oils by the pint or quart for wonderful herb-flavored oils for salad dressings and cooking.

OINTMENT: See "Salve."

PASTILLES: Also called scent balls. Same contents as sachets, herb pillows, and potpourri, except that they're melted together with a gum resin that makes them hard. Any size from a tiny bead up. Pound your ingredients in a smooth-sided mortar together with gum tragacanth, and moisten with a little rose water until you have a mixture that is like a dough. Shape and dry. Can be polished on a lathe. Can be sculpted into jewelry and so on; to make beads, pierce pastilles with a needle while they are still soft.

PHYSICK: An old-time word for any plant-based medicine.

PILLOWS, HERB: See "Sachets and Herb Pillows."

POMANDER: A mixture of aromatic or fragrant substances enclosed in a bag or box that has holes in the sides. A pomander is used to scent clothes or linens; in old-time usage it was worn on the body to guard against infection. The pomander ball was most often made of amber or a partially dried orange with cloves stuck into it. To make one, start with a thin-skinned, small orange and a handful of cloves. Press the point of each clove into the orange as you would a thumbtack into a wall. Continue until the orange is quite covered with cloves, with only their large "heads" sticking out. Now roll the orange in ground cinnamon, getting as much on it as you can. Set on paper in an airy place and let dry for 3 weeks. Then your pomander is done. It can be placed in the traditional box or hung by a ribbon.

POTPOURRI: That's pronounced "poe-purree" (it's French). The purpose of a potpourri is fragrance, but sometimes it can be very beautiful too. One formula is $\frac{7}{8}$ any flower petals, $\frac{1}{8}$ herbal leaves, and then just a few added spices and/or dried citrus zest. (For more potpourri recipes, see "Geranium" and "Rose" under "Alfalfa to Yucca—Garden to Table.") The container should be china or pottery with a lid you can close tightly. Keep that lid on tight after the potpourri is made, except when you want to scent a room; then

uncorking for half an hour should do it. I don't recommend using a glass container because light deteriorates potpourri; on the other hand, I've seen beautiful potpourris in glass bowls that were wonderful to both see and smell. When they deteriorated, the potpourri was simply replaced.

Using Herbs. A tablespoon or two of fragrant leaves adds to your potpourri's interest, but be cautious of adding more, because they may get overwhelming. Try rosemary, bay leaf, marjoram, cedar or balsam needle, basil, mint, sage, lemon verbena, scented geranium, sweetbriar, lavender, southernwood, sweet cicely, lemon balm, bergamot, myrtle, costmary, eucalyptus, chamomile, thyme, or anything else that catches your nose's attention. Also consider adding the flowers of rosemary and thyme.

Using Flowers. Although potpourris may contain many different ingredients (flowers, fragrant leaves, and spices), traditional potpourris were at least four-fifths rose petals—especially damask, moss, or gallica roses. You can make the other one-fifth any kind of sweet-smelling flower, or just use straight rose petals, or create your own flower mixes. Suitable additional flowers are acacia, bergamot, calendula, carnations, heliotrope, honeysuckle, hyacinth, jasmine, jonquil, lavender, lemon verbena, lilac, lily of the valley, mignonette, myrtle, narcissus, lemon or orange blossom, pansy, peony, philadelphus, pinks, stocks, thyme, violet, wallflower—or any combination of flowers you want to try. Use any fragrant petals so long as they're thin enough to dry well. Patricia Wiley, Watsonville, CA, wrote me, "Don't forget to include some small buds, as they add their personality to the dried mixture."

Drying Herbs/Flowers. Choose a dry morning to collect the herbs and flowers—after the dew has dried. Pick blossoms that have just fully opened early in the day. Don't pick roses that have already been fully open for several days. Don't use roses that have been in a vase for a week; most of their fragrant oils will be gone. Collect about four times as much as you expect to need, because they shrink in drying. Use the petals and buds of flowers only. Pull them carefully from the rest of the flower, which you discard. Dry them away from light, spread them out in a shallow layer on clean paper or cloth, and stir a couple of times a day. Dry to a papery state.

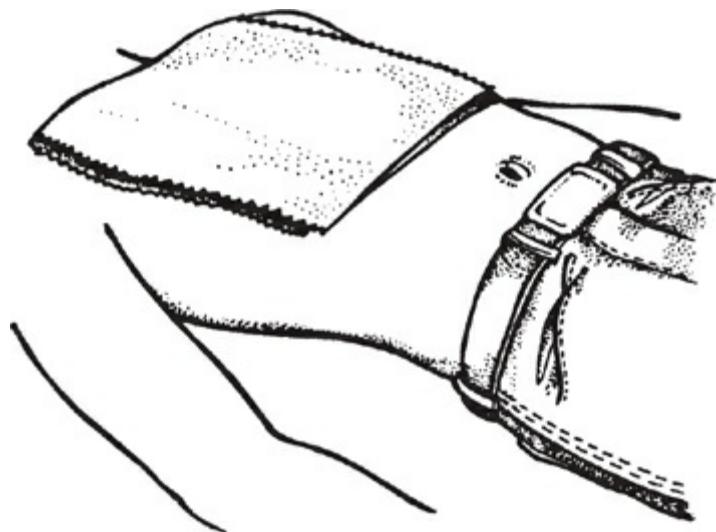

Using Spices. Two or three teaspoons of crushed spices add fragrance, but be careful not to use too much. Good spices to use are cloves, cinnamon, nutmeg, mace, coriander, aniseed, or allspice. Or you could put in a slice of lemon or orange peel stuck full of cloves.

Using Liquids. Traditional potpourris were either dry or moistened with fragrant oil. You can add a few drops of a fragrant oil like eucalyptus, lemon verbena, peppermint, rose geranium, or rosemary oil, or another strong scent like brandy or attar of roses. Add 1 drop at a time, and stir with a wooden spoon.

Fixatives. The fixative both acts as a preservative and helps to hold the scent. Rose expert Patricia Wiley wrote me, "A modern fixative is isopropyl alcohol, sprayed on. *Do not use any fixative until potpourri fragrances have had time to sit and blend together, about 3 weeks.*" Combine the scented materials with the fixative by layering—a layer of potpourri, then a layer of fixative. Pack into jars, seal tightly, and let rest 2–4 weeks. Your fixative can be a few dashes of orrisroot, or much more. You can grow and process it yourself or buy from an herbal supplier. An orris/salt fixative is made by mixing one-third orrisroot powder with two-thirds uniodized salt for your fixative. An antique Elizabethan fixative was made by combining $\frac{1}{4}$ oz. gum benzoin, 2 oz. orrisroot, and a spoonful of brandy. Gum benzoin

can also be used alone for this purpose.

Using Potpourri. Stir it. Moisten it with a little rose water, add a drop of fragrant oil, use as is as a source of room fragrance, or pack it into little cotton sachet bags. Every couple weeks or so, stir the potpourri bowl a little to release new fragrance.

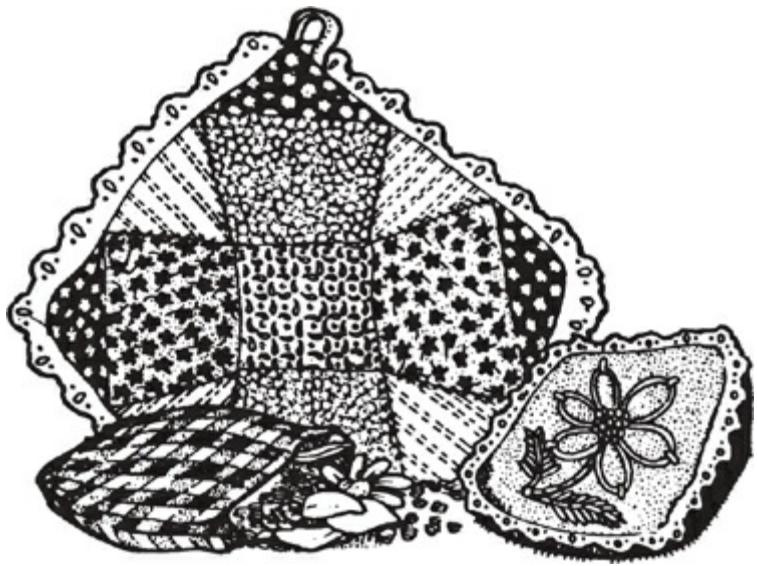

Poultice: A poultice is a bag of hot herbs held against an aching or infected portion of the body. Comfrey leaves make a healing poultice. Another traditional one is a bowl of hops mixed with a cup of hot vinegar. A poultice of boiled mullein leaves is good for cuts on animals. Chop green leaves finely and soak them a bit in almost boiling water. Let them cool before you put them on so they don't burn the patient. Then put them on the hurt place. You can make the poultice stay on by putting a cloth over it or wrapping the leaves in a clean cloth. Don't leave a cold poultice on; have a fresh one ready to go on when you take off the cooling one. Don't reuse the herbs. This may sound spendthrift of herb, but comfrey (the #1 healing herb) grows huge, so you'll have all you want once it gets a good start in your garden.

➲ **LINSEED POULTICE** *To help aching bodies, scatter ¼ lb. linseed into 2 c. very hot water, stirring constantly. The mixture will gradually turn into a dough. Mix in ½ oz. olive oil. Spread that thickly over a piece of prewarmed cloth. Fold over the extra ends of the cloth to make a sort of bag, and place the poultice on the hurting part.*

Powder: An herb powder is simply bark or dried herbs pulverized to a powder in your mortar.

SACHETS AND HERB PILLOWS: These are cloth "pillows" made to hold dried, crushed herbs and flowers. Sachets are tiny bags meant to be placed in a drawer or closet to scent clothing, sheets and pillowcases, or stationery. Herb pillows are several times larger and are traditionally used to overcome a sickroom smell and soothe nerves.

You can experiment to get your favorite scent. Lavender is traditional, but don't be afraid to try other mixtures. Lilac, rose petals, sweet peas, mint, rosemary, and thyme are all suitable. Or use lavender, sage, peppermint, and lemon balm in some combination, or sage, peppermint, and lemon balm without lavender. (For more ideas, see "Potpourri.") If you are making sachets intended to keep moths away, try a mixture of the insect-repellent herbs: cotton lavender, mint, rosemary, rue, southernwood, tansy, and wormwood.

As in the case of potpourris, the scent, whatever its source, will not last. To renew scent, every couple weeks or so, crush the sachet bag a little between your fingers to break some herbs and expose a new supply of their fragrant oil for scent. The aromatics will eventually run out; potpourris need to be refilled at least every year.

Preparing the Contents. Follow potpourri instructions. Once your planned ingredients are harvested and dried, mix them and grind to a powder in your spice mill, mortar, or blender/food processor. Add a fixative like orrisroot. (See "Fixatives.") If you are making a quantity of powder at once—more than you need to fill your sachets or pillows—store in a small tightly-lidded bottle in a cool place and protect from the light.

Making the Sachet. Pack the powder into "pillowcases" of cotton, and sew up the open side. You can make a large herb pillow by sewing together two men's handkerchiefs. You can cover the inner pillow with velvet, gingham, percale, ribbon-trimmed lace, or any other scrap material you have. To hang or pin in place, sew a loop of ribbon or bias tape into one corner as the fourth side is sewn. Just make sure the material and the seams are tight enough so that dust from the contents doesn't leak out.

➲ **HEADACHE PILLOW** A midwestern pioneer recipe. Mix together $\frac{1}{2}$ oz. cloves and 2 oz. each of lavender, marjoram, rose petals, and betony rose leaf. Proceed as above. You're supposed to sniff it to cure your headache.

➲ **TO-EASE-MELANCHOLY-AND-PUT-YOU-TO-SLEEP PILLOW** Mix 2 oz. rose petals, 1 oz. mint, and $\frac{1}{4}$ crushed clove for pillow.

➲ **HERB SACHET** Mix 1 part each dried sweet basil, dried thyme, dried marjoram, and dried rosemary leaves. With this one you don't need any fixative.

SALVE: This is a mixture of herb with a carrying agent that you rub onto the problem area. Gen MacManiman (www.drgit.com), who sells all sorts of food-drying information and supplies, is not only a food drying expert but also an herb lady! She wrote me, "For the base, salves and ointments use various wax/oil mixtures. An olive oil and beeswax combination is most commonly used. Freshly rendered lard is an excellent salve base. It has healing virtues and is just the right consistency. If stored in a cool place, it will keep a long time."

➲ **CHICKWEED OINTMENT** Gen MacManiman's recipe: "Warm one cup lard in the dehydrator. (Lard becomes fluid at low temperatures—80–100°F.) Add $\frac{1}{2}$ c. dried, powdered

chickweed, and mix well. Return the mixture to the dehydrator and dry it for two days at 100–110°F. The fluid will then be quite green (the greener, the better) and ready to strain and place into containers. Store in the refrigerator or a cool cupboard. This is very healing for any abrasion or scratch, but best of all, it instantly takes the itch out of a mosquito bite! Try it on any itch.”

➲ **BALM OF GILEAD SALVE** *This is good for cuts, scrapes, and chapped hands. The main ingredient is the sticky, brownish buds of the black cottonwood (*Populus trichocarpa*), commonly called balm of Gilead. It grows wild, west of the coastal Rockies, from California to Alaska. Pick the buds in spring before the green leaves form. Make sure you get the buds at the sticky stage. Put them into a big tin can, because the container will be almost impossible to clean out and it will be easiest if you can just throw it out after you’re done. Add enough lard to just cover the buds when the lard has melted. Don’t use cooking oil—you’d get liquid instead of solid salve. Simmer the buds/lard mix on low heat 2–3 hours. Then strain into sterilized jars or cans. You’ll end up throwing out the straining cloth, so make it something you can do without.*

SHAMPOO: You can make your own herbal shampoos. Start by finding a jar with a lid. Pour into it 1 T. olive oil, 1 bottle Castile soap, and 2–3 t. of your favorite culinary herb. Lemon verbena, rosemary, and thyme are good choices. Mix your ingredients well with a wooden spoon. Put the lid on the jar and let the contents rest in a dark, cool place for about a week. Then strain to get the solids out. What remains is your herbal shampoo. Or you can use it as a hand or body soap.

SIMPLE: A plant medicine.

SPIRIT: A solution of an herb made with brandy is called an herb spirit. The basic recipe for herb spirit is to use fresh herbs, picking just before flowering or when otherwise appropriate. Strip the leaves from the stems and pack lightly in a jar. Fill the jar with brandy and cover tightly. Let rest for a month. Strain and bottle.

➲ **HERB SPIRIT FOR SEASONING SOUPS** *Equal parts sweet marjoram, basil, thyme, savory, and parsley. Measure and mix before filling the jar. Proceed as above.*

SYRUP: You make an herbal syrup, used as a beverage or a medicine base, by adding simple syrup (sugar and water) to the herbal infusion when hot and somewhat evaporated. Bottle and seal when hot. Violet flowers make an excellent syrup.

TEAS: We gather wild mint for tea down along Brady Gulch Creek, which runs along the bottom of our canyon, and wild strawberry leaves from the tender little plants that grow in the timbered places. You can drink teas and coffees made from the dried leaves and stems of many plants, from barks and nuts, and from grains too. In colonial America, when tea drinking became unpatriotic during the Revolutionary War (remember the Boston Tea Party!), the conventional China tea leaves were replaced by raspberry leaves, loosestrife,hardtack, goldenrod, dittany, blackberry leaves, sage, and many others. Some other homemade drinks enjoyed on the frontier were teas made from wild rose hips, mint, oat straw, sarsaparilla, and the marrow from beef bones. Rye and chestnuts, ground and roasted, or roasted crushed barley alone, were made into “coffees.” Those alternative teas and coffees contain no caffeine.

Of Infusions and Decoctions. Those two aren't exactly the same thing. A decoction is made by boiling an herb in water (an average of 10 minutes) and straining while hot. Coffee is a familiar decoction. An infusion is made by pouring hot water over an herb and then letting it steep. In general, leaves and flowers are steeped; roots and seeds are boiled. That's why flower/leaf drinks are "teas" and dandelion/chicory root drinks are "coffees."

Leaf Teas. They're easy to make. Just boil water and measure out your herbs: from 1 t. dried to 1 T. fresh herbs for a cup of water, or from 1 T. dried to 1 c. fresh for a quart, depending on the strength of the herb. Then use one of the following methods.

- Pour water directly over herbs in teapot. To serve, put a little strainer over your cup and pour through that.
- Put your leaves or flowers into a tea ball or into a strainer. Set that into the cup and pour the hot water over it. Pour over leaves and let set 2–10 minutes. You really must experiment to get it just right. Every herb is a little different, and so are tastes. On average, the leaves are steeped in the hot water for 5 minutes. Get to know your teas, and you'll be able to judge by the color when you have the desired strength. Too little soaking and the tea will be too weak; too much and it will be bitter. Sweeten with brown sugar or honey to complement the taste of herb tea. You can freeze your leftover tea to use for quick servings, but strain out the herbs first, or it will get too strong.
- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or $\frac{1}{2}$ –1 oz. dried, or $\frac{1}{4}$ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.
- For herbed lemonade, add any concentrated herb tea to lemonade and chill for a nice, different drink.
- For sun tea, fill a gallon jar with water. Add your tea or herbs. Screw on a lid tightly. Shake a moment. Let set in the hot sun 4–5 hours—or more, like a day ... or two ... or three. Shake occasionally. Now strain out the tea leaves or herbs. Add honey or lemon juice. This is also a good way to fix dried fruit such as prunes, plums, or apples; just combine fruit, water, sweetening, and cinnamon, and let it set in the sun all afternoon.

I got these recipes from listeners to a phone-in radio program I appeared on in Wichita, Kansas, in January 1975. Folks in Wichita also recommended mint leaves in lemonade, raspberry leaves for when you're in labor, and sarsaparilla for any fella who needs more manhood!

TINCTURE: Here's Gen MacManiman's expertise again: "Vinegar tinctures are inexpensive, easy to make, and will last for many years. I have many tinctures which are over ten years old. They are simple to make. Herbs can be used in combination or individually. I use either vinegar or vodka and always use the dried herbs, finely crumbled or powdered. Basic proportions are 1 pt. vinegar or vodka to 2 oz. powdered herbs. Sunlight energizes these tinctures. Set the jar in a window for two weeks and shake twice daily. At the end of two weeks, strain and bottle the mixture. Dropper bottles are great."

TISANE: An old-time herb tea, often used with medicinal intent. It's a strong brew given by the tablespoon several times a day.

VINEGAR, HERB-FLAVORED: Vinegars can be flavored with leaf herbs, seeds, spices, or combinations thereof.

Secrets of Making Herb Vinegar

1. You can start with store-bought cider or wine vinegar or with your homemade. Match strong-flavored herbs to red wine vinegar, mild-flavored ones to white wine vinegar.
2. In general, use 3 T. seeds, 1 c. fresh herbs, or $\frac{1}{4}$ c. dried herbs per 1 qt. vinegar.
3. Gather your herbs fresh, if possible—the flavor will be more pungent. Crush just before steeping.
4. If you must use dried leaves, moisten them with a little hot water in a bowl before steeping.
5. Heat vinegar to boiling. If you are using seeds or spices, crush them with a mortar and pestle (or crush them in a wide-mouthed jar with a wooden spoon). Boil them in the vinegar for 10 minutes.
6. Pour the vinegar and seeds/spices over the herbs.
7. Cover and let stand several weeks in a warm dark place. Shake the bottle gently twice a day.
8. At or before the end of the recommended period, taste the vinegar. If it doesn't seem flavorful enough, strain and start over with more seeds or leaves.
9. When straining, first use a sieve and then a cloth.
10. When the vinegar suits you, bottle it: Place a fresh sprig of herb inside your long-term storage bottle. Strain your steeped mixture in on top of that. Herbal vinegars are best stored at room temperature.

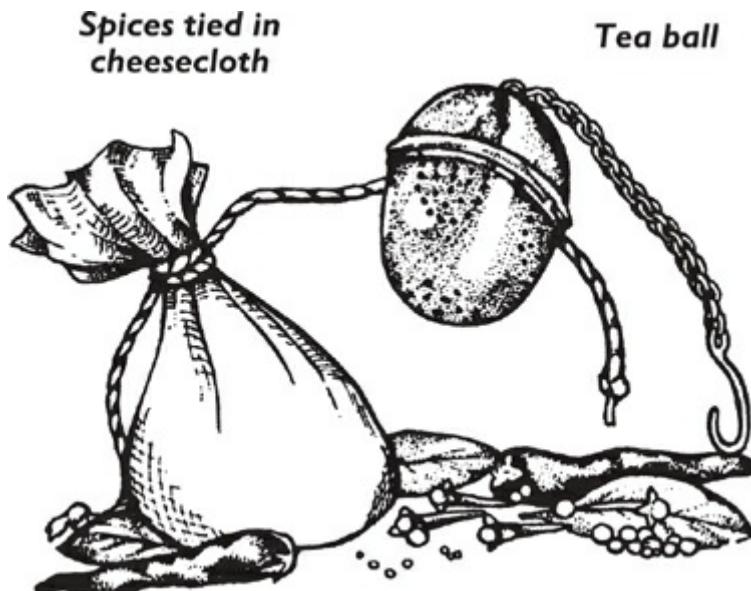

Here are specific recipes for herb vinegars (in alphabetical order by herb). Burnet (leaves or seeds), marjoram, dill, lemon balm, and chives are other possibilities. Mix and match to suit yourself. For chervil and tarragon vinegar recipes, see “Chervil” and “Tarragon” under “Alfalfa to Yucca—Garden to Table.”

- ⇒ **BASIL VINEGAR** Combine $\frac{3}{4}$ c. leaves and 1 qt. wine vinegar.
- ⇒ **CARAWAY, CARDAMOM, CELERY SEED, OR MUSTARD VINEGAR** Combine 3 T. seeds and 1 qt. white wine vinegar.
- ⇒ **GARLIC VINEGAR** Combine 4 cloves garlic, peeled and chopped, $\frac{1}{2}$ t. salt, 2 t. ground cloves, 1 t. freshly ground peppercorns, 1 t. caraway seeds and 1 qt. wine vinegar. Give it 2–3 weeks before you strain and use.
- ⇒ **MINT VINEGAR** Combine 2 c. mint leaves, 1 c. sugar, and 1 qt. cider vinegar. Or pack the leaves into a pint jar and fill the jar with wine vinegar. Let stand 2 weeks or more, then strain. Bottle.
- ⇒ **MYSTERY VINEGAR** Add burnet (leaves or seeds), dill, lemon balm, and chives.
- ⇒ **SALAD VINEGAR** A good combo is oregano, basil, garlic, and thyme. For an Italian salad vinegar, combine oregano, basil, garlic, and thyme. Or one part rosemary to one part tarragon in a red wine vinegar. Or a combination of fresh thyme, lemon peel, and black peppercorns in white wine vinegar.
- ⇒ **PLAIN ONION, GARLIC, OR CELERY LEAF VINEGAR** Use 24 green onions (shallots are best if you have them) or 4 cloves garlic or 2 c. celery leaves, peeled and chopped. 2–3 weeks in 1 qt vinegar. Strain and use.
- ⇒ **MULTI-SPICED VINEGAR** Combine 1 qt. cider vinegar, $\frac{1}{2}$ oz. celery seed, $\frac{1}{3}$ oz. dried parsley, 1 clove garlic, 3 small onions, grated, 2 whole cloves, 1 t. peppercorns, 1 t. nutmeg, salt to taste, 1 T. sugar and 1 T. good brandy. Cover in jar. Let stand 3 weeks, strain, and bottle.
- ⇒ **HOT, HOT VINEGAR** Add horseradish, onion, paprika, pepper, chili peppers, cayenne pepper, curry powder—any or all as suits you. Strain and bottle when you like the taste. These aren't for me, but some people love anything that scalds their gullet.

FOOD SEASONINGS

Seasoning Mixtures

Save your empty spice containers to hold your own mixes! Store seasoning mixes in an airtight container and in a dry, cool place—not over or beside your stove!

PACKAGING SEASONING MIXES: Combine your favorite spices, dried vegetables, and herbs. Lay out squares of foil or small plastic baggies. Spoon 1 serving size of your mix into the center of each foil square or baggie. Seal foil packets by folding over the ends and rolling them. To store in plastic, press the air out and tie tightly shut.

Spice Bag. When a recipe calls for a spice bag, put the whole spices listed in the recipe into a handkerchief-sized piece of cheesecloth or some such, tie firmly, and cook right with the dish to be flavored. Remove the bag before serving. Or use a tea ball for the same purpose. It will prevent your friend with an ulcer from biting down on a peppercorn.

SALT MIXTURES

Use uniodized salt and dried ingredients. Crush and mix the mixture using a wooden spoon or mortar and pestle. Store in a glass jar with a tight lid. Toss pepper or paprika in with any of these, if you like.

⇒ **SALTY HERBED SALT** *In a bowl combine 1 c. salt and 1 t. each dried parsley, chives, onion flakes, and summer savory. Store in an airtight container and use for roll or bread dough and to season salads.*

⇒ **LOW-SALT HERBED SALT** *Combine ¼ c. salt, 2 t. dried basil, 1 t. dried tarragon, 1 t. dried chives, and ½ t. dried oregano. Get it all very fine and well mixed. Good on popcorn, etc.*

⇒ **HERB-SALT MIX FOR HAMBURGERS** *Crumble until fine as possible 1 t. each of dried basil and dried oregano. Mix ¼ c. chopped parsley, the dried herbs, 1 t. paprika, and 1 c. salt. Keep in a salt shaker.*

⇒ **LOW-SALT SEASONING SALT** *Combine ½ t. garlic powder, ½ t. dried lemon rind, ½ t. onion powder, 2 t. paprika, 6 T. salt, ½ t. dried thyme, 2 t. dry mustard, ½ t. curry powder, and ½ t. powdered cumin. Blend well. This is good with anything: veggies, meats, fish, or salad.*

⇒ **SESAME SALT** *Put into a frying pan and heat gently until the seeds begin to brown (do not overheat): 8 parts raw sesame seeds and 1 part sea salt (available at health food stores). Remove and allow to cool. Mix well and grind. Sprinkle this on foods at the table—soups, salads, entrees—but when you do, leave out any other salt.*

⇒ **SALT/PEPPER MIX** *Keep a shaker of 3 parts salt and 1 part pepper near the stove if you use salt and pepper in practically everything.*

HERB MIXTURES

⇒ **HERB BAGS TO SEASON SOUPS AND STEWS** *In each of several 4-inch squares of cheesecloth combine ½ t. each basil and marjoram, 1 crumbled bay leaf, and 5 peppercorns. Tie the squares into bags with string. Store in an airtight container.*

⇒ **BOUQUET GARNI** *This classic French herb mix is packed into little 4-inch packets of cheesecloth. Spread the cloth out flat. Measure into the middle of it 1 bay leaf, 1 t. marjoram, 1 T. parsley, 1 t. savory, and 1 t. thyme. Bring together the corners of the bag and tie them with a string so it looks like a miniature peddler's bag. Good in soups and stews. You can vary it to taste, adding or subtracting herbs as you please.*

⇒ **FINES HERBES** *This is a standard herb mix for seasoning egg and other recipes. Combine ⅓ parsley, ⅓ chervil, ⅖ tarragon, and ⅖ chives—all gathered fresh and finely chopped.*

⇒ **HERBS AND PEPPER** In a bowl combine $\frac{1}{4}$ c. coarsely ground black pepper, 2 T. thyme, 1 T. each ground caraway seed and sweet Hungarian paprika, and 1 t. garlic powder. Store the pepper in an airtight container and use it to season roasts and steaks.

⇒ **POULTRY SEASONING** For each 2 T. commercial poultry seasoning called for, substitute 1 t. sage, 1 t. marjoram, 1 t. thyme, and 1 T. dried parsley; or 1 t. each of sage, thyme, savory, rosemary, and marjoram.

SPICE MIXTURES

⇒ **BEST NO-SALT SEASONING** Combine 1 T. garlic powder, 5 t. onion powder, 1 T. paprika, 1 T. thyme, $\frac{1}{2}$ t. celery seed, 1 T. dry mustard, and $\frac{1}{2}$ t. white pepper. Store tightly covered.

⇒ **DESSERT SPICE BLEND** This blend is nicely balanced in flavor and is good for spice cakes, cookies, and pies. Combine 2 t. powdered cinnamon, 2 t. ground nutmeg, 1 t. powdered ginger, $\frac{1}{2}$ t. powdered allspice, and $\frac{1}{2}$ t. powdered cloves. Optional are $\frac{1}{2}$ t. mace, $\frac{1}{2}$ t. ground coriander, and $\frac{1}{2}$ t. ground cardamom.

⇒ **HOMEMADE PUMPKIN PIE SPICE** In a bowl combine $\frac{1}{4}$ c. ground cinnamon and 1 T. each ground ginger, allspice, nutmeg, and cloves. Store in an airtight container. Use 1½ T. per pumpkin pie. Or use to flavor gingerbread, pies, and other desserts.

⇒ **PICKLING SPICE #1** In a bowl combine 2 T. each whole allspice and whole coriander, 1 T. mustard seed, 2 crumbled bay leaves, and a 1-inch piece of dried ginger root, peeled and chopped. Store the spice in an airtight container and use it for pickling fruits and vegetables, making preserves, and braising meats.

⇒ **PICKLING SPICE #2** Combine whole cassia buds, white peppercorns, black peppercorns, allspice, bay leaves, mustard seeds, dried sliced ginger, and chili pods.

⇒ **TACO SEASONING** 1) Combine $\frac{3}{4}$ c. chili powder, 9 T. paprika, 10 T. cumin, 6 T. onion powder, and 5 T. garlic powder. Or 2) Combine $\frac{1}{3}$ c. chili powder, 4 T. cumin, 2 T. garlic powder, 1 T. onion powder, and 1 T. oregano. To either mixtures 1) or 2), add as much or little crushed red pepper as you like. Then mix well, divide into serving-size packets such as small zip-top bags, and store.

CURRY POWDERS: Curry powder is a mixture of spices—from just a few to as many as fifty. The curry powders sold in grocery stores are usually a combination of 15–20 herbs, seeds, and spices, but people who really know about curry have special combinations of spices to go with various dishes, some of which need mild, subtle seasonings and others hotter ones. The strength of a curry depends on how much chili powder is used. Coriander seed is considered to be the one traditional and most necessary ingredient; other possible ingredients include allspice, anise, bay leaves, caraway, cayenne pepper, celery seeds, cinnamon, cloves, cubeb berries, cumin seeds, curry leaves, dill, fennel, fenugreek (seeds and leaves), garlic, ginger, juniper berries, mace, mint, mustard, nutmeg, oregano, pepper (white and black), paprika, poppy seeds, saffron, salt, and turmeric. Have all ingredients well powdered, using a mortar and pestle to grind. Sift together and keep in a tightly corked bottle.

⇒ **CURRY MIX #1** Combine 3 oz. turmeric, 4 oz. coriander seed, 2 oz. black pepper, 1 oz. fenugreek, 1 oz. ginger, and $\frac{1}{4}$ oz. cayenne pepper.

⇒ **CURRY MIX #2** Combine 6 t. coriander seed, $\frac{1}{8}$ t. cayenne pepper, 1½ T. turmeric, $\frac{1}{2}$ t.

whole cloves, 1½ t. fenugreek seeds, ½ T. cardamom seed, and 1½ T. cumin seeds.

➲ **FAVORITE CURRY MIX** *From Zubaidah Ismail, Penang, Malaysia: Combine 1 t. ground turmeric, 1 t. chili powder, 1 t. ground ginger, 1 t. coriander seeds, and 2 t. powdered cinnamon.*

MULLED BEVERAGES: You can mull any juice by adding sugar and spices and heating to a boil. Then simmer 10 minutes, strain, and serve hot. Grape juice, orange juice, cider, and red wines mull especially well. Spices invariably include cloves and cinnamon sticks. Whole allspice, nutmeg, and ginger are other possibilities. Lemon juice and lemon slices are good too. Sweeten with your favorite sweetener. Be sure to strain unless all will be consumed immediately. The longer the whole spices are in it, the stronger the drink gets—and it soon becomes too bitter to enjoy!

➲ **SPICED LEMONADE** *Put 2 qt. water, 4 T. sugar, 3 cloves, and about 2 inches of stick cinnamon into a pan. Bring slowly to a boil, strain, add the juice of 4 lemons, and reboil. Serve with a slice of lemon in each glass.*

➲ **MULLED RED WINE** *Use the cheapest red wine you can find (it will still be good). Heat 1 qt. wine and add 1 stick cinnamon, juice of 1 lemon, ½ c. sugar, 8 cloves, and ½ lemon sliced into sections. Strain. Serve with a slice of the lemon in each cup. Good for the old, cold, weary, and disheartened—a medicinal substance. Mull port or sweet wines without adding sugar.*

➲ **MULLED CRANBERRY CIDER** *Mix 4 c. cider (or grape juice), 4 c. cranberry juice, 6 cloves, 1 stick cinnamon, 4 whole allspice, and ½ c. brown sugar. Heat until the sugar dissolves, and serve hot.*

➲ **SPICED CIDER** *Mix 4 c. cider, 2 whole allspice, 2 whole cloves, and about 3 inches of stick cinnamon, and boil 5 minutes. Add ½ c. brown sugar, boil 5 minutes more, and serve hot.*

➲ **CIDER PUNCH FOR A CROWD** *Squeeze 1 orange and 1 lemon. Combine the chopped peels, ½ c. sugar, 1 stick cinnamon, ½ t. whole allspice, and 4 c. water. Boil gently 30 minutes. Strain; add the orange and lemon juice and 2 qt. cider. Reheat and serve.*

➲ **MULLED GRAPE JUICE** *Combine 4 c. grape juice (dilute if it is very strong), 4 sticks cinnamon, about ¼ c. sugar, and a dash each of nutmeg, cloves, ginger, and powdered cinnamon. Bring to a boil and serve hot.*

➲ **HOT SPICED TEA FOR A CROWD** *Combine 3 qt. boiling water, 3 T. tea leaves, 2 sticks cinnamon, and 1 t. whole cloves. When your tea is strong enough, strain and add ¾ c. sugar, ½ c. lemon juice, and 1 c. orange juice. Reheat. The “tea” leaves can be whatever kind you prefer—raspberry, strawberry, rose hip, etc.*

SAUCES

➲ **WORCESTERSHIRE SAUCE** *Pour 1 qt. wine vinegar into nonaluminum pan and heat. Add ½ t. curry powder, ¼ t. shredded and crushed pimento, 1 minced garlic clove, 4 t. cut and mashed green onions, ½ lb. brown sugar, and a pinch each of ginger, pepper, mustard, and salt. Stir into the vinegar, note how high in the pan the liquid is, put on a lid, and cook on very low heat for 1 hour, adding more vinegar occasionally to keep the liquid amount the same. When the time is up, add 2 c. sherry and let rest a week in a warm place. Then strain out the solids and bottle the sauce into sterilized, dark-colored glass. It tastes best if all your ingredients are fresh.*

⇒ **BARBECUE SAUCE** Combine 2 T. brown sugar, ½ c. vinegar, ½ c. water, 1 t. salt, 1 small chopped onion, ⅛ t. chili pepper, ¼ t. Tabasco sauce, ½ t. mustard, and 1 can tomato sauce.

⇒ **SLOPPY JOE SAUCE** Mix together 1 t. onion powder, 1 t. salt, 1 t. cornstarch, ½ t. garlic powder, ¼ t. dry mustard, ¼ t. celery seed, ¼ t. chili powder, 8 oz. of tomato sauce, and ½ c. water. Add 1 lb. ground meat, fried with 2 chopped onions. Stir together while heating until it starts to boil. (Then serve on toasted hamburger buns.)

⇒ **SPAGHETTI SEASONING AND SAUCE** All ingredients should be well dried. Combine ¼ c. oregano, 2 T. dried minced garlic, ¾ c. dried chopped onion, 2 crushed bay leaves, ⅓ c. sweet basil, 2 T. salt, ¾ c. flour, ½ c. sugar, and ½ c. dried parsley. Sir in ⅔ c. grated Parmesan cheese. Mix well. Store airtight. Spaghetti sauce: Combine ¼ c. of this mix with 3 c. canned tomatoes and ½ c. tomato paste. Cook over low heat 1 hour, covered. Optional: Sliced mushrooms, other chopped veggies, or any ground meat.

⇒ **KETJAP MANIS (SWEET SOY KETCHUP)** From Ruth, Bonaire, Netherlands Antilles: "Ketjap manis is sweet sauce, and more common than ketjap benteng, or sour sauce. To make it, simmer together equal parts of water, strong Japanese soy sauce, and molasses, and jazz it up with fresh or ground ginger, coriander, and pepper. It's basically a sweetened, thick, and rather spicy soy sauce, like North American ketchup!"

By the way, some years back I received a letter scolding me for using the word "catsup" to describe a thick sauce. The writer explained that the origin of the word "ketchup" was "ketjap," a Malay term for any thick sauce and *not* a trademark of Hunt's, etc. He wryly commented that the only meaning of "catsup" that he could figure out had to do with the position of a cat rather than a thick sauce!

After Ruth sent me that ketjap recipe, I knew he was right. The situation has gotten so far from the truth that even the dictionary calls "catsup" the real thing—and "ketchup" only a "variation." And it defines "catsup" as a *tomato* sauce, which is so incorrect it boggles my mind: "Ketjap" means all kinds of thick sauces, and "catsup" was also used by antique English recipe books to mean a thick sauce made out of any fruit or vegetable.

I like the sound of "ketchup," and I like knowing I'm using a word precisely—and that I'm now going to treat fairly all the great thickened, spicy sauces that may or may not have tomatoes in them! I always hated the sound of "catsup" anyway. It never felt right in my mouth or to my ear. "Cat's up ..." Yuk. "Ketchup!" Yeah!

Which Herbs/Spices for Which Foods?

Lillian Reed, Kirkland, WA, typed the 685,000 words from the eighth edition of this book, plus addenda, onto computer disks for me so I'd have an easier time revising and expanding it for the ninth edition. As she neared the end of half a year of hard work, I invited her to add something she had created herself to the book—something that would help people. She brought me this!

APPLESAUCE: anise, cloves (ground)

ARTICHOKE: chervil, coriander seeds, fennel seeds, oregano

ASPIC: allspice

AVOCADO: ginger (fresh or ground)

BEAN SPROUTS: ginger (fresh or ground)

BEANS: mint, oregano, thyme; or 1 part each parsley, savory, and onion

BEANS, GREEN: chervil, dill seeds, dill weed

BEEF: allspice, marjoram, oregano, thyme, turmeric; or 1 part each basil, savory, and thyme

BEEF, BOILED: dill seeds

BEEF, CURRIED: saffron (threads or powder)

BEETS: allspice, anise, dill seeds, dill weed

BOUILLON, COURT: allspice, anise, bay leaf, chervil, coriander seeds, dill seeds, fennel seeds

BREAD: anise, cumin (ground or seeds), fennel seeds, saffron (powder)

BREAD, SPICE: cardamom (ground), ginger (ground)

BROCCOLI: nutmeg

BUTTER, HERB: marjoram

CABBAGE: dill seeds

CABBAGE, RED: allspice

CAKE: cinnamon (ground), mace, nutmeg, saffron (powder)

CAKE, SPICE: allspice, anise, cloves (ground)

CANDY: anise

CARROTS: allspice, anise, bay leaf, cumin (ground or seeds), ginger (fresh or ground), mace, marjoram, mint, nutmeg, tarragon

CAULIFLOWER: nutmeg

CHEESE: mint

CHEESE, COTTAGE: dill weed, thyme

CHEESE, CREAM: sage, thyme

CHEESE, GOAT: rosemary

CHICKEN: chervil, cilantro (fresh coriander), dill weed, ginger (fresh or ground), marjoram, nutmeg, oregano, rosemary, thyme; or 1 part each marjoram, parsley, savory, and tarragon

CHICKEN, CURRIED: cloves (ground), saffron (threads or powder)

CHICKEN, FRICASSEED: dill weed

CHICKEN SOUP: nutmeg, rosemary, tarragon

CHILI: cumin (ground or seeds)

CHOWDER: rosemary

CHOWDER, CLAM: marjoram, caraway seed, sage, thyme

CHOWDER, FISH: bay leaf, curry powder, dill, thyme

COLESLAW: chervil, dill seeds, tarragon, thyme

COOKIES: anise, cardamom (ground), cinnamon (ground), coriander, mace

CONSOMME: basil, marjoram, savory, tarragon

CRANBERRY JUICE: cinnamon, allspice, cloves

CREPE: cinnamon (ground)

CUCUMBER: dill weed, marjoram

CUSTARD: cinnamon (ground), mace, nutmeg

DIP: cloves (ground), cumin (ground or seeds), thyme

DIP, CHEESE: chervil, marjoram

DIP, CREAM CHEESE: dill seeds

DRESSING, SALAD: marjoram

DUCK: marjoram, rosemary, thyme

EGGPLANT: coriander seeds, oregano, sage, thyme

EGGS: basil, chervil, cumin (ground or seeds), ginger (fresh or ground), tarragon, thyme, or 1 part each chopped chives or green onion, marjoram, and parsley

EGGS, DEVILED: cloves (ground), turmeric

EGGS, SCRAMBLED: saffron (threads or powder)

EGGS, STUFFED: dill weed

FENNEL BULBS: fennel seeds

FISH: basil, bay leaf, chervil, mace, marjoram, mint, nutmeg, thyme; or 1 part each chopped green onion, dill, tarragon, and lemon juice (or lemon peel or a lemon-flavored herb)

FISH, BAKED: cumin (ground or seeds), dill weed

FISH, BROILED: cumin (ground or seeds), oregano

FISH, POACHED: cardamom (ground), dill seeds, dill weed

FISH, STRONG: sage

FRITTERS: cinnamon (ground)

FRITTERS, VEGETABLE: sage

FRUIT, COOKED: nutmeg

FRUIT, FRESH: ginger (fresh or ground)

FRUITCAKE: cloves (ground)

FRUIT COCKTAIL: rosemary, mint

GAME: bay leaf

GINGERBREAD: cardamom (ground), cinnamon (ground), coriander, ginger (ground)

GUMBO: bay leaf, filé, thyme

HAM: cardamom (ground), cinnamon (ground), ginger (fresh or ground)

LAMB: allspice, basil, cinnamon (ground), cloves (ground), marjoram, nutmeg, oregano, rosemary, saffron (threads or powder), tarragon, thyme. Or lamb seasoning 1: Combine ¼ c. dried onion flakes, 1 T. each ground cumin seed, garlic powder, pepper, and basil. Or lamb seasoning 2: Combine 1 t. each marjoram, parsley, rosemary, and thyme.

LAMB, CURRIED: turmeric

LAMB, ROAST: coriander seeds

LEEKs: chervil, sage, tarragon

LENTILS: cilantro (fresh coriander)

LIVER: basil, sage

MACKEREL: fennel seeds

MARINADE: allspice, bay leaf, ginger (fresh or ground), nutmeg, oregano, rosemary

MARINADE, GAME: coriander seeds

MARINADE, MEAT: cumin (ground or seeds)

MARINADE, PORK: fennel seeds

MEATBALLS: cardamom (ground), coriander seeds, fennel seeds

MEATLOAF: cardamom (ground), cinnamon (ground), cloves (ground), marjoram, nutmeg, oregano, thyme

MEATS, VARIETY: tarragon

MEXICAN DISHES: cilantro (fresh coriander) as topping

MINESTRONE: marjoram

MUSHROOMS: coriander seeds, oregano, rosemary, tarragon, thyme

MUSHROOMS, MARINATED: fennel seeds, marjoram

MUSHROOM SOUP: curry, oregano, marjoram

OMELET: marjoram, oregano

ONIONS: basil, sage

ORIENTAL DISHES: ginger (fresh or ground)

PAELLA: saffron (threads or powder)

PASTA: basil, cilantro (fresh coriander)

PATE: bay leaf, cinnamon (ground), tarragon, thyme

PEAS: chervil, mint, rosemary, sage

PEPPERS, HOT: cilantro (fresh coriander)

PEPPERS, SWEET: cilantro (fresh coriander)

PICKLES, DILL: dill seeds

PIE: cinnamon (ground)

PIE, APPLE: cardamom (ground), coriander

PIE, FRUIT: allspice
PIE, MINCEMEAT: ginger (ground)
PIE, PUMPKIN: cardamom (ground), cloves (ground), coriander, ginger (ground), nutmeg
PILAF: turmeric
PORK: allspice, basil, chervil, cinnamon (ground), cloves (ground), marjoram, oregano, rosemary, sage, tarragon, thyme, turmeric; or 1 part each basil, sage, and savory
PORK, CURRIED: saffron (threads or powder)
POTATOES: basil, bay leaf, chervil, nutmeg, oregano, rosemary, tarragon, thyme; or 1 t. each oregano, thyme, pepper, and rosemary
POTATOES, BOILED: dill weed
POTATOES, SWEET: cardamom (ground), mint
POULTRY: basil, sage, tarragon
POULTRY, CURRIED: cardamom (ground)
PUDDING, RICE: cinnamon (ground)
QUICHE: nutmeg
RABBIT: chervil, marjoram, rosemary, tarragon
RICE: cardamom (ground), cilantro (fresh coriander), ginger (fresh or ground)
RISOTTO: saffron (threads or powder)
ROLLS: cardamom (ground)
SALAD, AVOCADO: cilantro (fresh coriander), dill weed
SALAD, BEET: chervil
SALAD, CARROT: cinnamon (ground)
SALAD, CELERY ROOT: turmeric
SALAD, CHICKEN: basil, tarragon, thyme
SALAD, CUCUMBER: thyme
SALAD, EGG: cilantro (fresh coriander)
SALAD, FRUIT: basil, cardamom (ground), cinnamon (ground), cloves (ground), mace, mint
SALAD, GREEN: chervil, marjoram, mint, tarragon
SALAD, GREEN PEPPER: cumin (ground or seeds)
SALAD, POTATO: dill weed, fennel seeds
SALAD, SEAFOOD: oregano, tarragon
SALAD, SHELLFISH: fennel seeds
SALAD, TOMATO: basil, cumin (ground or seeds), thyme
SALAD, WALDORF: mint
SALMON: fennel seeds
SALMON, SMOKED: dill weed
SAUCE, CREAM: chervil
SAUERKRAUT: dill seeds
SAUSAGE: allspice, coriander seeds, cumin (ground or seeds), fennel seeds, marjoram,

nutmeg, thyme
SEAFOOD, BROILED: tarragon
SHELLFISH: basil, dill weed, mint (garnish), turmeric
SHRIMP: allspice, ginger (fresh or ground)
SOUFFLE: chervil, nutmeg
SOUP: cilantro (fresh coriander) as topping
SOUP, TOMATO: tarragon
SPINACH: nutmeg
SPREAD: basil, cloves (ground), cumin (ground or seeds), thyme
SPREAD, CHEESE: chervil, tarragon
SQUASH: cardamom (ground)
STEAK: rosemary
STEW: chervil, cilantro (fresh coriander)
STEW, BEEF: cumin (ground or seeds)
STEW, CHICKEN: cinnamon (ground), cumin (ground or seeds)
STEW, FISH: coriander seeds
STEW, LAMB: bay leaf, dill weed, fennel seeds, mint, turmeric
STEW, PORK: dill weed
STEW, RABBIT: fennel seeds
STEW, SEAFOOD: saffron (threads or powder)
STEW, VEAL: bay leaf
STUFFING: allspice, chervil, cloves (ground), dill seeds, dill weed, ginger (fresh or ground), marjoram, mint, nutmeg, oregano, sage, thyme
TOMATO JUICE: $\frac{1}{4}$ t. dried basil per cup
TOMATO SAUCE: basil, oregano
TOMATOES: allspice, basil, bay leaf, chervil, cilantro (fresh coriander), dill weed, oregano, sage, tarragon, thyme
TOMATOES, STEWED: oregano
TURNIPS: dill seeds
VEAL: allspice, basil, chervil, nutmeg, oregano, rosemary, sage, tarragon, thyme
VEGETABLES, CURRIED: cumin (ground or seeds)
VEGETABLES, MARINATED: coriander seeds, oregano
VENISON: chervil, rosemary
ZUCCHINI: marjoram, mint, oregano, thyme

AJWAIN TO YUCCA—GARDEN TO TABLE

Mail-order sources for various herbs and spices are listed in specific entries. Look for the addresses of those firms in the source list at the beginning of this chapter. If they're not listed, look in the source lists in [Chapter 2](#) (for firms that also carry vegetables) or [Chapter 6](#) (for those that specialize in trees and fruits).

AJWAIN: Also known as ajowan (*Curum copticum*, according to The Fragrant Path and *Trachyspermum ammi* in Redwood City's catalog), ajwain is grown for its pungent, aromatic seeds. Ajwain is an annual that grows 1 to 3 ft. high. Grow like cumin or dill. Start in peat or paper pots in April, so that you will not disturb roots when transplanting. Seeds are available from Fragrant Path, Redwood City, and Richter's.

Ajwain seeds provide a flavor similar to thyme. They are popular in the Middle East and India where they flavor vegetarian lentil and bean dishes, are used in curries, or mixed in dough and fried. Ajwain is said to compensate for the effect of a heavily legume diet. Steam leaves like spinach or add chopped leaves to sandwiches.

ALFALFA: This plant makes wonderful high-protein hay for winter feed for herbivores. Also, a tea can be made from the leaves or seeds. Sometimes it is combined with peppermint. Harvest your leaves when the plant is in early bloom. Separate out the stems and discard them. Cure in the shade. Pour boiling water over the dried alfalfa to make tea. You can also eat the young tips as greens.

Violet Stewart wrote me, "I go out in a field of fresh alfalfa where there is new growth. Cut an armload and bring home. Put into a tub and wash thoroughly. Shake water out and lay on trays to sun-dry. When dampness is gone I strip tender leaves off and lay the leaves on trays and dry in 200°F oven to kill any bug eggs left, and when thoroughly dry put into a tight can ready for tea making. I think it keeps arthritis in check. I drink it every day instead of coffee or tea." Available as "green manure" or hay crop. (See Chapter 2 for information about planting alfalfa.)

ALLSPICE: The berry of the 40-foot evergreen pimento tree (*Pimenta officinalis*), allspice tastes like cinnamon, nutmeg, and cloves rolled together. You can grow a little tree in your garden, even in a moderate temperate zone, if you bring it in the house to winter in a pot, but it will only bear fruit if you live in Guatemala, Honduras, Jamaica, or Mexico. The tree does not bear fruit until it is 7 years old—and then bears for maybe 50 more years. If you have a fruiting tree, climb it and pick the branchlets with green fruit about $\frac{1}{4}$ inch in diameter. Throw them down, strip the berries from the branch, and sun-dry them for about a week, or until they're one-third their original size and are dark brown in color. Then you have "berries," the whole allspice. Use whole or grind to make a powder. Use in fruit pies, cakes, sausage, cabbage, and curries. *Pimenta dioica* is hardy down to 26°F and is available from Pacific Tree Farms.

"Allspice" (*Calycanthus floridus*). This perennial shrub or small tree is no relation to the

true allspice, but its leaves, when crushed, and its wood emit an aroma very similar to that of allspice berries.

ALOE VERA: This is one of the most highly regarded medicinal plants. Of the several *Aloe* species, the one you want is *Aloe barbadensis*, or Medicine Aloe. You can buy one from a florist or get a starter plant from a neighbor. Or order by mail from a source such as Merry Gardens. To use, snap off the tip of one of its fat, cactus-type leaves (they are smooth with no stickers at all). Squeeze out the natural salve from inside the leaf onto your burn, scrape, rash, or other skin problem. It's also good for sunburns. The plant will heal its broken tip and refill for the next time you need it.

AMBROSIA: See “Epazote.”

ANGELICA (*ANGELICA ARCHANGELICA*): A hardy biennial with lush, 2–3-foot leaves when mature, angelica can get up to 8 feet tall—the largest herb that isn’t a tree. Much like celery in its growing requirements, angelica does best in rich soil kept constantly moist and partially shaded.

Planting. Let the seeds mature on the plant; in August, gather and lay them in a flat or seedbed, uncovered by soil. (Seeds are viable for up to a year, but are best used right away.) Or just let the falling seeds self-sow and transplant. Young angelica plants grow slowly their first year, developing only a small leaf rosette. But in the second or third year, the plant begins growing rapidly. Consistently removing buds before the early spring flowers open—or at least before seed develops—turns your biennial into a perennial. Seeds available from Le Jardin du Gourmet, Nichols, DeGiorgi, and Thompson & Morgan.

Using. Use angelica root and leaves to flavor stewed fruit. They are a natural licorice-flavored sweetener for tart fruits.

➲ **CANDIED OR “CRYSTALLIZED” ANGELICA** *To make this Victorian delight, which can be used in fruitcake or as a decoration or confection: Cut young, tender stems (harvest only the topmost section for this purpose) into 2–5-inch sections. Using only a little water and a covered nonaluminum pan, boil to tenderness. Pour off the water, but save it. Peel off the tough outside layer of the stems. Return to the pan with the same water and cook over very low heat until stems are green. Drain once more. When the stems are dry, put them on a kitchen scale and weigh them. Then scatter them over a baking or drying tray or a sizable plate, and scatter*

over them an amount of sugar equal to the weight of the herb. Let them sit in a loosely covered container in the refrigerator or a cool room for 2 days. You want them to dry, but not harden.

COMPANION HERBS

Companion plants improve the growth and flavor of or repel the pests of other plants.

Anise helps coriander.

Basil helps tomatoes; repels flies and mosquitoes.

Beebalm helps tomatoes.

Borage helps tomatoes, squash, and strawberries; deters tomato worm.

Calendulas deal with asparagus beetles, tomato worms, etc.

Camomile helps cabbages and onions.

Caraway loosens soil.

Castor bean plant kills plant lice, repels moles (poisonous seeds).

Chervil helps radishes.

Datura is disliked by Japanese beetles (poisonous seeds).

Dead nettle (*Lamium*) holds back potato bugs.

Dill helps cabbage, harms carrots.

Fennel deters other plants; plant away from garden.

Garlic helps raspberries and protects roses from aphids, Japanese beetles, and rose bugs.

Geranium is avoided by Japanese beetles.

Horseradish deters potato bugs; plant at corners of potato patch.

Hyssop is friendly with grapes and cabbage; deters cabbage moth; keep away from radishes.

Lovage helps other plants.

Marigold is the workhorse of the pest deterrents; plant it throughout the garden; it discourages Mexican bean beetles, nematodes, and other insects.

Nettles are good near broccoli.

Parsley is good near tomatoes.

Petunia is good with beans.

Rosemary is good with sage.

Sage (and rosemary) is good with broccoli, carrots, Brussels sprouts, and peas.

Summer savory is good with beans (repels bean beetle).

After 2 days, the mass will have toughened considerably and you'll have to scrape with a knife to get it off the plate and back into the pan. Add just a few teaspoons of water so it won't burn, and heat that just to a boil. Remove the stems and drain the liquid. When the stems have cooled, return them to the pan and pour over them a newly made syrup (1 c. water to 1 c. sugar), enough to completely cover. Simmer 10 minutes. Drain off most, but not all, of the liquid. Spread the stems on waxed paper on a drying tray, and let dry until they are no longer damp to the touch.

ANISE SEED: There are 2 different, easily confused anise spices—anise seed (see below) and star anise. Anise seed grows on *Pimpinella anisum* (Umbelliferae), a native of the Mediterranean area and a favorite herb of Italian cooks. An annual, it is a relative of parsley that looks like dill, grows 18–24 inches tall, and bears decorative yellow flowers. The plant parts have a mild, sweet licorice flavor. Anise doesn't require fertilizing, weeding, or full sun. Available from William Dam, DeGiorgi, etc.

Growing. Anise is naturally a warm-climate plant; it needs at least a 120-day season to grow and produce seed. If you live in a cold, northern region, start seeds indoors in the fall in very moist soil in a fiber pot. Next spring, after the last frost, plant the whole pot in full sun, because anise doesn't transplant well. Or plant directly to garden, or just keep it in a container. Space plants 18 inches apart. You can save your own seed; it remains viable for 3–4 years.

Harvesting. Gather leaves while still young and tender. For your seed harvest, cut the plants off at ground level in August, when the seeds are fully formed and are drying on the plant. Dry the plants and store them inside a big paper bag (seed heads down) in a warm, dry place for further drying—or dry in oven or dehydrator at 110°F. Then loosen seeds, separate from chaff, and store in tightly closed jar.

Using. Anise leaves can be chopped and added to a salad or to fish dishes. Use seeds in cakes, cookies, and other sweet dishes, in curry mixtures, and in Italian anisette toast. Anise root is also edible; it can be chewed on or candied in very thin slices, like ginger. Oil of anise is used in commercial cough medicines. Anise tea is a valid home remedy for asthma, bronchitis, cough, and congestion.

ANISE, STAR: This spice is the fruit of a variety of evergreen magnolia tree.

➲ **CHINESE 5-SPICE BLEND** In a blender or mortar combine 2 T. black peppercorns, about 40 whole cloves, 10 inches cinnamon stick, 2 T. fennel seed, and a dozen star anise. Blend or grind together. Store in an airtight container. Good in Chinese recipes and any chicken dish.

ARTEMISIA: In my childhood I knew it as plain old sagebrush. It was my favorite plant. I loved the silver-gray leaves and their pungent sage scent. Sagebrush is not a true sage, but is actually in the sunflower family. Native Americans used to dry and burn the sagebrush leaves as a sacred incense. You can order big sage, *Artemisia tridentata*, and prairie sage, *Artemisia ludoviciana*, from Redwood City. (See also “Southernwood” and “Wormwood”; these are related sage species.)

ARUGULA: See “Rocket” in [Chapter 4](#).

BALM, BEE (*MONARDA DIDYMA*): This North American hardy perennial herb (a New York native) is called bee balm because its splendid scarlet or pink flowers are strongly attractive to

bees. (Hummingbirds like them too.) It's also called bergamot, Oswego tea, and Monarda. It is bush-shaped and grows up to 4 feet tall.

Planting. Bee balm is best started by root division in the spring or fall. Plant in fertile, moist soil. It tends to spread, but not invasively. Keep it under control and divide it at least every 3 years.

Growing bee balm from seeds is difficult. Try planting seeds in the spring or fall; growth will be very slow. Seeds remain viable 2–3 years and are available from Harris and Hudson.

Using. The heavily aromatic, lemony leaf is edible and makes a good tea (so used by the Oswego Indians). It's also good in fruit punches, fruit soups, and potpourri. Leaves picked right before flowering are the most scented, but they can be picked and dried anytime during summer. Good in poultry stuffing.

⇒ **BEE BALM FANCY TEA** Combine 1 part each dried bee balm leaves, dried basil (or sage), and dried citrus peel.

BAJM, LEMON (*MELISSA OFFICINALIS*): Also called sweet balm, lemon balm is another hardy perennial herb bush; it grows 2–3 feet tall and has little white flowers and lemony-mint-flavored leaves. There are several varieties. Seeds available from Hudson, Nichols, Redwood City, DeGiorgi, etc.

Planting. Lemon balm starts nicely from seed and will spread by seed drop in your garden as well as by runners. You can also propagate it by planting cuttings and root divisions. It will grow well in northern as well as southern zones, but plant in damp, fertile soil. It actually prefers partial shade, so plant near a tree or fence.

Harvesting. For preserving, pick whole stems just before the plant flowers. Dry quickly and package in an airtight container. For fresh use, just go out and pick leaves. Always use or preserve balm without delay; the flavor and scent quickly disappear into the air.

Using. Its leaves are so strongly flavored that they will give a lemony touch to any dish, and you can substitute fresh or dried balm for lemon in any recipe. Use fresh leaves in salads. Leaves are used commercially in perfumes and toilet waters and to flavor Benedictine. Balm makes great herb tea and is famous as a headache relief. Serve as an iced tea in summer and hot tea in winter. Balm is also good for scenting your soap. Fresh balm is best for cooking; dried leaves are good in potpourri or sachets for linen storage, being somewhat insect-repellent.

⇒ **PARTY BALM-MINTADE** Combine $\frac{1}{2}$ c. balm that has been cut fine, $\frac{1}{2}$ c. mint also cut fine, $\frac{1}{4}$ c. honey diluted with $\frac{1}{4}$ c. water, $\frac{1}{2}$ c. lemon juice, and $\frac{1}{4}$ c. orange juice. Let stand an hour. Now add 4 qt. ginger ale—homemade or store-bought.

BASIL: Another favorite annual herb, basil is a basic Italian seasoning with a clove-like scent that's easy to grow, in or out of a container (although a frost will kill it). There are many varieties, ranging in color (green, dark purple), size (dwarf basil is smallest), flavor (cinnamon basil, lemon basil), and zone hardiness (bush basil is hardiest). Sweet basil (*Ocimum basilicum*) is the traditional variety. All grow 1–2 feet tall in an erect bush shape and are very fragrant.

Planting. Basil starts easily from seed as long as your soil is warm. (Seed remains viable 2–3 years.) If you plant indoors, start about a month early, and then set out after frost

danger is over. Space 6 inches apart. Basil prefers partial shade; plant near a tree or fence if possible. Basil grown in poor soil has more strongly fragrant leaves. Water regularly. Plant every 2–4 weeks through spring for best continuing supply of nonblooming plants, because fresh basil is so much better than preserved. Or grow in containers, where it does well, for a fresh supply year-round. Seeds are widely available; Redwood City offers 8 varieties; DeGiorgi, 10.

Harvesting. Cut both leaves and buds when buds appear. The flowers are edible cooked or fresh, and pinching off developing blossoms keeps the quantity and quality of the leaf crop going. (If you don't pinch the buds and the plant succeeds in fully flowering, it will seed and then die.) Basil will grow a second crop if you don't cut all the way to the ground.

Cut leaves will keep in the refrigerator for several days; frozen ones, for up to 6 months. Use fresh or frozen leaves in a salad, or substitute for dried basil in recipes. To dry basil, tie in bunches or spread on trays out of direct sunlight. Or dry in oven or dehydrator (110°F) until leaves crumble. Basil must be dried quickly to prevent molding. Now crumble the leaves off the stems, discard stems, and store leaves.

Using. Dried basil is weaker and different than fresh or frozen, but is still useful. Make a medicinal tea; flavor vinegar, tomato dishes, eggs, fish, cheese, soups, stews, meat pies, lamb chops, squash, peas, green beans, or salad dressing. Or use in potpourri—or pesto ...

⇒ **PESTO** In your blender, mix 4 cloves garlic, 2 c. freshly picked basil, ¼ c. nuts (pine nuts or walnuts are good), 1 t. salt, ¼ t. pepper, and ¼ c. olive oil. As you blend, gradually add another ¼ c. olive oil. Pour into a bowl. Stir in 3 oz. just-grated Parmesan or other firm cheese. Use pesto right away. If you must keep it, store in an airtight container (air exposure makes pesto turn brown). Pesto is great as a sauce for noodles or green beans, or as a flavoring for pasta, soups, or cooked fish. To freeze pesto, omit cheese, adding only when thawed and ready to serve.

⇒ **BASIL CREAM SAUCE** Melt 1 T. butter in a pan. Stir in 1 T. flour. Add 1 c. milk, a little at a time, stirring constantly until thickened. Stir in 1 or 2 T. chopped basil. Add salt and pepper to taste, and maybe a pinch of cayenne or nutmeg. Serve over steamed veggies, hot pasta, or baked potatoes. Add chopped cooked chicken for chicken a la king. Add chopped spinach for creamed spinach. Add cheese for a cheese sauce.

⇒ **BASIL SALAD DRESSING** In a blender, combine 1 c. extra virgin olive oil, ½ c. wine vinegar, ¼ c. honey, 2 cloves garlic, ½ c. packed basil leaves, 2 T. dried tomatoes, 1 t. Dijon mustard, salt and pepper to taste. Store in refrigerator.

⇒ **TOMATO BREAD** Combine 2 c. warm tomato juice, 2 T. olive oil, 1 T. instant yeast, 2 T. honey, and 2 t. salt. Stir in enough whole wheat flour to make a kneadable dough. Knead 10 minutes. Divide and shape into 2 loaves. Place in oiled bread pans. Let rise until doubled in bulk. Bake at 350°F for a half hour.

Bay: There are 2 varieties, sweet bay and California bay. Both are warm-climate plants, although sweet bay is hardier than California bay, which is subtropical (zones 8–10). Both are evergreen trees. Both can be grown either in sun or semi-shade. If you live in the desert, you'll need to water them once in a while. Keep the soil well drained, and let it dry out between waterings.

Sweet Bay. Sweet bay is the seasoning leaf you find in the stores. Also known as bay laurel (*Laurus nobilis*) and Grecian laurel, it grows 25–40 feet high. It can be clipped into

almost any shape you want and thus severely limited in size, and it does well in containers. It's your best choice if you're in a northern climate (bring it inside for the winter). In a container, bay needs a coolish room; repot it once a year or prune it back severely. Outside, it needs to be in a partially shaded site if you have blistering sun; it's somewhat drought resistant. You can start it from seed (allow a month for germination at 70°F), or take a sucker cutting and root it (allow 6 months). Plants available from Nichols, DeGiorgi, and Thompson & Morgan.

California Bay (*Umbellularia californica*). Also known as California laurel, Oregon myrtle, and pepperwood, this bay grows wild on the California coast and in southwestern Oregon. It can get much taller than sweet bay—up to 75 feet high and 100 feet wide—but it's planted only from seeds and grows slowly, so you're not likely to see that size outside of the forest. It is naturally multi-stemmed and drought-resistant. Fruits are inedible. Plants available from Pacific Tree Farms and Raintree Nursery.

Using. The flavor of the California bay leaf is similar to that of the sweet bay but is significantly stronger. Both are used to perk up soups, stews, and meats. Both can be gathered any time of year, but late summer is preferable. Choose small but mature leaves. The leaves should not be crumbled, so handle them carefully. Discard any broken ones. Dry outside away from direct sunlight, turning once, until brittle. Or dry in oven or dehydrator at 110°F. Store in airtight jar. Add 1, 2, or 3 whole leaves at the beginning of the cooking process to any dish you want to flavor: stews, soups, spaghetti sauce, any meat or fish dish. Do not eat the leaf itself; remove it before serving, or warn the unknowing to discard it if found in their portion. A wreath for the head made of sweet bay leaves was a Roman award of honor.

BEE BALM: See “Balm, Bee.”

BERGAMOT: The bergamot oil used by the perfume industry is extracted from the Italian bergamot orange.

BORAGE (*BORAGO OFFICINALIS*): This is an easy-to-grow, ornamental and edible annual herb with hairy cucumber-flavored leaves and numerous lovely bee-attracting, intensely blue flowers. Grows up to 2 feet tall—more in heavily manured soil. Does well in a container, and can handle partial shade.

Planting. Plant seeds in spring, early summer, or fall. Plant several seeds per spot, and then thin to 1 plant. Plant in succession to keep prime plants available. Doesn't like wet feet. Once established, it will self-sow and create a dense clump, so allow room for that when planting. It grows quickly whether in a bed, row, or pot; it's nice to have indoors in winter. Available from Thompson & Morgan, William Dam, Redwood City, DeGiorgi, etc.

Harvesting and Using. Both flowers and leaves can be eaten. In general, preserve and use like basil. Leaves will be ready in about 6 weeks. They're best harvested before flowers appear—while the leaves are still young, tender, not too hairy, and about 2½–5 inches long. Mince them fine and add to an early spring salad or to cool drinks. Or cook like spinach (the hairs will cook away) or add to soup. Flowers are best harvested when they are just opening. Add them to salads and lemonade.

➲ **BORAGE TEA** Soak a handful of borage leaves in water that has been boiling. Then chill, sweeten to taste, and add ice. Serve with a borage flower floating atop!

⇒ **CANDIED BORAGE FLOWERS** You can actually do this to any tiny flower. Dip the flower in egg white and then into sugar. Dry and use plain or as cake decorations.

BURNET (*POTERIUM SANGUISORBA* OR *SANGUISORBA MINOR*): This herb perennial with cucumber-flavored leaves and lovely flowers is also known as salad burnet. A wild variety called great burnet (*Sanguisorba officinalis*) can be used in the same way as salad burnet.

Planting. This very hardy plant is a creeper, easily grown from seed or by root division in early spring. Seeds or plants are available from Comstock, DeGiorgi, William Dam, Hudson, and Park. But I don't recommend burnet because it's not that important as an herb, and is so likely to become a weedy nuisance in your garden.

Harvesting. Burnet doesn't dry well, but it can be picked off the plant even in winter, so that doesn't matter. Pick center leaves; older, outer ones are tough and taste unpleasant. Leaves (only!) are used in salads, as garnish, as flavoring for vinegar, in any cream soup, as a sandwich topping (minced and mixed with butter), or as a tea.

CALENDULA: See "Marigold, Pot."

CAMOMILE: See "Chamomile."

CAPERS: *Capparis spinosa* originates in the Mediterranean area of Europe. The plant is grown for the unopened flower buds, or capers, which can only be eaten pickled but are considered a delicacy. They grow 3–5 feet tall. (Nasturtium is used similarly but is *not* the real thing.)

Planting. Plant seeds or cuttings in full sun. The plant is easy to grow if you have a dry, mild climate. It thrives in sandy or rocky ground, relatively poor soil, and on hillsides—in a sunny, warm, well-drained site. It will be an evergreen perennial in the warmest zones (9–10), but will winterkill in zones 6–8. Grow it there as an annual, starting indoors if your summer is on the short side. Seeds available from Park and Pacific Tree Farms.

Harvesting. In summer, harvest the flower buds just before they open. They will look small and green. Keep them in the dark 3 hours; then pickle them. The fruit of the caper is also edible and can be pickled.

⇒ **PICKLING CAPERS** Have ready clean, hot pint (3) or cup (6) canning jars. Divide 1 qt. washed capers between the jars. In a stainless steel or enamel pan, mix together ½ c. brown sugar, ½ c. water, 1½ c. wine vinegar, 1 crushed clove of garlic, and 1 t. each mustard seed, salt, dill, and celery seed; if you wish, add mace, green onions, garlic, nutmeg, or peppercorns. Boil the pickling solution hard for 10 minutes. Pour it through a strainer to get out the solids and then boil once more. Pour the almost-boiling liquid over the capers. Pack in ½-pint jars. Process in boiling-water bath 15 minutes. Keep in a cool, dark place and wait at least 10 days before using to allow capers to pickle. Use pickled capers in soups, stews, vegetable dishes, salads, sauces, fancy sandwiches, and poultry stuffing. (See "Nasturtium" for more recipes.)

CARAWAY (*CARUM CARVI*): This plant comes in 2 varieties. The old-timer is a biennial: You plant it one year, and it grows that first year and makes seed the next. Now there's an annual kind too.

Planting. Plant 8 inches apart in the spring (or fall) in a well drained, sunny place where you can leave it for 2 years, such as the border of your garden. Mulch roots in the fall to

avoid freezing. It grows about 2½ feet tall. Once you've got it, it tends to self-sow. Caraway seed is viable for 2 years and is available from DeGiorgi.

Harvesting. When seed clusters ripen the second year (turning brown), cut off flower heads. Dry away from direct sun in a warm, dry place, laying flat on screen, paper, cloth—a surface from which you can easily gather spilled seeds. Once the seeds are dry, finish threshing by rubbing the heads with your hands. Blow off chaff and store seeds for planting or eating.

Using. The seeds make good additions to rye bread, biscuits, sauerkraut, and cottage cheese. Or cook them with cabbage and cauliflower. The flavor of caraway stems and foliage is similar to the seeds but milder. Use them in cheese and fish recipes and salads.

⇒ **CARAWAY-STUFFED CELERY** Mix cream cheese with caraway seed and stuff into hollow side of celery. Cut into 2-inch sections. Sprinkle with paprika.

CARDAMOM (ALSO CARDAMON): *Elettaria cardamomum*, whose seed is an aromatic spice, is a relative of ginger and a native of India. It grows on a shrubby little tree, 8–10 feet high, also known as the cinnamon palm. You can grow it in a temperate-zone garden if you move it to a pot and bring it into the house before winter. The leaves are deep green with a spicy ginger-like scent. It bears fruit only when 3 years old.

Planting. Cardamom is propagated 2 ways, by seed and by transplanting the plant just after harvest. That causes the top part to die, but the roots send up a new one—which fruits after 2 years. Available from Merry Gardens.

Harvesting. Pick it whole (seeds inside their pods) and grind before using, pods and all. The pods will disintegrate as a result of the cooking but will enrich the flavor. Also use pod and all in pickling mixes. Use ground to flavor puddings, pies, ice cream, and Danish pastries.

⇒ **CARDAMOM TEA** Set 3 T. black tea leaves (or 3 tea bags) to soak in 6 c. boiling water. In a pan, combine 1 c. milk, ¼ c. sugar, 3 whole cloves, 3 cracked cardamom pods, and 1 cinnamon stick, and simmer 10 minutes. Strain the spice mixture. Add it to the tea and serve.

⇒ **CARDAMOM COFFEE** Put 2 cracked cardamom pods in the bottom of your coffeepot before starting brewing. Brew the coffee. Let the pods soak in there an extra 10 minutes. Sweeten and serve.

CASSIA (*CINNAMOMUM CASSIA BLUME*): This is a Chinese flavoring agent, reminiscent of cinnamon and cloves. And no wonder, for the plant is a close relative of cinnamon. Cassia bark is sometimes sold as cinnamon; it is indeed the same flavor, but stronger. It's raised and harvested in the same way as cinnamon. Cassia "buds" are sold for use in pickling. They are the unripe fruit of the cassia, dried.

CATMINT: See "Catnip."

CATNIP: There are 2 kinds, similar in many ways and frequently confused. Both are perennials of the mint family. Both are energetic spreaders that like full sun and regular watering. Both are used in old-time medicinal remedies for humans. But in a cat's opinion, the true catnip is *Nepeta cataria*, which grows 2–4 feet tall. This is the one that makes cats go crazy. It has gray-green, downy leaves and either lavender or white flowers at branch tips in spring (June).

Catmint (*Nepeta faassenii*, a.k.a. *N. mussinii*): Catmint also has grey-green leaves and bee-attracting, lavender-blue flowers in loose spikes. The word “catmint” used to mean both types of catnip; more recently, catmint is used as the common name for *N. faassenii* only. It is much more ornamental but weaker in the cat-crazing element.

Planting. First plan how you’re going to keep the little plants safe from cats. That means a catproof barrier all around the plants. Otherwise cats will discover them and roll on or eat them. Once the plants grow larger than the cats, they don’t need protection any more. For either catnip or catmint, start the seed inside, or outside once the ground is really warm. Or plant in late fall, plant a cutting, plant in a container, or divide existing clumps of older plants and replant in sandy soil in full sun. Provide fertile soil and shelter from cold winds. They can grow in a semi-shaded spot, although they like sun. The flavor will be stronger if the plants grow in sandy rather than clay-type soil. Catnip seed available from Redwood City.

Harvesting and Preserving. Cut off the tops when the plant is in full blossom. When drying catnip, keep it in shade and high above the ground, or you’ll have every cat in the neighborhood coming to call! (They don’t seem to smell it if it’s high off the ground.) Or dry indoors at 110°F. Dry and discard the stems. To freeze: gather, wash, pat dry, and pack leaves in layers with waxed paper between. Take out a few at a time to make a happy cat.

Using. Make a tea from the leaves (fresh or dried). It is a traditional remedy for menstrual difficulties. Adding a few fresh leaves to your salad is a good way to greet spring. Or sew little gingham or felt mice come winter, stuff them with catnip, and give them as Christmas presents to all your cat-owning friends!

CATTAIL: The fibers of cattail down make excellent cushion stuffing. Start with a sackful and use in your pillows as you would any other stuffing.

CHAMOMILE: Half the time you’ll see it spelled “chamomile,” half “camomile.” And are we talking about garden (Roman) chamomile or sweet false (German) chamomile? The two plants are unrelated, although they have similar leaves, blossoms, and uses. They look very different: Garden chamomile is a low-growing creeper, while sweet false chamomile is tall and upright. The blossoms look like those of feverfew. And for the first 8 editions of this book I got it confused with yet another lookalike, dog fennel, and gave wrong information. Well, I’m straight at last!

Roman/Garden/True Chamomile (*Chamaemelum nobile*, a.k.a. *Anthemis nobilis*). This small evergreen perennial is grown either from seed or by root division. It makes a good ground cover and can survive in partial shade and without fertilizer. Available from Redwood City and Thompson & Morgan.

Sweet False Chamomile (*Matricaria recutita*). This 2–2½-foot-tall annual is propagated only by seed. Plant 1 foot apart in full sun and well-drained, light soil. It germinates easily, self-sows, and has pineapple-flavored flowers. Available from DeGiorgi.

Harvesting, Preserving, and Using. The little daisylike flower heads are the usable parts of both types of chamomile. Gather when in full bloom and dry at 110°F. True chamomile is the best for medicinal and tea use.

⇒ **CHAMOMILE TEA** Pour 1 pint boiling water over 3 t. dry flowers and steep to make tea. It's bitter medicine; Peter Rabbit had some when he got back home. It's supposed to be good for indigestion, chills, and nervousness, and he had all three. It's also used as a rinse for blonde hair and as a treatment for plant diseases.

CHERVIL (*ANTHRISCUS CEREFOLIUM*): This hardy annual grows 1½–2 feet tall. Delicate and ferny in appearance, it is easy to grow and does well in poor soil as long there is water. The 2 basic varieties are “curled” and “flat.”

Planting. Chervil does best shaded from hot afternoon sun. Plant in spring or late fall in the garden; it doesn't transplant well. Don't cover the seed; it requires light to germinate. Plant every few weeks thereafter until midsummer to keep it coming prime. Available from William Dam, Thompson & Morgan, Redwood City, DeGiorgi, etc.

Harvesting. For freezing, use tender young leaves cut from seedlings at least 6 weeks old. You can use older leaves for drying (at 110°F until brittle). Cutting off seedheads promotes leaf growth. If you allow the plants to flower, they will self-sow but basically stay in the same area.

Using. Chervil is the gourmet's parsley. Use it fresh as you would parsley, as a garnish and in salads, especially when you want a milder flavor than parsley. Use frozen or dried in soups, salads, poultry, fish, and egg dishes. Its flavor is mild; use 1 T. dried herb for salad, 2–3 T. for cooked dishes.

⇒ **CHERVIL VINEGAR** It's good in salad dressings. Half-fill a bottle with fresh or dry leaves. Fill the bottle with good vinegar, and heat it gently by placing in warm water. Bring water to boiling point. Remove from heat; when cool, cap. Let steep 2 weeks. Then it's ready.

⇒ **HERB SOUP** Seasoned with chervil, this can be varied indefinitely as to the green vegetables. For a start, pick sorrel, spinach, and lettuce fresh from your garden, and get rid of any tough midribs. Wash and shred. Use 1 c. finely shredded spinach, ½ c. shredded sorrel,

and $\frac{1}{2}$ c. of the white heart leaves of head lettuce. Use about $\frac{1}{4}$ c. butter and saute (don't brown). Add 4 peeled potatoes, 1 T. salt, and 2 qt. boiling water. Let the soup simmer gently for 1 hour. Crush the potatoes, add 1 T. chervil, and simmer 5 minutes more. Add a cup of croutons before serving.

⇒ **SOUR CREAM AND HERB DRESSING** Mix this in a jar and serve on green salads as you need it. Mix 2 c. sour cream and 1 t. each chopped parsley, chives, tarragon, and chervil. Add 2 T. brown sugar, $\frac{1}{4}$ c. vinegar, $\frac{1}{2}$ c. oil, a grind of pepper, a dash of salt, and 1 t. dry mustard. Mix well.

CHICORY: See "Coffees that Aren't Coffee" under "Cocoa, Coffee(s), and Tea" in this chapter, and "Leaf Vegetables" in [Chapter 4](#).

CHILIES: See "Peppers, Hot" in [Chapter 4](#).

CHINESE PARSLEY: See "Coriander."

CHIVES: See "Allium" in [Chapter 4](#).

CILANTRO: See "Coriander."

CINNAMON: This is the bark of a tropical evergreen bush (*Cinnamomum zeylanicum*) that only grows in India and Sri Lanka. There are several other varieties of cinnamon tree. Cassia cinnamon (see "Cassia") and Ceylon cinnamon are most common. The tree is hardy down to only 30°F. The bark can be burned as incense, turned into scented bath oil, and used to season food. Available from Pacific Tree Farms. For detailed instructions on harvesting cinnamon, see the herbal section of Rodale's *Encyclopedia of Organic Gardening*.

⇒ **MAKING COARSELY CRUSHED CINNAMON** Break sticks into pieces, put them into a bag, and pound with a hammer.

⇒ **CINNAMON SUGAR** Combine $\frac{1}{4}$ c. sugar with $\frac{1}{2}$ t. ground cinnamon. Mix well and store in a covered jar. Use on toast, etc.

CLARY SAGE: See "Sage, Clary."

GLOVER: This is wonderful stuff. All the varieties of clover are legumes, can be planted for a green manure crop, and should be inoculated. There are other fun things you can do with the clover blossoms! Redwood City offers *Trifolium pratense*, a red clover variety whose dried blossoms make a sedative tea and whose seeds make good salad sprouts.

⇒ **ALASKA HONEY** Larry Malcom wrote me from Eagle River, AK, to supply this recipe "for people who for reasons cannot have bees but still want to make honey! Boil together 10 c. sugar and 2 c. water for 10 minutes. Remove from heat and add 1 t. alum and 25 fireweed flowers, 45 pink clover flowers, 45 white clover flowers (or 90 clover of any color). Let stand 5 minutes. Strain and pour into jars. Simple, isn't it? And it comes out nice and thick and wonderfully good! We're having a taffy pull this weekend. Hooray! Went dog-sledding yesterday for the first time. Beats sno-machines hands-down! So quiet, with a full moon!"

⇒ **CLOVER BLOOM VINEGAR** Combine 6 lb. brown sugar, $\frac{1}{2}$ bushel clover bloom, 4 qt. molasses, and 9 gal. boiling water. Let cool. Add 3 T. dry yeast dissolved in $\frac{1}{4}$ c. water. Let

stand 14 days, strain, and store until it tastes like vinegar.

CLOVES: These are actually the unopened flower buds of an evergreen tree. The tree grows wild in the Molucca islands, the West Indies, Sumatra, and Brazil. To harvest, gather the purplish buds (growing on those familiar little clove stalks) before they open. Dry. The drying will turn them from reddish to dark brown. Use whole or ground. Powdered cloves can be used as a louse or flea powder on small animals.

COMFREY: Comfrey is controversial. It used to be considered totally harmless, a traditional cure for anything, food for anything. Well, it's not *deadly* poison, but modern chemistry has identified a poisonous substance in it, pyrolizidine, so the up-to-date recommendation has to be that it *should not be eaten in any form*.

Too bad, because this is a deep-rooting, hardy perennial with lush green leaves that can grow 3 feet high and come back quickly after being cut back. (The same hardiness has been known to result in a comfrey-turned-weed problem.) *Symphytum officinale* is widely available. Russian comfrey (*Symphytum peregrinum*) is slow-growing, is a source of compost material for organic gardeners, and is used to feed animals. Comfrey cannot be raised from seed. It has to be propagated by root cuttings. Plant a 2-inch root cutting 4 inches deep any time of the year—3 feet apart, because they get really big.

CORIANDER (*CORIANDRUM SATIVUM*): This herb is a hardy annual, a member of the dill family. It's also called cilantro, Chinese parsley, and Mexican parsley.

Planting. Plant in spring or fall, $\frac{1}{2}$ inch deep, 6 inches apart, in full sun or partial shade. (Don't transplant.) Keep seedbed moist until germination. It grows 2–4 feet tall. Let 1 head go and it will self-seed for future years. Plant every 3–4 weeks for an ongoing supply of choice leaves for flavoring. Northern gardeners should buy only non-bolting kinds (Johnny's Seeds and Nichols have them), which can handle the long days that trigger bolting in other varieties. Lane Morgan, who lives in northern Washington, says, "The standard kind bolts as soon as it's out of the ground up here." Seeds are widely available from Burgess, Burpee, Hudson, Nichols, Park, Redwood City, DeGiorgi, etc.).

Harvesting for Leaves. The very first leaves to appear are the best for cooking—the fan-shaped ones rather than the later dill-type ones. Start picking when plants are 6 inches

tall. Divide your patch into plants for leaves and plants to be let alone to make seed. Don't dry the leaves; they must be used fresh to have value.

Harvesting for Seed. Do this when some seed pods have ripened (around 2 months after you planted). Don't wait for all the pods to ripen, or you'll go out there one day and find the pods shattered and seed scattered on the ground. Proceed as you would for caraway. Mash seeds with a rolling pin. Put in apple pie and apple butter; also see "Curry Powders" under "Food Seasonings" for recipes.

Using. Some people hate cilantro's smell. Strange but true: When cooked, the flavor of the plant will be milder and more pleasant than its odor in your garden. Use the pungent leaves to flavor salsa verde, guacamole, soups, stews, salads, stir-fries, egg, fish, pork, hot dogs, etc. It's great with anything tomatoey and is used in Mexican and Indian cooking and in pickling mixes. Just don't use too much!

➲ **CILANTRO CHICKEN TOMATO SOUP** Shelley Dalen, Pasco, WA, sent me this. "My husband's grandmother gave it to him. It's quick, easy, one-pot, cheap, delicious, and can be changed around. It also can use lots of tomatoes when your garden is going nuts. Turn your burner on medium. Put a cut-up fryer, or just chicken pieces, in a Dutch oven (on the burner). Cover the chicken about 3 inches deep with tomatoes (canned or sauce is OK but fresh is best). Use more if you want more broth. Stir once to get a few tomatoes under the chicken and to prevent the chicken from sticking to the bottom of the pan. Put 1 large peeled and chopped onion on top of the tomatoes. Put ½ c. snipped fresh cilantro (or any other fresh or dried herb you like, in the amount you like) on top of the onion. Cover tightly, and let cook for 30 minutes. I serve with corn tortillas."

CRESS: Pepper grass is the most peppery of the cresses and the easiest to grow, given its ability to tolerate more dryness and heat than the others. It grows fast to 4–5 inches high. Another variety of seasoning cress is Upland, also with peppery-tasting leaves. Add chopped cress to a green salad or potato salad, or sprinkle over sliced tomatoes with a dash of vinegar/oil dressing. Cress is a good winter pot plant too. Available from DeGiorgi.

CUMIN (*CUMINUM CYMINUM*): This annual plant, an ancient Mediterranean herb, resembles fennel. It blooms with pink and white flowers and is raised for its seeds.

Planting. Plan for the 16 weeks of growth necessary to mature seed. So if you live in the northern United States, start indoors and transplant only after the soil is warm. Plant in light soil. The seeds will grow on the flower head and by late summer, they will be too heavy for the plant to hold; instead it will sprawl over the ground. Let the seed pods dry on the plant until they are just about to burst and be scattered. Then harvest, shell, and dry. Cumin seeds are good mixed with any cheese, in bread, beans, rice, sausage, pork, or wild meat sauces. Ground cumin is used in curry, pickling, and chili powder mixes. Available from Redwood City and DeGiorgi.

DAYLILY: Originally from East Asia, the many species of *Hemerocallis*, the daylily, have long since become local weeds. They are perennials with bright flowers, sold in a multitude of named varieties; they also live in the wild. The entire plant is edible: spring shoots, summer buds, flowers, leaves, and the small tubers. Like weeds, they do well in any soil and in either sun or shade. Some varieties need occasional dividing; some need almost nothing at all. Daylilies (or seed) available from Burpee, Park, Thompson & Morgan (seed

only), etc. The best selection of all is from Gilbert H. Wild and Son, who is a daylily specialist and offers a huge number of kinds: P.O. Box 338, Sarcoxie, MO 64862, (417) 548-3514.

Using. Harvest young outer leaves in early spring when 3–6 inches long. Steam, sauté, or stir-fry. The flower buds and blossoms are all edible. They have a sweet taste and an okra-like, mucilaginous quality. Closed buds can be pickled like capers, prepared as tempura, or cooked into omelets. To gather the little tubers, wait until fall or even winter, when they have had a chance to store food all summer. While you're dividing too-dense clumps, you can harvest the daylily tubers. Wash, peel, and prepare like potatoes; eat raw or in a salad like Jerusalem artichokes; or prepare like salsify fritters.

DANDELION: See “Leaves We Eat” in [Chapter 4](#).

DILL (*ANETHUM GRAVEOLENS*): This common garden herb is an annual with little yellow flowers and feathery leaves.

Planting. Available from almost any catalog, dill doesn't transplant, but will grow from seed (viable for 2–3 years). Plant ½-inch deep, spaced 3 inches apart, in garden in spring or fall, or in 6–8-inch pot indoors. Needs moist soil, especially before germinating. Germinates slowly. You need only a row about 1½ feet long to meet your needs. It can be interplanted with any member of the cabbage family, or cucumbers. Dill can get up to 4 feet tall but doesn't shade its neighbors because of its fine, ferny leaves. When harvesting, leave 1 plant to self-seed; it won't become a problem weed. For winter use, dig up little 2–3-inch plants grown from self-seeding in the fall and pot them.

Harvesting. If dill is allowed to dry out completely, it may flower prematurely. The leaves (dill weed) and seeds and flower heads (dill heads) are all used to flavor foods.

To harvest dill weed, cut off what you want any time after it gets 1 foot high. It's strongest in flavor just before flowering, so you can plant some early for seed at pickling time and some late for milder “weed,” because once the plant flowers the weed isn't as good.

To harvest dill heads, pick before the seeds have formed, and pick only the heads. Plants are likely to make a second or third crop of heads. These are nice added to each jar of dill pickles.

To harvest dill seed, cut the plants before the seed heads turn dark brown, because after that seeds begin falling. Harvest on a dry summer day. Tie in bunches and hang in an airy but shady place. Have something underneath to catch seeds that drop, or just lay them on a clean paper. When the heads are dry, shell off the seeds and store in covered glass jars, or fold up stalks and all in your paper (they'll keep fine). One school of thought says the seed is better dried off the heads; I can't tell the difference. You can also freeze dill or grow it in a kitchen pot through the winter. It's amazing stuff. A friend of mine poured the brine from a jar of dill pickles on the ground by her garbage cans, and—“lo!”—a crop of dill grew there.

Using. Use fresh or dried. Dill weed is milder than the seed. Add it to vegetable dishes, salads (especially macaroni and potato), and soups. Heads, seeds, and stems can be used to make dill pickles or any recipes involving raw cucumbers. You can put a whole dill head in a jar of homemade pickles or dill vinegar. Dill also goes well in bread, yogurt, cheese, sour-cream vegetable dips, mashed potatoes, eggs, and mustard mixes; with fish; and with sauerkraut or cabbage in any form. Dill seed tea is a traditional treatment for

adults with indigestion. A tea made from the branchlets is a traditional solace for babies with colic or gas.

⇒ **DILL VINEGAR** *Crush 1½ t. dill seeds; then soak in 1 pt. cider vinegar for 2–3 weeks. Strain, and it's done.*

⇒ **DILL SOUP** *Ellie Allers, Eureka, MT, wrote me, "This recipe for dill soup is my grandmother's wash day standby. I have eight grandchildren myself so it's no recent one. This consisted of every vegetable available, plus tomato sauce or ketchup, a handful of rice or some other grain, 2 or 3 sprigs of dill, salt, pepper, 2 or 3 hefty T. bacon fat carefully saved from day to day and, if you had it, a bit of chopped bacon. It simmered on the stove all morning. It sounds horrible, tastes marvelous. My husband loves it, and I have canned it for future emergency needs. Best served with hefty chunks of homemade bread and butter."*

ECHINACEA: There are many varieties. All are of some medicinal value. Most echinacea seeds are very slow (30 to 90 days) and hard (up to 50 percent success) to germinate. Cold stratifying the seed before planting helps. It appreciates full sun and is appreciated by butterflies. Once established it will reseed itself. If you don't want that to happen, clip off the finished flowers. Available from Seeds of Change, Richter's, J. L. Hudson, and Southern Exposure Seed Exchange. The University of Kentucky's info on this subject is at www.uky.edu/Ag/CDBREC/introsheets/echinacea.pdf.

EPAZOTE (*CHENOPODIUM AMBROSIOIDES*): This ancient herb (pronounced “eh-pah-SO-tay”) grows wild throughout the United States and is a close relative of the grain quinoa. It was used by the Aztecs and is used by modern-day Mexicans as well as Europeans and others. Epazote and cilantro are possibly the two most characteristic spices in genuine Mexican cooking. It's also called ambrosia, Mexican tea, and wormseed. Epazote looks like a bush, grows about 3½ feet high, and is noticeably odorous. It's an annual where winters are cold, a perennial elsewhere. (In marginal areas, cut it to 12 inches high and lay mulch over it.)

Planting. One or two plants will meet a family's kitchen needs. It will grow under almost any conditions (it's sand-tolerating and drought-resistant). Hardship simply makes it more aromatic. If you start with nursery plants, set them out in your garden after the last frost, 2 feet apart. Or plant seed ¼ inch deep. Available from Redwood City.

Using. Like cilantro, epazote should be used fresh for cooking purposes. And like cilantro, it cooks up milder than it smells in your garden. It will keep up to a week wrapped in a wet towel in the fridge. Unlike cilantro, though, you can dry some to make epazote tea in the off-season. Pinching back the stem ends not only supplies greens, it also keeps the plant from flowering and going to seed. Use in almost all Mexican recipes, especially those containing beans, such as black bean soup. (Mexicans believe that epazote diminishes the gas effect of beans.) Use about 3 chopped epazote leaves per 1 gal. of food. Add when beans are about three-fourths cooked. Also good in cheese and chicken mixtures. But don't use too much, or you'll get the medicinal rather than the culinary effect. Epazote got its folk name of “wormseed” because native Americans took it to remedy intestinal worms.

EUCALYPTUS: This family of trees and shrubs has over 500 species in its native Australia, about 150 of which are now thriving in Arizona and California, since it is a natural for deserts. Some have leaves with odd colors, such as blue; many have beautiful flowers. Some species have lemon, peppermint, or medicinal scents. The leaves of some species are

always fragrant; others must be crushed to release the scent (use their leaves in potpourris and sachets).

Eucalyptus plants are extraordinarily fast-growing, as much as 10–15 feet/year while young, and they can live a century. All species are tender, so if you have one in a planter, keep it in the house in cold weather and move it outside only for warm weather. Doesn't transplant well; don't change it from container to ground or back again. For more information, see the *Sunset Western Garden Book*.

⇒ **EUCALYPTUS COLD REMEDY** From Clara Magers, Modesto, CA: “We had eucalyptus trees out in front. My mother took some leaves and boiled them in a saucepan with some water and then let it simmer. We who had a cold would stand over the stove with a towel over our heads and breathe the steam. It clears your head.”

FENNEL: This herb comes in a confusing number of varieties. [Chapter 4](#) discusses sweet fennel (stalks eaten) and finocchio or Florence fennel (bulb eaten). The herbal fennel for flavoring, *Foeniculum vulgare*, is a hardy biennial. It can become a weed in your garden, hard to control. The answer to that is Bronze fennel, a less aggressive variety. Available from Redwood City.

Fennel vs. Dill. Fennel is different from dill in that it prefers slightly alkaline soil, but it resembles dill in growing 3–5 feet tall, with feathery branches and yellow flowers. The resemblance is familial, for the two are relatives and shouldn't be planted close together due to the risk of cross-pollination. Plant and harvest as you would dill, but don't interplant as you can with dill; instead, put fennel at the back of your herb garden, since it has a reputation for inhibiting vegetable growth.

Using. Fennel weed or seed can be substituted in any dill recipe, but it's on the strong side, so just use a pinch or two. Fennel is also used in apple recipes and to flavor candies.

Fennel Seed Tea. Straight fennel tea is an old-time remedy for baby colic. For an interesting combo, try fennel-mint tea: half peppermint leaves and half fennel seed or weed.

⇒ **BENGALI CRACKERS** Crush $\frac{1}{4}$ t. fennel seed and $\frac{1}{2}$ t. black peppercorns. Mix with 1 c. whole wheat flour and 1 t. baking powder. Add 1 t. tamari, $\frac{1}{4}$ c. lemon juice, and water as needed; work into a dough. (Be careful not to overwork.) Roll out one half of the dough at a time, $\frac{1}{16}$ -inch thick cut into 2-inch squares. Bake 8–10 minutes. (Cover half of dough while working with other half.) From Ruth Miller of Bonaire in the Caribbean.

FENUGREEK (*TRIGONELLA FOENUMGRAECUM*): Also called bird's foot or Greek hayseed, this legume grows a wheat-sized pea in a long, yellow, beaked pod. It's easy to grow, has a sweet clover scent, doesn't take up much room, and is good for the soil. Once started, it self-sows.

Planting. Plant $\frac{1}{4}$ -inch deep, 3 inches apart. Keep well weeded. It will grow about 2 feet high. In summer weather, fenugreek matures and makes seed quickly. In warm zones you can plant in fall as a leguminous green manure to plow under before spring planting. Seeds available from Park, Redwood City, DeGiorgi, or William Dam.

Using. Use leaves in salads, stews, or soups. A few leaves go a long way. Use seeds in honey as a dessert, or steep to make tea. The seeds are pretty bitter taken straight. Dried seeds, until you cook them, are hard as rocks. The seeds are also good for sprouting, or

grind them and mix with spices to make curry.

FEVERFEW (*CHRYSANTHEMUM PARTHENIUM*): I just discovered that for the first 292,500 copies of this book, the following description was listed under “fennel” instead of “feverfew”! I deeply appreciate Marie Oesting, who obviously knows her herbs well and took the trouble to call the error to my attention. Feverfew is an annual that grows like a weed. It has foliage with a strong, medicinal odor and small, midsummer-blooming, daisylke white flowers resembling those of chamomile. It got its name from old-timers who believed that a tea of its leaves would reduce a fever.

Planting. Seeds need to be chilled before planting for 3–6 weeks. Seeds available from Redwood City.

Harvesting. Harvest the plant when the blossoms are just starting to open. It’s a close relative of chamomile and is a traditional folk medicine for colds, fever, and flu. Combine with sage for a sore throat. Old-time feverfew was single-rather than double-flowered. A strong feverfew tea on your skin is reputed to have insect-repellent value. Feverfew has been closely studied by pharmacologic researchers, who have established that its use has no risks and that it helps prevent migraine headaches! It wouldn’t hurt to try it on a fever.

FILÉ: See “Sassafras.”

GERANIUM: There are many kinds of genus *Pelargonium*, family Geraniaceae. The “scented” or “sweet-leaved” geraniums are tender perennials originating in South Africa. They have very minor flowers compared to their beautifully blooming unscented relatives. What they do offer is fragrance of every sort—you choose the variety: almond, anise, apple/nutmeg, apricot, balm, balsam, cinnamon, clover, eucalyptus, filbert, ginger, lavender, lemon, musk, orange, peppermint, pine, rose, strawberry, southernwood, or violet. The plants vary extremely in the intensity of scent. Usually the leaves must be in the presence of the hot sun or else lightly rubbed in order to release their fragrance, but some are extremely fragrant without that help. The rose geranium (*Pelargonium graveolens*), which has a spicy rose scent, is one of the oldest and still one of the most popular kinds.

Planting. Geranium bushes grow 1–4 feet tall: only up to a foot if grown in a pot in the north, up to 4 feet if grown outdoors in a subtropical zone. They can be grown in the garden in summer in a moderate temperate zone, but must be moved inside in a container before frost. They’re most often kept permanently in a container; they actually do better when pot-bound and will keep thus for years. Don’t move the pot outside until the sunny days of early summer. Propagate by making stem or root cuttings from new young shoots. They can be planted from seed, but since you cannot depend on the seeds to grow true to type, you’re better off starting with a plant. Plant in dry, sandy, fertile soil. Place in full sun. Keep on the dry side.

Using. Good in sachets and potpourris, as floaters in finger bowls, and for making perfumes, scenting cosmetics, and flavoring drinks. Make a tea out of the leaves, or flavor a compote or pound cake. To flavor any cake, put a leaf in the bottom of your cake pan and pour the cake batter over it. To flavor jelly, put a leaf of rose geranium in the bottom of the glass. Oil of geranium has some insecticidal value.

⇒ **GERANIUM POTPOURRI** Combine 8 c. geranium leaves, 2 c. geranium flower petals, 1 c. leaves from your choice of a fragrant mint (all pre-dried), and 1 T. each of powdered

coriander seeds and powdered cardamom seeds. Use gum benzoin (1½ oz.) or orrisroot as your fixative. From Janice Lamp, Port Orchard, WA.

⇒ **GERANIUM-ROSE POTPOURRI** Combine 3 c. rose petals, 3 c. geranium petals, 1 c. peppermint leaves, 1 c. lavender petals, 1 T. powdered nutmeg, 1 T. powdered cloves, and powdered orris or 2 oz. gum benzoin for fixative. (See “Potpourri” under “Products and Processes” for additional recipes and instructions about fixatives.)

⇒ **ROSE GERANIUM CAKE** Sift together 2 c. flour, ½ t. salt, and 1 t. baking powder. Cream ½ c. butter and 1 c. sugar. Add alternately the flour and ⅔ c. water. Finally, add the unbeaten whites of 4 eggs. Whip hard for 5 minutes. Line a loaf pan with buttered paper and rose geranium leaves. Pour in batter. Bake in a 350°F oven for 30–45 minutes. Pull the leaves off with the paper when the cake is done.

⇒ **ROSE GERANIUM JELLY** Make by flavoring apple jelly. Wash the apples, but do not peel or core. Quarter the apples and barely cover with water. Simmer until tender. Get the juice and put it through the jelly bag, measure apple juice, and return it to the stove. When it is boiling, add ¾ c. sugar per 1 c. juice. Boil on to jelly stage. When almost done, put a few rose geranium leaves into the boiling jelly. They quickly give off their flavor. Dip them up and down until you have the desired taste and fragrant smell. Use 2 or 3 leaves for each pint. Tint a rose color with food coloring. Remove the leaves. Pour the jelly into your jars and seal.

GINGER (*ZINGIBER OFFICINALE*): This is a tropical Asian native; it can grow outside in Puerto Rico or Florida, but north of that needs a greenhouse or comparable hot, humid room in your home to thrive. Cold wet dirt kills ginger. Ginger is grown for the root, which is not really a root but a “rhizome,” an enlarged underground stem. Ginger root is spicy. An old-time horse trading trick was to poke some ginger up the tail end of a tired old horse right before sale time; it would prance around and act very young!

Planting. Ginger does well in a medium-sized container. Plant in well-and regularly fertilized dirt—but not sandy, pebbly, or gravelly soil. Water well and frequently. If outdoors, it needs partial shade. The stems grow 3–4 feet tall, leaves almost a foot long. Outdoor tropical plants are harvested in December and planted in February; you can actually harvest anytime after 5 months, but the longer you wait, the bigger the root gets. When purchasing, make sure you get *Zingiber officinale* and not an ornamental ginger variety. You might be able to get one from the store to grow, but best would be to order root from Exotica or Gurney.

To propagate, save a rhizome out from the harvest. Like a potato, it has “eyes.” Wait 2 months; then divide the root and plant the eyes 3 inches deep and 14 inches apart. Multiple plants can grow from the knobby root, one from each place where it bulges and gets closer to ground level.

Fresh Ginger Root. If in good condition, the root will be firm, with a light-brown outside skin that is papery. Wash, dry, and bag. It will keep in your fridge for 2 weeks. If you substitute grated or minced fresh ginger (or sliced ginger, or ginger put through a garlic press) in a recipe that calls for ground ginger (as in gingerbread), be prepared for the fact that fresh ginger is stronger and also has quite a different taste.

Preserving. Fresh ginger can be candied, crystallized, or preserved in syrup. If peeled and immersed in sherry, it will keep a long time, and you can use the sherry for flavoring too. For one of these sweet methods of preservation, ginger should be harvested at 8 rather than 10 months. To freeze ginger root, just wash a whole piece, dry, wrap in freezer

paper, and freeze. Don't blanch it. To cook with your frozen ginger root, just take it out, grate or slice off as much as you need, and put the leftover part back in the freezer.

Using. To make fresh ground ginger, trim off the leaves, cut the root into pieces, wash in very hot water, spread the pieces outside, and dry in the sun. When totally dry, grind. Ginger root has been discovered by researchers to counter motion sickness, so give your children gingerbread or pumpkin pie to take on a long drive! Or serve ginger-flavored preserves, fruit pickles, Chinese dishes (anything with soy sauce in it!), Indian food, or applesauce. Ginger is also a time-honored home remedy for worms and nausea.

➲ **GINGER SUGAR** Into a bowl, sift together 2 c. sugar and $\frac{1}{4}$ c. ground ginger; combine well. Transfer the mixture to an airtight container, and let stand for at least 3 days. Use to flavor cakes, puddings, squash, and applesauce and to glaze hams.

➲ **GINGER ALE** Ginger ale is a good base for lots of other drinks when mixed with various fruit juices. If you like it stronger, just add more ginger. If your weather is cold, add more yeast. If it's hot outside, be prepared to refrigerate it as soon as you have the desired amount of fizz. It takes only a couple of days for it to work enough to be a real "pop" beverage.

Dissolve 2½–3 c. honey or 5¼ c. sugar in 2 gal. water. Add the beaten whites of 3 eggs and 1 T. ginger moistened with water. Put into a large pan and bring to the boiling point. Skim and set aside to cool. (You'll think you're losing all the ginger, but don't worry. Even though a lot of it gets caught in this skimming, the flavor is there.) When lukewarm, add the juice of 4 lemons and $\frac{1}{4}$ t. dry yeast. Stir well. Let stand a few moments. Strain through a cloth. In 48 hours it will be ready to drink.

NOTE: Don't seal ginger ale into anything unless you then heat it enough to kill the yeast, or you'll have an explosion from the gas pressure, and somebody could lose an eye or something awful!

➲ **ANOTHER GINGER ALE RECIPE** Pound 3 T. ginger root. Pour 4 qt. boiling water over it. Add the juice of 1 lime, 3 c. sugar or the equivalent in another sweetening, and 3 T. cream of tartar. Cover with a cloth so flies don't drop in. Cool to lukewarm. Add 1 T. yeast. Let rest 6 hours; then chill and serve.

➲ **UNFERMENTED GINGER ALE** Cut 4 oz. ginger root into small pieces and mix with 4 lemons. Cut into strips as thin as you can manage. Pour 2 qt. boiling water over the mixture and let set 5 minutes. Strain out the solids and chill your liquid. Add 2 c. lemon juice and sweeten to taste. Dilute with cold water if it tastes strong or if intended for small children. Serve with ice and mint leaves in the glass for a hot weather special.

➲ **MINT GINGERADE** Pour 2 c. sweetened boiling water (with a dash of salt in it—helps draw out the mint flavor) over 2 c. finely chopped mint leaves. Let stand until cool. Strain out the leaves. Add 2 qt. ginger ale or gingerade and serve very cold, garnished with a pretty mint sprig.

Now here are some recipes for nice beverage mixes you can make once your ginger ale is done. (Or start with store-bought ginger ale or fizzy water.)

➲ **GINGER SPICED APPLE** Combine 1 qt. apple juice, 6 cinnamon sticks, 16 whole cloves, and $\frac{1}{4}$ t. nutmeg, and bring to a slow boil for 10 minutes. Strain. Chill. Add 1 qt. chilled ginger ale.

➲ **GINGER GRAPE** Combine 4 c. ginger ale, 2 c. grape juice (or grapefruit or orange juice), 3 T. lemon juice, and a sprig of mint (optional). Add the ginger ale just before serving over

ice.

⇒ **GINGER, GRAPE, GRAPEFRUIT** Combine 3 c. ginger ale, 2 c. grapefruit juice, and 2 c. grape juice.

⇒ **GINGER MINT LEMON** Gather a bunch of mint, discarding the stems. Bruise the leaves and cover with ½ c. water and 1 c. lemon juice. Let soak an hour. Add 6 c. ginger ale, sweeten to taste, and serve over ice.

⇒ **GINGER PUNCH** Cook ¾ c. sugar (or ½ c. honey) in 4 c. water for 3 minutes. Add ½ c. lemon juice, 1 c. orange juice, grated rind of ½ orange, and 1 T. grated lemon rind. Cool. Add 1 qt. ginger ale (or 1 qt. tea).

GINKGO BILOBA: You'll find much about the amazing ginkgo biloba tree at www.xs4all.nl/~kwanten/.

GINSENG (*PANAX QUINQUEFOLIUS*): This herb can be grown outdoors in many parts of the United States. More than 90 percent of the crop is exported. This is a great commercial crop if you can grow it, the most expensive herb in the marketplace, prized by Asians for its effects on both women and men.

A great info resource for ginseng growers is back issues of the bimonthly newsletter *Northwest Ginseng News*, which was published from 1992 through 1999. All back issues are available, with subject index, in a 3-ring binder. This is the complete reference guide to the markets, history, establishment, maintenance, disease management, weed control, harvesting, and drying of ginseng. The cost is \$115, plus \$5 shipping: 360-887-3128; fax 360-887-0320; Pacific Rim Ginseng, 1600 NE 236th St., Ridgefield, WA 98642; www.nwginseng.com. There's more ginseng info at ahc.caf.wvu.edu and search for ginseng.

Ginseng roots are expensive, however, and they need a northern habitat to grow. In its fourth season, each plant will produce 20 seeds—unless you've already lost them to rodents of all sorts, who devour both root and tops. Even having seeds isn't an easy answer. Ginseng seed, even if viable when grown or purchased, takes as long as 18 months to germinate. If it dries out before that, it is likely to die. Don't plant ginseng in an ordinary greenhouse; it will probably die or do poorly. What it needs is well-drained, highly organic forest soil in a shady area. Plant your roots or seeds spaced 12–18 inches apart, weed conscientiously, and mulch with fallen leaves.

Harvesting. If you can avoid climate and rodent problems, you can indeed do well financially from a few acres of ginseng—if you can afford to wait long enough: The roots are not harvested until mid-October of the sixth or seventh year after planting! Dig the roots out with their forks intact; don't scrape or scrub! To cure, dry them at 60–80°F for 3 days and then at 90°F. Roots over 2 inches in diameter will need 6 weeks at 90°F to cure, smaller ones less. Have them well-ventilated and spread thinly; turn frequently to prevent mildew.

Using. Ginseng is a stimulant. Much of the commercial stuff is only mildly effective, but fresh ginseng can be very powerful, so use discretion.

NOTE: Prolonged use of ginseng can result in nervousness, insomnia, and high blood pressure.

GOLDENSEAL: Steven Foster, of Frontier Natural Products Co-op, sells goldenseal root (bulbs) and buys its product: www.frontiercoop.com. Meeks Farm & Nursery, 37305 160th Ave.

SE, Auburn, WA 98002; 877-809-1737; www.meeksfarms-nurserys.com; provides goldenseal roots and growing instructions to interested persons. Steve Edwards sells starts of ginseng, goldenseal, and other medicinal plants at Aspen Hill Farms: 231-582-6790; Box 753 Anderson Rd., Boyne City, MI 49712. Or buy whole plants, large or small, and a goldenseal growing video (30 minutes, \$30) from NC Ginseng & Goldenseal Co.: 828-649-3536; 300 Indigo Bunting Lane, Marshall, NC 28753; robert@ncgoldenseal.com; www.ncgoldenseal.com.

The Herb Growing and Marketing Network, www.herbworld.com, offers a report, "Goldenseal: A North American Treasure! Will It Disappear in Our Lifetime?" Jeanine Davis or George Cox of the Mountain Horticultural Crops Research and Extension Center, Fletcher, NC, provide a production guide and list of sources on their website: www.ncherb.org; 828-684-3562; fax 828-684-8715. A free brochure, "Agroforestry Notes: Forest Production of Goldenseal," is available from the USDA National Agroforestry Center: 402-437-5178; East Campus, UNL, Lincoln, NE. ATTRA provides info on growing ginseng, goldenseal, and other native roots in a "Horticulture Technical Note" and in personal consultations: 800-346-9140; www.attra.org/attra-pub/ginsgold.html#commercial. Read "Commercial Production of Ginseng and Goldenseal" at www.hort.purdue.edu/newcrop/NewCropsNews/94-4-1/ginseng.html.

Goldenseal is listed by the Convention on International Trade of Endangered Species, so be cautious when exporting. A general permit can be obtained from the USDA, Animal and Plant Health Inspection Service, Division of Plant Protection and Quarantine, 4700 River Rd., Riverdale, MD 20737-1236; www.aphis.usda.gov.

NOTE: Goldenseal is strong medicine. Consult a reputable practitioner or a good herb book for instruction before using it. It can raise blood pressure.

HEMP: For more info, read *Comeback of the World's Most Promising Plant* (Chelsea Green); and *Hemp Culture* by Chas. Richards Dodge (1895), available from Caber Press (call/fax 503-735-3942; tcl@teleport.com; www.teleport.com/~tcl).

HENNA (*LAWSONIA INERMIS*): You can grow the henna bush, a well-known source of cosmetic and hair products, even in the temperate zone—if you dig it up, pot it, and bring it inside for the winter. It's an Old World tropical shrub or small tree of the loosestrife family. It bears aromatic white flowers and small leaves. The famous dye is made from those leaves and is used to make paint for skin designs in India or as a rinse that gives hair a reddish tint. In quantity, you can give yourself a serious dye job. Available from Hudson.

HOPS (*HUMULUS LUPULUS*): Once every farm had a few of these hardy perennial vines. The light green flowers of the female plant, which look and smell like pine cones, bloom in the summer and are harvested in the fall. Speaking precisely, those flowers are your "hops." They are used commercially to flavor ales and beer and can also be used to season food. Because of its alkaline qualities, hops were also used by some pioneer bread bakers to help leaven the sourdough. Publications on hops are available from ATTRA (800-346-9140) and WSU (pubs.wsu.edu).

Planting. Hops are usually started from root division of female plants, although you could start with seed. Plant in full sun. They need well-drained, fertile ground, and regular and generous watering. They must be helped to grow where you want them. Their natural inclination is to grow straight up and very high. They can be trained over an arbor, up a

trellis or support post, or out of a pot. And they grow fast—15–25 feet in a summer. Chop them back annually to keep them from taking over the place. They shed their leaves for winter, like grapes, but come back in the spring.

Harvesting. Gather the hops before they get to the shattering point and before they get frosted. Dry in an airy but shady place.

⇒ **ZHEDAHOOBLO** This spring specialty of the American pioneers is still an epicurean treat in Europe. Cut off the top 6 inches of the earliest spring shoots of hops, and cook just like asparagus. Because of their thinness, you'll need a lot for a meal. Adding lemon juice to the cooking water helps them hold color. Serve with a white sauce. Eating the shoots helps thin the crop, for once established, the hop vines will send up twice as many shoots as they should.

HOREHOUND (*MARRUBIUM VULGARE*): This is also called white horehound because the leaves and stems are covered with thick silky hairs that make it look frosted. (There is a Spanish horehound, *Marrubium suppinum*, which is not the one you want.) It's a small, hardy perennial bush that gets around 15 inches tall. It's a medicinal herb that has been used for centuries to treat coughing and bronchial congestion. Because of its extreme bitterness, it has usually been administered in association with sugar, as in the famous horehound candy (cough drop) of Victorian times. Either in tea or cough drops, it's still considered a good treatment for a cough or asthma.

Planting. To propagate, plant a clump division in the spring, or plant seeds 1 inch deep early in the spring in a sunny, well-drained place with light soil. Thin later to 8 inches. Although horehound is hardy, it tends to die if a harsh winter is also a soggy one. Place it in a well-drained site, and mulch the roots. Available from DeGiorgi.

Harvesting. Just before flowers open in late summer, cut off smaller stems near the ground, and cut off just the tops of larger stems. Break into 3–4-inch sections. Dry in a warm, shaded, airy place or in an oven or dehydrator at 115°F until brittle. Store in covered glass.

⇒ **HOREHOUND TEA** Bring 3 pieces horehound just to a boil in 4 c. water; then steep 15 minutes. Serve hot and sweetened. If unbearably bitter, dilute some more.

⇒ **HOREHOUND CANDY** These are basic instructions for making saltwater taffy.

1. Prepare the herb: Combine 2 heaping t. dried horehound and 1 c. water in a nonaluminum pan. Gradually bring to a boil. Take off heat and let steep 30 minutes. Strain. Put the horehound in a cloth, and press or twist to get every last drop of flavor. Boil juice down to concentrate. (If you want, you can also boil to make tea. The medicinal component in horehound is not hurt by boiling.)

2. Make the candy: Mix 1 c. sugar and 2 T. cornstarch in a 1½ qt. nonaluminum pan. Now make the candy: Stir in ¾ c. light corn syrup, ½ c. water, 2 T. margarine, and ½ t. salt. Cook over medium heat, stirring constantly, until sugar completely dissolves. Continue cooking, without stirring, until temperature reaches 260°F, or until a hard but shapeable ball is formed in cold water. Remove from stove.

3. Combine and finish: Stir in horehound flavoring concentrate. At this point you could substitute 1 t. of any herbal or commercial flavoring extract, plus coloring, instead of horehound.) Pour onto lightly greased cookie sheet. Let stand until cool enough to handle. Grease hands and pull until it has a satin-like finish and a light color. Cut into 1-inch pieces. To store, wrap in waxed paper.

HORSERADISH (*ARMORACIA RUSTICANA*): Because this is strong stuff, a comparatively few plants will suffice for your family use. It is a perennial relative of mustard, not of the proper radishes. Tender, young, early-spring horseradish leaves will add a mustard-like taste to a ham or cheese sandwich with their hot taste, but most commonly it is grown for the roots. It's a good plant for a cold climate.

Controlling. You can grow horseradish in a container. In fact, that might be the best way, since it can be hard to control once started in your garden; any bit of separated root will grow into a new plant. Or plant outside with edging, such as a bottomless bucket or a trench lined with plastic or slate. Give manure occasionally and water once in a while.

Planting. Horseradish is propagated from a root cutting. Any root has several side roots growing from the upper part of the main one. Cut those off straight-sided where they join the big root. Trim off the tip of the root at a slant. The time to do this is in the fall, when you are harvesting your horseradish crop. Store your root cuttings in damp sand in your root cellar until late winter or very early spring, when you can get into the garden. Dig 6-inch-deep trenches in fertile, heavy, well-tilled soil. You can make horseradish rows just a foot apart and space the plants also a foot apart. (These instructions are for commercial scale.) Lay the root cutting in at something approaching a 45° angle, straight-cut (thicker) end to the topside. Cover with dirt so that the top of the root is about 3 inches underground. Pack soil firmly around the roots.

Making “Straight” Roots. Commercial growers clean off the lateral roots by digging away the dirt from the top 4 inches of the horseradish root when it's 9–12 inches long and stripping off the lateral roots from that area. Then they replace that dirt.

Harvesting. Some people insist that horseradish roots are tastiest when little and that harvesting should commence as soon as the roots are well started. Some are positive that horseradish is at its best only in the fall after experiencing several frosts. You can dig up the thick, white roots the fall after you planted them, any time from September until the ground freezes. You can also dig up the roots in the early spring before the leaves start. But keep in mind that horseradish makes its greatest growth in late summer and early fall, so you'd get the biggest harvest in the fall. (You could dig all winter if the ground isn't frozen and you want to.) Harvesting horseradish also keeps the plants from spreading beyond where you want them. (Any root, or piece of root, left in the ground will grow again.) About 4 days before harvesting, remove the tops of those you plan to harvest as near to the ground as possible; that makes them die back. Dig up; after digging, use them very soon, or store them.

Storing. Folks usually just dig as they need roots, because they keep best right in the ground. If you must dig and then wait, store them layered in damp sawdust or sand in a root cellar or outdoor pit. If roots are stored at 32–40°F and 90–95 percent humidity, they'll keep 4–6 months.

Preparing. It's a good idea to wear gloves when you are preparing horseradish. Keep juice away from your eyes! The hot flavor comes from the “mustard oil” they contain. Scrub roots clean. Don't be disturbed about how they look; homegrown horseradish roots are more crooked than those raised for market, which are uprooted, trimmed, and then replanted. Peel off the brown outer skin with a vegetable peeler. Drop them into cold water right after peeling to prevent discoloration. Then put in a blender, through a food grinder, or grate. (Makes you cry worse than onions.) Put the ground horseradish in a half-pint, pint, or baby-food jar.

Preserving. Add vinegar to moisten your grated horseradish and prevent it from turning color: white wine vinegar (unless you want pink horseradish) or distilled vinegar. (Cider vinegar causes the grated horseradish to turn dark within a comparatively short time.) Add $\frac{1}{2}$ c. vinegar per 1 c. grated horseradish. Optionally, add $\frac{1}{4}$ t. salt (or sugar), or a little beet ground in to make it red. Mix, pack in jars, and tightly cap. It is important to get the grated root finished and bottled as quickly as possible. Refrigerate the prepared horseradish to keep it "hot." It's preferable to just make it as you need it, since over long usage, the vinegar will gradually evaporate and need replacement. After a month or so, your horseradish may be turning brownish and have less flavor even though kept in the fridge.

⇒ **NO-TEARS HORSERADISH** *From Lois Rumrill, Forks of Salmon, CA: Scrub and cut roots into pieces. Pour 1–2 c. vinegar into blender pitcher. Put in several pieces of horseradish and turn blender on. Keep adding pieces of the roots until the vinegar just covers them. Pour all into clean, small jars, cap, and refrigerate. For additional batches, just repeat the process.*

Lois wrote me, "I like the horseradish in the vinegar a lot better than in water, and making it this way I don't shed any tears when 'grinding' it. But if you prefer water, use water in place of the vinegar in this process. The thing you can't do with horseradish is heat or can it, because that weakens it."

Drying. Dry the root, grind to a powder, and put up in bottles in dry form. Prepared this way, it will keep much longer, but it does not make as good a relish as when grated fresh.

Serving. Serve horseradish with hot roast beef or any cold meats; or hot; or in salad dressing, with fish, or just on homemade dark buttered bread.

⇒ **SIMPLEST HORSERADISH SPREAD** *Mix grated root with a little bit of vinegar and a big bit of thick cream.*

⇒ **SOUR CREAM HORSERADISH** *Chill $\frac{1}{2}$ c. sour cream thoroughly, and then whip it until stiff. Add $\frac{1}{2}$ t. sugar (or pinch salt) and whip some more. Fold in 2 T. of your prepared horseradish. Serve with meatloaf or ham.*

⇒ **FANCY SOUR CREAM HORSERADISH** To the above recipe, add 1 T. chopped chives, or parsley and 1 T. vinegar, or a pinch cayenne pepper, or $\frac{1}{2}$ t. prepared mustard, or a dash Tabasco, or $\frac{1}{4}$ t. pepper, or a combination thereof.

⇒ **HORSERADISH SANDWICH FILLING** Mix equal quantities of finely grated horseradish and mayonnaise. The horseradish can be topped with thinly sliced tomato, cucumber, radish, or chopped watercress. Spread between thin slices of buttered brown bread.

⇒ **HORSERADISH SAUCE** Melt 1 T. butter. Blend in 1 T. flour. Add 1 c. soup stock or water. Cover and heat to boiling. Stir in $\frac{1}{2}$ c. freshly grated horseradish, 1 T. lemon juice, and salt and pepper to taste. Simmer 2 minutes and serve. This is especially good with tongue.

⇒ **HORSERADISH MILK SAUCE** In the top of your double boiler, combine 3 T. butter and 3 T. flour. Make a paste. Gradually add $1\frac{1}{2}$ c. milk and then $\frac{1}{3}$ c. grated horseradish. Cook over simmering water 20 minutes. Add $\frac{1}{2}$ t. salt and a pinch pepper, and you have your sauce.

HYSSOP (*HYSSOPUS OFFICINALIS*): This unusually attractive, hardy perennial herb grows 1½–2 feet high and provides an old-time medicine for sinus/chest problems. Great for bees, since it blooms profusely all summer (July–Nov.) with lovely, intense blue flowers. (There are also white and pink varieties. Grows like a low shrub (cut it back to keep it blooming), and leaves stay on most of the year, so it makes good edging for your herb garden. Birds like the seeds.

Planting. Plant seeds (viable 3–4 years) indoors and cover. Germinates easily in 10 days, if warm. (In garden, hyssop tends to self sow.) You can also propagate by division or tip cuttings of young shoots. Set out 10 inches apart in slightly alkaline soil, full sun or partly shaded spot. Can handle some drought. Available from William Dam and DeGiorgi.

Harvesting. Cutting back the plant regularly makes it keep producing the tender young leaves you'll want for harvesting. Dry as you would basil.

Using. You don't need many leaves. Hyssop is bitter, strong stuff. Use it to flavor sausages or any stuffed meat or pork, or use it in any strongly flavored meat dish, soup, stew, or vegetable juice. The tea, especially sweetened with honey, is a traditional treatment for colds, coughs, asthma, and sinus problems. Gourmet restaurants put anise hyssop leaves in salads.

INDIGO: The indigo shrub (*Indigofera suffruticosa*) is a 3–6 ft. tall perennial that grows in frost-free areas of the Sonoran Desert in Mexico. It can be grown as an annual by saving seed every year. It is most valued for the permanent blue dye extracted from its leaves. Seeds are available from Native Seeds. After soil has gotten warm in the spring, plant seeds (that have been soaked overnight) $\frac{1}{2}$ in. deep. Space plants 1 ft. apart. Indigo loves heat and cool weather slows its growth. If you don't have a warm enough climate, it will grow happily in pots in your house. It is a self-pollinating legume. To harvest seeds, wait until they are dry, crush, and remove seeds.

IRIS: There are a multitude of varieties of iris, but old-time orrisroot powder is made from the "white flag" kind (*Iris florentina*). It's a perennial that grows 2 feet high, blooms early in summer, and is cultivated for the dried root, which is fragrant (violet-scented) and is powdered to make a fixative for potpourris and sachets.

NOTE: All parts of the iris plant and the orrisroot powder made from it are poisonous!

Planting. Rhizomes (underground stems that look like roots) are planted lying

horizontally with the upper side showing just over the ground level. They prefer light soil and partial sun. The plants propagate rapidly at the root and need to be dug up in late summer (August) and divided every few years. To divide, cut them apart, leaving each piece some roots, a stem, and a fan of leaves above that. After they bloom, cut off the flower stems. That will improve the quality of the root.

Preparing. Use your surplus roots to make orrisroot powder. Wash the dirt off the roots with running water. Dry them like other roots. When absolutely dry and brittle, cut them into very fine chips. Dry those chips about 3 more days, stored in a paper bag in a dark, dry place. They will then keep fine for years. You'd better label them "Poisonous!" The orrisroot chips (or a powder made from them with a mortar and pestle) keep potpourris and sachets fragrant for years. Orrisroot also absorbs the general fragrance of the other substances in there and holds it. Use $\frac{1}{4}$ c. chipped or powdered orris to 4 c. fragrant materials (see "Potpourri").

JOJOBA: This plant does well in a dryish situation. The oil extracted from the seeds is used in shampoos, etc. Available from DeGiorgi.

JUNIPER (*JUNIPERUS COMMUNIS*): This shrubby perennial conifer grows to only 6 feet at most—even less in the windswept areas to which it's naturally adapted. It's hardy and will grow just about anywhere it can get sun. The plants are male or female. The females bear berries, which ripen extraordinarily slowly—2 to 3 years. As they ripen, they change color, from green to black with a bluish cast. Wait until fully ripe to pick. Dry and then store. Before use, crush lightly. Juniper is used commercially to flavor gin. You can use it to flavor sauerkraut, stews, wild meat sauces, or casseroles. But go easy on it—it's strong stuff.

KENAF: This is an annual non-wood fiber plant from central Africa. Related to okra and cotton, it can grow to 12–18 ft. in a 6-month growing season. It's the great new hope for a pulp plant to replace trees in papermaking: "Kenaf Production" is at www.attra.ncat.org/calendar/question.php/2008/05/05/what_information_can_you_give_me_on_kena. The American Kenaf Society, which recently merged with the Association for the

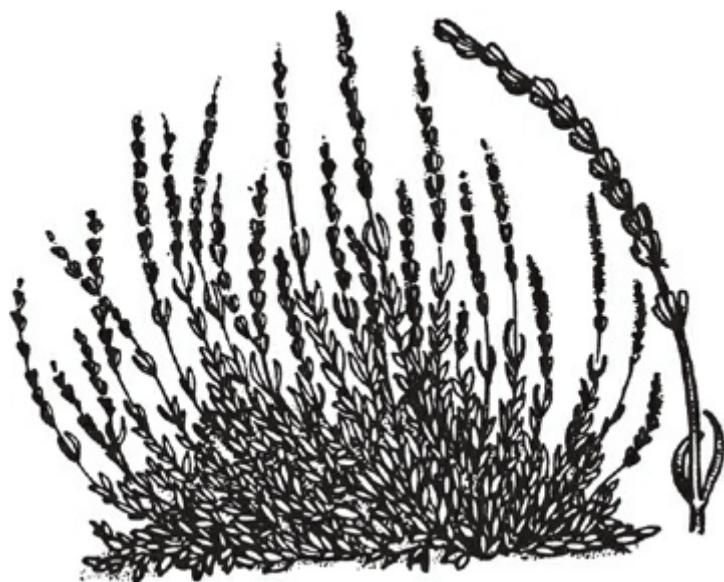

Advancement of Industrial Crops, promotes products and uses of this plant: 520-621-2817; University of Arizona, PO Box 210036 Forbes Bldg., Rm 207, Tucson, AZ 85721; www.aaic.org. For seed and growing info contact The International Kenaf Ass'n at 101 Depot, PO Box 7, Ladonia, TX 75449. Seeds are also available from www.kenafseed.com.

LAVENDER: This semi-hardy perennial blooms from June to August with fragrant blue and purple bee-attracting flowers—possibly the most wonderfully scented plant, fresh or dried. It grows 1–3 feet high (trim back after harvest of flowers if you want it shorter). Catherine Shirley wrote me, “The true lavender is a small shrubby plant native to southern Europe. The plant thrives best in hot sun and light and rather dry soil well supplied with lime. On low and wet land it is certain to winterkill. It also should be loosely covered to prevent the snow from getting inside the branches which freeze and thus winterkill.”

There are many different varieties: English lavender (*Lavandula vera*), spike lavender (*Lavandula spica*), and French lavender (*Lavandula stoechas*). *Lavandula angustifolia* is another name for all three. English lavender is the hardiest, and mulching can get it through a winter. Dwarf kinds grow 12 inches tall and are suited to a pot life, 1 or 2 plants in a 6–8-inch pot. More tender varieties are best brought in for the winter.

For more info request ATTRA's free brochure, “Lavender as an Alternative Farming Enterprise” (800-346-9140; www.attra.ncat.org). Read Virginia McNaughton's book, *Lavender: The Grower's Guide* (Timber Press, 2000). And visit fletcher.ces.state.nc.us/staff/jmdavis/lav.htm.

Planting. Be choosy about the plants you buy. Some lavenders are not of commercial quality and do not produce quality oil. Lavender seeds can live 2–3 years. The plant can be started from seed, but it grows very slowly. It is more readily propagated from stem cuttings (6 inches long), by layering, or by division. Plant deep. Cuttings should be set in well-prepared soil in early spring, 12–15 inches apart, in rows spaced to suit the cultivation intended.

Lavender can be grown as a hedge to give plenty of flowers for harvesting. Frequent and thorough cultivation is desirable. Growth is slow, and plants do not produce any considerable quantity of flowers for several years, but full crops may be expected for some time thereafter if the plants are given proper care. They should not be watered very much. Lavender grown in poor soil that is limy and gravelly produces the most strongly scented

flowers. Available from William Dam and DeGiorgi (3 varieties).

The Sequim area of Washington state has many lavender specialists who offer plants, products (aromatherapy, sachets, dried lavender, lotions, fragrance, etc.), and/or volume plugs. Here are some specifics:

Cedarbrook Herb Farm: 50+ varieties; 360-663-7733;

www.cedarbrookherbfarm.com; 1345 S. Sequim Ave., Sequim, WA 98382.

Leyden House: 413-772-0858; fax 413-772-8858; 56 Glenbrook Rd., Greenfield, MA 01301; www.leydenhouse.com.

Olympic Lavender Farm: 360-683-4475; 1432 Marine Dr., Sequim, WA 98382;

www.lavenderfarms.com/olympic/main.htm or www.olympiclavender.com.

Purple Haze Lavender Farm: Mike Reichner; 888-852-6560 (orders); office 360-683-1714; fax 360-681-5427; 180 Bell Bottom Rd., Sequim, WA 98382;

info@purplehazelavender.com; www.purplehazelavender.com. Great website and links!

Harvesting. Gather the flowering tops or “spikes” as soon as the first buds on a spike begin to open. That’s when the flowers have their strongest scent. Catherine wrote me, “A lot of fragrance can be lost if they’re left standing too long, especially if rain falls on them. If the plant got wet already, cut without waiting for all buds to bloom. For production of oil, the leaves are generally used rather than the flowers, and they are distilled at once without drying. (To prevent plants turning woody, prune them back sharply every year after harvest.) If dry flowers are wanted for sachets, shake the spikes over spread-out paper, as some buds will fall off. Carefully hang the spikes up to dry in an airy room (in the shade). Takes about 3 weeks. Once dried the flowers are stripped from the stems by hand.”

CAUTION: *Inhaled lavender can cause sneezing, tearing, and even vomiting, so wear a dust mask or respirator while working with it, and keep animals out of the room!*

Using. Old-timers kept it simple; they just hung some bunches of dried lavender from the ceiling or placed them between folded clothes in a drawer. But the dried flowers and buds can be used in bath water, potpourris, fragrances, and sachets for scenting linens; as a tea herb; as a scent for soap and commercial cosmetics; and in jellies and wine vinegar. They’ll keep moths out of the cupboard too. You can also get a good and useful lavender oil that improves with age.

➲ **LAVENDER BOOKMARKS** Catherine wrote, “Real short lavender spikes with flowers and buds can be artistically arranged between 2 small squares of nylon tulle, nylon organdy, or any stiff transparent material in a sandwichlike fashion. Secure the spikes with glue that dries clear or a few small staples so the spikes do not move around. Then sew patches of pretty braid or tapes around the edge on all sides to suit your fancy. Good gift for people who read a lot.”

➲ **LAVENDER SACHET POWDER** Mix $\frac{1}{2}$ oz. dried powdered lavender flowers with $\frac{1}{2}$ t. powdered cloves. Sew them up tightly in a little cloth pillow and leave the pillow in a bureau drawer to perfume the clothes. That’s old-time elegance.

➲ **LAVENDER WATER** Dissolve 3 drops oil of lavender in 2 c. distilled water. Age at least a week. It’s better with a lump of sugar in it, but then it has a tendency to ferment and go bad. A perfume.

LEMON BALM: See “Balm, Lemon.”

LEMONGRASS (*CYMBOPOGON CITRATUS*): This tender Asian native looks like a green onion, but the leaves are greyish green and spearlike. It's not pretty. It can be grown in the temperate zone but must come indoors in a container for the winter because frost kills it.

Planting. One way to get started is to find it at an Oriental grocery. Look for some with the root still on it. Put it in water in a glass jar. Set the jar by a window that gets lots of sun. The roots will grow. Once the roots have expanded a good bit, plant it where it can get 4–6 hours of sunshine each day. Water only once in a while, but water thoroughly when you do.

Using. Lemongrass needs to be harvested. Cut the long blades, wash, and drain. To use fresh, cut into short sections. Or dry those sections at 110°F until crisp and crumbly (6–8 hours). You can powder and store it, but it will lose its flavor quickly. Its peculiar citrus flavor is great in Mexican and Asian cuisine. Some people like a tea made from its steeped dry leaves. Soak dried lemongrass in hot water for an hour to get the flavor out.

LEMON VERBENA (*LIPPIA CITRIODORA*, FORMERLY *ALOYSIA CITRIODORA*): This is an attractive perennial shrub (up to 6 feet tall) with pink flowers.

Planting. Plant after last frost, and bring back in before the last warm summer evenings are over. To propagate, make cuttings of shoots early in the summer and plant in light, well-drained soil.

Harvesting. The lemon verbena leaves are at their best during early apple harvest season. You can dry leaves for winter use or use fresh (finely chopped) to make a soothing tea, good at bedtime. For lemon flavoring, add fresh lemon verbena leaves to drinks, fruit desserts, fruit salad, and jellies. The leaves are also good in potpourri or sachets.

LICORICE: *Glycyrrhiza glabra* is the plant from whose root licorice flavoring comes. It's a perennial. Plant seed in spring, or do root division in spring or fall. To harvest, wait until the roots are 3 years old. Licorice has a mild laxative effect, a very sweet taste, and a tradition of flavoring cough syrups and candies.

➲ **LICORICE ANISE ROOT BEER** Combine 2 T. chopped licorice root, ¼ c. molasses, 1 c. sugar, and ½ gal. water. Boil slowly for 15 minutes. Remove from heat. Add 1 t. anise extract. Let cool and soak a half hour. Strain. Variation: Add a pinch of yeast for a bit of carbonation and a yeasty flavor.

LOVAGE (*LEVISTICUM OFFICINALE*): This Mediterranean-originating hardy perennial resembles angelica, grows 6–7 feet high, and is considered by some to be one of the loveliest herbs.

Planting. Plant seeds (they won't keep) in fall or spring, or do root division. Plant in moist, fertile soil, in sun or light shade, 12 inches apart. You need only a few plants. Dies in winter, but comes back from roots in spring. Available from William Dam and DeGiorgi.

Using. You can harvest and use in your kitchen lovage leaves, seeds, stalks, and roots, fresh or dried. They all taste somewhat like celery and can be used to flavor salad, soups, or meats. (Go easy; they're strong.) You can save the seeds and use them anywhere you would celery seed. To harvest roots, give them 3 years to get well-grown.

MACE: This spice comes from the seed (nutmeg) of the tropical nutmeg tree (see "Nutmeg").

It has an outer shell that is covered by a lacy red network called aril. The peachlike fruit of the tree is edible. Save the kernel. Remove the aril and sun-dry. The dried pieces of aril are called blade mace. When ground, the powder is called mace and is used to flavor meats, fruit, sweet baked goods, and jams—but nutmeg is considered the better choice for sweet dishes, with mace the better choice for meat.

MARIGOLD, POT (*CALENDULA OFFICINALIS*): This hardy annual flower has a bold and pleasant golden color. Of all the varieties of marigolds, the pot marigold (also known as calendula) is the most important. The flowers and leaves of all marigolds can be used in salads or soups, but the pot marigold also yields an ointment used by traditional healers to treat ulcers and wounds. Plant in fall or early spring in full sun. Because pot marigold repels many garden insect pests, organic gardeners like to grow lots of it around or in the garden. Petals are good in salads; you can also add petals (or a strong petal tea) to casseroles, soups, cakes, and puddings.

MARJORAM: This is one of the main branches of the Origanum family (the other is oregano). Some marjorams are merely ornamental. The culinary varieties are pot marjoram (*Origanum onites*) and sweet marjoram (*Origanum majorana*). Sweet marjoram, the generally preferred type, comes from the Mediterranean area and is “semi-hardy,” unable to withstand frost and snow, so in zones 1–7 it must be grown as an annual or taken indoors. It grows 1–2 feet high, and has small gray-green leaves and small lavender or white summer blooms. If your climate allows it to grow as a perennial, it will enlarge each year to a 2–3-foot-wide bush shape. That one plant will probably be enough to meet your kitchen needs for marjoram.

Planting. Start marjoram from seeds (viable for 2–3 years), cuttings, division, or layering. Seeds germinate easily but slowly (2 weeks). It helps to soak seeds in water overnight before planting and keep planted areas moist until they’re up. Plant after frost or, for most northern gardens, start inside and then transplant after last frost. Allow 5–6 square inches per plant in solid block plantings, or 9 inches in rows. Marjoram is easy to grow but is happiest in a fertile, neutral pH, well-drained, well-watered and -mulched situation. Plants also prefer partial shade. Once established, they self-sow. Marjoram is a good container plant for a windowsill that gets sun (it has a naturally shallow root system). Or just stick it in the basement for the winter; it will go dormant. Prune to avoid woodiness. Available from William Dam, Redwood City, DeGiorgi, etc.

Harvesting. For fresh leaves, cut marjoram year-round, anytime after the plant is at least 5 inches tall. When the plant begins to bloom, take the top 4 inches and dry. You can harvest again in the fall by cutting the whole plant off and drying. Don’t wash; just sort the leaves and dry like basil. Marjoram is unusual in that its flavor is improved by drying!

Using. Marjoram is a basic herb in Italian cooking (spaghetti sauce! poultry stuffing!) and sausages. It makes one of the best herb butters. In the kitchen, use on hot vegetables, especially zucchini, potatoes, lima or green beans, and peas. Use fresh or dried in egg dishes, stews, soups, and gravies and with fish or meats. Orange juice flavored with marjoram makes a nice herb jelly. And you can make a good herb vinegar with it. Also good in sachets.

MARTYNIA: This unusual annual from the botanical family Martynacia is a native of the southwestern United States and is also called Proboscidea. There are more than a half-

dozen types that come from various regions, from the United States south to Brazil. A desert and plains native, the plant has bristly leaves.

Varieties. *Proboscidea fragrans*, a common Mexican type, has bright red flowers whose pods pickle especially well. *P. lutea* has yellow blooms and is from Brazil. *P. annua*, *P. parviflora*, and *P. louisianica* (a.k.a. *P. jussieus*) all also have edible pods. *P. louisianica* is considered the best risk for northern gardeners.

Planting. You need 120 warm days to get martynia from seed to a harvest of pods. This is easy if you're gardening in the south. Northern gardeners should start martynia in a protected place. In the garden, plant 1 inch deep, rows 3 feet apart. In either case, plant near the end of February or early in March. Indoor plants in individual peat pots should go to the garden about the same time as your nightshade fruits (tomato, pepper, eggplant). Plant them in the garden 4 feet apart, rows 3 feet or further apart in full sun and fertile soil. They need to be that far apart because they spread out widely, although they get only a few feet tall. Seed available from DeGiorgi, Hudson, and Park.

Harvesting. Martynia will start flowering about 6 weeks after germination. Its large (2 inches across), lovely flowers grow in clusters of up to a dozen at the end of each stem. Each is followed by an edible seedpod that somewhat resembles an okra pod (fuzzy and green) but has a curved shape. Harvest while still tender and green. They are good cooked (either whole or sliced) in soups and stews, pickled using a dill recipe, or cooked, chilled, and served with a vinegar/oil dressing. Flower arrangers like to let them dry on the plant because of their unusual double-forked tip, which they use in dried flower arrangements, etc.

MELALEUCA: There are many Australian evergreen shrubs and small trees in the family Myrtaceae grown because of their exquisite flowers. *Melaleuca alternifolia*, also known as "oil tea tree," "paperbark," or "cajeput," is the only Myrtaceae which produces the well-known tea-tree oil. The valuable oil distilled from melaleuca leaves is used as a solvent and as an antiseptic. The tree's tall straight trunk has white bark with a ½-in. layer of "cork" inside (making it very fire resistant). Its tiny seeds won't germinate unless you scatter them over shallow water, which then evaporates and the seed germinates and quickly grows in the mud. Melaleuca blooms in the fall and winter in southern Florida and produces seeds when the tree is as young as a year. It can also be propagated by cuttings. Starts are available from J. L. Hudson.

MEXICAN PARSLEY: See "Coriander."

MEXICAN TEA: See "Epazote."

MIGNONETTE (*RESEDA ODORATA*): Its name means "little darling." This plant is *not* for culinary use, but it dries well and is useful for potpourri because of its intense musky scent. Available from Thompson & Morgan, William Dam, etc., it's easily grown from seed and is not particular about soil. Mignonette is best suited to a dryish place with a warm summer.

MINT (*MENTHA*): The most important thing to understand about mint is that it is a large family of plants with various characteristics and uses. There are purely ornamental mints that are not good in the kitchen. There is an insecticidal mint, pennyroyal, that can be deadly poisonous and should never be consumed in any form. (See "Pennyroyal.") Mints

are just about the easiest herb to grow—very hardy perennials that can be overly aggressive in the garden. Other than lemon balm and horehound (which have their own entries elsewhere in this section), the main culinary mints are listed below.

Apple Mints. These are a whole family in themselves. *M. rotundifolia*, called “apple mint,” “woolly mint,” or “Bowles variety,” is popular in English and Italian kitchens but is not considered the best culinary mint in the United States, where it grows wild. The American apple mint (*Mentha gentilis variegata*) is preferred in the United States.

Ginger Mint (*Mentha gentilis*). Also called “Golden Apple,” this has a spicy mint scent and mixed gold and green leaves. It grows on the tall side for a mint, to 2 feet.

Peppermint (*Mentha piperita*). This grows 3 feet high and has small purple blooms and dark leaves with toothed rims. Peppermint has been scientifically proven effective in treating digestive problems. It’s also reputed to have soothing effect, so chew on a peppermint leaf! For a good tea, mix half peppermint and half rose hips. Peppermint and spearmint are sizable commercial crops. Peppermint oil is used to make candy and medicines. It isn’t an important culinary mint, but it is *the* important medicinal mint.

Orange mint (*Mentha piperita*, var. *citrata*) is a variety of peppermint. It’s also called bergamot or eau de Cologne mint. It has light blue flowers and nice minty fragrance. It’s good for scenting bath water. Available from William Dam, Thompson & Morgan, DeGiorgi, etc.

Pineapple Mint (*Mentha suaveolens* ‘Variegata’). This kind has variegated foliage, soft leaves, and a pineapple scent and flavor.

Spearmint. There are several varieties, including *Mentha spicata* and *Mentha viridis*. This is the most commonly grown mint; it has pointed deep green leaves and grows 1½-2 feet high. Spearmint is good with new potatoes and green peas and is used to make mint jelly and mint sauce. *Mentha spicata* is available from DeGiorgi.

Planting. Planting from seed is one option. Or to get new plants from old, just dig up and replant runners, plantlets, or root divisions. The little plantlets grow just below the dirt surface. Be careful to cut between rather than through any baby or adult plants. Or plant a 6-inch piece of root 2 inches deep in fertile soil in spring. Mints can handle semi-shade (as little as 4–6 hours of sun per day), but they are more aromatic in drier, brighter situations. Supply lots of water to get them going. Once established, they’ll thrive on neglect, but they need to be divided regularly. Thin by using. Having the right climate

helps too. Gayle Lowery, Phoenix, AZ, wrote me wondering why she can't get mint to survive when grown from seed, and her store plants started by division don't thrive either. Trade them in on a cactus?

NOTE: Mint spreads ruthlessly by those creeping underground stems. To keep it where you want it, sink 12-inch boards out side its assigned growth area, or plant in a sunken, bottomless 5-gallon bucket, tub, or plastic-lined hole. Do not try to get rid of mint by rototilling it. Each piece will grow into a new plant!

Container Mint. An 8–10-inch pot is a good choice for a tall variety in a container, a 5-inch pot for a dwarf one; a wide, shallow pot for mint grows out rather than deep down. But mints can be left out through the coldest winter, and even harvested in winter! Not everybody has boisterously growing mint, though. You can use regular dirt, but the more clay in your soil, the less likely the mint is to be able to handle waterlogging. Put enough stones or broken crockery in the bottom of the pot for good drainage. Choose a shallow pot rather than a narrow, deep one, since mint is a surface spreader rather than a deep grower.

Harvesting. Cut off plant tips; wash, dry, and cut off the leaves with your scissors. Mint can be harvested anytime, even after blooming. The more you cut, the faster it will grow. Use fresh, frozen, or dried.

Preserving. Frozen mint keeps its strength better than dried. To freeze mint, just wash, dry, and wrap a few tips of mint at a time in freezer paper or a baggie. To dry it work quickly, or the mint leaves' color will turn black. Gather only as much as you can dry in 1 batch. Spread leaves thinly over surface and dry in shade or in oven/dehydrator at 110°F. Two tablespoons fresh chopped mint are equivalent to 1½ t. dry mint or 1 t. mint extract.

Using. Good in Greek cooking and potpourri and sachets. Mint goes especially well with lamb or mutton, peas, baby potatoes, little carrots, and parsnips, and in salads, cucumber sandwiches, or a cup of tea. Crush fresh leaves just before using to release flavor. Chopped mint is good in a drink made with fresh tomatoes plus salt and pepper to taste.

➲ **BASIC PEPPERMINT TEA** Pour boiling water over a handful (4 T.) of peppermint leaves. Steep 5 minutes (less if desired less strong). Strain, pour into serving cups, sweeten to taste. Serve with affection.

➲ **MINT SYRUP** Boil ½ c. water and ½ c. sugar for 5 minutes. Add 6 T. chopped mint leaves and ⅔ c. lemon juice. Let stand overnight. Strain. If you want it greener, color with food coloring. Put into jar and store in refrigerator. Add to iced tea, lemonade, punch, and the like for mint flavor. Garnish drink with a fresh sprig.

➲ **MINT JELLY** You'll need 1 c. fresh mint leaves, ¼ c. boiling water, 2¾ c. sugar, and 1 qt. apple juice. Wash mint leaves; strip from stems. Add boiling water and 2½ c. sugar. Let stand a few hours. Bring to boiling point and strain through several layers of cheesecloth. Add the remaining ¼ c. sugar to apple juice and stir until it reacts to jelly test. Skim and pour into hot, sterilized jelly glasses. Seal with paraffin. If the color is too pale, add a little green food coloring.

➲ **ICED MINT TEA** Peel and quarter a lemon. Combine 4 sprigs mint, juice of the lemon, 2 T. sugar, and 2 c. hot water and let steep a half hour. Strain. Add strips of the lemon peel. Chill and serve.

➲ **MINTED GREEN PEAS OR NEW POTATOES** Add some sprigs of mint while boiling. Figure about 6 leaves per 4 c. vegetables plus 1 t. of butter.

⇒ **PINEAPPLE-MINT DRINK** In a blender, combine 1 c. mint leaves with 1 c. pineapple juice. Add more (about 3 c.) pineapple juice to dilute to taste. Serve over ice cubes.

⇒ **MINT VINEGAR SAUCE** For roast lamb or chops. Wash and then chop very fine 1 c. mint leaves. Dissolve 1 T. sugar in 1 c. vinegar. Add the mint and let stand in the liquid 1 hour. Optionally, add 1 T. lemon juice and a dash each of salt and pepper.

⇒ **MINT JELLY SAUCE** Combine 1 T. chopped mint with 1 c. currant jelly in a saucepan over low heat. Serve hot with lamb or mutton.

⇒ **BAKED PEARS WITH MINT** Place 3 large, thinly sliced pears in rows in a greased baking dish. Sprinkle with ¼ t. salt and 2 T. sugar. Dot with butter. Cover and bake at 300°F for 30 minutes, or until tender. Garnish with mint sprigs and serve hot.

⇒ **FRUIT SALAD DRESSING** Combine 2 T. mint vinegar, 2 T. cream, and 1 c. mayo.

⇒ **RUTH'S MINTY TABOULI** Pour 4 c. boiling water over 1¼ c. cracked wheat and let stand until fluffy (about 2 hours). Drain well; then mix with 1 c. cooked garbanzos, 1¼ c. minced fresh parsley, ¾ c. minced fresh mint, ¾ c. minced scallion or onion, and 3 chopped tomatoes. Dressing: 1 c. lemon juice, ⅓ c. water, dash tamari. Chill dressed salad well before serving (at least 2 hours), and serve on lettuce leaves.

MUGWORT (*ARTEMISIA VULGARIS*): Also called *Lactiflora*. Do not eat. Plant this perennial by seed outdoors. When dried, makes a good homemade moth repellent in cedar chest and closet. Available from Redwood City.

MUSTARD: There are 2 basic mustard varieties (black and yellow) whose seeds are used for seasoning. They are ancient and important culinary plants, their usage dating back at least to the Greeks. In addition to that spreadable yellow product, their unground seeds can be used to add a spicy hotness to recipes. Indian mustard, spinach mustard, and “mustard greens” are close relatives. Mustard seed can be viable as long as 6 years. Seeds for various mustard varieties available from Hudson, Redwood City, and DeGiorgi.

“White” or “Yellow” Mustard (*Brassica sinapalis alba*). This variety gets about 1½ feet tall. *Plant it away from your garden patch because it freely self-sows and can become a problem weed.* It's not the wild mustard we know in the Oregon and Idaho valleys. Yellow prepared mustard is made from it, and the whole mustard seed is used in pickling mixtures and to add spicy hotness to recipes. Available from DeGiorgi.

Black Mustard (*Brassica sinapalis nigra*). This hardy annual herb can get 4 feet tall. Plant in fertile, moist ground for best seed production. Has smaller blackish-red seeds. The seeds are a good flavoring and preservative for mayo, curries, and salad dressings. In France this is the prime ingredient for mustard paste. In the US it's used as a pickling spice. Available from DeGiorgi.

Harvesting and Processing. Harvest when pods have turned yellow but before they have finished ripening: once dead-ripe, they shatter and the fine seed is lost onto the ground. The harvested pods should then be spread out to dry—outdoors in the sun is fine. Once pods are thoroughly dry, smash them to free their seeds and sift to separate seeds from pods. Now work with the seeds in a mortar to loosen the hulls from the seeds. Sift and discard the papery hulls. The seeds can be used as condiments as is. Or grind your mustard seed to make wet mustard recipes. The finer you grind it, the smoother your mustard will be. But there is an important element in the processing of commercial dry

mustard that I haven't been able to find out for you, so your homegrown mustard won't be quite the same as the commercial kind.

Using Leaves and Buds. Add mustard leaves that are very young and tender to soup, and cook. Or add them, in small amounts, to a salad and eat raw. Mustard buds are edible too. Gather unopened mustard buds in the early spring and serve them like broccoli with a cheese sauce.

Mustard Plaster. These were used in traditional medicine. I well remember my mother's mustard plaster remedy for a chest cold. Mix 1 part mustard with 8–10 parts flour. Add lukewarm water until you have a smooth paste. Then spread between 2 pieces of cloth, such as muslin or old sheets of flannel. Rub the chest well with Vaseline before applying to prevent blistering, and don't leave it on after the skin is well-reddened. Keep away from mouth and eyes.

Wet Mustard Recipes. Wet mustard is ground dry mustard moistened with vinegar or water, and sometimes with other seasonings added. For a thickening agent, cook your mustard mix together with beaten eggs, or evaporate to a spreadable state. Note: Commercial mustard powders vary in their ingredients and therefore also in their hotness and ability to absorb liquid. If any mustard is too spicy-hot, steaming it in a heatproof container for 15 minutes may make it milder. For more gourmet homemade mustard recipes, see *Better Than Store-Bought* by Helen Witty and Elizabeth Schneider Colchie (Harper, 1979).

⇒ **HOMEGROWN MUSTARD** In a blender combine unground mustard seeds with enough wine vinegar to moisten, a bit of allspice, some peppercorns, and a pinch salt. Here's a more precise recipe: Combine $\frac{1}{4}$ c. mustard seeds, $\frac{1}{4}$ c. red wine, and $\frac{1}{3}$ c. wine vinegar, and let soak overnight. Then put in blender. Add $\frac{1}{4}$ c. water, $\frac{1}{4}$ t. allspice powder, pinch pepper, 1 minced garlic clove, $\frac{1}{2}$ t. salt, 1 broken-up bay leaf, and 1 t. honey. Blend on slow. Then move mixture to the top of a double boiler and simmer over boiling water until the mix has thickened. Store in fridge.

⇒ **BASIC WET MUSTARD** Mix 1 part dry mustard powder and 1 part wine vinegar. Add to taste: salt, mustard seed (cracked or whole), turmeric, garlic, other herbs, sugar or honey, etc. Then use your choice of thickening agent or process.

⇒ **SWEET-HOT MUSTARD** Combine 2–4 oz. dry mustard (how much depends on how hot you like it!) and 1 c. vinegar. Cover the bowl and let rest in cool place overnight. In the morning, beat together 3 eggs and $\frac{1}{2}$ c. sugar. Add to mustard/vinegar mix. Cook over medium heat, stirring constantly, until thickened (about 8 minutes). Refrigerate 2 days for flavor to ripen before using. Optionally, combine the mustard you just made with $2\frac{1}{2}$ c. mayonnaise for a milder, delicious mix.

⇒ **SPICED MUSTARD** Make by first spicing the vinegar and then adding other ingredients. Put 2 T. finely chopped onion, 3 bay leaves, and 1 chopped clove garlic into $1\frac{1}{2}$ c. vinegar. Cover and heat in a moderate oven (325°F) for about 20 minutes. Strain out the solids. In another container, mix the amount of dry mustard you want to make up with a pinch each of powdered cinnamon and cloves and a bit of sugar. Gradually stir in the hot vinegar until the mustard is the consistency you want. Save the rest of the spiced vinegar for making salad dressing or more spiced mustard when you want it. Pack your mustard mix into small jars and cover when cooled.

⇒ **DIJON MUSTARD** Combine 1 large chopped onion, 3 minced cloves garlic, and 2 c. dry

white wine in non-aluminum pan. Cook on low heat 10 minutes. Then let steep 15 minutes. Strain and discard solids. To your flavored liquid, now add 4 oz. dry mustard, $\frac{1}{4}$ c. honey, 1 T. plain-flavored cooking oil, and salt to taste. Simmer again, stirring constantly, while you evaporate it until it's thick enough to spread.

MYRRH: See "Sweet Cicely."

MYRTLE (*MYRTUS COMMUNIS*): This tender perennial fragrance herb gets 3 feet high when grown outside in a warm enough climate. Its leaves and flowers are useful in potpourri and sachets.

NASTURTIUM: This annual, one of the easiest plants to grow, originated in Peru, traveled back to Europe with the conquistadores, and is now known on most continents. Its pretty, brightly colored summer flowers (cream, yellow, orange, red), leaves, seeds, and stems are all edible and have a peppery taste. There are 2 basic species, the tendril-climbing (*Tropaeolum majus*) and the dwarf (*Tropaeolum minus*), which is nice in a flower border.

Planting. Start these tender annuals from seed in late spring and warm soil. They need full sun and well-drained soil. For your plants to be loaded with blossoms, their soil must be poor; fertile soil results in more leaves but fewer flowers. Plant $\frac{1}{2}$ inch deep, rows well spaced apart. Nasturtiums do well in pots (2–3 seeds in a 6-inch pot). The climbers are lovely in a hanging basket. Or plant to climb around a window casing or up a fence or trellis. It tends to reseed itself. Seeds available from William Dam, Redwood City, DeGiorgi, etc.

Harvesting. Any and every part of the nasturtium plant is edible. Pick leaves and flowers fresh anytime you want them. Nasturtium plant parts, however, are not dried. The small green seed pods are picked green and pickled like capers. Pick just after the flower has dried off and *before the seed dries*. If your nasturtium seeds are appearing during an inconvenient period of time, pick them as they are ready and keep in a brine of $\frac{1}{2}$ c. salt to 4 c. water. Change it every 3 days. When you have all the seeds you are going to get or that you want, you can go ahead and pickle them.

Using Flowers. Add the fresh flowers to salads and sandwiches, plain and fancy. Add leaves to sandwiches and salads. To make nasturtium blossom sandwiches, wash and dry the blossoms. Lay on buttered white or brown bread; if you wish, add mayo. Fresh seeds are also good in sandwiches or added to chutneys or pickles. Cut in fancy shapes and add a blossom to the top of each sandwich.

Pickling Nasturtium Seeds. Below are some recipes for pickled seeds. To preserve, pack in $\frac{1}{2}$ -pint jars and process in a boiling-water bath 15 minutes. To use, sprinkle on pizza or add to soups, stews, veggie dishes, salads, sauces, sandwiches, and poultry stuffing.

⇒ **PICKLED NASTURTIUM SEEDS (PLAIN)** Brine seeds in salt water for 2 days, then in cold water for 1 day; drain and pack with a hot vinegar solution.

⇒ **SPICED** Put 1 c. white vinegar in a pan. Add $\frac{1}{2}$ t. salt, 1 bay leaf, and a few peppercorns, and boil. Remove from heat and let steep 2 hours. Strain. Pour over nasturtium seeds.

⇒ **SWEET** Combine $\frac{1}{2}$ c. cider vinegar and $\frac{1}{2}$ c. sugar and pour over seeds.

⇒ **FANCY** In a pan bring to a boil 1 c. vinegar, 2 sliced cloves of garlic, $\frac{1}{2}$ t. each dill seed and mustard seed, and 1 t. each peppercorns and salt. Strain and pour liquid over 2 c.

nasturtium seeds.

⇒ **CAPERED** Pickle using the recipe for capers. (Or you can pickle capers using these recipes!)

NETTLE (*URTICA DIOICA*): A common perennial weed, this is also called the common stinging nettle because of its leaves, which have fierce little stingers that poke through your skin at the slightest touch. Then you get red welts that burn and itch like crazy, on and on. (An old-time remedy for nettle stings is crushed mullein leaves pressed on the welts.) I used to have to navigate around a dense patch when I was a little girl hauling buckets of water up from the “crick” to fill the porch water tank. Miserable stuff. I’d just as soon never have anything to do with nettles again. But they are edible once cooked—worth considering if you’re starving for food or looking for a dish that’s also a conversation piece (“How I captured the nasty nettle”).

Planting. I wouldn’t plant it on purpose. It self-sows and thrives under most conditions. However, seeds are available from William Dam.

Harvesting. *Don’t touch nettles with bare skin until cooked!* The points are tiny silica needles that inject formic acid. Use gloves to pick, clean, and work with them in the kitchen! Use the tops of young plants in spring, when they are about 6 inches tall. Otherwise, take *only* the top rosette of just-growing leaves and the topmost bud plus the few leaves just under that. You can go on harvesting to mid-June.

Using. Don’t let them sit around. Pick and then boil them. The cooking disarms them. Serve sprinkled with caraway or dill seed. Nettle leaf tea, sweetened with honey, is an old-time remedy for a stuffy nose or a sore throat. Nettle root makes a yellow dye. A nettle poultice is an old-time remedy to stop the bleeding from a wound.

Nettle Fabric. The fully mature nettle plant (a hemp relative) can be used to make a fiber that can be woven into a fine white linen-type fiber nearly as strong as flax and comparable to cotton in its uses. Nettles were commonly used to make a linen-type fabric in Europe years ago. American Indians used the nettle variety *Urtica gracilis* for that purpose.

⇒ **NETTLE RENNET** Combine 6 c. very strong nettle tea with 4 c. uniodized salt Use just enough to get the curdling action for your cheese-making.

⇒ **CREAM OF NETTLE SOUP** Steam 4 c. young nettle leaves until soft. Puree. If they need more liquid, add a little meat or vegetable soup stock. Melt 2 T. butter. Cook 2 T. grated onion in the butter. Add 2 T. flour to that and cook stirring, until mixture is turning brown. Now gradually add 2 c. more stock salt and pepper to taste, and the nettle puree. Simmer on low heat 10 minutes. Add 2 c. milk and heat just warm enough to serve. Good with grated cheese sprinkled on top.

NUTMEG: Nutmeg and mace both originate from the same tall East Indies evergreen tree, *Myristica fragrans*. The edible, peachlike fruit of that tree has a shell and inside that a brown seed, which is the nutmeg. The nutmeg trees are male or female. They take about a decade to bear but then continue for a half century more. Eat the peachlike fruit. Strip away the “aril” (mace) from the outside of its seed and dry. Sun-dry the pit a few weeks. This will cause the nutmegs inside to shrink enough so you can hear them rattle in there. Take off shell, finish drying the nutmegs, and store for use.

Using. Grind as needed. It's always better when fresh. Burn as incense or use to flavor desserts, sausage, or pickles.

OREGANO: Be choosy about which oregano you buy. There are several varieties, but only one is of culinary quality. Wild marjoram (*Origanum vulgare*) is weak in flavor. If a plant is called *Origanum* spp., that means no one is sure just what it is. Hold out for Greek oregano (*Origanum heracleoticum*), which is the real stuff.

Planting. Buy and then, after last frost, transplant to a sunny place in your garden that's well drained. Plant about 10 inches apart. It gets 1–2 feet high. Greek oregano is a winter-hardy perennial. It's also drought resistant once mature.

Container-Grown. The flavor of leaves grown outside is much better than that of those grown inside, but oregano can also thrive potted. You could use 4–5 plants. Start in 8–10-inch pots. If you don't repot to larger pots by at least the end of the third year, the plants will stop thriving. Eventually the stems get woody; then you need to replace the plant. Propagate from cuttings or root divisions.

Using. Harvest and dry like marjoram. Dried oregano is as good as, or maybe better than, fresh. Rub it to a fine powder before storing. Keep it cut back by adding it to any Italian, Mexican, or Greek dish. Use fresh or dried in chili, tomato sauce, salad dressings, pasta, hamburgers, wild game, broccoli, and eggplant. The leaves can also be used to dye.

ORRISROOT: See "Iris."

PAPRIKA: See "Peppers" under "Nightshade Fruits" in [Chapter 4](#).

PARSLEY: There are several varieties of this easy-to-grow, popular herb, a dark green, semi-hardy biennial that does well just about anywhere. Curly parsley (*Petroselinum crispum*), the one restaurants use because it keeps its freshness longest, gets 8–10 inches tall. Its cousin, the stronger-flavored flat-leaf or plain-leaved parsley (*Petroselinum hor-tense*), is a little hardier to both cold and wet weather than curly, and gets much bigger—3 feet tall. Celery-leaved (or Neapolitan) parsley grows stalks that can be eaten like celery. (Both plain-and celery-leaved parsleys get called "Italian parsley.") Mitsuba is a perennial Japanese parsley. For parsnip-rooted or Hamburg parsley, you harvest and use the tops like parsley and also have a sizable edible root. (See the root section in [Chapter 4](#).) Parsley doesn't inhibit the growth of other plants and may help repel insects.

Planting. Plant ½ inch deep in any fertile soil in early spring (April-May), or in August for growing in a cold frame (parsley is much nicer fresh than dried). Plant in sun or partial shade (it can manage on a half day of sunshine), directly in the pot (2–4 plants per 8-inch pot) or in a cold frame or garden. Allow 4 square inches per plant in a bed, one plant every 6 inches in a row. Allow 20 inches between rows.

Once well-started it doesn't transplant well, because of a long, sensitive taproot, but harder varieties can stand some freezing weather, so consider starting it outside. Germination takes 3–8 weeks (a 1–14-day pre-soak in cold water helps). Parsley seed is viable for only 1–2 years and has a high failure rate in germination, so overplant it. Keep the soil moist during its early period. Parsley takes about 90 days to mature. Time your plantings if possible, so you have it fresh year-round. Most seed houses carry some parsley; good variety available from William Dam, etc.

Container-Grown. Parsley does well as a potted plant and can even be dug up in the fall, potted, and brought in for fresh winter parsley—if you make sure to get all the roots, don't let them get exposed to air, and settle plants in a big, deep pot because of the roots. Let soil dry between waterings. Two or three parsley plants will be enough for a family.

Harvesting. You can expect a yield of 50 lb. per 50-foot row by commercial standard. Harvest all you want anytime after the plants have had a good start. Take leaves from the outside of the plant just as they mature. Let the center leaves finish maturing. If you are in a warmer climate zone where you can leave parsley out all winter, you can harvest it right on through its first year and first winter, until it starts to flower in its second year. In harsher zones (even quite northern ones), your plants may survive outside year-round, but they won't grow leaves in frigid weather. Survival depends on the parsley variety, your climate, and how well they're mulched (cover with thick hay or leaves after first few frosts). The second year you must either let it make seed (cuttings from a parsley plant going to seed are bitter and worthless for cooking), or else cut off the flowering stalk as soon as you recognize it. If you do that, you can keep on cutting it for culinary use. Once parsley goes to seed, just yank the plants out and put them on the compost heap unless you're saving the seed.

Saving Parsley Seed. Parsley is a biennial. In its second year, uncover mulched plants in the spring. Parsley flowers have both female and male parts and are pollinated by insects. They do need isolation from other varieties. Once some seeds have turned brown, which means they are mature, go out periodically and rattle the parsley flower head around inside a paper bag. The ripe seeds will fall off, while unripe ones will stay on. When most of the seed head is brown (around September) you can cut the head off and spread it on cloth or paper to finish drying. Seeds are viable only about 2 years.

Chopping Fresh Parsley. Pinch the tufts of parsley tightly between the thumb and forefinger of your left hand; then cut finely with your kitchen scissors. Try adding parsley to fresh corn in place of salt.

Drying. Cut off parsley tops with new leaves. Dry either whole or chopped. Spread thinly over your drying surface. Dry in oven or dehydrator at 110°F. Drying parsley bunches outdoors is risky; they don't dry easily. They're done when crisp. Put the dried leaves or powder in a glass jar with a tight lid, and keep it in a dry place. Drying destroys most vitamins and flavor in parsley.

Freezing. The easiest way to preserve parsley is to shove a bunch into a quart jar, put a lid on, and freeze. Remove as needed. Or roll a bunch up tightly like a cigar, wrap in foil, and freeze.

Using. Parsley is grown for its low-calorie, attractive, edible leaves, which contain lots of vitamins and minerals, including lots of vitamins A and C. Add to meat, stew, soup, salads, vegetables, carrots—anything but fruit—just before you serve it, for parsley shouldn't be cooked. Or use a pretty sprig as an edible garnish beside food on a plate, or as a bouquet in the center of the table. Eating boiled parsley is said to be helpful for a urinary stone and for eye inflammation. It's also said to be a breath sweetener, a natural antidote to garlic and onion breath.

➲ **PARSLEY BUTTER** Add the juice of 2 lemons, drop by drop, to 1 c. softened butter. Keep stirring as you add it—it takes quite a while. Then add 2 T. crumbled dried parsley Good as a clam dip.

⇒ **PARSLEY-DILL POTATO SALAD** Peel and cook 5 lb. potatoes in boiling water with 1 t. salt until tender. Drain and cool. Dice or slice. Add ¼ c. parsley, chopped. Combine 1 c. sour cream with ¾ c. mayonnaise. Add 2 T. dill seed and 2 T. vinegar. Combine potatoes, parsley, and mayonnaise mixture. Chill. Optionally, add 6 chopped hard-boiled eggs.

⇒ **QUICK PARSLEY FLAVOR** When you have lots of extra parsley, grind it and make ice cubes out of the juice. Wrap each cube separately in foil or in a baggie and store in freezer for flavoring soups, sauces, and gravies.

⇒ **PARSLEY SALAD DRESSING** Mix thoroughly together ½ c. buttermilk 6 T. mayonnaise, 1 T. vinegar, ½ c. fresh chopped parsley, 3 T. grated Parmesan, and 3 minced cloves garlic. If it's too thick add a little water until it's the consistency you want. Use for pasta and cooked vegetable salads, asparagus, and artichokes. It's also good spread on bread and broiled until the top bubbles and starts to get brown. From Monica Ipswich, Salt Lake City, UT.

⇒ **PARSLEY TABOULI** Combine ½ c. soaked raw bulgur wheat, 3 chopped tomatoes, 1–1½ c. chopped fresh parsley, ⅓ c. chopped green onions, ½ c. lemon juice, ½ c. cooking oil (sesame or olive is best), 2 T. chopped fresh mint, ½ t. salt, and a pinch paprika. Mix well and let rest in fridge several hours. Taste. Add more seasoning if wanted. Optionally, add chopped black olives or other chopped greens.

PATCHOULI (POGOSTEMON PATCHOULI): This is a shrublike mint from India. Its aromatic oil is a powerful perfume. Even in a temperate zone, you can grow patchouli if you dig it up, pot it, and bring it into the house for the winter. Available from Merry Gardens, www.shaman-australis.com.au, www.inharmonyherbs.com, www.richfarmgarden.com, or www.davesgarden.com

PENNYROYAL (MENTHA PULEGIUM): A potentially deadly variety of mint, this semi-hardy plant prefers moist soil and has a low, creeping growing style, reproducing by runners.

NOTE: Do not give pennyroyal to humans in any form or for any purpose. It contains a powerful abortifacient, which means it causes miscarriages, but don't take it for that purpose, because it also causes permanent liver and kidney damage and can cause death! In book after book on herbs I see pennyroyal tea recommended for something or other. That horrifies me. Please don't believe these books.

Pennyroyal is a fly repellent when planted around doors and windows because mosquitoes, ants, and fleas all avoid it. Powdered pennyroyal will take care of your cat's fleas. Available from Redwood City, William Dam, DeGiorgi, etc.

PEPPER: The familiar partner of salt is made from ground peppercorns, which grow on a vine (*Piper nigrum*) that thrives on the Malabar coast of India (and nowhere else!). Use whole, coarsely ground, or powdered.

For green peppercorns, harvest fruit while still unripe, soft, and green. Preserve them in salt water or vinegar, or dry in the sun. For black pepper, pick somewhat more mature berries and sun-dry until they turn black. For white pepper, let the peppercorns stay on the plant until they have a pink-red cast, which means they're fully mature. Then pick, pack in quantity, and let set until they ferment some. Then wash them well and dry. White pepper is milder than black. To most Americans, "pepper" means black pepper, but many European cooks prefer white pepper. It's good with gravies, vegetables, and soups.

PEPPERMINT: See "Mint."

PINEAPPLE SAGE: See “Sage.”

POKE SALET (ALSO CALLED POKE SALAD): My friend Hazel, in Georgia, wrote me, “Poke salad is a wild plant with large dark berries which are poison. Gather in early spring around wet swampy places. Use the first tender green leaves. It’s the first thing ‘fresh’ we can get around here so when we see it in the early part of the year, we know spring has arrived. The stems are good fried like okra.”

I’ve got another friend who loves poke salad greens. She’s Violet Stewart, a woman of Native American descent from Okay, Oklahoma, who says ripe poke salet berries make a deep red dye. They are ripe in the fall. And the Native Americans in Oklahoma still use them to dye clay, wood, cloth, wool, and feathers.

Dee of Hopewell, VA, also of Native American decent, wrote to warn that poke salet leaves are also “somewhat poisonous—unless cooked a long time through several changes of water, more trouble than they’re worth.”

➲ **POKE SALET DUMPLINGS** Make dumplings with cornmeal. Shape into balls and drop into the pot of boiling poke salet. Be sure to use hot water for the dumplings. I’ve heard another way to fix poke salet greens is to mix them with mustard leaves, cress, or other greens. Add a dash of salt and some ham or bacon. Keep covered while cooking. Gardening in the South, a great book has a section on poke salet.

POPPIES: There are numerous varieties. The California poppy (*Eschscholzia californica*) attracts birds who love its seeds, but it is entirely different botanically from the “poppy” whose seeds are used as a bread topping. That’s a species of Papaver used since the Stone Age for the food value in its seeds. The seeds have a mildly spicy taste and are good used whole, pressed into the dough, to top breads, rolls, cakes, or cookies. Because one variety of poppy is also the source of heroin, a disgusted friend told me that one day Drug Enforcement Agency agents came stomping through all the front and back yards in her north Idaho neighborhood, yanking out every poppy they saw. (The seeds have no narcotic qualities; only the milky exudate from the opium poppy’s green seed pod does.) Redwood City offers several varieties, including “Breadseed,” a good one for growing those baking seeds.

Growing. This plant is best adapted to a Mediterranean or southeast Asian climate. In northern zones the seeds won’t have time to mature in your garden unless started indoors. Plant in peat pots to avoid overt transplanting, which usually fails. Plant 6 inches apart in fertile, damp soil and full sun.

Harvesting. Let the seed pods ripen on the plant until that golden moment when they are fully ripe but have not yet turned their salt-shaker top openings toward the ground and dumped out the seed. Take the pods indoors to finish drying. When dry, thresh by rubbing between your palms. Then put the pod/seed mixture into a strainer and shake onto a cloth. The tiny seeds will fall through. The coarse pod pieces will be caught and can be discarded.

Using. Add poppy seeds to any baked goods. Poppy seed is also used in birdseed mixes and can be crushed to make an oil used like olive oil.

PURSLANE (PORTULACA OLERACEA): This Brassica relative is also known as pouplier, pussle, verdolaga, carti-choy, and portulaca. Purslane is a common weed in the United States and many other places. It can endure drought and thrive in any soil. It will reseed itself.

NOTE: Purslane is a risky plant to start in your garden. It has a neat trick of being able to make and mature seeds even if pulled out of the ground and left for dead! The joints of purslane stems root down and make new plants any place they contact soil. Many gardeners swear that purslane must have three or four more, still unknown, ways of spreading. If you choose to grow purslane, grow only in a container!

Varieties. Wild purslane has jointed, purplish-green stems and fleshy reddish-green foliage; it's a creeper. The cultivated variety that Europeans have grown for hundreds of years grows taller; it has larger leaves that are golden yellow instead of reddish green. The cultivated French purslane has a milder flavor than the weedy wild one. Plant after frost danger has passed. Seeds for French purslane are available from William Dam and Le Jardin du Gourmet.

Using. Best to harvest before flowering, for after that stems get tougher. Use young shoots and leaves raw in salads, stems in pickle mixes, and leaves and stems in any cooked form. Purslane stems are thick and fleshy and, when cut, ooze a mildly acid fluid that will thicken a recipe much as okra does.

PYRETHRUM (*CHRYSANTHEMUM ROSEUM*): This perennial is a related species of insecticidal chrysanthemums. It is a powerful natural insecticide that grows up to 2 feet tall.

NOTE: Pyrethrum is poisonous to people. Do not eat it.

Pyrethrum blossoms are daisy-like and pink, white, or red. Propagate by root division or seeds. Plant in well-drained, slightly alkaline soil, in full sun. The plant gets about 18 inches tall. Plant them 1½–2 feet apart. To harvest, gather the flower heads and dry them. Make a spray of fresh or dried flowers by blending with water, or make a powder of dried blossoms. The spray will repel soft-bodied insects such as aphids. The powder is a good flea control for your animals. Two varieties available from Redwood City.

Rose: These fragrant, hardy perennials grow 2–8 feet high. Most have thorns. Modern roses are more varied in color than wild or old-fashioned roses, but as hybridizers have moved the species toward more photogenic blooms, their fragrances have weakened and even disappeared in the process. The scentless rose is a modern reality. That's why, to grow roses for use in potpourris, rose jars, beads, and food, you can't start with just any of the vast variety of roses; you need an "old-fashioned" rose. (Lovers of old or new roses might enjoy *American Rose Magazine*, published by the American Rose Society. Annual dues are \$37, Canadian \$42, international \$47, and include a subscription. Contact: PO Box 30,000, Shreveport, LA 71130-0030, 318-938-5402; ars@ars-hq.org; www.ars.org. They also offer a *Handbook for Selecting Roses*, in which members rate more than 3,000 commercially available roses.

Old-Fashioned Roses. The heritage roses are usually more winter hardy, more able to handle hot summers, and more strongly scented than the moderns. Patricia Wiley, owner of Roses of Yesterday and Today, reviewed this rose section, and made valuable corrections on my facts.

She added: "There are roses dating back to the time of Christ and before. An 'old' rose was discovered/introduced before the date of the first Hybrid Tea, which was La France. Most old roses are overpoweringly fragrant. The fragrance intensifies with drying the petals and buds. The old-fashioned roses vary in their bloom time. Some bloom only once in the spring, but there are many that bloom again and again throughout summer and fall. Much more interesting and lovely than the modern roses, each of the old roses has its

own personality. Beyond the ease of care, there are many reasons for planting them: mass of bloom, fragrance, foliage color that varies from pale green to grey, and even leaves that change color in the fall of the year.

"Most old-fashioned roses shed their old bloom cleanly and do not have to be constantly clipped back. Just shape up the plant after it blooms in the spring and then leave it alone. Its beauty is in the large plant with masses of flowers. It should never be pruned severely.

"The most fragrant types of old roses are the Damasks, Bourbons, Centifolias, Moss roses, Albas, and Gallicas. Many hybridizers are bringing fragrance into the modern roses by combining them with the old roses for new varieties, so you must use your nose in discerning fragrance. Choose rose varieties with petals varying from deep pink to deep wine if you want to make the most colorful potpourri. The Hybrid Perpetuals are old roses of Grandma's time and she called them 'cabbage roses.' There are many varieties of these roses, and most are very fragrant: 'Paul Neyron', 'Heinrich Munch', 'Prince Camille de Rohan', 'American Beauty', and 'Henry Nevard', all excellent for making potpourri, and all good garden roses."

Planting. Buy young plants. Set out in a sunny, absolutely weed-free bed of somewhat heavy soil, with plenty of compost or manure worked in. It's best to plant early in spring, when the soil is no longer frozen. Water and add more manure or compost regularly, as the rose grows. Lay a thick mulch over the roots to suppress weeds, hold in moisture, and protect the roots through severe winters. Old-fashioned roses don't need much pruning, just cutting away of dead wood.

Rose Sources

High Country Roses specializes in one-year-old old-fashioned and hardy roses (tested in Colorado at 8,000 ft.) grown on their own roots. They offer 200+ varieties, shipped in 1-qt. pots; free catalog: 800-552-2082; 435-789-5517; PO Box 148, Jensen, UT 84035; www.highcountryroses.com.

Jackson & Perkins calls itself "one of the foremost producers of new roses in the world," especially floribunda: 800-292-4769; www.jacksonandperkins.com; 2 Floral Ave., Hodges, SC 29653.

Roses of Yesterday and Today does mail-order retail sales of old, rare, and unusual roses—more than 240 varieties; catalog \$3; 831-728-1901; 803 Brown's Valley Rd., Watsonville, CA 95076; www.rosesofyesterday.com.

Using. The petals are the part of the rose where the fragrant oil for scent or flavor is concentrated, so that's the part you work with to make sachets or to flavor jelly, cake, etc. You can do more with roses than perhaps you ever guessed! But first let's consider the fruit of the rose, used not for its fragrance but for its huge vitamin C content.

Rose Hips. A rose hip (or "hep") is the round orange-to-reddish "fruit" (also called "haw") formed after the flower of a rose has bloomed. The hip is the seedpod of the plant. Some hips are better-tasting and bigger than others. *Rosa rugosa*, the Japanese rose varieties, flower with large and lovely blooms in almost every color. They also grow the largest rose hips, about 1 inch across, which are much easier to work with. Sweetbriar eglantine (*Rosa eglanteria*) also has good hips. The sweetbriars have the extra gift of aromatic leaves that smell like ripe apples and can be added to your potpourri. Wild rose hips are also good. There are wild roses in every state except Hawaii. The rugosa has escaped and gone native in some areas.

Rugosa Rose Varieties. These sucker profusely, so it's wise to plant in a big container or some other kind of root-limiting structure. Or buy grafted plants, so you don't get a forest of roses that takes over the yard. It isn't a good idea to plant them near wide open spaces either, because birds are likely to disperse their seeds and create thorny rugosa thickets out in your pasture. They do make a great 6-foot-tall, impenetrable hedge, the kind Sleeping Beauty had. They are easy to grow, exceptionally hardy, and can endure wind, seaside exposure and drought conditions (once established). They can be planted from seed in either full sun or partial shade and almost any well-drained soil. They have almost no problem pests or pestilences, and actually produce hips better with little to no pruning. *Rugosa* does need winter chilling and won't grow in subtropical climates. *Rugosa* or *eglanteria* available from Gurney's, Raintree Nursery, Farmer, Roses of Yesterday and Today, or High Country Rosarium.

NOTE: When picking rose petals or hips to eat, be sure they have not been sprayed by you or anyone else. Those growing along railroad tracks and major highways probably have been sprayed and should be avoided.

Harvesting Hips. Some people gather hips any time after they have turned from yellow to orange and on to scarlet. Some wait for the first frost, convinced they taste better after that. If allowed to get soft, they're definitely not nice anymore.

Processing. We're talking vitamins here. That means keep them cool until you can use or preserve them, and the sooner you do that the better—same day, if possible. Stew, dry, or freeze. Wash and cut off both ends of hips with scissors. Cover if you cook them. Use wooden spoons and earthenware or china bowls. Cook in glass or enamel pans or stainless steel. Hips are so high in vitamin C that they are valuable for winter use to supply that vitamin in tea, etc.

Cooking. Process into jelly; combine with honey to make a syrup; make granita, jam, extract, cold rose-hip soup, or hot tea.

Freezing. Just toss them into plastic bags and freeze until needed. Or make sugarless rose hip syrup by pouring boiling water to cover the hips and cooking on low heat 15 minutes. Let that cool and steep 24 hours. Strain and freeze. When needed, use your sugarless syrup to enrich soups, toppings, teas, etc.

Drying. For large hips, wash, cut open, take out seeds, spread, and dry in oven or dehydrator at 110°F until they are hard and brittle. For small hips, you can dry whole without cutting or removing seeds, or you can cut into slices and dry, also without removing seeds. When thoroughly dry, store in airtight jars. (If not very dry, they will mold.) When ready to use, cover with water and simmer until soft. Use the pulp to make jam or jelly. Hips mix well with other fruits like apple or cranberry.

⇒ **ROSE HIP TEA** Boil dried coarse-ground rose hips with water, about 1 T. for each cup of tea. The longer you boil, the stronger your tea. Mash the hips with a spoon to get out all the juice, and strain. Sweeten with brown sugar or honey.

⇒ **DORIS'S HIP MIX TEA** Rose hips are not strongly flavored, although they are nourishing, so a hip mix makes for a tastier tea. Stem the hips, dry them, and grind. Mix dried ground hips with mint and well-dried strawberry leaves: ¼ rose hips, ¼ mint, and the rest wild strawberry leaves. Or leave out the mint, or combine hips with lemon balm, etc.

⇒ **ROSE PEAR GRANITA** This recipe is from Lane Morgan's Winter Harvest Cookbook (Sasquatch Books, 1990), an excellent little collection of gourmet recipes for homely vegetables that you might have in your field, garden, or root cellar in the winter: "No special equipment is required for this simple ice from Le Gourmand. The rose hips give the crystals a

bit of tartness and a gorgeous red-gold tint. This makes a good digestive as well as a deceptively simple dessert. 1 quart pear juice. $\frac{1}{2}$ cup rose hips, cut in half and seeded. Pour juice into a saucepan, add rose hips, and simmer, covered, until liquid is reduced by half. Put through a food mill and pour into a shallow pan. Freeze. Stir when mixture starts to get slushy and return to freezer until time to serve. Makes 1 pint."

⇒ **ROSE HIP SYRUP** Wash 2 lb. fresh hips and remove stems. Put through food chopper using medium blade. Cover with 6 c. boiling water and boil 2 minutes. Strain through sieve and put solids in a jelly bag to drain. There should be $1\frac{1}{2}$ pints of liquid. If more, boil it down. Add $\frac{3}{4}$ c. sugar and boil for 5 minutes. Bottle.

⇒ **ROSE HIP JAM** Try to preserve the hips the same day you pick them. Boil 4 c. hips with $2\frac{1}{2}$ c. water until the hips are tender. Put through sieve to remove seeds. Add 1 c. sugar for every 2 c. pulp. Add 1 t. lemon juice. Mix thoroughly and bring slowly to a simmer. Cook about 20 minutes. Seal.

⇒ **ROSE HIP EXTRACT** From Lila Morris, Beavercreek. OR: "Add it to breakfast juice, gelatin, desserts, meat sauces, soups or sherbet for lots of vitamin C Gather rose hips, chill, and remove blossom ends, stems, and leaves. Rinse off. For each 1 c. hips bring to a rolling boil $1\frac{1}{2}$ c. of water. Add the rose hips. Cover and simmer 15 minutes. Mash with fork or potato masher and let set 24 hours. Strain off liquid part. That's your extract. Bring extract to a good boil. Add 2 T. vinegar or lemon juice for each pint Pour hot into jars and seal.

⇒ **ANN MARIE'S EXTRACT** For each 1 c. hips, pour over 1 c. boiling water. Let soak 48 hours. Strain off the juice. Add $\frac{1}{4}$ c. honey per quart of juice. Heat to boiling point. Pour into clean hot jars and seal. Take 2 t. per day in winter for your vitamin C.

⇒ **ROSE HIP JELLY** Wash, stem, and chop your hips. For every 4 c. hips, boil 2 c. water for 5 minutes and then let hang overnight in a jelly bag to get the juice. For every 1 c. rose hip juice, add 3 c. apple juice. Boil 10 minutes. Gradually add 1 c. sugar for every cup of juice you are working with, and boil until it jells.

Harvesting Rose Petals. Gather just when the rose has fully expanded. If you wait a day longer, until they start to fade, they will have lost some of that precious fragrance. Gather in the morning after the dew has dried, but before they have gotten really warmed by the sun. Dry before proceeding by pressing them gently between layers of cloth. Dry them in a dehydrator or on a muslin cloth laid over a screen in an airy, shady place.

⇒ **ALL-ROSE POTPOURRI** This potpourri has a prettier color, but it doesn't stay near as fragrant as long as the moist one. Gather your fragrant roses in the early morning just after the dew is off. Use roses between three-quarters and full bloom. Simply hold petals together with the tips of your fingers and twist. They will usually all come off in your hand. Gather small buds too. Dry your petals and buds on a screen or cloth or in a dehydrator, out of direct sunlight. When dry, combine with powdered orrisroot and set out in an open-topped jar. Or use in a sachet.

⇒ **A DAMP POTPOURRI** Dry the rose petals just until they feel leathery—8 hours or overnight. Use ice cream-type salt that is coarse and not iodized. Layer salt and rose petals in the bottom of a glass jar, $\frac{1}{4}$ c. salt to 2 c. petals. Add some orrisroot, too. Keep a lid on the jar and open only when you want to let out some fragrance.

⇒ **ATTAR OF ROSES** "Attar" is rose petal oil. The damask rose varieties (*Rosa damascena*) are good for making attar. I'd heard that *Rosa damascena trigintipetala* is the most highly

regarded variety for making potpourri and attar. But Patricia Wiley says the best is Rosa damascena bifera, the rose of Castile. Pure attar of roses is extracted from fresh petals. The finest potpourris are made by spraying attar on dried, mixed petals and buds.

Fill a large glass jar with rose petals, carefully separated from the rest of the plant. Add just enough water to cover them and let the jar set in the sun 2-3 days, bringing it indoors overnight. At the end of the second or third day, small particles of yellow oil will be floating on the surface of the water. In the course of a week, they will have increased to a thin scum. The greenish-yellow scum is attar of roses. Take it up with a little cotton tied to the end of a stick, and squeeze it into a small container. Or use a feather. On the commercial market, attar of roses is very pricey stuff, a valuable ingredient of perfumes. It takes a whole lot of roses to make even a tiny bit of attar: approximately 5 lb. of petals for 1 oz. of oil!

⇒ **ROSE EXTRACT** Put petals into a wide-mouthed bottle and pour over them some pure alcohol. Let stand a month, and then strain. The liquid is rose extract, or essence of roses.

⇒ **ROSE WATER** Combine 1 part attar with 1 part alcohol and 10 parts distilled water. Or 1 t. extract mixed into ¾ c. distilled water. Or combine 1 oz. attar with 1 gal. distilled water. Age 2 weeks. You have to shake a long time, slowly at first, to get a solution.

⇒ **ROSE BRANDY** To flavor sauces for cakes and puddings, gather rose petals while the dew is on them. Fill a bottle with them. Then pour into the bottle a good brandy. Steep 3 to 4 weeks. Strain and rebottle.

⇒ **ROSE VINEGAR** Boil 2 c. white vinegar in non-aluminum pan and pour over 1 c. rose petals. Add ½ t. lavender or rosemary. Cover and steep 10 days. Strain and bottle. Patricia Wiley wrote me, "You can use 2 cups vin rosé wine for a light wine vinegar—pretty, too!"

⇒ **ROSE PETAL HONEY** This recipe was a favorite of Martha Washington's. Bring 2 pints of honey to a boil. Add 1 pint rose petals. Let stand 4 hours. Heat again. Strain into jars.

⇒ **ROSE PETAL JAM** Chop the petals into pieces and pack firmly into a measuring cup. You'll need 2 cups for this recipe. Cover the 2 c. petals with 2 c. boiling water in a pan and simmer for 10 minutes. Strain, keeping the liquid. Add 2⅔ c. sugar and 3 T. honey to the water in which the petals were cooked. Simmer, uncovered, for 30 minutes. Add 1 t. lemon juice and the chopped petals, and simmer 30 minutes more. The rose petals will have dissolved. Have ready your clean, hot jelly jars. Pour hot liquid into the hot jars and seal.

⇒ **SARA'S ROSE PETAL JELLY** Corean Morgan, Sweet Home, OR, wrote me about her friend Sara, "Dear Carla, The recipe book I bought has been given to a friend—who lives on top of Green Peter Mountain, and who shot a bear (a real, live bear) that was getting honey from the hives. Not only did she shoot it, she skinned it and put both hide and meat into the deep freeze. Perhaps you would like to have this recipe of hers:

"Combine 2 qt. pink rose petals, 3 c. boiling water, 3 c. sugar, ¼ c. lemon juice, and 1 package MCP pectin. Gather rose petals in early morning just after the dew has left. Yellow petals may be added if you are short of your quarts. Red rose petals may also be used, but be careful, since they have a much stronger flavor. Pour the boiling water over the petals and steep until all color is absorbed. Measure sugar into a dish to add later. Measure rose water and lemon juice into a 6-or 8-qt. kettle. Add pectin and stir well. Place on hottest fire and bring to a boil. Add measured sugar and mix well. Continue stirring and bring to a full rolling boil. Boil exactly 2 minutes. Skim and pour into prepared glasses and seal."

⇒ **ROSE PETAL BREAD** Add to a regular 2-loaf white bread recipe 1 c. lightly packed rose petals, 1 t. rose extract, 3 t. lemon extract, and extra sweetening.

⇒ **PETAL-SCENTED TEA** *The Chinese use cabbage rose petals and/or jasmine flowers to float on and scent a cup of steaming tea.*

⇒ **ROSE AND RHUBARB SYRUP** *Simmer 1½ lb. chopped rhubarb about 20 minutes. Strain. It's the liquid you want to save. To that rhubarb juice add 1 lb. sugar and petals from about 8 red roses. Simmer 20 minutes more. Strain again, this time discarding the rose petals. Bring the syrup back to boiling. Simmer until it thickens. Pour into small (for it will ferment soon after opening) hot bottles and seal them. To use, add to a milk shake for flavor or to hot water to make a tea.*

⇒ **CRYSTALLIZED ROSE PETALS** *From Catherine Shirley: "I pick a few first roses. They are dark pink fragrant ones of the old-fashioned kind. They have thorns. This project is rather tedious and time-consuming, but makes nice gifts when put in nice containers at Christmas time. They are also pleasant to eat. I picked a few roses with short stems. This makes the roots get stronger. I cut off the white part, which is the base of the rose, because it is bitter. I take the petals apart and wash each carefully under running water; if water is not plentiful, I swish each petal in a pan of water and change the water quite often. Put on paper towel to dry. Then take an egg white, add a little cold water, and beat slightly. I dip each petal in the egg white, lift it out with a fork, and lay on granulated sugar, press gently, and carefully turn it over and treat same way and lift and lay on piece of waxed paper. Let dry thoroughly, turn over, let other side dry thoroughly. Then pack in a dark jar so they will keep their color. P.S. I make crystallized pinks or carnations called 'pinks,' and they taste nice, like clove-flavored candy."*

⇒ **ROSEBUD ICE CUBES** *Freeze a tiny rosebud in each cube to float in special summer drinks.*

Rose Beads. A curious thing about rose petals: You can make them into beads. The first people to do this were monks making "rosary" beads. The beads smell fragrant and get darker and harder when aged. First you make the dough. Then you shape it.

⇒ **PURE PETALS BEAD DOUGH** *Blend 8 c. fresh rose petals with a little water. You can do a few at a time and freeze until you accumulate a total of 8 or more cups. Now put petals in a cast-iron pan and add several rusty nails too. Add enough water to no more than just cover the petals. Cook over lowest heat, uncovered, for several hours. Once in a while, stir (wooden spoon only!). Don't worry about the disgusting odor. Take off the heat, cover, and let rest until the next day. The next day, cook it just like before. Add a little water as needed. Then let set overnight. Do the same thing again the third day and the third night. By now (or maybe it will need yet another day and night), you should have a black pulp. Soak out the extra water from the pulp using paper towels. You'll be able to start bead making when you've got the pulp dry enough to hang together. Store the pulp in the refrigerator until you can make the beads.*

⇒ **PETALS/SALT BEAD DOUGH** *Combine an amount of firmly packed rose petals with an equal amount of salt. Mash together and add half as much distilled water or rainwater as you have salt. Mix in an enamel or iron pan. If in enamel, add a drop of oil paint if you want artificial color. Heating them in a rusty iron skillet will make the beads velvety black. Bring it up with low heat to just under simmering stage. Stir constantly until you have a smooth mixture.*

⇒ **PETALS/FLOUR BEAD DOUGH** *Combine 1¾ c. flour, ¼ c. salt, and enough water to shape a dough. Add 3 c. rose petals that have been chopped very, very fine. Work the petals thoroughly into the dough.*

Shaping the Beads: The hardest dough to work with is the all-petals one. It will also stain your hands, so use rubber gloves or else plan to wash your hands a lot for the next few days.

Measure the pulp for one bead with a melon baller—one scoop will make one bead. (All petal pulp will shrink by two-thirds.) Be patient with the shaping. For salt and flour rose beads, roll the dough out on a floured bread board to $\frac{1}{4}$ inch thick. Use a thimble to cut out sections, because those will be a good bead size. Roll each bead like clay in the palm of your hand to make it smooth and round.

Stringing Beads: To make holes in the beads so you can string them, string the finished beads onto florist's wire (#24 or #26). Hang them on the wire in a dark room until dry, shifting them around once in a while so they won't stick. For your final necklace, string beads on cord or dental floss. For a very special rosary, string with gold or crystal beads or both. For a final scenting, you can dip the pin you use to make their holes in a rose oil, or dab a little onto each bead.

ROSEMARY (*ROSMARINUS OFFICINALIS*): This decorative, tender perennial has leaves somewhat like soft green evergreen needles. Rosemary has the widest range of uses of any herb. Bees love it. The plant can be used as a hedge (2–3 feet high) if you start with the upright variety, 'Collingwood Ingram'. The other varieties of rosemary are trailing in nature, beautiful in a hanging basket or cascading over a wall. Delicate blue flowers bloom on branch tips in early spring. Rosemary looks like a tiny pine tree, but it can't survive a serious winter; move it into the house in a pot for the winter, or keep potted all the time (start in 6-inch pot), for it does fine on a windowsill. Or keep in a 12-inch container outside in the summer and inside in the winter. Do note that dry indoor heat will cause leaves to drop.

Planting. You can propagate by seeds, but they germinate so slowly and unreliably that stem cuttings are preferable. Spring cuttings can be started in water and then planted. Or take cuttings of non-flowering shoots in early fall and plant in a cold frame to get through the winter. Or layer. Plant in well-drained, alkaline (add lime regularly), light soil in full sun, but sheltered from cold winds. Rosemary can handle dry conditions, but it needs at least several deep waterings each summer. Plant the upright species 12 inches apart. You can dig up and divide an older plant. Two or three will be enough to meet a family's needs. It handles pruning well.

Harvesting. Pick rosemary needles anytime to use fresh.

Drying. Pick needles that are mature enough to have developed aroma but still relatively young and tender. You can cut foliage several times a summer. Remove poor-quality needles. Don't wash. Spread thinly and dry in shade or slow oven/dehydrator at 110°F to crispness. Crumble before using.

Using. Called "the herb of remembrance," rosemary has been used both at weddings to symbolize fidelity and at funerals, placed on graves, to signify remembrance. More mundane uses: in perfumes, as a hair rinse (leaves hair scented and shining), in potpourri, as an insect repellent where food and clothing are stored, and, of course, as a fresh or dried seasoning for food (a little goes a long way). Pluck some needles to add to boiling potatoes, summer or winter squash, turnips, broiled lamb chops, pork roast, and rabbit. Add some to spaghetti sauce. Rosemary and cranberry juice combine for a good herb jelly.

⇒ **HERBAL HAMBURGER** Melt 1 T. butter with $\frac{1}{2}$ t. dried rosemary in a frying pan. Stir a bit to let rosemary flavor butter (Don't brown butter) Add about 1 lb. hamburger shaped into patties, and cook. Remove hamburgers when done. Add another 1 T. butter to pan drippings together with $\frac{1}{2}$ t. dry mustard and a dash Worcestershire sauce. Stir a minute. Pour over hamburgers.

⇒ **ROAST POTATOES WITH ROSEMARY** Use 2 lb. really fresh new potatoes, scrubbed and cut into 1-inch cubes. Preheat oven to 425°F. Place potatoes, leaves from 4 large sprigs of fresh rosemary, and 4 large cloves of peeled and crushed garlic in a roasting pan. Pour ½ c. olive oil over that. Sprinkle in salt and pepper. Now bake, stirring occasionally, until potatoes are browned and crisp on the outside, tender on the inside, 30–40 min. Sprinkle with parsley and serve. From Winter Harvest Cookbook by Lane Morgan.

⇒ **ROSEMARY TEA/HAIR RINSE** Pour boiling water over the needles, and steep until to your liking.

RUE: Do not drink or eat this plant; it is toxic. Propagate by stem cuttings or seeds. Plant in well-drained, light soil in full sun. The plants are only a foot high. Both the stem and leaves can be used. Rue is avoided by the Japanese beetle. Its smell is unpleasant. In hot weather, handling rue can cause poison-ivy type blisters on sensitive skins. Use only as an insect-repellent or decorative plant. Available from William Dam, DeGiorgi, etc.

SAFFRON (CROCUS SATIVUS): This strongly aromatic crocus gets only 4–6 inches high. It has thin, grasslike leaves. It's easy to grow, but takes 3 years to produce flowers from seed, so it's much quicker to start with plants, propagating by planting divisions of "corms" (enlarged underground stems) called "offsets" in late summer.

NOTE: The autumn crocus (*Colchicum autumnale*) resembles saffron crocus but is not a true crocus and is poisonous.

Planting. Plant 3 inches deep in rich, well-drained soil, full or partial sun, 3 inches apart, outdoors (zones 6–9) or in a container. Saffron corms available from Nichols Garden Nursery.

Harvesting. The saffron crocus develops purple flowers in the fall. Saffron is the most expensive spice because of the effort, tedium, and small return of harvesting the red-orange, edible stigmas—the "threads" at the center of the flower. Gather the stigmas using tweezers. Dry them in a warm and airy but shaded place. You can buy either ground saffron or whole dried stigmas or "threads." It's safest to get the threads because ground saffron may well be adulterated.

Using. Saffron colors sauces (or dyes fabrics) a golden shade and adds a unique flavor to foods. It is essential for making bouillabaisse, Spanish rice, paella, and saffron breads.

SAFFRON, MEXICAN: This is an imitation sold in some Latin American outlets; it's made of dried, ground safflower petals. For more information, see [Chapter 4](#).

SAGE: This herb is a semi-hardy perennial that grows to 2 feet high and has light-bluish flowers. It has numerous varieties—narrow-leaved, broad-leaved, purple-and red-leaved, and dwarf, which is good in a pot. (For information about the fragrant sagebrushes of drylands in the western United States, see "Artemisia.")

Broad Leaf Sage (*Salvia officinalis*). This is the historical medicinal variety, but it can also be used at table. It's a perennial that needs direct sunlight. Available from DeGiorgi.

Clary Sage (*Salvia sclarea*). This 3–4 foot biennial is valued for both its attractive, aromatic flowers and its use as a fragrance fixative like orrisroot. It originated in the Mediterranean. Plant seed every year to get flowers. Plant in full sun and average soil. Plant outdoors 1 foot apart, or in shelter and transplant later. Clary sage leaves are used fresh to flavor drinks and egg dishes. Dried leaves are good with rose petals, lavenders, and mints in potpourris or sachets, or added to soups or stews. Dried clary sage flowers make a fine herb tea. Clary sage seeds, like quince seeds (see [Chapter 6](#) for recipes), release a mucilaginous material when soaked in water. This paste was traditionally used to bathe eyes. Available from Redwood Seed.

Pineapple Sage (*Salvia elegans*). This is a tender perennial, the last herb of the season to bloom. You can add its red flowers to fruit punch or salads for a pretty color and a nice fruity flavor. The leaves are edible too, and have a mild pineapple flavor. Use them in fruit dishes and to make an herb jelly. This plant has to be transplanted to a pot and brought inside to survive a real winter. It is different from scarlet sage, which is an inedible ornamental.

Planting. Sage grows easily from seed and transplants easily. Seed is easy to find and is viable for 2–3 yrs. Or use stem cuttings, or root division in the early spring. Fine in average-to-poor, well-drained soil (let dry between waterings) and full sun. Plant 2–3 plants for family use in 6-inch pots or a foot apart in the garden. Plant it away from your annuals, since it will inhibit their growth. Broad-leaved sage and clary sage freely self-sow. Because sage grows well in a pot, some people bring it in for the winter. Too much fertilizer or water weakens the aroma of the leaves. In the spring, prune away the old, dead, woody parts, or thin by removing 3–4-year-old plants because of their developing woodiness. Sage naturally dies after about 5 years.

Harvesting. If you want just a few leaves, go out and pick them anytime after your plant is 8 inches high. The best leaves are newly grown from the tips of the branches, or stems, cut just before flowering. But you can cut off whole stems to dry even at the last moment in the fall, and they'll definitely be sage. Sort them over. Don't wash. Tie in bunches and hang up to dry, or dry in the sun, dehydrator, or very slow oven at 110°F until crisp. Sage has a dryish quality even on the plant, and once dried, it stays dry. To store, rub off the stems and pack into airtight jars.

Using. Chopped fresh sage leaves add flavor to pickles, cheese, and sausage. Dried sage is best in poultry or pork stuffings; if you are using fresh sage, soak it 5 minutes in boiling

water, dry, and then chop.

⇒ **SAGE BREAD** This is a good sandwich bread. If your milk is raw, scald it first. Use 2 c. milk, ¼ c. sugar, 2 t. salt, 2 t. celery seed, and 1 t. powdered sage. Add ¼ c. cooking oil, 2 eggs, and 2 T. yeast. Mix well. Add enough flour to make a kneadable dough. Knead, let rise, punch down, and divide into 2 loaves. Put loaves into greased bread pans, and let rise again until they double in bulk. Bake at 400°F until loaves sound hollow when rapped.

⇒ **SAGE TEA** Steep fresh sage leaves or 1 heaping t. powdered sage in 2 c. boiling water. Strain. Sweeten to taste. Drink hot. For a medicinal gargle, brew until dark green in color. This is a traditional comfort for the cold victim as well as a good hair rinse.

SALAD BURNET: See “Burnet.”

SALT: Salt is sodium chloride. Just $\frac{1}{10}$ t. salt per day is necessary to keep you alive. But too much more of it day in and day out will give you high blood pressure and put you at risk for stroke and heart disease. A person who does little physical labor and spends the summer in an air-conditioned office doesn't need much salt. However, if you spend your summer days working hard out in the sun, and in the evening come home to a hot house, you need as much salt as you hunger for as well as plenty of water or diluted, unsweetened fruit juice to compensate for all that perspiring.

The secret is not to let salting become a habit, because salt needs vary according to the time of year and your activity. In the old days salt was used to preserve food, but now there are healthier ways of preservation. Most foods naturally contain sodium, as do some water supplies. Almost everybody in a grocery-store, restaurant-eating lifestyle gets too much salt in their diet.

How to Lower Your Salt Intake

1. Don't salt your cooking water.
2. Don't eat “processed” foods. Cook from scratch so you can leave the salt out of the recipe (or greatly reduce it). The worst offenders in the grocery store are canned soups, lunch meats, canned vegetables, and all “snack” foods. Fast-food restaurants typically serve high-salt meals, and virtually all restaurants use some salt.
3. Avoid beets, carrots, shellfish, cheese, and celery, because those foods are naturally high in sodium.
4. To flavor your food, use herbs, spices, flavored vinegars, wine, and garlic instead of salt. Thirteen-year-old Ruth, doing her best to wean me entirely from the salt habit, advised me, “Try things like finely chopped onion, tomato chunks, sweet pepper, lemon juice, and various herbs instead of fostering that salt taste. There is such a thing as low-sodium tamari, but don't become dependent on that either.”

And read *Cooking Without a Grain of Salt* by Elma W. Bagg (1971).

SASSAFRAS: Do not eat products made with sassafras bark or root. The sassafras tree can be grown in mild climates like Texas and Arkansas. The leaves are made into filé, a traditional gumbo ingredient. In the past the wood, root, and bark have all been used to make beverages; however, the FDA has taken the bark (which was an old-time root beer ingredient) off the market because of its risk as a carcinogen.

Filé. Pick young, tender sassafras leaves in the spring. Spread over your drying surface and dry outdoors in an airy, shady place or in oven or dehydrator at 110°F until they are crisp. Then pulverize them to make your filé powder. When added to soup (gumbo), they give it a distinctive flavor and have a thickening effect. Note: Never boil the gumbo after adding the filé powder. If you do, it becomes ropey, stringy, and disagreeable. For this reason, reheating leftover gumbo can be a problem, so just make enough for 1 meal at a time.

Filé Variations—Mix filé with a few leaves of sweet bay. Or, if you don't have sassafras, substitute young okra pods for the filé.

⇒ **SASSAFRAS BEEF GUMBO** Add 1 large spoonful of dried and powdered sassafras leaves to a pot of beef soup after taking it off the heat.

⇒ **FROM-SCRATCH OLD-TIME SASSAFRAS GUMBO** Start with 6 squirrels or 2 chickens. Cut up small and cook until flesh falls from bones. Add 1 qt. okra, 2 onions cut fine, 6 diced white potatoes, grated carrot, a little cabbage, pepper, and salt. Add pod of red pepper and filé just before serving.

SAVORY: There are 2 basic varieties of savory, summer savory (*Satureja hortensis*) and winter savory (*Satureja montana*). They are used the same way in cooking. Both grow fine in a pot. Both attract bees, prefer full sun, do well in poor, stony soil, and prefer soil to dry out between waterings. But they have significant differences.

Summer Savory. This savory is an annual that gets about 18 inches tall and is grown from seed planted in the early spring (allow 4 weeks to germination). Transplant 2–3 plants to a 6-inch pot, or plant outside, 10 inches apart. Seeds stay viable for only 1–2 years. Plant in April to May. Prefers light soil. The beauty of summer savory is that it's so easy to get going. Space plantings at 3-week intervals for continuous prime leaves. Thin when 3 inches high to be about 6 inches apart. Summer savory's flavor is sweeter and finer than that of winter savory. Available from Redwood City, Thompson & Morgan, DeGiorgi, and William Dam.

Winter Savory. This hardy perennial survives down to 10°F with mulch and a sheltered position. Compared to summer savory it's a little smaller and much prettier, with its little lavender summer flowers. Winter savory seeds are so slow to germinate that it's easier to propagate them via cutting or root division in the fall. Grow in 6–8-inch pots, or plant 1 foot apart outside. The flavor of winter savory leaves is similar to but stronger than that of summer savory. One plant is enough. It will die after 5 years, so figure on replacing it. Available from William Dam and DeGiorgi.

Harvesting and Drying. The flavor is strongest when the plants are in flower. Summer savory leaves can be harvested in mid-summer or can be pulled out by the roots in the fall for drying. Winter savory tips can be cut 2 or 3 times a summer. Don't wash. Dry in shade or at 110°F. Done when crisp.

Using. The leaves of both types of savory have a peppery quality that goes well in salads, soups, and sauces. Dried leaves are good in poultry stuffing and with meats, fish, cheese, eggs, and green beans. It's also used in sachets. Crushing and rubbing summer savory leaves on a bee sting can help make it better.

SESAME (*SESAME INDICUM*): This annual does best in full sun, grows to be about 2 feet tall, and blooms with pretty trumpet-shaped white flowers. In late summer the flowers wither and a

seedhead develops that contains the small nut-flavored seeds we know as sesame seeds. These must be harvested before fully mature; otherwise, they will shatter onto the ground. Use fresh or toasted.

➲ **SESAME SALT** Put 8 parts raw sesame seeds with 1 part sea salt in a frying pan. Heat gently until the seeds begin to brown (don't overheat them). Cool, mix well, and grind. Sprinkle this on soups, salads, or entrees at the table—if they are unsalted.

➲ **SESAME SEED BREAD CRUST** Before you put your bread loaf into the oven to bake, work warm water into the top of the loaf until it's goopy. Then work in as many sesame seeds as you want. Then bake.

➲ **TAHINI** Blend sesame seeds into a smooth paste of mixed seed and oil. Pour off the oil that rises to the top after it sets a while and use it like any cooking oil. Use the solid portion like peanut butter, or to thicken a salad dressing.

➲ **TAHINI-YOGURT SALAD DRESSING** Combine 2 T. vinegar, 1 crushed garlic clove, 2 T. tahini, juice from half a lemon, and salt and/or pepper to taste. Now gradually mix in about $\frac{2}{3}$ c. unfavored yogurt Good with strong-tasting greens.

SLIPPERY ELM: Old-timers would break the inner bark of slippery elm into bits to make the famous tea. They would pour 1 c. boiling water over 1 t. slippery elm bark and let it steep until cold. When cold, it was strained, and lemon juice was added to sweeten it to taste. But since the elms are having such a hard time now anyway, I'd leave them alone and try something else. If you do have an eco-harmless source, slippery elm is an edible herb with thickening ability. It's good for thickening edible leathers (dried food paste). Use 2 T. slippery elm for each 1 c. pulp and soak 5 minutes; that will do it.

SORREL: Sorrel originated in Eurasia. The variety called garden sorrel now grows wild in many places in the United States. All true sorrels are very hardy (zones 5–9) perennials, members of the buckwheat family. They all have a similar taste and can be used as leafy flavorings for salads and meat, fish, or egg dishes.

NOTE: Oxalis acetosella or wood sorrel, although it has a similar name, is not related and is not safe to consume!

Varieties. There are several true sorrel varieties, wild and domesticated. The preferred eating kind, French sorrel or oseille, is easily confused with its wild relative, sheep sorrel. The various sorrels are also known as sourgrass. The other domesticated sorrel is garden sorrel or Grande de Belleville (*Rumex acetosa*). Its leaves get up to 2 feet long, compared to the 6-inch French sorrel. Available from DeGiorgi.

Sheep Sorrel (*Rumex acetosella*). Also known as dock, this is a common weed. It is related to, looks somewhat like, and is as delicious as French or garden sorrel, and it can be used in exactly the same way. But I don't recommend letting sheep sorrel into your garden, because it propagates by underground runners (like morning glory) that tend to be terribly difficult to control in the garden. If you want a sorrel, plant French or garden instead. If you must plant sheep sorrel, do so inside outer barriers that will safely stop those roaming roots from taking over.

French Sorrel (*Rumex scutatus*). This one propagates slowly by developing clumps on its perimeter (which you can divide and move) as well as by seed. In fact, it's a good idea to pinch off all developing seed heads, for French sorrel will self-sow and can become a weedy garden nuisance in that way. Pinching off seedheads also keeps its energy going

into making leaves for flowering and cuts way back on, or even ends, leaf production. Still, French is more controllable than sheep, and that's why it's the sorrel variety of choice for gardeners. Available from DeGiorgi, etc.

Planting. French sorrel prefers somewhat acid soil and does not grow in quite alkaline soil. Being perennial, it needs a permanent location and appreciates nitrogen. If you have scorching hot summers, choose a site with partial shade. If your summers are frequently cloudy, plant in full sun. Otherwise, it is easy to grow, a bush that will become between 18 inches and 3 feet high. Once started, it will basically make it on its own, although it produces leaves best in moist soil. Sorrel has relatively deep roots and so can handle dry spells better than some other plants. Plant from seed in March or by root division, directly outdoors, in either spring or fall. Plant $\frac{1}{2}$ inches deep in 6-inch pots or outdoors a foot apart. Keep the dirt moist until the plants appear. Thin to 6 inches in a dry climate, 12 inches in a wet one. French sorrel runs out of "oomph" and needs to be divided, moved, or given generous nitrogen feedings at least every 3–4 years. Wherever sorrel has been growing, the nitrogen will be depleted. Sorrel has a chronic problem with Japanese beetles.

Harvesting. French sorrel will be the first green to appear in your spring garden. The arrow-shaped leaves can be harvested in spring, fall, and winter. Choose fully formed leaves, 3–7 inches long. Take only the outer leaves so the rosette heart will be undamaged and able to continue growing new ones. Harvesting those outer leaves, whether or not you need them, is desirable because it keeps the tender new ones coming. Basically, you harvest in spring, give it up for a while in summer, and trim back the dense summer growth around September; then you'll get a fall crop of tender leaves that continue to come until a really heavy freeze stops them for the winter.

Preparing. Discard tough, overmature leaves, unless they're to be pureed. Sorrel wilts unusually quickly, as greens go, and must be moved promptly from garden to table. If you're harvesting sorrel for a cooked recipe, pick lots, because it shrinks! And never cook sorrel in aluminum or iron pans, because the sorrel leaves will turn an unappealing brown or even black. Carefully rinse off and drain the leaves.

Sorrel Recipes. The leaves have an acid, lemony, tart flavor that is surprising and pleasant in small quantities—when slivered thinly and added to the milder lettuce-type greens of a salad, for instance, or used like parsley to garnish fish or tossed in to help flavor a soup. Or use some chopped sorrel with your favorite other ingredients (tomato, cheese, etc.) as an omelet filling. Or blend with mayonnaise for added zip and green coloring. But sorrel is one of those plants that is high in oxalic acid, a substance that both prevents calcium uptake in your system and in quantity is a carcinogen, so it's best used sparingly (unless well cooked before use, which totally disarms it).

In larger quantities, sorrel's strong flavor can be disagreeable unless covered, as in a cream soup recipe, or heavily balanced, as in combination with fish, chicken, or game. For example, sauté sorrel with butter and chopped olives and serve with fish. Or cut the sorrel into small pieces, cook with trout or salmon, and serve with a white sauce or lemon juice. Or puree 1 lb. sorrel, combine with shredded, cooked chicken and chicken stock, and serve with lemon juice or cream. Or sprinkle chicken or fish with lemon juice and basil or pesto, wrap it inside large sorrel leaves, and bake.

SOUTHERNWOOD (*ARTEMISIA ABROTANUM*): This close relative of wormwood is a decorative perennial bush 2–3 feet high with small yellow flowers in late summer. It's not hardy and

needs a sheltered planting where severe frosts won't affect it. Plant in full sun in well-drained, heavy soil. Propagate by seeds or semi-ripe summer stem cuttings. Southernwood leaves are insect repellent and can be made into mothproofing sachets to be stored with clothing. They're also used in potpourris. Because they taste so bitter, they are not used in the kitchen. Harvest and dry sprigs as you would wormwood.

⇒ **A SHAKER CLOSET BAG** From Janice Rebstock, Boonville, IN: Combine 2 c. southernwood, 1 c. tansy, 1 c. lavender, ½ c. orange peel, and 2 T. crushed cloves.

STEVIA: Stevia (*Stevia rebaudiana*) is a small shrub from Paraguay, Brazil, and Argentina that sweetens anything without adding sugar or calories or raising blood sugar levels. *How to Grow Stevia* can be bought at www.guaranibotanicals.com.

ST. JOHNSWORT: It is classed as poisonous (not recommended as a tea or tincture herb), but might be marketable as a bulk raw material for the herbal products industry. Read "St. Johnswort as an Alternative Crop" at attra.ncat.org/new_pubs/attra-pub/PDF/stjohns.pdf?id=DC.

SWEET CICELY (*MYRRHIS ODORATA*): Also called "myrrh," this perennial herb has ferny foliage, grows 2–3 feet high, and is a serious self-sower that can become a weed in your garden.

Planting. Plant the black seeds in fall or spring, or root pieces with a bud on each. Sweet cicely thrives in light shade and any type of damp soil. Allow 8–10 square inches per plant. Seedlings can be transplanted. To save your own seed, note that seeds should be chilled in damp peat for about 2 months (at least 40°F) for good germination. Seeds available from Thompson & Morgan and DeGiorgi.

Harvesting and Using. It's best not to harvest the first year unless you plan to treat the plant like an annual and expect it to die off at summer's end. The plant parts all have an anise scent and flavor. Use leaves in salads and desserts. Sweet cicely can be cooked with very acid fruits like rhubarb and gooseberries. It sweetens any food it's cooked with, reducing the need to add sugar, and is thus favored by diabetics. Harvest and preserve leaves as you would dill. The seeds have a spicy taste. Pick while still green, after the flowers fade. The taproot is remarkably large and can be cooked and added to salads or used as a vegetable.

TANSY (*TANACETUM VULGARE*): *Do not eat tansy.* This medieval herb is now used only in dried arrangements and as an insect repellent. Propagate by seeds or plant division; it can be transplanted. The problem is usually over-propagation; tansy can become a problem weed in your garden, especially its running roots, which you have to constantly pull out to keep the plants from taking over the entire garden. Plant in average, well-drained soil, in full sun, about 3 feet apart. Available from DeGiorgi.

Tansy in various forms, especially the oil, has been effective against flies, mosquitoes, ants, and some intestinal worms. It was used in the middle ages to flavor puddings, cakes, and in medicinal teas, to scent cosmetics, and to make perfumes, but it is now considered poisonous.

TARRAGON: Originally from Siberia, tarragon is a perennial that comes in 2 basic varieties. French (also called German) tarragon (*Artemisia dracunculus*) is called "little dragon" for its pungent taste. It is not very hardy; if your winters are severe, mulch or bring in. It is a

smaller plant (2–3 feet) that is most difficult to propagate, since it never makes seed, but is better tasting.

Russian tarragon (*Artemisia dracunculoides*) grows to 5 feet tall and will make seed, but it has poorer flavor. It's preferred only where French can't make it. Available from DeGiorgi.

Note: Mexican tarragon (*Tagetes lucida*) is a perennial marigold whose leaves have a distinctive tarragon flavor and can be used as a substitute. Available from Redwood City.

Planting. Because French tarragon produces no seed, propagate it by layering, stem cuttings, or root division in the early spring (divide before growth is 2 inches tall). Plant in well-drained, fertile, light (sandy) soil, in full sun or semi-shade. Divide large plants every 2–3 years. Grows well in a pot (use part sand).

Harvesting. Cut off fresh leaves any time through summer.

Drying. Cut off leaves and tops of young plants just after their dew has dried. Dry away from sun or in oven or dehydrator at 110°F until crisp. Or harvest whole stalks in early fall by cutting them off several inches above the ground and hanging them loosely to dry.

Using. A favorite with French chefs for its wonderful flavor, fresh tarragon leaves are good in oil and vinegar salad dressings and with beets, sauces, and any meat, seafood, or cheese. Also used to make perfumes. Dried tarragon is good in tomato juice or any tomato dish. If you're using Russian tarragon, use more, since its flavor is weaker. Grape juice and fresh tarragon make a good herb jelly. You can sauté tarragon leaves in butter or oil and baste meat or poultry with it.

⇒ **TARRAGON EGGS** A mixture of finely chopped tarragon, onion, and parsley is good in an omelet or scrambled eggs.

⇒ **TARRAGON VINEGAR** Tarragon keeps its flavor better if preserved in vinegar rather than dried. Gather the tarragon just before it blossoms. Discard the larger stalks. Mash the leaves some. For a plain tarragon vinegar, place two 5-inch sprigs of fresh tarragon in 2 c. white wine vinegar. Or make a fancy one by combining 4 c. tarragon leaves and smaller stalks, 1 qt. white wine vinegar, 3 cloves, and 1 small clove garlic (remove garlic after 24 hours). Takes 2 months to get really good.

THYME: This popular, semi-hardy, low-growing (to 4–12 inches) Mediterranean perennial has a host of varieties. Common thyme (*Thymus vulgaris*) is easily grown, 6–12 inches tall with grey leaves and lavender blooms, great in the kitchen, can be used for fragrance, makes exceptional honey, and is an antiseptic. Lemon thyme (*Thymus citriodorus*) grows 4–12 inches high, has green leaves and lavender blooms, is good in salads, is superior for poultry stuffing, but is not as hardy as common thyme. Other types such as dwarf thyme and creeping varieties are grown as ornamentals and used in perfumery, but for kitchen use, what you want is common or lemon thyme. Almost every seedhouse carries one or more kinds.

Planting. Thyme grows slowly, so you're best off starting with a plant. Or plant seeds (viable for 2–3 years) in spring. Plant either indoors (1–2 plants per 4-inch pot, or 3–4 plants per 6-inch pot) or out—good in a rock garden or as a border—slightly alkaline soil. Thyme can handle full sun or part shade. Poor soil and infrequent watering actually improve the flavor. You can easily propagate creeping varieties by cuttings in spring or summer, or by root division or layering of lower branches starting in the second year. Thyme grows well in a pot. Bring in for the winter if weather is harsh. Creeping kinds are

nice in a hanging basket.

Harvesting and Preserving. Snip some off and use fresh as seasoning, or dry for future use. Thyme is the easiest herb to dry, dried thyme is as effective as fresh, and harvesting makes your plant more bushy and attractive. If you are harvesting from an outdoor, creeping variety, wash the thyme thoroughly, because it tends to contain dirt. If harvesting from common or lemon thyme, which are bushy, cut down as far as the stem remains tender, and you won't need to wash it. Harvest anytime for fresh use. To preserve, cut when thyme has flowers, but snip only the non-flowering shoots. Dry at 110°F until crisp.

Using. The dried leaves are a seasoning ingredient for many soups and sauces, the herbal equivalent of pepper. You can make tea from the dried leaves or flavor vegetable juice, meats, soups, peas, poultry, clam chowder, and gravies. Use fresh leaves in salads. The only rule is to go easy; it's strong stuff. A pinch will usually do, or else you risk the thyme overwhelming the other flavors. Use flowers or foliage in potpourri. Or combine a strong thyme tea with honey and take for a sore throat, or use with a poultice because thyme contains thymol, an oil of proven antiseptic value. Old-timers also gave thyme as a wormer.

TOBACCO: Check with your local USDA and U.S. Treasury Dept. (Bureau of Alcohol, Tobacco and Firearms) so you can comply with any rules or regulations regarding the cultivation, production, or manufacture of tobacco or tobacco products before planting any tobacco seeds. *Nicotiana* species are one of the great natural insecticides. Just keep in mind that it's highly addictive, and don't smoke it. Redwood City sells 3 varieties as well as copies of an 1892 USDA instruction booklet for tobacco cultivation. You can buy seeds from Southern Exposure, Hudson, Seeds of Change, Native Seeds/SEARCH, Eden Organic Nursery (954-455-0229; www.eonseed.com), or Jim Johnson, 3421 Bream St., Gautier, MS 39553. Virtual Seeds Co. offers 30+ varieties (530-686-9735; www.virtualseeds.com). The U. of Kentucky College of Agriculture offers an 80-pg booklet titled *Tobacco in Kentucky*. ATTRA's brochure, "Organic Tobacco Production," is at www.attra.org/attra-pub/tobacco.html. Start in pots as you would plants of the nightshade family (see Chapter 4). Transplant 1–2 feet apart to well-fertilized soil in full sun.

NOTE: Uncured tobacco can be much stronger than commercial cigarettes and dangerous to smoke. Curing lowers the nicotine content.

TURMERIC (*CURCUMA DOMESTICA*, A.K.A. *CURCUMA LONGA*): This relative of ginger can be grown and harvested as you would ginger. It originated in tropical Asia and is now commercially grown in Haiti. Plant the root pieces 2 feet apart. Harvest the roots; wash them, sun-dry them for about 10 days, and then grind to a powder. The spice is used to make curry powders, as a food coloring and dye agent to make a golden shade, to season Far Eastern recipes, in wet mustard recipes for both its color and flavor, and as a saffron substitute. The dictionary says it's also used as a "stimulant." Available from Pacific Tree Farms.

VANILLA: Vanilla beans are the fruit of a Mexican climbing orchid (*Vanilla fragrans planifolia*). The orchid fruits naturally there, but anywhere else on the planet it has to be hand-pollinated. Vanilla begins fruiting at 3 years old, dies at about 10. If you don't live in a tropical climate, this is a greenhouse plant, wintering at no less than 60°F.

Processing. The skinny, 6-inch green pods and their beans don't have the sought-after

flavor when picked. They have to be sweated and fermented for days while wrapped in a blanket. Next they are dried in the sun until thoroughly cured. The total time for fermenting plus sun-drying can be several months. They're done when vanillin, an aromatic substance, has developed in the beans; then they have that characteristic, wonderful flavor and fragrance and can be used in perfumes, potpourris, and cooking. By then they are dark brown in color.

Using. Cooking with the whole bean and pod results in remarkably better flavor than just using the extract. The seeds are edible. The pod adds to the flavor if tossed in too, but should be tossed back out after using and not eaten. That outer pod is good for flavoring baking custards and puddings. A 3-inch section of vanilla pod stirred into your mixture equals the flavoring of 1½ t. vanilla extract. To cook with the pod, first split it; then scrape the beans into your food mixture. They can be boiled, or you can make your own extract. Use vanilla or its extract to flavor desserts of any sort.

» **OLD-TIME VANILLA EXTRACT** Use 4 oz. vanilla beans, 16 oz. edible alcohol, and 16 oz. water. Slice the beans and cut into fine pieces with a sharp knife. Thoroughly powder them in a mortar with 1–2 oz. granulated sugar. Put the powder into the alcohol and water mixture. If you don't have pure alcohol and are substituting a strong whisky blend or brandy, use correspondingly less water. Let the vanilla soak in the liquid for 4 weeks. Strain. The liquid is your extract. Old-time imitation vanilla extract was sometimes made using half or all tonka beans in place of vanilla beans to make it cheaper.

» **EASY VANILLA EXTRACT** Violet Stewart, Okay, OK, wrote me that she simply takes 1 qt. of any good 80-proof brandy, splits 2 vanilla beans, and drops them in. She corks it and lets it sit for 2 months before using.

» **NONALCOHOLIC VANILLA EXTRACT** Mrs. G. Goodman, Randallstown, MD, wrote me, "Cut up vanilla bean into small pieces, place in a bowl. Pour ¼ c. boiling water over them; cover bowl, allow mixture to steep overnight. Blend mixture. Strain and return juice to the blender. Add ½ t. liquid lecithin, 1 T. honey, and 1 T. vegetable oil. Blend, pour into a bottle, cap, and refrigerate. Before using, shake well. Use same as commercial vanilla extract in recipes."

VERBENA, LEMON (*LIPPIA CITRIODORA*): This semi-hardy, perennial, fragrant bush has crinkly, pointed leaves and tiny mauve blossoms growing in spikes. It is sometimes confused with lemon balm, which is the one you want for culinary use. Lemon verbena has non-culinary usages such as perfume making and potpourri. (See also "Lemon Verbena.")

VIOLET: There are several varieties of violet. *Viola tricolor* has edible flowers and leaves and is pretty in your garden or salad. Most violets are great in a potpourri because of their heavy perfume.

WINTERGREEN (*GAULTHERIA PROCUMBENS*): This is a very hardy (to -30°F) little evergreen plant with small white flowers. It grows wild, ground-cover style, in coniferous forests of Minnesota, Wisconsin, New York, and Connecticut. Or you can order from Richter's or Raintree Nursery. The berries are bright red and edible raw; nice in a fruit salad. Both leaves and fruit have that wintergreen flavor. Good ground cover.

Planting. It's difficult to grow wintergreen in a domesticated setting. It will grow between 1,000 and 3,000 feet above sea level, but 2,000 feet is ideal. It is naturally adapted for a

forest setting of open shade and acid soil. You'll have better luck starting with nursery plants than with wild ones. Propagate by root division in the fall before frost or spring. Plant 12 inches apart in acid (its natural habitat is pine woods), well-drained, light soil. It's a good idea to grow it in a lathe shelter, since it must have full or partial shade to grow well. Or fake the woods to make it happy: Plant on a wooded hillside with a heavy pine needle mulch.

BUG & WORM REMEDIES

Mosquito Repellent: Rubbing lemon balm leaves over exposed body parts will keep mosquitoes away. Or rub chamomile tea on exposed skin. When Hazel in Georgia goes fishing and berry gathering she rubs her ankles and other exposed skin with a homemade sulfur salve. She buys flowers of sulfur at the drugstore. She mixes the flowers of sulfur with plain old lard until the mixture is a "good, deep yellow," then stores the salve in small jars with tight lids.

Insect Repellent for Poultry: Apply dried, crumbled pennyroyal dust (leaves) all over the chicken house, and don't forget the cracks. Dust the animals too (while they're sleeping). Don't breathe the stuff! Use a pennyroyal "tea" (poisonous) to "wash" animals to prevent flies and sucking insects from bothering them. Wash dogs and cats with it to exterminate fleas. Or soak 1 pack of chewing tobacco in 5 qt. water. Pour the juice into roost cracks, or wherever else the treatment is needed.

Yellow Jackets: Mrs. Harvey Thompson, Yelm, WA, says that a dish one-third full of cider vinegar will drive off yellow jackets.

Silverfish: Costmary (*Chrysanthemum balsamita*) leaves placed in cupboards will make silverfish move on. Or sprinkle a mixture of sugar and boric acid in there.

Remedy for Pet Fleas: Mary Alice Ames, Anacortes, WA, wrote me: "If you don't like chemicals, try talcum powder. Saturate the animal's fur with the powder. This may not get rid of every last one, but it helps. The talc clogs the fleas' breathing tubes. It makes people sneeze too, so do it outside and then let the animal run. Also, bay leaves repel fleas. Cedar boughs do too."

Louse Control: Mix 1 part melaleuca (tea-tree oil) with 4 parts vegetable oil. Rub the animal all over with this. Two weeks later, give the treatment again. This works on both animals and people.

Roach Killer: The first step in your battle is to avoid leaving food and water where roaches can get at it because they won't eat the poison if they can find something better. Combine 4 T. borax, 2 T. flour, and 1 T. cocoa powder. Or 2 parts borax and 1 part sugar. Put in small, flat containers where roaches will run across it but pets and children won't. (This looks like chocolate. Make sure kids don't taste it.) Joyce Darling, Harrodsburg, KY, writes that boric acid powder "will rid the house of roaches in 2 or 3 weeks. Put it in drawers and on shelves. It will last 6 months. Then clean out the old and sprinkle fresh around."

Chiggers: Repel by taking vitamin A daily during chigger season.

Goat Flies: Terry Bedard, Warner Robbins, GA, wrote: "Here's something you might like to try. Add apple cider vinegar when you feed your goats (about $\frac{1}{4}$ c. per goat). They love the taste, and it will cut down tremendously on the flies they attract, not only to their body, but also to their manure."

Scabies Remedy: Mix powdered mustard with water. Pat the paste directly onto the affected skin. Leave on until you can't stand the heat any longer. (If you leave powdered mustard on too long, it blisters the skin.) Then wash it off. Treat the same way as needed.

Moth Control: Lots of dried herbs or their oils will repel moths: camphor, basil, cedar oil, eucalyptus, pennyroyal, pyrethrum, southernwood, or tansy.

Using. Wintergreen or its extract is excellent in homemade root beer. Wintergreen flowers are edible and can be added to fruit salads or ice cream. Wintergreen leaves are nice to chew on fresh. Dried or fresh leaves make a fragrant tea. Harvest both berries and leaves in early September or October. Use 1 c. fresh leaves per 1 qt. water. The extract is used commercially to flavor gum and candy. The bright red berries are edible, sweet, and tasty. Neither berries nor leaves are dried. Make oil of wintergreen for out-of-season flavoring and fragrance uses.

WITCH HAZEL (*HAMAMELIS VIRGINIANA*): This slow-growing shrub (10–15 feet) native to eastern North America has yellow flowers that bloom in October and November. An alcohol extract of witch hazel bark is sold commercially as an astringent lotion. Available from Thompson & Morgan, Richter's, etc.

WOAD (*ISATIS TINCTORIA*): *Do not eat.* This European herb, also called dyer's woad, is grown for the blue dye that can be extracted from its leaves. Seedpods are used in arrangements. It reseeds. "Woad" also refers to the dye itself. In 1861 a whimsical Orson Fowler wrote of "singing woad" which, when boiled, results in a "bird-pitched warbling and whistling that issue from the pot." Available from Richter's, etc.

WORMSEED: See "Epazote."

WORMWOOD (*ARTEMISIA ABSINTHUM*): This hardy perennial grows 2–14 feet high. Propagate by root division or fall-planted seeds (viable for 2–3 years). Plant in poor, light soil, in partial shade. It gets several feet tall. Give it a spot by itself. Wormwood is strong stuff. It has a strong, disagreeable smell and can inhibit the growth of nearby plants, even herbs such as caraway, fennel, and sage. If you have harsh winters, cut it back and mulch heavily in the fall for protection.

Wormwood is usually harvested in fall. Dry the sprigs and use to make moth-repellent sachets. A strong wormwood tea can be used as a fleakiller bath for your pets. It is used in flavoring absinthe and was traditionally used to treat worms (hence its name). A wormwood spray can protect against some pests. Available from Redwood City, Richter's, etc.

YUCCA: The roots of yucca contain saponin, a natural sudsing agent, good for washing delicate fabrics.

Planting. It takes 1–2 months to germinate at 65–75°F. Even after that, its growth tends to be slow and erratic. It needs easily draining soil. If in a pot, it actually does better if a little pot-bound. It's not very hardy. Available from Richter's, Thompson & Morgan, etc.

Using. Chop roots, soak in water, and stir to a lather.

COCOA, COFFEE(S), AND TEA

Cocoa: Cocoa trees (*Theobroma cacao*) originated in the tropical lowlands of Central America and southern Mexico. The tree seeds are cocoa beans. Foods made from them contain theobromine, a mild stimulant; caffeine, a stronger stimulant (in a much smaller amount than tea or coffee); and possibly also phenylethylamine, a mood lifter. So for medicinal purposes, chocolate can help the lethargic, the depressed, and the lovelorn. It can also make your toddler temporarily hyperactive. Hardy only to 32°F, cocoa trees are available from Pacific Tree Farms.

Cocoa to Drink. The original beverage made by ancient Native Americans by steeping the crushed bean in hot water was bitter but treasured. The Spanish tried adding sugar to sweeten it, and that helped. They also mixed ground cocoa beans with cinnamon and used them to create a wonderful meat sauce.

Cocoa Butter. In its natural state, the cocoa bean is about half fat, or cocoa butter. Because of all that fat, it is hard to dissolve cocoa. A Dutchman discovered a way to remove half the fat; the resulting product, our familiar cocoa powder, is much more soluble and pleasant to drink. An enterprising Swiss entrepreneur discovered a way to use the cocoa butter removed in the process of making cocoa powder. He perfected a method by which machines rolled and kneaded the beans and at the same time doubled their fat content by adding the surplus cocoa butter from the powder-making process. The result was confectioner's chocolate.

Milk Chocolate. Another Swiss man added milk and so created milk chocolate, a less concentrated and more pleasant product. Since then, chocolate has been selling by the ton.

White Chocolate. This is pure cocoa butter (all the rest of the bean removed) with sugar to sweeten it and vanilla to flavor it.

Basic Cocoa Bean Processing. Harvest the pods that hold the cocoa beans. Then split them open, shell out the beans, and let them ferment for a period. Then dry them and

roast them. The familiar scent and taste of chocolate will not emerge until after the roasting. The beans actually consist of 2 layers, the outer shells and the inside “nibs,” which are the central “heart” of the bean. After the roasting, crack open those outer shells and discard them (they make great mulch). Grind the nibs enough to create some heat. The heat melts the cocoa butter portion of the nibs into a thick paste, referred to as the “chocolate liquor.” That liquor mixture is then poured into molds, square or bar-shaped, and cooled. After cooling, you now have unsweetened baking chocolate, the same stuff you can buy in the store!

Making Cocoa Powder. You have to get rid of half the fat and grind. To make fondant chocolate, add extra cocoa butter and knead it in. If you add sugar, vanilla, and powdered milk and knead them in, you’ll have milk chocolate. Results are affected by the varieties of cocoa beans you start with, the nature of the roasting stage, how much cocoa butter and sugar you add, and how long you knead it. More detailed recipes are manufacturer’s trade secrets that I couldn’t find out for you.

➲ **HOT FUDGE SAUCE** Break 8 oz. unsweetened or semisweet baking chocolate into chunks. Combine chunks with 1 c. light cream in a heavy pan set on very low heat. Once the chocolate begins melting, stir constantly until the fudge is smooth and thick. If it’s too bitter for your taste, mix in sugar. Then take the pan off the heat source and stir in ½ t. vanilla. This is traditionally served over vanilla ice cream. Pour surplus sauce into a jar, cover, and refrigerate. It will keep at least several weeks. When you want to use it again, just reheat, again constantly stirring.

➲ **BASIC MOCHA** “Mocha” means flavored with a mixture of chocolate and coffee. Combine 2 c. strong black coffee (instant is OK), 3 c. hot milk 4 heaping T. chocolate powder, and 3 heaping T. sugar. (If chocolate powder is already sweetened, skip sugar.) Beat until foamy.

➲ **SPICED MOCHA MIX** Combine 1 c. dry nondairy creamer, 1 c. cocoa powder, ⅔ c. instant coffee, ½ c. sugar, ½ t. cinnamon, and ¼ t. nutmeg. Keep it in a jar in a cool place. To serve, add 3–4 heaped t. to 1 c. very hot water. Nice served hot with a dollop of whipped cream on top, or cold with ice chunks in it, or with a big scoop of vanilla ice cream in it!

➲ **COCOA INSECTICIDE** Soaking poultry with a strong tea made from cocoa leaves will clear them of lice. Cocoa shells are also lice-repellent and are useful mixed with animal bedding.

COFFEE (GENUS COFFEA): The coffee plant is native to east Africa. It looks like a small tree or shrub and grows up to 8 feet tall in a pot (up to 15 feet outdoors). A dwarf variety gets only 3 feet tall. Coffee can be grown in a temperate-zone garden if you transplant to a container and bring inside for the winter. The coffee plant is quite ornamental with its scented white flowers and shiny dark green foliage. The coffee plant can’t survive a frost and needs some shade to protect it from excessive sun. It can be grown outdoors in the California coastal area from about Santa Barbara on south. Pacific Tree Farms says their variety is hardy to 28°F.

Plants or seed are available from Richter’s, Pacific Tree Farms, and Banana Tree.

Planting. Keep seeds dry before planting. Plant coffee seed on the soil surface in a sand-peat or half-organic mix. Keep warm (about 85°F) and allow a sizable time (a month or more) for germination. Once well started, transplant outdoors or to 4-inch pots. Grow potted coffee in well-drained soil; situate in a sunny window. Young coffee plants grow best at 70–75°F. If you have trouble with brown leaves, it means you’ve been watering too

much, need to move the plant to a larger pot, or both.

Harvesting. For flowering and fruiting, the plants need 55–58°F night temperatures. Without those conditions, the plant will just grow bunches of lovely dark green glossy leaves—no flowers, no beans. Also be cautious with pruning. Cutting off the top does no harm, but trimming branches eliminates your crop, since flowers and beans grow there. The white flowers evolve into ½-inch fruits that are first green and then red, purple, or scarlet when ripe. When ripe, harvest them.

Using. Each pod contains 2 coffee beans, which you rescue from the outer pulp, dry, roast, grind, and soak in very hot water to make your beverage. (You can mail-order a coffee grinder from Lehman's, 888-438-5346; www.lehmans.com.) Coffee contains a lot of caffeine. An occasional cup can be a helpful sustainer in an emergency, but I know too many people who are addicted: They drink 30–40 cups a day, desperately wish they didn't, and can't stop. Heavy coffee consumption is definitely linked to pancreatic cancer.

Coffee Grounds. These, on the other hand, are a first-class, environmentally harmless deterrent to ants. To keep ants out of your house, or any other building, just lay a solid 3-inch layer against your foundation all the way around. To deal with an anthill, surround it likewise with a sizable ring of grounds. Grounds will also prevent cutworms (as do wood ashes). Just dig a shallow ditch around vulnerable plants and pour grounds into it. As they break down, they'll also add fertility to the soil. Grounds are also great in your compost pile; earthworms love them and will quickly turn them into rich humus. And a manure/grounds/ leafy mulch mixture added to poor soil will practically instantly make it fertile. No need to strain your pancreas! To get enough grounds to accomplish all this, just contact a business that brews coffee in quantity, and ask them to let you take all those unwanted coffee grounds off their hands!

COFFEES THAT AREN'T COFFEE: You can buy them at the store: Postum, Kaf-free Roma, etc. Mike and I have drunk Postum for years and enjoy it. It's made from ground and roasted grain. Mike drinks a heaping teaspoon of Postum in a cup of hot water. That's too strong for me. I like a level teaspoon with honey and milk, about one-third or one-fourth milk. I often make a whole coffeepot of it that way and share it with the children for breakfast. Unlike real coffee, "coffees that aren't coffee" can safely be shared with them. It's more comfortable than saying to children, "That's not good for you; you can't have any," while they stand there watching me drink it. The wise psychologists say our children imitate what we do and not what we say. In their innocent devotion, they try to follow the truest form of our behavior.

You can drink Postum in all milk, in milk with a dash of cocoa, made into an eggnog with milk, or with milk flavored with molasses. Another store-bought non-coffee product is called Yannoh. It is made from barley, wheat, soya, chickpeas, rice, dandelion, and burdock roots. You perk it just like coffee. If your grocer, co-op, or health-food store doesn't have it, ask them to order it for you.

⇒ **ROASTED GRAIN COFFEE** Combine 8 c. wheat bran, 3 beaten eggs, 2 c. cornmeal, and 1 c. molasses or sorghum. Spread the mixture on a cookie sheet and bake slowly at about 200°F, stirring often. Boil with water to serve.

⇒ **ACORN COFFEE** Select plump, round, sweet acorns. Shell and brown in oven. Grind in a coffee mill and use as ordinary coffee. Or hull ½ c. small sweet acorns. Add ½ c. cracked wheat. Mix. Roast in your oven. Pound in a mortar. Boil with water to get your coffee. Add honey, molasses, or brown sugar to sweeten.

⇒ **DANDELION ROOT COFFEE** Dandelion coffee makes a surprisingly good substitute. Gather roots in the fall (October) or in the early spring before blooming. Scrub unpeeled roots with a stiff brush. Use the big part for a root vegetable (see “Dandelion” in [Chapter 4](#)). The skinny side roots are what you dry, grind, and roast. Dry them in the oven (150°F) until they are brittle and snap easily. Then roast them at about 375°F for 15–20 minutes or until they are dark brown inside. Grind in blender until they look like coffee, or use a rolling pin to grind to a coarse powder. Store in glass jars and use just as you would coffee. Boil about 1 t. per cup and stir it in. Your brew will have a flavor all its own, vaguely chocolaty and pleasing. You’ll like it better every time the price of coffee goes up. But bear in mind that dandelion root is a powerful diuretic, so it may not be the best choice if you’re pregnant.

Chicory Coffee. The mature roots of the Magdeburgh chicory variety (available from William Dam) can be dried, ground, and mixed with coffee to stretch it. Added to oven-browned barley, it makes a coffee substitute that has been very popular in Europe. (See “Chicory” in [Chapter 4](#).) You can also make a chicory coffee from Witloof or wild chicory roots, but Magdeburgh is the specialist.

Unlike the other chicories, this is a perennial and needs a permanent corner of your garden. It has broad, smooth-edged, dark green leaves that grow in loose, upright (edible) heads. But what you’re after is the 14–16-inch roots. Grow those roots an entire season long, at least 100 days. Or better yet, let them grow 2 summers. Then cut off the green tops (make salad). Scrub or scrape the roots, slice them, and string your little circles or strips of chicory on a thread. Hang up to dry. When completely dry, spread on a cookie sheet and roast at a low temperature until a very dark brown—they start to smell like chocolate cake. Taste to detect the moment of roasted perfection. Now cool the chicory. Grind it with mortar and pestle or some other means.

To brew chicory coffee, first boil a pot of water. Then drop in a spoonful of ground chicory, stir, let steep a few minutes, and there you are. Chicory is stronger than coffee, so use less. Serve plain or with honey and cream. You can make more chicory coffee out of the same grounds.

TEA: Tea leaves come from tea trees (*Thea sinensis*). They still grow wild in a few parts of the world, but they’ve been domesticated since ancient China. Tea handles pruning well and makes a fine hedge. It blooms in fall with small, fragrant, lovely white or pink flowers. The stimulant, caffeine, is a natural component of tea leaves. For more information, read *Tea Growing* by C. R. Harler (London: Oxford University Press, 1966), *All About Tea* by William H. Ukers (New York: The Tea & Coffee Trade Journal Co., 1935), or *Tea for Home Use*, a USDA pamphlet on how to cultivate and harvest home-grown tea, available from Redwood City. Also read *Taking Time for Tea*, *The Book of Green Tea*, and *Steeped in Tea*, all by Diana Rosen; and *Herbal Teas* by Kathleen Brown, all available from Storey Books.

Climate. Tea is a subtropical, evergreen plant of the camellia family that can’t handle frost or snow and also dislikes high winds. If your climate has blistering sunshine, plant in partial shade. If you have a relatively cloudy, cool weather pattern, plant in full sun. Tea does best where there is warm, humid weather, temperatures don’t drop below 24°F, and quite a bit of rainfall falls evenly distributed throughout the year. Morning fogs are wonderful for it. Tea will grow in southern California and the deep South. In colder areas, your tea trees can thrive and produce leaves in a container.

Varieties. There are about 30 different varieties. Unpruned wild teas grow 30–40 feet tall

and belong to a large-leaf group. The domesticated teas are small-leaved, pruned to be shrubby, and allowed to grow only 4–15 feet high for easier harvesting. The tea tree has a round, dense nature. In the Far East you'd have many named varieties to choose from, but here you don't.

Planting. Tea plants are hard to find. Plant a half dozen to meet the tea-making needs of a family. You can mail-order seed from Park. Almost any soil, from sand to clay, will do, but tea needs acid soil with lots of organic material in it, a pH of 4–6, and good drainage (and no saltiness!). Plant tea seeds with their “eye” face down. Once you've grown a plant from seed, layering is another possible way of propagating, as is planting a cut branch or grafting. Water young plants regularly enough that their roots never dry out. Keep thick mulch over the roots. Be patient; tea plants grow very slowly. It will be years before your plant gets even 4 feet tall. Mature plants can get along with less regular watering.

Harvesting. In commercial tea plantations, the trees are fertilized, seeded, pruned, and harvested—all mechanically. (Pruning is done to cause new small leaves to grow as well as to shape the plant.) You'll be doing it by hand. Wait until your tea tree is at least 2–3 years old before you start. Then in early spring, when the weather gets warm and new leaves start to grow on the plant, pick just 2 or 3 leaves from the very tip of each branchlet. Those make the best tea. Harvesting doesn't hurt a tea plant's growth because you take only the new, outside leaves. Tea leaves can be harvested from spring to fall—as long as you always choose the new leaves. Specialty teas may have special harvest times. Green tea and Pao Chung tea are harvested in spring and autumn. Certain black teas and oolong tea are harvested in the summer. “Green” and “black” teas refer not to tree varieties but to the result of different processing methods.

Making Green Tea. Place your just-plucked leaves in the top pan of your double boiler as is, covered but with no water over them. Fill the lower pan with water, bring it to boiling, and boil about 10 minutes. The leaves will now be much softer.

Pre-Drying: Spread them out thinly on a drying surface. Place your leaf-covered tray in an airy but shady spot. You want them to get limp, but not brittle! After 12–24 hours (you'll learn the golden moment from experience), the leaves will be ready to roll.

Rolling: Lay out 1–2 cups of leaves on a clean rolling surface, roll firmly with a rolling pin, and then knead with your hands, just like bread dough. Spend about 10 minutes on this stage. Now evolve your kneading motion to incorporate a twisting, rolling movement that will gradually transform those leaves into a tight roll. By now some moisture should be coming out of them. If it isn't, you dried them too long, and you need to add about 1 T. water. Veteran tea-makers say that the tighter and longer the leaves are rolled (at least 30 minutes, please!), the more flavorful the tea.

Final Drying: After that, distribute leaves over a drying tray and dry in oven or dehydrator at a very low temperature and with good ventilation (oven door open). Toss and turn the leaves around once in a while to help the drying process. Continue drying at that very gentle heat until they become totally dry (brittle).

Making Black Tea. Pick your leaves. Skip the heating process and go directly to the pre-drying and rolling. Then, before the final drying, add this curing step.

Curing: Press the leaves together into a dense ball shape. Wrap the ball tightly with plastic or a faintly moist cloth, and let rest in a somewhat cool room for about 8 hours. By now the leaves are distinctly fragrant and have changed to a copper color. Now do the final drying.

Storage. Have ready airtight containers for storage. Keep them in a cool place.

⇒ **EAST INDIAN TEA** Make black tea; add milk and honey. Keep heating. Add ginger, cinnamon, and ground cardamom to taste and serve.

⇒ **HOMEMADE SPICED ORANGE TEA** Crush 2½ t. whole cloves and five 2-inch cinnamon sticks to a chunky but not powdery stage. Combine with 1 lb. orange pekoe tea, 4 T. candied ginger (chopped fine), 4 T. dried orange peel, and 1 t. nutmeg. Just 1 t. of this tea makes 1 cup for serving. Steep about 10 minutes before drinking. For company, serve with an orange slice and sweetener.

The oldest sections of my book were written before my readers got the message through to me that I was supposed to sound like myself instead of a book. I figured that out later. With the first 2 issues of the book that I mailed out to "subscribers," I also sent cover letters to explain a few things (make my excuses). So many people wrote back to say my book would do, but what they really enjoyed was the cover letters! After that, I tried to do all my writing the same way as those cover letters. I've been leafing through those old letters. Here's part of one I wrote in February 1971:

"Thank you very much for your check and order for the *Old Fashioned Recipe Book*! I will send it as soon as possible, but I must beg your patience because that may be as long as a month yet."

No kidding, I said that. At that time I had no understanding of the real size and nature of the job I'd gotten myself hooked into. It wasn't until 3 years later, in 1974, that I actually finished that first edition.

Do-It-Yourself Cosmetics

Here's another whole category of environmental poisons that we could do away with. In Japanese the words for "pretty" and "healthy" are the same. Once when I was bemoaning my adolescent imperfections, my mother said, "To be young is to be beautiful." At the time I thought she was talking nonsense. Now I'm the age she was then and I understand the truth of it. The lily doesn't need to be gilded. My father taught that beauty was on the inside, that it consisted of glowing good health and a fine character. On the other hand, maybe I lean too far toward being unconscious of appearances. I could have won the worst-dressed prize every year of my life. And somebody else had to tell me to put natural cosmetics in this book.

I'm glad she did, for once I got started looking for these formulas, they turned out to be great fun to try! Experiment and see which ingredients suit you best. But don't forget that your skin's condition is influenced most of all by your diet, age, amount of exercise, and amount of sleep. Too much stress in your life, too little humidity in your air, too much exposure to sun, and too much fatty, sweetly, junky, chemicalized food can be doing your appearance far more harm than these treatments by themselves can relieve.

NOTE: To prevent allergic reactions, test a small quantity of any unaccustomed substance by rubbing it on the underside of your arm. Then wait 24–48 hours to see if a rash develops.

FOR YOUR FACE

Analyze Your Skin Type. What you put on your skin should be appropriate for its type. Only very oily skin should be dosed with highly acid treatments like citrus fruits (lemon, lime, grapefruit), Concord grapes, strawberries, or apples. If you don't have very oily skin but want an acid skin treatment, use fruits that are a little less acid than the previous list—peaches, apricots, grapes other than Concord, and tomatoes. If you want a beneficial fruit treatment whose acidity is about the same as that of normal skin, use bananas, green

peppers, cucumber, watermelon, or persimmon. If you want a treatment that will moisturize dry skin using substances very low in acid, go with carrots, iceberg lettuce, cantaloupe, avocado, or honeydew melon.

Steaming. This is a good treatment for skin problems and a general pick-me-up. I've enjoyed it many times. It deep-cleans your facial pores. To experts, steaming means putting your face in a hot towel tent. To me, it means spending 5–10 minutes with a few hot washrags on my face. When you're done, wash out any dirt that's left; then close those pores with cold washrags or an astringent.

NOTE: Don't use this or any other heat treatment on a face that already has broken veins, because it can make them worse.

Face Masks. A mask consists of a “binder” (which makes it adhere) and other ingredients mixed in with the binder. Choose your binder according to whether your skin tends to be oily or dry. For oily skin, use yogurt or egg white as a binder. For dry skin, choose lanolin, honey, sour cream, or egg yolk. Experiment with the other ingredients. You can blend vegetables and fruits and combine them with your binder, or use any of the recipes below. Wash your face clean before applying the mask. Don't ever put a mask onto the area around your eyes. Rinse off after a half hour or as soon as the mask dries. (While you're waiting, it's a good time to take a nap.) To remove the mask, use a washrag and warm water. Then use cold water to close your pores.

NOTE: If you feel any irritation, rinse off immediately!

⇒ **EGG WHITE MASK** *This helps drag blackheads and whiteheads out of your pores. Slightly beat an egg white and spread it fairly thickly over your face. Let it dry. Do the same thing with another egg white right on top of the first.*

⇒ **OATMEAL MASK** *Mix together $\frac{2}{3}$ c. oatmeal and enough honey to make a pasty consistency. Optionally, add 2 t. rose water.*

⇒ **HONEY/LEMON MASK** *Mix 2 T. slightly warmed honey with 1 t. lemon juice. Put the mixture on your face and leave for about a half hour.*

⇒ **BREWER'S YEAST MASK** *Mix yeast with enough water to create a paste. Smooth it over your face (not into eyes!). Let dry. Then remove with warm water. Do this 1–2 times a week. For dry skin, add 1 T. wheat germ oil or 1 egg yolk to mask. You can also add 3 t. brewer's yeast to milk or fruit juice and drink it daily.*

Skin Cleansers

- ➲ **INSTANT SKIN CLEANSER** Get a lather up with mild soap. Sprinkle some kitchen cornmeal into the lather and rub and scrub your face with the mixture. See “Elderberry” in Chapter 6 for more recipes.
- ➲ **YOGURT CLEANSER** Mix yogurt with a tiny dash of salt Not for dry skin.
- ➲ **CLEANSING CREAM** In a double boiler, melt and mix together $\frac{1}{2}$ c. safflower (or sweet almond) oil, 1 T. cocoa butter, and 1 T. anhydrous lanolin. Take off the heat, beat until partly cooled, and store in a jar. Shake before using.
- ➲ **FRUIT CLEANSER** Sliced tomato or cucumber.
- ➲ **HERBAL STEAMING FACIAL** Moisten your hot washrags with an herb tea—chamomile, nettle, rosemary, or peppermint.

Other Treatments

- ➲ **ASTRINGENTS** Use peeled cucumbers, lemon juice and water, or rose water.
- ➲ **SKIN FRESHENER** Try a strong mint-tea facial.
- ➲ **PEACHES AND CREAM MOISTURIZER** Blend together 1 ripe peach and heavy cream. Refrigerate. Massage onto your skin wherever needed once per day.
- ➲ **TREATMENT FOR LARGE PORES** Put 4 T. bran mixed with the chopped skins of 2 lemons into a jelly bag. Dip it into boiling water. Apply to face with enough pressure on bag contents to squeeze out a little of the lemon quality. Repeat for a while.
- ➲ **FOR OILY SKIN** Try cold parsley tea dabbed on several times a day.
- ➲ **HOMEMADE LIP GLOSS OR ROUGE** Mix a drop of food coloring with a fingerful of petroleum jelly. Kids have fun with this, and it won’t hurt their skin.

FOR YOUR BODY

For a recipe for herbal hand lotion, see “Products and Processes.”

Herbal Bath. Make a strong tea by pouring boiling water over your chosen herbs. Let steep while you draw your bathwater. Then strain into the water. Or just put herbs right in your bath water—either loose or in a little cheesecloth bag. Let them steep 10 minutes; then join them in there. Good herbs for bathing are chamomile, lemon verbena, mint, peppermint, and rosemary.

➲ **HERBAL BATH SALTS** With Epsom salts, mix sage, thyme, and pennyroyal; lemon balm and peppermint; lavender, rosemary, and pennyroyal; or another herb or herbal combination that pleases you. Or use Epsom salts with a few drops of your favorite fragrance or herbal oil mixed in. When bottled attractively, this makes a nice gift.

FOR YOUR HAIR

- ➲ **HEALTHIER HAIR** Take vitamin A and D supplements daily, plus 1 t. brewer’s yeast.
- ➲ **VINEGAR HAIR RINSE** Mix 3 T. vinegar per $\frac{1}{2}$ gal. water.
- ➲ **HERBAL HAIR RINSE** Rinse your hair in herb tea. Chamomile is best for blondes, rosemary for brunettes.

➲ **BALSAM HAIR RINSE** Pound 1 qt. balsam fir needles with a hammer to release the oils. Then soak them in cold water overnight. Rub in 2 T. of your balsam rinse after shampooing and rinsing. Rinse well again.

➲ **CHAMOMILE SHAMPOO** Barb Ingram, Santa, ID, says she uses this formula: Put 1 T. soap flakes, 1 t. borax, and 1 oz. powdered chamomile flowers into a basin. Add ½ pint hot water. Heat until thick lather is formed. Wet hair with warm water, massage, rinse, and wash again. (For a general herbal shampoo recipe, see "Products and Processes.")

FOR YOUR TEETH

➲ **HOMEMADE TOOTHPASTE** You can use common table salt for a toothpaste. It's rougher on your teeth and mouth and doesn't taste as good, but it's cheap and available. Takes care of bad breath too! Or use plain baking soda; baking soda with a drop of oil of spearmint, peppermint, cinnamon, or cloves in it; a mixture of 3 parts baking soda and 1 part salt; or, best of all, a mixture of 4 t. baking soda, 1 t. salt, 1 t. mint flavoring, and just enough water to get a toothpasty texture (about ½–1 t.). Keep any moist homemade toothpaste in a covered container so it won't dry out.

➲ **BREATH FRESHENER** Chew up some mint leaves!

WILD FOOD FORAGING

May 25, 1976. Last summer a forest ranger near here sat down to eat his packed lunch out in the woodsy open. He spotted an interesting-looking plant nearby, broke off a leaf, added it to the inside of his sandwich as an experiment, and ate his lunch. He was dead within 2 hours. A little boy 25 miles down the road from us at Lapwai, Idaho, spotted a big reedy plant that looked just right for whistle making. He carved himself a very fine whistle out of it, blew on it to see if it worked ... and died.

Those are true stories. They both happened in the summer of 1975, and in both cases hemlock was the cause. Hemlock is one of the most poisonous plants in the world. It belongs to the same family as the plant substance that killed Socrates when it was fed to him in a cup. That was water hemlock, which is native to Greece and causes death within 5 minutes. Hemlock has migrated from Europe to the United States and is spreading all over North America. It likes to grow in shady places and spreads along river and creek banks. The North American kind takes ½–2 hours to kill you.

POISONOUS PLANTS

Here are some poisonous plants to look out for. This list was sent to me by my dear friend Violet Stewart. She wrote me, "I hope you can find a space for this in your book. I'll feel I may have had a part in saving one life." I did find space—and since then I've learned and added more.

Aconite: All parts.

American False Hellebore

Anemone (wind flower): Nemerosa is poisonous.

Angel's Trumpet (*Datura*): All parts poisonous.

Arrowgrass

Azalea: All parts very dangerous—nausea and vomiting, depression, hard to breathe, prostration, fatal coma.

Baneberry: Berries, red or white, are poisonous.

Black Locust: Flower is edible; rest is poisonous.

Bleeding Heart: Leaves and roots may be poisonous in large amounts.

Bloodroot

Bouncing Bet

Butterflyweed

Castor Oil Plant (*Ricinus communis*): One or two castor bean seeds are a near fatal dose to an adult, let alone a child.

Celadine Poppy

Chokecherry: Leaves and seeds are poisonous.

Christmas Rose (*Helleborus*): Seeds and all plant parts are poisonous.

Cockle, Corn or Purple: All parts are poisonous.

Columbine (*Aquilegia*): Seed/all plant parts poisonous.

Crocus: Autumn crocus bulbs can be dangerous.

Daffodil: Bulb causes nausea, vomiting, diarrhea, and may be fatal. Sap makes your hand swell up if it gets into a cut.

Daphne: A few of the berries can kill a child.

Datura: See “Angel’s Trumpet.”

Daylily: Roots are poisonous.

Deadly Nightshade

Death Camas

Desert Rose (*Adenium*): The milky juice may be a heart poison.

Dieffenbachia: All plant parts cause intense burning and irritation of mouth and tongue. If the tongue swells and closes the throat, no air can get through.

Digitalis: See “Foxglove.”

Dutchman’s Pipe (*Aristolochia*): All plant parts are poisonous.

English Ivy

European Bittersweet

Foxglove (*Digitalis*): All plant parts poisonous. Leaves contain digitalis, a heart stimulant. In large amounts it can be fatal.

Frangipani (*Plumeria*): Poisonous sap.

Garland Flower: Poisonous berries.

Hemlock: Read the story at the end of this chapter.

Horse Chestnut, Horse Nettle, and Horsetail

Hyacinth: Eating the bulb will cause nausea, vomiting, diarrhea, and may be fatal.

Iris: Entire plant is poisonous.

Jack in the Pulpit

Jessamine: Berries are fatal.

Jimson Weed

Larkspur (annual delphinium): Poisonous seeds and leaves.

Larsonia: The seeds can be fatal.

Laurel: All plant parts can be fatal, producing nausea and vomiting, difficulty in breathing, prostration, and coma.

Leafy Spurge

Lily, Flame: All plant parts are poisonous.

Lily, Glory: The tubers are highly poisonous.

Lily of the Valley: The leaves and flowers disrupt heartbeat, stomach, and mind.

Lobelia: Poisonous.

Lupine: All plant parts, including seeds, poisonous.

Marsh Marigold

Marvel of Peru (*Mirabilis*): All plant parts poisonous.

Matrimony Vine

Mayapple: Poisonous; fruit is also poisonous if too much is eaten and must be yellow, totally ripe, and smell sweet.

Meadow Saffron

Mistletoe: Berries can be fatal to children or adults.

Monkshood (*Aconitum*): All parts, including roots, are poisonous.

Morning Glory (*Ipomoea*): All plant parts poisonous.

Mountain Laurel

Narcissus: Bulbs are poisonous—cause nausea, vomiting, diarrhea, and may be fatal.

Oleander: Leaves and branches are poisonous—affect heart, cause severe digestive upset, have killed.

Pennyroyal: Poisonous.

Poinsettia: Even one leaf can kill a child.

Poison Ivy

Poison Oak

Pokeweed: Young shoots up to 6 in., if free of purple coloring, are edible if boiled in a sequence of two discarded waters. Rest is poisonous.

Poppy, Horned (*Glaucium*): Roots are poisonous.

Poppy, Iceland: All plant parts are poisonous.

Poppy, Somniferum: Fruits and sap are poisonous.

Privet

Rhododendron: All parts can be fatal—nausea and vomiting, difficulty in breathing, prostration, coma.

Rhubarb: The leaves, even cooked, can cause convulsions and coma, soon followed by death.

Rosary Pea: A single seed has caused death.

St. Johnswort

Skunk Cabbage

Snowdrops

Solomon's Seal (*Polygonatum*): The seeds and all plant parts are poisonous.

Star of Bethlehem

Tobacco (*Nicotiana*): All species/plant parts poison.

Wisteria: Poisonous.

Yew: Berries and leaves (more so) are fatal. Death is sudden—no warning symptoms.

Hemlock is a biennial and a member of the carrot family. The first year it grows low and has a very carrot-like top; its energy goes into making a sturdy root, which is its most poisonous part. The next year, energy from that big root pours up into building a sturdy, tall stalk, 5–6 feet high—perfect-looking whistle material. Then it flowers and makes seed at the top of the stalk.

Its flowers and seeds are poisonous too. Some neighbors down the road with a lot of the stuff chopped it all down, gathered it into a pile, and set fire to it. The smoke made their whole family sick. The county weed control agent, Homer Fudder, told them that fumes from burning hemlock were also poisonous. Homer has a personal campaign to try to stop the hemlock and to stop people from dying of it. He told me you can even die if you try to pull out the plant and have a cut on your hand that hemlock juice gets into.

But you say you've got a book that tells you which wild foods are edible and which aren't. Well, right in front of me I have an article called "Principal Food Plants of the United States," published in an utterly respectable wilderness and country living magazine. It says, "HEMLOCK—(all year) young tips used for tea and formerly in root beer; inner bark used for breadstuff; sap, potable." It doesn't distinguish between the nonpoisonous hemlock tree and the poisonous hemlock plant. If that one entry in a list of a couple hundred "food plants" is so potentially misleading, how much can others be trusted? What about the books that describe plants that have "medicinal uses"? I found hemlock in one of those, too. It said it was "good to strengthen male potency."

Take it from a professional author. Don't believe everything you read. So often authors end up simply collecting information already in print—with the ever-present danger of passing on somebody else's error. Or they have to put the ideas in their own words so it isn't plagiarizing, and they end up restating something in such a way that the facts become distorted. Or they write down hearsay that simply isn't true. That's scary when the results could be fatal. That's why this book doesn't have a real wildfoods section. You'll find wild foods mentioned here and there within it: nettle tea, poke salet from the South, dandelion root and greens, elderberries and chokecherries—but only when I know from personal experience or from common experience of friends and neighbors that at least part of the

plant really is edible, and when it's commonly known and easily identified.

I don't mean to put down the bulk of the wonderful research that has been done on wild foods, but be cautious what you put in your sandwich. A good program on wild foods comes from Sherilyn Booth at Wilderness Leadership International: 509-738-4545; PO Box 1061, Kettle Falls, WA 99141. They sell correspondence courses in edible wild plants, using herbs, and wilderness survival. "Dining on the Wilds" is a 6-hr. video set with two manuals.

The Wild Foods Forum is published by Vicki Shufer, Virginia Beach, VA; 757-421-3929; wildfood@cox.net. Goosefoot Acres: Center for Resourceful Living publishes a *Directory of Edible Wild Plant Educators*, sells books, sponsors contests, and publishes a newsletter on using wild foods: 216-932-2145; orders 800-697-4858; PO Box 18016, Cleveland, OH 44118; petergail@aol.com; www.edibleweeds.com. Peter is a Ph.D. ethnobotanist, author of eight books, 250 articles, and inspiration of the National Dandelion Cook-off (first weekend in May; Dover, OH)! For \$35/yr, join Defenders of Dandelions, and get Peter's book, *Dandelion Celebration: A Guide to Unexpected Cuisine*, plus T-shirt or tote bag and newsletter, *Dandelion Doings*.

Could a rancher who had lived in the country all his life make a mistake in his plant identification? Just a month ago, I happened to be standing close by when three innocent visitors to the School of Country Living (Julaine Konselman, a young widow; her 12-year-old only son; and Jack Clark, a local businessman) ate hemlock after a local pointed out a plant he called "Indian celery" and urged, "Try it." (The showing-off-his-"knowledge" local didn't himself partake.)

I wish I'd managed to stop them before they swallowed the stuff. But I did break up their idyllic stroll through a pasture immediately after they ate it, rushed them to town, ran to the drugstore, bought Ipecac (the stuff that makes you throw up), and made them drink it. Jack and Julaine's son threw up, but she didn't. "I'm sorry," she apologized miserably. "I never throw up." Then I recruited friends to rush them the 28 miles to the emergency room of the Lewiston hospital, where all three got their stomachs pumped.

After a night's sleep, they all felt okay—good enough, in fact, that Jack kept wondering

if I'd put him through all that misery for nothing. The Ipecac and the stomach pumping was enough to make a person feel lousy, he figured. And the rancher kept insisting it really was just "Indian celery." So a week later, Jack returned to that pasture, picked a specimen of the exact same stuff he and the others had eaten, and took it to the office of a poison weed specialist at the University of Idaho. When he walked into the professor's office, it was noontime and the gentleman was reading at his desk. Jack set the plant down in front of him and said, "I ate some of that."

The scholar looked up from his book at Jack, and at the plant. His eyes widened. He half-rose from his chair. "How long ago?" he nervously asked.

"A week ago," Jack coolly replied.

There was a long silence. "You ought to be dead," the professor finally muttered. "You're very lucky."

"What is this plant?" Jack asked.

"Hemlock ... deadly poisonous."

Poison Control Centers

National Poison Hotline: 1-800-222-1222 (TTY/TDD)

This number is valid in every state and uses a routing system to direct incoming calls to a local poison control center. American Association of Poison Control Centers website is www.1-800-222-1222.info or www.poison.org. Of course, if a victim is not breathing or unconscious, call 911.

Alabama: Poison Center, Tuscaloosa: 800-462-0800 (AL only); 205-345-0600.

Children's Hospital, Birmingham: 800-292-6678 (AL only); 205-933-4050.

Alaska: Anchorage Poison Control Center, Anchorage: 907-261-3193.

Arizona: Poison & Drug Info Center, Tucson: 800-362-0101 (AZ only). Good Samaritan Regional Medical Center, Phoenix: 800-362-0101 (AZ only); 602-253-3334.

Arkansas: Poison & Drug Information Center, Little Rock: 800-376-4766; TTY/TDD 800-641-3805.

California: Poison Control System: 800-876-4766 (CA only); TTY/TDD 800-972-3323.

Colorado: Rocky Mountain Poison & Drug Center: 800-332-3073; 303-739-1123 (Denver metro).

Connecticut: Poison Control Center: 800-222-1222; TTY/TDD 866-218-5372

Delaware: Poison Control Center, Philadelphia: 800-722-7112; 215-386-2100.

District of Columbia: National Capital Poison Center, Washington, DC. Hotline for battery ingestion: 202-362-3867.

Florida: Poison Information Center, Jacksonville: 800-282-3171 (FL only); 904-244-4480; TTY/TDD 800-282-3171. Miami: 800-282-3171 (FL only).

Georgia: Poison Center, Atlanta: 800-282-5846; 404-616-9000; TTY/TDD 404-616-

9287.

Hawaii: Poison Center, Honolulu: 800-222-1222; TTY/TDD 866-218-5372.

Idaho: Rocky Mountain Poison & Drug Center, Denver: 800-222-1222 (ID only).

Illinois: Poison Center, Chicago: 800-942-5969 (IL only); TTY/TDD 866-218-5372 or 312-906-6185.

Indiana: Poison Center, Indianapolis: 800-382-9097 (IN only); TTY/TDD 866-218-5372.

Iowa: Statewide Poison Control Center, Sioux City; 800-352-2222; 712-277-2222.

Kansas: Mid-America Poison Control Center, Kansas City; 800-332-6633; 913-588-6633; TTY/TDD 866-218-5372.

Kentucky: Regional Poison Center, Louisville: 800-722-5725; 502-589-8222.

Louisiana: Drug and Poison Information Center, Monroe: 800-256-9822 (LA only).

Maine: Poison Control Center, Portland: 800-222-1222; TTY/TDD 866-218-5372.

Maryland: Poison Center, Baltimore: 800-492-2414 (MD only); 410-706-7701; TTY/TDD 866-218-5372.

Massachusetts: Regional Center for Poison Control and Prevention, Boston: 800-222-1222; 617-232-2120; TTY/TDD 888-244-5313.

Michigan: Regional Poison Control Center, Detroit: 800-764-7661; 313-745-5711; TTY/TDD 866-218-5372.

Minnesota: Hennepin Regional Poison Center, Minneapolis: 800-222-1222 (MN only); TTY/TDD 612-904-4691.

Mississippi: Regional Poison Control Center, Jackson: 800-222-1222; TTY/TDD 866-218-5372.

Missouri: Regional Poison Center, St. Louis: 800-366-8888; 314-772-5200.

Montana: Rocky Mountain Poison & Drug Center, Denver: 800-222-1222; TTY/TDD 866-218-5372.

Nebraska: The Poison Center: 800-955-9119 (NE & WY only); 402-955-5555.

Nevada: Oregon Poison Center, Portland: 503-494-8968. Rocky Mountain Poison & Drug Center, Denver: 800-446-6179 (NV only).

New Hampshire: Poison Information Center, Lebanon: 800-562-8236 (NH only); 603-650-8000.

OF GREEN LEAVES, AND COURAGE, AND FOOLISHNESS

INTRODUCTION

The bulk of what follows used to make up the “Sweets” chapter, and there was a lot more in it about how to make apple butter than about how to grow a tree. Now, as I sit down to write this new edition, I am more worried about preserving the topsoil, maintaining our atmospheric oxygen, and reducing the earth’s carbon dioxide level (and risk of a disastrous “greenhouse effect”) than I am in making sure you can cook apple butter. Apple butter is still here, but I’ve added as much as I could (not as much as I

wanted) about trees. Trees are the single most important answer to those 3 most critical challenges for the future of life on earth.

The massive, semipermanent root networks of trees forestall erosion and make possible a form of long-term agriculture that can sustain humans and their livestock without the loss of topsoil and the desertification of their agricultural land, which is the great risk of annual tillage for generations. The leaves of trees both yield oxygen and remove carbon dioxide as part of their natural chemistry. And, as if that isn't good enough, you can plant entire forests, or plantations, or farm crops of trees that also provide food. Fruit, yes, of course. But not just fruit. Tree fruits are wonderful: apples, pears, peaches, and nectarines from the temperate zones, and avocado, banana, persimmon, guava, and a long list of others that grow in warmer climates. In Central Asia there are forests made up entirely of various kinds of fruiting trees, all growing wild—gardens of Eden. In the United States before 1900 there were vast wild nut forests, mainly chestnuts, which made up a third or even a half of the total tree population, and under which the pioneers' pig herds roamed unintended—reproducing and flourishing until their surplus was needed for table meat. But the magnificent, towering hardwood forests of walnut and such have long since been cut down to make dressers and coffee tables. The Eastern chestnuts all died in the terrible epidemic of a new disease (some Western ones survived!)—chestnut blight—that struck the forests in the early 1900s.

There are trees that build up the soil—nitrogen fixers, exactly like beans, peas, and alfalfa in your garden and field. Mesquite is one, for example, and it also has the gift of being able to live in desert conditions. There are bread trees, bean trees, sugar trees, protein trees, chocolate trees. Some of each broader category are suitable for any major climate zone. You could feed your family and all your livestock entirely from trees (and some people do!). And, of course, the dead branches and overage trees are a practical fuel source and building material. All these possibilities exist so long as trees aren't cut down to clear land for the plow, or carelessly killed off by the burning of high-sulfur coal, which then causes the atmosphere to rain sulfuric acid down on them.

In certain areas of the Mediterranean, farmers for centuries have practiced a “2-story” agriculture. Tall trees are the upper story: carobs for stock fodder and olives for the delicacy of their fruit or cooking staple of their oil, or some other tree. Underneath the trees they may let pigs or cattle or goats roam to fatten on the tons of nourishing foodstuffs seasonally cast down from the generous tree branches above. Trees whose leaves and fruits are edible and relished by meat, milk, and egg producers are called “livestock fodder trees.” These trees are important because such an agriculture is virtually permanent and totally nondestructive. The trees and the pasture beneath them stay put so there is no soil erosion from tilling multiple times each year, no bare fields of dirt to blow or wash away. And the dense tree foliage and pasture beneath maximize the contribution green stuff makes to good air, as well as to meat supply. The Mediterranean farmers have a garden space, too, but it doesn’t have to be very big.

There are farmers in the United States who also do some variety of 2-story farming. They can turn swampy, marginal land into an almost effortless wealth producer by planting a forest of stock-feed dropping trees—not just accidentally this kind or that, but a carefully planned layout to provide as nearly as possible a year-round fall of fodder for the animals: one tree crop raining down its bounty early in spring, another that fruits in mid-summer, still another in fall, and another for late fall feeding. And the animals in turn nourish the trees by their manure. That’s how it has to be for this ecosystem to be

permanently healthy. The cycle has to be complete: plants give what animals need; animals return what plants need.

Or underneath and between their trees (which are perhaps 40 feet apart), these 2-story farmers raise annual crops of grain or vegetables. Because of the partial shade of the trees, their tilled crop doesn't yield as much as it would in full sun. But the Mediterranean communities of which I spoke have been doing this for centuries, and the depth of their topsoil and its fertility is undiminished, whereas in far too many neighboring countries there is bare rock or desert now where centuries ago fertile farms provided the basis of ancient civilizations. The success of their 2-story farming is due to the trees, which hold soil in place and perpetually enrich it with their annual generosity of falling leaves and fruits. (Did you ever hear of terrible famines like those of Ethiopia and Somalia happening to people who live in the middle of a dense forest? I haven't.)

Another form of 2-story farming is described in the Tilth organization's visionary classic *The Future Is Abundant* ("Chopaka Nut Orchard," by Michael Pilarski, p. 106): a nut orchard with 2 heights of trees. "The upper story of the nut orchard consists of walnuts, Chinese chestnuts, heartnuts and a few Turkish tree hazels (*Corylus colurna*). The middle story is composed mainly of filberts, with some pears, peaches, and plums. The south side of the orchard is planted to peaches and nectarines to take advantage of the warm, sunny exposure. On the west side grapes have been trained along the high deer fence which surrounds the orchard ... Bill [the grower] has found that spacing the walnut trees 60 feet apart and the filbert trees 25 feet apart is ideal." On the ground story of his orchard, Bill raises yet another crop, peacocks and peahens, which protect his trees from insects and also provide a cash crop from feathers that Bill collects during their molting seasons, plus sale of live birds. He also raises bees, which feed themselves from the tree blossoms, perform pollination duties, and make prime honey.

So we need to keep the trees we have. And we need to plant more. In England farmers love their pastures, and I've heard they fence them not with posts hacked from the bodies of dead trees but with ingeniously devised barriers made of closely growing and intertwined living trees called "hedgerows." Their hedgerows, made of ash, elm, heather, holly, ivy, and willow, provide some winter food for livestock, summer and winter harvests for people and animals, shelter for some wild critters, privacy, and a guaranteed role on their land for trees. For how to create one, refer to *Hedgerow* by Eric Thomas and John T. White (New York: Morrow, 1980).

We need to shut down or convert the high-sulfur coal-based industries and replant the forests that have been poisoned. We need to replant as much as possible of all the earth's lands that were once forested. In areas where natural rainfall supports forests, we need to make a conscious agricultural evolution from an open-field-based agriculture to a tree-based or 2-storied agriculture. That's the next great agricultural revolution.

I have an insistent vision of a wonderful earth thousands of years from now, with healthy air and water and healthy, happy, cultured, literate humans living on it. They survive and thrive in carefully maintained balance and companionship with and humble service to the plants and animals that sustain them. In those places where trees can naturally grow, I see people living contentedly under a canopy of green leaves.

I like the idea of planting trees for grandchildren—or for generations to come. As each year goes by, other people's children look more like my children to me. The older I get the more it feels like I'm related to everyone I meet and that the children and their children to come are all somehow my offspring, too. I'm understanding at last in a fully integrated way that all humans are ultimately family, and beyond them, we are connected to all animals, too, and beyond them, with all life. Yes, related to a tree. And not so distantly as

we might think. Trees and people are far more closely related to each other than either is to a rock!

Choosing trees to plant can be very exciting. How about a Dawn Redwood, one of the ancient species that dates back to the Upper Cretaceous era, 100 million years ago? How about the honey locust, a wonderful drought-resistant cold-hardy tree that will grow hundreds of pounds of pig and cattle fodder each year for winter feeding and also, being a legume, enriches the soil? Plant a tree for your anniversary, or your birthday, or Arbor Day, or ... It's actually good to mix your species. Get the right combination and you have an ideal permaculture.

NOTE: For easier reference, most recipes in this chapter are grouped together with a particular nut or fruit. However, preparation details are not repeated each time if they are covered in Chapter 7. If your recipe seems incomplete or vague, refer to that chapter to find the rest of the processing information.

PLANTING A TREE

Someone asked Martin Luther, "What should I do on the last day of earth?" Luther replied, "Plant a tree."

It's a wonderful, spiritual thing to plant a tree. Each tree is a living thing that can share the rest of your life. It will grow and give you shade, elegant beauty, food to eat, and branches for birds to nest in and children to climb in and for you to hang your hammock on and take a well-deserved nap. No matter what, plant one or more trees every year. And plant as many—or more—as what you take out. If you're planting various kinds of trees your harvesting will be staggered because they grow at different rates and you may be harvesting different sorts of products from them. You can sell Christmas trees, nuts, maple syrup, firewood, fence posts, sawlogs, and fruit. If you have livestock fodder trees, you can get rich selling pork, because pigs can more easily get a total diet from tree crops than any other animal. So plant some nut, fruit, sugar, stock forage, timber, or woodlot trees every year on your land. And if you don't have land, or have no more room, then plant them on someone else's land, doing your share to guarantee our mutual future.

NETWORKING: To network with other dedicated tree planters, contact TreePeople: 818-753-4600; fax 818-753-4635; 12601 Mulholland Dr., Beverly Hills, CA 90210; treepeople@treepeople.org; www.treepeople.org. Friends of the Trees, based in Tonasket, WA, seeks solutions to world deforestation and offers programs, seminars, and info at local, regional, national, and international levels (www.friendsofthetrees.net).

A TREE QUIZ

Hint: All answers are shrubs or trees that bear an edible crop.

1. If you can grow oranges on your irrigated fertile bottom land, what tree will thrive on your steep, rocky, poor-soil, arid hillsides?
2. What temperate-zone fruit has an 8-to 12-inch deciduous leaf, bears a delicious 5-inch fruit, is hardy to -30°F, can grow in partial shade, can handle the competition of being in the middle of a lawn, and is virtually pest-and disease-free?

free?

3. What tree takes 40 years to reach full maturity but then will produce a generous human-food and stock-food crop annually—even through drought and total neglect—for centuries?
4. What tree, hardy to 20°F or able to live in a container and winter in a basement, will bear 2 crops of fruit, one in June and the other in August, and (out of the South) is usually not bothered by pests or diseases?
5. What temperate to subtropical zone fruit will grow in subsoil clay where all the topsoil has washed away, or in sand; is drought-resistant once established; can grow in a lawn; can provide ripe fruit continuously from August or September to December or February; will store fruit in good condition on the tree all that time (or the fruit will keep on the ground for another month or two, even after freezes); bears fruit generously; and yields prized carving wood?
6. What plant that is not a pear, but is related to the pear, is a good choice if you have poorly drained soil. This plant can produce yellow, baseball-sized fruits in zones 5–9 despite late frosts, or drought.
7. What temperate-zone fruit tree can grow almost anywhere, can handle the competition of a lawn, heavy or poor soil and poor drainage, could get along on one deep watering a month, needs little pruning, is immune to fire blight, can produce for up to 75 years, and bears fruit you can store in your cellar 2–3 months while you get around to eating or preserving them?

Answers to quiz: 1. Carob. 2. Pawpaw. 3. Carob. 4. Fig. 5. American persimmon. 6. Quince. 7. Keiffer pear.

For more tree information, contact American Forests: PO Box 2000, Washington, DC 20013; 800-545-8733; fax 202-737-2457; info@americanforests.org; www.americanforests.org; www.historictrees.org. And The National Arbor Day Foundation; 888-448-7337; 100 Arbor Ave., Nebraska City, NE 68410; www.arborday.org.

Read *The Theory and Practice of Agroforestry Design* by Paul A. Wojkowski (1998); *Tree Crops: A Permanent Agriculture* (1987) by J. Russell Smith; and *Temperate Agroforestry Systems* (1997) by Andrew M. Gordon and Steven M. Newman, eds. If you live west of the Rockies, read Lance Walheim and Robert L. Stebbins's classic of technical how-to: *Western Fruit, Berries, and Nuts: How to Select, Grow, and Enjoy*. Readers east of the Rockies will profit from Theodore James Jr.'s book, *How to Grow Fruit, Berries, and Nuts in the Midwest and East* (1983). The Association for Temperate Agroforestry (AFTA) encourages use of permaculture know-how in temperate North America, combining trees and shrubs with crops and/or livestock to increase and diversify farm and forest production while conserving natural resources. They publish a quarterly newsletter, *The Temperate Agroforester*, cosponsor a biennial conference, and supply tree crop info: 573-884-3216; fax 573-882-1977; 203 ABNR Bldg., U. of Missouri, Columbia, MO 65211. And see "Agroforestry Overview" at www.attra.ncat.org and search for agroforestry or order a print copy (it's free) from 800-346-9140.

The USDA's National Agroforestry Center offers info, too (Alley Cropping; Forest Farming; Silvopasture; Windbreaks; etc.): www.unl.edu/nac. Rodale's Agroforestry Articles & Resources has an article on "Little-Known Acacias [such as *A. baileyana*]: Promising Agroforestry Species" at fadr.msu.ru/rodale/agsieve/txt/agrofor.html. Plants for a Future (a database of 7,000+ useful species of plants, worldwide!, with details on how to grow and uses) has a website section on "Edible Trees and Shrubs" at www.scs.leeds.ac.uk/pfaf/index.html. The Australasian Tree Crops Sourcebook is another amazing online resource, listing all sorts of nut, fruit, and timber tree crops (and plant sources of useful oils) with links to plant sources: www.aoi.com.au/treecorps.

Guerrilla Tree Planting

I'm for it, urban, or rural: guerrilla tree planting. Choose the right species for the climate and suitable sites: a neglected space on private land, or an open one on public land. Then you sneak up and plant your tree there. Trees can handle a lot of crowding; 15 feet apart is fine in a forest setting. During the planting seasons of spring and fall, plant trees on your weekend outings. Plant trees on your holidays. Don't leave town without some seeds or seedlings in your back seat. Don't go picnicking or backpacking without a few gifts to the earth in the form of seeds or seedlings: evergreens, or fruit or nut trees. You can start them in a nursery bed in your yard, or in a flat or pot in your window. Plant in the morning sun or by the full moon. Keep a private tally: how many trees you've planted so far. Take pride in it. Go back and visit some of them years later and say, "Hi, I'm your parent. My, but you're looking good!" Expect some losses; it's okay.

If people are the whole problem, people can just as easily be the whole answer. All they gotta do is do it. A guerrilla tree-planting friend, ex-Vietnam vet, proposed with a crooked grin and a twinkle in his eye, "Let's cluster-bomb the planet with trees!"

Amen.

It takes a long time for a tree to grow, and some of them may not make it. And, sooner or later, grown trees, like people, die of old age. But then they can be fuel or building material, or a home for wild things until they finally decay and become food for other trees in the fullest completion of their life cycle. In the space where they once lived, plant new trees, continuing their spirit of hope. Plant a tree for your housewarming, and one for each anniversary, one for farewell—any excuse will do, the more often the better!

Hopefully you'll end up with a big, diversified nut and fruit orchard, and vine and berry plants, too. You'll probably be surprised at the amount of fruit and nuts your family could use if they had all they wanted. I canned 100 qt. of cherries last summer, and here it is the first day of February and I have only 1 qt. left. But I still have apricots, plums, grape and tomato juice, apple plum butter, and a lone jar of applesauce, so we aren't clear to the end. The cherries are my family's favorite fruit, and I haven't been too strict on the rationing. As the year wears on and the favorite fruits like cherries, peaches, and pears are eaten up, the others start looking better and tasting better to them. Your local extension agent or nursery can advise you what varieties do best in your climate, when they ripen, what pollinators they need, etc.

Climate

Is your climate subtropical or tropical, or temperate? What fruits you grow depends mainly on climate unless you're doing greenhouse farming. The amount of sunshine falling on leaves directly affects the plant's rate of food production in its leaves. The more

sunshine there is, the greater the fruit production per acre. The farther north you live, the higher in altitude you are, the shorter your frost-free season. In colder areas you may be limited to apples and cherries, and colder than that to crab apples. Colder yet, and chokecherries or sand or bush cherries, gooseberries, and maybe a few other berries are your only possible fruit crops. The farther south you live, the more fruits you can add to the list. But temperate-zone fruits won't do well where bananas grow. Deciduous trees need a cold winter for their normal annual cycle. Each temperate-zone species usually needs a specific number of hours spent below a certain temperature in order to break its dormancy and make it resume growing and bearing fruit normally again in the spring: its "chilling requirement."

If you live in a hot zone, here's a letter from Ella Hupman, Fort Lauderdale, FL, that's bound to set you dreaming. "Dear Carla, We decided that it was just as easy to raise vegetables as flowers and grass, and fruit trees instead of shade trees. We took out all our areca palms and planted about 10 varieties of bananas. Also put in orange, grapefruit, tangerine, avocado, mango, Key lime, lemon, calamondin, and carambola trees. After 3 years of gardening, we know what vegetables we can produce with greatest success. Our tomatoes have been most successful and I've canned them in every form. Rabbits are our source of fertilizer besides a source of meat."

She didn't plant any apple, cherry, apricot, plum, peach, nectarine, or pear trees. Those are temperate-climate fruits. So you can be blessed with fruit wherever you live—but not necessarily the same fruit. However, there are some tropical fruits you can grow in a tub and bring in when it's too cold for them outside: banana, pygmy date palm, everbearing fig, pineapple, pomegranate, and dwarf citrus.

Choosing Your Plants

You need expert advice about what combinations to buy.

POLLINATORS: Some nut and fruit trees, and vines (such as kiwi), can't make fruit alone; they can be either male or female, and they need another tree to be a pollinizer for them. Other trees are "self-fruitful" or "self-fertile" or "self-pollinating." There are trees that are kind of in-between; they'll produce some harvest, but only a small crop unless they get cross-pollinated by a different plant. Trees that are to be wind-pollinated should be planted within 100 feet of each other.

LATE FROSTS: If there happens to be a freeze while fruit or nut flowers are blooming, there will be no crop of fruit. Having as large and diversified a fruit patch as possible guarantees that, although frost will probably catch some of your trees in bloom (and pests and diseases may take a toll on others), lots more will still make it through, because different kinds of fruit and different varieties of the same fruit have different blossoming dates—earlier and later. Furthermore, if late frosts are a problem in your area, you can avoid trouble by seeking out varieties that bloom late enough to be fairly safe.

SIZE: DWARF, SEMI-DWARF, AND STANDARD: One of the main questions you have to ask when shopping for a tree is, "How big will it get?" Little seedlings can grow into awesome 100-foot giants. Don't choose a size you'd have to keep amputating to live with. Better to go with a genetically smaller one. You'll often have a choice between dwarf, semi-dwarf, and standard-sized trees. The big difference in the trees is the rootstock. If you decide to do your own grafting, you will be offered a choice of dwarf, semi-dwarf or standard

rootstocks, and as the rootstock is chosen so the tree will grow.

Dwarfs are, of course, smaller, so most growers can spray, prune, or pick fruit easily. Dwarfs don't need nearly as much room to grow as standards. If you have a small yard in a city, the obvious choice would be to divide the area among different kinds of dwarf fruit trees for as much variety as you could get for the given area. Many years ago dwarf trees were more expensive. That was when they were becoming popular and demand was greater than supply. Now at the nursery I go to, dwarf, semi-dwarf, and standards are exactly the same price.

Production Time/Amount. Somebody wrote and asked me, "What trees produce the fastest and largest quantities?" The answer is: not the same ones. That's the big decision in dwarf versus standard. Dwarf trees bear fruit sooner. A standard apple tree may not produce fruit for 6–8 years, while a dwarf may in 2–4 years. (Apple takes the most time.) The fruit is the same size on either tree. However, standards produce the largest quantities of fruit per year per tree once they get going, and they will live longer than dwarf varieties. A dwarf tree will live for maybe 25 years, a standard tree for maybe 40. Semi-dwarfs are a compromise between the extremes. You have to make your own decision based on goals for your family and your orchard and then get the appropriate kind of tree.

TRANSPLANTING "WILD" TREES: Evergreen seedlings can usually be transplanted. In fact, curious but true, forest conifers that have already been transplanted once tend to have stronger roots and grow better when transplanted a second time. At the other extreme, most nut trees, wild or domesticated, have a central taproot that grows straight down. Any tree with that sort of taproot will not transplant successfully if the taproot is cut or broken off, or even bent over, when replanting. Thus nut trees over 6 feet are a high risk to transplant—whether from the wild or the nursery.

Tree/Fruit Propagation

PLANNING YOUR ORCHARD AND BERRY PATCH: It takes a few years to get production going (unless you inherit mature plants). In the meantime you can compensate by scavenging for wild fruit and berries. Find out where they are and when. The general rule is to freeze berries and can fruit, but you may also can berries, or dry any of them. You'll want a good supply of canning jars. Figure on at least 80 qt. of fruit annually for a couple and 40 more for each child, and that's a desperate minimum. That's only 1 qt. a week per person during the 9 months when fruit is out of season. Then you can use rhubarb, strawberries, raspberries, cherries, and early apples to carry you until the later, larger fruits are ripe again.

SEEDLINGS VS. GRAFTING: Nursery and mail-order trees may be seedlings or grafted trees. Seedlings have some definite drawbacks compared to grafted, or "named," trees. Grafting gives you the hardiness of a "native" (near-wild) rootstock combined with the fruiting ability of a highly selected variety of branch. So grafted trees usually have better weather or disease resistance, bear larger nuts or fruits, may bear more regularly, and yield heavier crops than seedlings, and are totally predictable in performance. With seedlings, you never know for sure what kind of tree or product you'll get because of its wide range of inherited possibilities; only about half, or less, of the progeny will probably be top-notch. You could wait a long time to find out if your tree is worth keeping. You can avoid

that problem by choosing grafted (or budded) trees.

GRAFTING AND BUDDING: To plant an orchard you may plant seeds, but usually you'll start by buying young trees from a local nursery or by mail-order. Eventually you might get involved enough to want to do your own grafting and budding. The main principle of grafting is that if you graft a Golden Delicious branch onto the rooted stub of another young tree, the future tree will produce Golden Delicious apples, even though the rootstock may have been from a different variety. Grafting techniques go back to the Romans, or maybe earlier.

To do your own grafting, you can buy rootstocks from a nursery or mail-order house. Or grow your own from seed. You could get prunings from neighborhood fruit trees to graft onto them. Any twig will do it. But the twig will fruit like the tree it came from. So you're probably better off buying top-quality plants for grafting or select from your own good-quality stock.

Grafting and budding are easily learned. Get a neighbor who does it to show you how or you could order the booklet *Grafting Fruit Trees* from Storey's, Schoolhouse Rd., Pownal, VT 05261. A wonderful book on this subject is *Plants-a-Plenty* by Catherine Osgood Foster (Rodale Press, 1977). Someone in your area probably offers a grafting course. Ask your extension agent, or ask around at nurseries. In this case, watching somebody doing it is the best way to learn. But in general:

To graft, cut off the top of a young rootstock tree. Rootstocks are selected to get roots that are resistant to disease, and hardy against cold winters, early frosts, poor soil, lack of moisture, etc. You can grow your own from seed or order it from a fruit specialist such as Adams County Nursery, PO Box 108, Aspers, PA 17304, which carries a large selection of rootstocks.

The fruit-tree part is usually chosen for abundant production of quality fruit. Select a whip or branch that has one or more buds. Cut off the bottom of that young fruiting tree. Make the cuts for both top and bottom in a matching zigzag so the fruiting top and rootstock will fit together tightly and firmly. Now fit the top into the bottom and bind them in place. Eventually they'll grow together.

If you're budding, the difference is that instead of cutting off the whole top of the rootstock, you place just one bud of the fruiting selection into and beneath a slit cut in the bark of your chosen rootstock. As new branches grow, prune away any that are from the rootstock rather than from the bud, or graft.

GRAFTING AND BUDDING DEFINITIONS: A top (scion) from a plant with good heredity for fruiting is patched onto a bottom (rootstock) with good root and trunk qualities so they'll grow together and give you the best of both. Here are some other relevant definitions:

- Multi-stemmed: The plant will have more than one trunk.
- Rootstock: The bottom, root part of a graft combo.
- Scion: The top of a graft combo.
- Spur: This is a short special-purpose twig that certain fruit trees (apples, pears, etc.) grow flowers and fruit on.
- Stone Fruits: Apricots, cherries, nectarines, peaches, and plums have a hard cover over their seed—so they're the “stone fruits” or “drupes.”
- Sucker: When the rootstock (or root) decides it wants to grow a top of its own and sends 1 or more new stems up, those are suckers. Suckers must be promptly cut off

from a grafted plant or they'll take over. Some plants sucker a lot naturally (pawpaw and jujube), and will form a thicket if you don't keep the suckers cut back.

- **Taproot:** Certain trees have a large central root growing straight down from its center way down. This is the taproot. The opposite of a taproot tree is one with a spread-root system. Taproot trees can pull up water from the water table so they're drought resistant, but they're hard to transplant once that root gets very long.

PROPAGATION BY CUTTINGS: A cutting is a piece of a parent plant that when planted on its own can develop into an independent plant. You can plant a cutting taken from the branches (a "stem cutting") or a piece of root ("root cutting") or in some cases you can even use a single leaf ("leaf cutting"). You can take a cutting from a dormant plant or from one that is actively growing in the spring and early summer. Later than that you are past the time for planting cuttings. Your planted cuttings need halfway agreeable weather, protection from getting dried out—keep them well watered until they take—and protection from curious children who would pull them up to see if they've got roots yet!

In general, for a shrub or tree-type plant, you cut off an entire branch of the previous season's growth (1–2 feet), or the end of a branch, or a sucker. Don't cut it off until the plant is in thorough dormancy, its leaves all dropped if it's deciduous. Plant the cutting, half underground and half above, in suitable soil for the type of plant in the place you intend for its permanent home, since transplanting is risky and stressful for the plant. When you want some berry or grape plants, or more berry or grape plants, you don't plant a seed—you plant a "cutting" of some sort.

PROPAGATION FROM SUCKERS: Many berry runners travel under the ground like the nuisance lilac "suckers" and then pop up anywhere to reach for the precious light. Various trees and shrubs put out suckers too. Any plant that suckers from the roots is a good bet for propagation by this method. In the spring you just dig up these nearly independent sticklike shoots, replant them where you want them, and with luck and care they'll go ahead and grow.

TREE SEED? If yours is a grafted tree, this is not a good idea. If you plant a pit from your prized cherry or apple tree, the chances are significant that the offspring will have little in common with the parent. The offspring fruit, if any, might be very small and sour. The reason fruit seeds from grafted stock don't breed true is because the top of the tree is usually grafted onto a hardier rootstock, but one whose seed may not have the fruiting capacity of the top part.

GROWING TREES FROM SEED? The answer is that sometimes you can, and sometimes it's practical. When it works, it's certainly the cheapest, easiest way to get a tree. You just plant the seed wherever you want the tree to grow. There's no expensive purchase, no transplanting, no early pruning needed. Growth from seed is how the great wild nut, fruit, etc., forests of the earth got planted and replanted—by squirrels who buried nuts and forgot where, or fruits that were carried away by hungry critters who consumed the tasty flesh and left behind the unwanted seed. Growing from seed does mean a few years longer to wait before bearing—and 99 percent of the time, growth from seed results in a plant not as high in quality as one you might obtain through grafting or budding from a plant with known, superior abilities. A tree that was grown from a seed is called "a seedling."

In general: Wait to take seeds from the fruit until it is fully ripe, but don't let them stand

in fermenting juice an overly long time; that might kill the embryo. Dry the seeds and store them until late autumn. Plant 3 inches deep. The winter chill and freezing will break the seeds' dormancy, and next spring they will grow. (Specifics are found below under each fruit.) Or order fruit tree seed to plant. You've a better chance of getting good heredity doing that.

Buying Tree, Vine, Bush, or Bramble

If you can, avoid buying fruit trees mail-order. Or buy mail-order from nurseries that are near where you live—or located in the climate zone where you live. The catalog salesmanship is great, but in the long run I think you'll be happier with what you buy in person from a local nursery. The mail-order trees are cheaper. They are also smaller and in worse condition and get off to a much poorer start. Your local plant nursery knows expertly what trees are already acclimated, and if your tree should die they will quite likely replace it for you at no charge if you ask (save your receipt!). Buy the biggest (oldest) trees you can afford. It takes them long enough to grow anyway.

BARE Root: These are plants sold with no soil around their roots. They are usually deciduous perennials, dug while dormant. Bare root is an affordable and healthy way to buy.

GENETIC DWARF: This plant is a natural shortie and not a standard plant grafted or budded onto dwarfing rootstocks. Genetic dwarfs are smaller than plants on dwarfing rootstocks.

CATALOG SOURCES

NOTE: These sources primarily carry trees and fruits. General seed and plant suppliers are listed in Chapter 2. Very specialized nurseries are listed with their plant entry but are not listed here.

California

Exotica: Rare Fruit Nursery ships one of the world's largest selections of fruit trees worldwide. Their list includes acerola, Asian pears, bamboo, bananas of many sorts, carob, cherimoya, Surinam Chercitrus, coffee, curry leaf, figs, ginger, guavas, jujube, kiwi, loquat, longan, lychee, mango, mulberries, palms, papayas, passion fruit, persimmon, pineapple, quince, pomegranates, sapotes, star fruit, sugar cane, tamarind, pine nut, cashew, chestnut, ginkgo nut, Italian stone pine, jojoba, and macadamia; 760-724-9093; fax 760-724-7724; PO Box 160, Vista, CA 92083. Visit them at 2508-B E. Vista Way, Vista, CA; www.exoticararefruits.com.

Midwest

Seed Savers Exchange offers a 40-pg color catalog of heirloom vegetables, all open-pollinated. A truly unique selection of outstanding vegetables, flowers, and herbs: 297 varieties produced by networking home gardeners: 563-382-5990; 3094 N. Winn Rd., Decorah, IA 52101; www.seedsavers.org.

Southmeadow Fruit Gardens offers a very large collection of old, new, regular, and rare fruits. Free price list: 269-422-2411; fax 269-422-1464*51; Box 211, Baroda, MI 49101; www.southmeadowfruitgardens.com.

Northeast

Adams County Nursery is a wholesale/retail operation that serves the northeastern U.S.:

Michigan to Maine, south to Virginia. Their free catalog offers a large selection of rootstocks: apple, plum, sweet cherry, nectarine, and peach; and detailed, good instructions on pruning apple trees: PO Box 108, Aspers, PA 17304; 717-677-8105; fax 717-677-4124; acn@cvn.net; www.acnursery.com.

Miller's Nursery offers berries, grapes, apples, nuts, and plums. Catalog: 800-836-9630; 5060 County Rd. 16, Canandaigua, NY 14424; www.millernurseries.com.

Nourse Farms specializes in small fruit plants: strawberries, raspberries, blackberries, blueberries, currants, etc.: 413-665-2658; fax 413-665-7888; 41 River Rd., South Deerfield, MA 01373; www.noursefarms.com.

F. W. Schumacher Co. specializes in seeds of trees and shrubs such as Christmas trees, etc. Good, conscientious folks. Details to plant each seed species on their website: www.treeshrubseeds.com; 508-888-0659; fax 508-833-0322; PO Box 1023, Sandwich, MA 02563-1023.

St. Lawrence Nurseries is an apple specialist, offering 100+ varieties and also specializing in fruits and nuts for northern climates (pears, plums, cherries, Juneberries, grapes, blueberries, lingonberries, mulberries, raspberries, edible ornamentals, nuts, and timber trees, all raised in their own nursery). They also sell books, tools, and tree tags: 315-265-6739; 325 State Hwy. 345, Potsdam, NY 13676; trees@sln.potsdam.ny.us; www.sln.potsdam.ny.us.

Northwest

Burnt Ridge Nursery specializes in unusual trees, shrubs, and vines that grow edible nuts or fruit: Carolyn and Michael Dolan; 360-985-2873; fax 360-985-0882; 432 Burnt Ridge Rd., Onalaska, WA 98570; mail@burntridgenursery.com; www.burntridgenursery.com.

C & O Nursery is a wholesale/retail fruit-tree specialist; catalog: PO Box 116, Wenatchee, WA 98801; 800-232-2636; tree@c-onursery.com; www.c-onursery.com.

Cloud Mountain Farm is a demonstration garden par excellence, a nursery that sells young fruit trees, and also a teaching facility: 6908 Goodwin Rd., Everson, WA 98247; 360-966-5859; info@cloudmountainfarm.com; www.cloudmountainfarm.com.

Columbia Basin Nursery sells fruit trees and rootstock, wholesale/retail. Brochure: 800-333-8589; 509-787-4411; fax 509-787-3944; Box 458, Quincy, WA 98848; www.cbnllc.com.

Raintree Nursery offers 500 varieties of fruit, nut trees, bamboo, and berries: aronia, akebia, sweet gooseberries, currants, figs, persimmons, mulberries, lingonberries, alpine strawberries, pawpaws, etc. Free 88-pg catalog: 800-391-8892; 391 Butts Rd., Morton, WA 98356; customerservice@raintreenursery.com; www.raintreenursery.com.

Van Well Nursery sells fruit trees wholesale or retail; catalog: 509-886-8189; 800-572-1553; fax 509-886-0294; PO Box 1339, 2821 Grant Rd., East Wenatchee, WA 98802; vanwell@vanwell.net; www.vanwell.net.

South

Vernon Barnes & Son Nursery offers fruits, nuts, and berries mail-order at bargain prices and good service. Free catalog: 931-668-8576; fax 931-668-2165; PO Box 250, McMinnville, TN 37110.

Cumberland Valley Nurseries sells fruit trees, wholesale and retail. Free catalog: 931-668-4153; PO Box 471, 394 Shaffie Lane, McMinnville, TN 37110;

fruitrus@blomand.net.

Hidden Springs Nursery offers organically grown unusual and disease-resistant varieties including apple, pawpaw, mulberry, persimmon, and quince; catalog \$1; 170 Hidden Springs Lane, Cookeville, TN 38501; 931-268-2592; www.hiddenspringsnursery.com. Conscientious service from Annie!

Ison's Nursery and Vineyard offers fruits, nuts, berries, and grapes, wholesale or retail; catalog: 800-733-0324; 770-599-6970; PO Box 190, 6855 Newnan Hwy., Brooks, GA 30205; www.isons.com.

Lawson's Nursery offers a free b/w catalog. Jim Lawson does his own grafting/budding. Trees: delicious quince, butternut, filbert, plum, fig, peach, pear, apple, grapes, gooseberry; walnut cracker, pecan trap (roll it across the ground and it picks up anything round!). Old-fashioned and unusual apples (more than 100 varieties): 770-893-2141; 2730 Yellow Creek Rd., Ball Ground, GA 30107; lawsonsnursery@aol.com; www.lawsonsnursery.com.

Ty Ty Nursery specializes in nuts, fruits, and berries for Southern growers: 888-811-9132; PO Box 130, Ty Ty, GA 31795; www.tytyga.com.

West

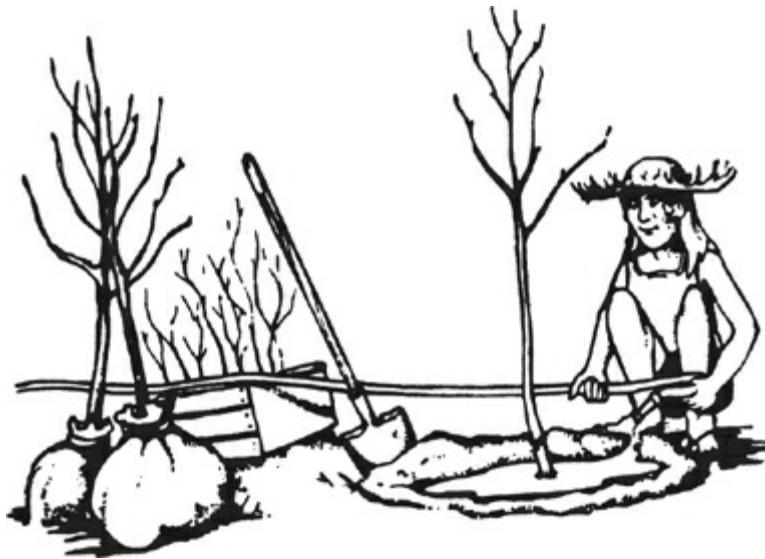

Pikes Peak Nurseries sells retail and wholesale fruits, nuts, berries, grapes, etc.: 719-632-4751; fax 719-630-8902; 630 Abbott Lane, Colorado Springs, CO 80905; lelandppn@aol.com; www.pikespeaknurseries.com.

TREES TO REJECT

1. Any tree that can't stand up without support.
2. Any tree with bark wounds on its trunk. (Look under the tree wraps.) Such a tree has a much lower chance of survival.
3. Any big tree in a small pot. An 8-foot tree with a trunk that's 1 inch in diameter needs a rootball about 1½ feet in diameter to be healthy.
4. A tree with kinked or girdling roots. However, it's hard to detect these because they are often deep within the rootball.
5. Species that are known to cause problems with dropping limbs, by raising sidewalks, getting pests and diseases, or perishing from climate extremes.
6. Look out for varieties that are merely ornamentals—such as “flowering almonds” or “flowering plums, quince, pears, etc”. They grow flowers, but not necessarily nuts or fruit.

How to Plant a Tree

In general, the best time to plant a tree is in the early spring or the late fall, but research your specific plant in case of exceptions. Where to plant is the spot where the tree will have the amount of sunshine it needs—full or partial, as specified; full if not specified. And, if it isn't hardy, plant it where it will have shelter from the wind. Plant big deciduous (shade) trees on the south side of the house where they will shade in summer and let warming light enter your windows in the winter. Conifers do well as winter windbreaks on the north or windy side of the house. (Wisely placed trees can improve your home's heating/cooling situation a lot!)

SITING URBAN TREES: Proper siting of trees that must compete in an urban setting is a challenging art and science and something landscapers do for a living. A tree that lives 200 years in the forest has an average urban life span of only 20 years. (Incidentally, the more urban your dwelling, the shorter *your* probable life span also.) Above all, plant where the tree will have enough room, both for its above-ground growth and its rooting area. Imagine the full-grown tree 10 or 20 years from now. How close are walks, driveways, windows, houses, and cars?

- Keep in mind that fruit and nut trees can be a problem in the middle of a lawn. Mowers frequently damage young trees; or the droppings from mature and fruiting trees (especially nut trees) can damage mowers. The moistness of lawns can contribute to fungal disease in the tree. And the dense grass planting competes for food and water with your tree and will probably reduce the size of the harvest you might otherwise have from it. On the other hand, if the lawn is the only place you have, then do it anyway. Plant that tree!
- Don't plant under telephone lines unless the expected mature maximum height will be substantially less than the height of the wires (usually 25–30 feet).
- Watch for fire hydrants; sewer and water lines; and underground gas, electric, and cable lines. Most cities will send someone out to locate underground utilities for you for at no charge—and be grateful that you cared enough to ask. Your phone directory or operator will tell you whom to call.
- Don't plant your tree where it will obscure a stop sign or make it impossible to see around a corner, or otherwise impair drivers' visibility. A big tree close to a street can risk impact between trucks and branches.
- Sidewalk planting strips less than 5 feet wide are not big enough for any but the smallest (mature height shorter than 30 feet) species of trees. Near a sidewalk branches can be a problem to pedestrians. And powerful roots can eventually buckle the pavement. Plant any larger-sized tree in the yard.
- There is a long-standing notion that tree roots don't go out beyond the drip line on the outer circumference of the branches and that they go very deep under the trees. Certain kinds of trees (nuts) do have very deep taproots. But all the trees tend to root more spread out, wider, and shallower than imagined. A lot of tree roots are in the top 18 inches of soil. Deep digging around them can harm those roots. That's why herbicides laid on a lawn may harm a tree at the edge of the lawn.

DIGGING A HOLE: Dig planting holes wide and shallow, no deeper than the rootball's size, and make them wider than needed to accommodate the tree's spreading roots. The larger the area that you dig up around the hole in preparation for planting the tree, the easier it will be for its roots to spread and find food and water. Remove any grass for 3 feet in diameter.

Testing for Clay or Compacted Soil. Dig a hole about 10 inches deep (a shovelful), and fill it with water. Check it again in 10 hours (overnight). Is it empty? If it has drained less than an inch an hour, you have a serious drainage problem.

Soil. Any kind of tree that needs "well-drained soil" is at risk to drown within 2 years if it's planted in compacted and clay-type soils—those that are poorly drained. Instead, plant tree varieties that are adapted to poor drainage—hardy plants that don't specifically need "well-drained soil." Or else rebuild the soil in a very large rooting area for your tree by working lots of organic material into the top 12 inches of dirt; or bring in better soil from somewhere else and create a large planting mound out of it. And dig wide: every inch of diameter dug out to the side before planting literally increases your tree's chances of survival in such difficult soil. It may also help to set the tree higher than usual in the planting hole. The sides of a hole in clay should be left with a rough surface rather than slick-cut by the digging tool. Don't work clay or saturated soils on the day you plant. Do your digging a bit ahead for the most normal soil structure to put the tree into.

Built-In Special Drainage. This is an option if you want to put a whole line of trees into a poor-draining area. Install "perf" pipe, or drain tile in gravel, and connect it to a storm drain. But don't put gravel under the roots!

PLANTING THE ROOTBALL

1. Unpot the Tree. Speed matters. Don't let the roots or rootball dry out. Care matters also. Don't let the roots or rootball break. Your plant either will be "bare-rooted" and wrapped in some sort of protective substance or will come with the roots in a ball of dirt in some kind of container to hold it together—a peat pot, burlap, wire basket, or bag. If it's a metal pot, cut off the pot with tin snips. Tear it off if it's made of paper. You have to get as much of the wrapping off as possible without actually harming the rootball. This may have you struggling with knives, wire cutters, etc. Untreated burlap can, if necessary, be planted with the tree.

2. Double-Check Hole Depth. Do this by setting the tree in the hole to see how it fits. The "collar" (or "crown" or "root flare") should be just at soil level or a little above (to allow for mulch). Usually it's easy to see because you'll be looking for the same soil line that the tree had at the nursery. Trees planted too deep can die within a few years, or develop problems as many as 15 years later.

3. Set Tree in Hole. Then spread out the roots. If you see any girdling, damaged, or circling roots, cut them off. Try to lay the roots out in a way that they make good, straight contact with their new soil.

4. Fill in Dirt. Place dirt over and around it. Don't add anything to the dirt you're going to put back into the hole to cover the tree roots—not peat moss, not fertilizer. It does more harm than good to spot fertilize a newly planted tree. This is because it tends to make the soil around the tree roots of a significantly different composition from the soil next to it. Water doesn't move normally across the difference. The result is a tree that's liable to be

abnormally wet, or too dry. Don't bury incompletely decomposed organic litter around the seedling tree either. This can mess up the pH, the nutrient balances, and the populations of microscopic soil creatures. On the other hand, fully composted organic material that is evenly distributed across the top of the ground in your young tree's area could be helpful. Stomp dirt all around it to be firm and create a depression into which water can settle.

5. The First Soaking. When soil is dry, watering the tree as soon as possible after planting is critical for its survival. Use water also for the final settling of the soil. If additional settling occurs, add more soil, but *don't step on the wet soil around the tree*.

6. Mulch. Mulching the surface of the soil around your newly planted trees 2–4 inches deep does help them by controlling competition and gradually releasing nutrients. In nature, trees mulch themselves every fall. By keeping weeds away, retaining water, and moderating the soil temperature, mulch improves the chances of survival for your tree. But *never let mulch pile up against the trunk*. After mulching the planting pit, brush back the mulch that is in contact with the trunk.

7. Avoid Staking. Natural flexing is necessary for the plant to develop a normally strong trunk and roots. Use staking only if needed to hold the tree up until the roots have become established (usually within a year). To stake, use 1 or 2 wooden stakes (pipe or rebar are too hard to pull out), which have been pounded firmly into undisturbed soil. Place the tie about a third of the way up the tree in order to allow maximum trunk movement. Use soft, flat tie material (inner tube, flat soaker garden hose, commercial products). Never use straight twine or electric, or any other type of wire, against a trunk. Remove stakes and ties as soon as possible. Trees are frequently girdled by ties that people forgot to take off.

8. Prune. But do not prune the tree top to “compensate for root loss.” That’s a myth. You may prune to take off broken, rubbing, and weak branches, but try not to remove more than $\frac{1}{5}$ of the branches.

9. Dirt Dam. Build a circular dirt dam to create a basin effect around the outer edge of your tree planting area to retain water. Trees need water that soaks in deeply to establish good root systems. Water trees a lot the first year or two and during a drought. Let the root zone dry out between waterings unless your tree is a swamp variety. Five to 15 gal. a week is typical.

10. Care After Planting. Young trees benefit if they are irrigated, fertilized, and weeded, being a crop like any other. Water them at least twice a week. Regularly rescue them from weed and grass competitors. Or, easier and better yet, mulch around them so thoroughly the competition doesn’t get through. If your trees don’t grow well and aren’t an obviously healthy green color, they need fertilizer. Spread some manure from your barnyard. However, there’s such a thing as too much nitrogen, so spread it in reasonable amounts. For long-term care, young urban trees are most at risk for being bashed by cars or lawn mowers, or vandalized.

To SPRAY OR NOT TO SPRAY: I think spraying is a vicious habit. It just creates ever more resistant insects and diseases, exactly the same way that super gonorrhea and super tuberculosis have been created by antibiotics. In a few decades fruit growers have gone from spraying once in a while for a specific problem to spraying regularly as many as 30 times a season. The pests they spray to kill just get more and more resistant because there

are always a few that survive—the toughest, of course—and they pass their toughness on. Even organic fruit-growers tend to fall into the trap and call themselves “organic” because they spray only, maybe, 6 times a year. And they may spray on only petroleum (“dormant spray”), plus perhaps even some truly biodegradable and environmentally nontoxic botanics. It’s hard to roll over and play dead when something is eating your fruit crop.

The pendulum is swinging back now, with people more willing to accept some scars on the sides of the fruit and an occasional worm. If you can accept a reasonable amount of damage you can usually manage by using nontoxic control measures such as predator birds and insects, and planting resistant species. Another organic option, if your crop is getting wiped out anyway, is to take out the plants and burn them and plant other kinds of fruit that you can get a crop off of without poisonous chemicals.

I’d like to see that both government and private-party buyers adopt that policy. If a crop can’t be grown without massive use of poisons, it should be unrewarding to grow it. Environmental costs need to be charged as part of the product cost. If the pests are denied their usual diet, maybe they’ll become extinct. And anyway, then we won’t be poisoning the field workers, our air, water, and soil, and the fruit eaters on down the food chain. We won’t be messing up the balance of nature and breeding super pests trying to get a fruit crop past them.

So if your peaches can’t make it without spraying, I suggest you switch to persimmons and figs and kiwi and nuts and hardy berries. Same for apples, pears, or whatever. If everybody plants the same fruits and the same varieties of those fruits, a huge opportunity opens for any predator organism. There are so many lesser known fruits and varieties of fruits deserving of cultivation, which are not so troubled by pests. Give them a chance to perform for you!

PRUNING

In the first edition of this book, I was both very scared of pruning and very ignorant about it. Frank Reuter, Berryville, AR, wrote me these reassuring words: “A friend once told me, after planting several new apple trees, ‘Pruning just doesn’t seem natural.’ Having obtained the bare-rooted trees from a local nursery, she had dug them into the ground on a crisp, late autumn day. Then she hesitated. ‘There’s so little to start with, and I paid so much. I’d hate to cut anything away.’

“‘Look,’ I said, ‘do you want puny little apples seven years from now, or would you like to sink your teeth into a juicy, large apple in just a few years? I know cutting away branches on something you want to grow fast seems crazy, but experience has taught fruit producers again and again that careful pruning really does increase production.’

“‘But I don’t know how,’ she worried. ‘I’d botch it for sure.’

“That’s the problem: knowing how. Pruning itself is not a difficult task, but it is complicated by the fact that there are so many different pruning situations. You don’t prune an apple tree like a plum, nor do a grape vine like a raspberry cane. I had another friend who put in about 15 blueberry plants and waited the long 6 or 7 years until they came into full production. For several years, blueberry pies and muffins literally spilled from his house on a year-round basis. And then he noticed a gradual decrease in his crop. He started asking experienced gardeners and got the same advice from every source: ‘Prune harder. Some of those canes look mighty tired. Your stand is losing its vigor.’ He took the advice and in just a few years he had a growth of new vigorous canes bending under the weight of their load of fruit. If he hadn’t changed his ways and started pruning

more heavily, he might have destroyed the entire stand.

"Point number one about pruning: in almost all cases, the problem is not in pruning too much, but in pruning too little. On the other hand, it is possible to prune too much. The results of excessive pruning can be disastrous."

Frank's right. I saw a yard full of adult trees that had been pruned by a professional yard-care person, and it was just heart-breaking how severely they'd been cut back. A year later some of them had actually died from their injuries; others would clearly need several years more before the damage would be concealed by fresh growth and their beauty recovered.

A wonderful lady named Cass Turnbull has made herself the advocate for those who cannot speak, the trees. Her beat is an urban one, Seattle. Her self-defined mission is to fight pruning excesses and unnecessary killing of trees. Cass founded an organization, PlantAmnesty, which puts out a "newsletter published for the fertile minds of PlantActivists—people who don't beat around the bush." PlantAmnesty's goal is to "end the senseless torture and mutilation of trees and shrubs caused by malpruning." It carries "Adopt-A-Plant" and "Eco-Exchange" information. This award-winning little quarterly paper (16 pages, printed with soy ink on recycled paper!) can be yours for \$20 per year regular, or \$10 if you have limited income.

PRUNING SAFETY RULES

1. Always protect your free hand by wearing a leather glove on it.
2. Be careful when using the bow saw. It can get hung up in wood and then, when suddenly freed, slash across the hand holding the wood.
3. Be careful when cutting a limb above your head. It may not fall the way you expect it to, especially if it gets caught somehow in the tree.
4. Be careful not to overreach if you are standing on a ladder to prune. It's safest not to use a ladder at all, but use pole pruners, or get help.
5. Don't use power tools to prune. They are wrong for the job and can cause serious injury to the pruner.
6. Beware of electrical power lines hanging over the tree you are pruning. A tree can serve as ground for current. One careless mistake could cost a life.

Cass never stops trying to get the facts out: "Most of us who have horticultural knowledge are frustrated that those who do the work, either pruning or planting, don't have the same knowledge." So she's also the author of a book on how to do this necessary evil of pruning right: *The Complete Guide to Landscape Design, Renovation and Maintenance: A Practical Handbook for the Home Landscape Gardener*. Join PlantAmnesty or order her book (\$17.50 postpaid) by contacting Cass Turnbull, 906 NW 87th St., Seattle, WA 98117, (206) 783-9813.

So the secret lies in between: some pruning, but not too much. And then again it depends on the plant, because some plants need a lot of pruning and some shouldn't be pruned at all; and it depends on the time in the plant's life, because plants are most likely

to need “training” when they are very young, and then some should be left pretty much alone after that, but others need frequent attention. Plus no 2 people prune alike. So there are specific pruning instructions in the how-to-grow it section for each plant. And here are some basics.

Pruning Tools

Back to Frank: “When you shop for pruning tools, be forewarned: there is a lot of cheap stuff on the market. But bargain tools are likely to get dull in almost no time. Pruning requires you to cleanly remove a limb or cane, sometimes in a very tight space. If your equipment is not razor sharp, you will slash and tear your plants, leaving wounds or scars which invite disease and insects. With some garden tools, you can get by with less than first-rate equipment. But for pruning tools, be sure you are buying quality. When you are finished pruning, your plants should not look as if one of those whirring, mechanical, roadside-clearing tree slashers had a shot at them. Cuts must be made cleanly.”

Cass would approve of that!

Experience helps you know which tool to use for each cutting situation. Always use the smallest tool available. Only if it is not doing an adequate job do you move on to the next larger one.

BASIC PRUNING EQUIPMENT

1. Snips: Hand-pruners, “snips” (also called “pruning shears” or “hand clippers”) are your basic and most important tool. Be sure not to confuse this tool with a grass trimmer or a scissors-type shears. A hand pruner is an anvil-type instrument consisting of a sharp blade that snaps against a piece of metal.
2. Lopping Shears: Also called “long-handled pruners,” these are necessary for reaching higher limbs or for heavier cuts.
3. Saw: A pruning saw (a bow saw or a narrow, curved pruning saw) is used for thick wood that can’t be handled by the lopping shear. Such a saw can have a straight or curved blade, be fine-or coarse-toothed. A bow saw has the advantage of giving you leverage; a narrow curved pruning saw is better for getting into tight places. Incidentally, the saw will be your least-used tool. Never cut large branches unless you have a good reason. A “good reason” would be because a branch is diseased or dead.
4. Pole Pruner: This tool is useful if you have standard or semi-dwarf trees and you find it necessary to prune beyond the reach of your lopping shears. These are clippers mounted on top of a pole, activated by rope and spring.
5. Here is what is *not* a pruning tool: For home fruit-tree pruning, don’t use hedge clippers or a chain saw. Hedge clippers are intended only for very fine twigs, and chain saws produce too rough a cut.

SHARPENING PRUNING TOOLS: Frank says: “In general, always keep them sharp and clean. Sharpen pruners or shears as needed the same way you sharpen a pocket knife: Use an oiled whetstone. Place the blade on the edge of the stone with the cutting edge facing away from you. Tilt the dull side of the blade toward you, making sure that the cutting edge stays in contact with the sharpening stone. Then draw the blade toward you. Repeat until nicks and cuts disappear and the blade again is sharp to the touch. If your whetstone is fairly large, you may have to disassemble a pair of hand pruners. If you must, do what

all smart mechanics do when they take anything apart: make a sketch of all the pieces and their position relative to each other so you can put your shears back together again. Saws, of course, are a special case. If your saw gets dull, either purchase a new one or pay a professional to sharpen it."

WINTER TOOL STORAGE: "To prevent rusting and corrosion of your tools, lubricate them lightly with oil, especially if they have to be kept in a damp place." If your tool becomes gummed up with sap or pitch, use kerosene sparingly to clean it.

How to Prune

Cass let me borrow heavily from her book on pruning for this section. So, if it sounds like I know what I'm talking about, that's the reason. In addition to the information here, you'd find Cass's entire book helpful. Also you can get bulletins from your local extension service, get other books, and take classes. Pruning can get really complex, and pruners don't necessarily agree with each other about even basic principles. There's a lot more to it than learning how to spread open young limbs (some people use clothes-pins) or to shore up old limbs with 2×4 s to keep them from breaking.

TREE SURGEON'S HYGIENE: With fire blight in mind, Frank advises: "Certain plant diseases can be passed from one plant to another on your pruning tools, so clean them periodically while you work. Use a rag soaked with a bleach and water solution (1 part bleach per 10 parts water) to ... wipe the cutting surface of your tools. For small jobs, you can use a paper towel soaked in isopropyl alcohol, which is the ordinary rubbing alcohol and available in a drug store. If you are making cuts on plants which are clearly diseased [like fire blighted], clean your tool after each and every cut to prevent spreading the disease to healthy plants. And, of course, after every pruning job, clean your tools with your cleaning rag before storing them away. Also clean them with your sterilizing solution before beginning any job; someone else may have used your tools on a diseased plant without you being aware of it."

HOW A TREE HEALS: Research suggests that none of the "wound healers" on the market really help much. A tree does its own healing, and it heals by creating a barrier against the injury that rot won't get through. A tree doesn't fill in the wound with replacement living tissue the way people do. It just puts a wall in there and does the best it can with what's left at that site. So leave a "rotten" hole in a tree alone. Don't gouge at it. Because under the rot is the layer that stops it, and you don't want to cut that open.

PRUNING AWAY FIRE BLIGHT: Fire blight is a misery of a disease that can afflict many temperate-zone fruit trees. If it's a problem in your area, prevention of fire blight is a 3-part program: First, avoid feeding excess nitrogen to fruit trees because succulent young growth makes them more likely victims. Secondly, avoid any but the most necessary pruning. Finally, avoid unnecessary watering. Keep an eye on your trees, especially from bloom until fruit, because next to prevention, early detection to bring fire blight quickly under control is the best.

If blossoms, twigs, and leaves on your tree die and turn black but stay on the tree, you have a case of fire blight. You may also see mummified fruit and cankers. The cure is a radical pruning away of all the infected wood. Inspect carefully to identify all branches that are infected. They are a total loss. In addition, cut a foot beyond the infection

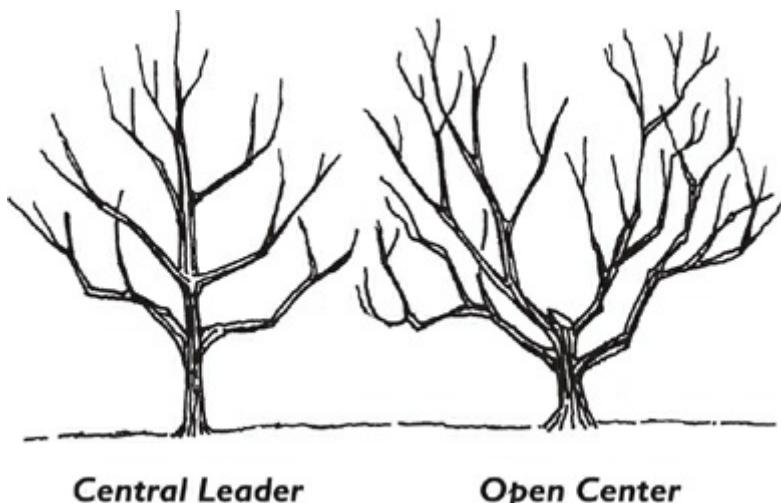

because the bacteria tend to be working somewhat ahead of where their damage is visible. Keep in mind that the branches, leaves, even twigs that you're taking off carry the problem organism, so don't handle the blighted areas and then touch the healthy tree. Keep the blighted cuttings away from the tree. As soon as you have them off, move them well away from any orchard trees. Burn them in a hot fire so they won't spread disease. And disinfect!

But hopefully, all your pruning will just be routine procedures.

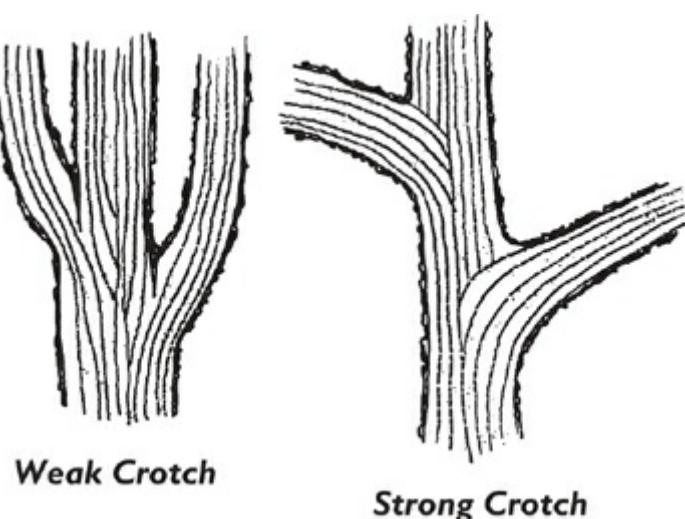

PRUNING DEFINITIONS

Whip. This is a young tree that has no branches, or one that someone made to look like that by cutting back all the branches to the main stem, leaving the top intact but no side branches.

Pinch. It is less stressful for a tree to have new sprouts pinched off as they form rather than pruned off when they are larger. Pinching maintains all the leaves possible, which helps to feed the tree, yet halts all unwanted new growth. But this method takes much more time than pruning since you have to pinch regularly during the first few weeks of new growth.

Central Leader. The single, central tree trunk that grows straight up is your "leader," sometimes created artificially by pruning. The goal of creating a strong central leader can be assisted by "training" the tree while it's very young. But, sooner or later, you have to quit the struggle and let the plant go as it will.

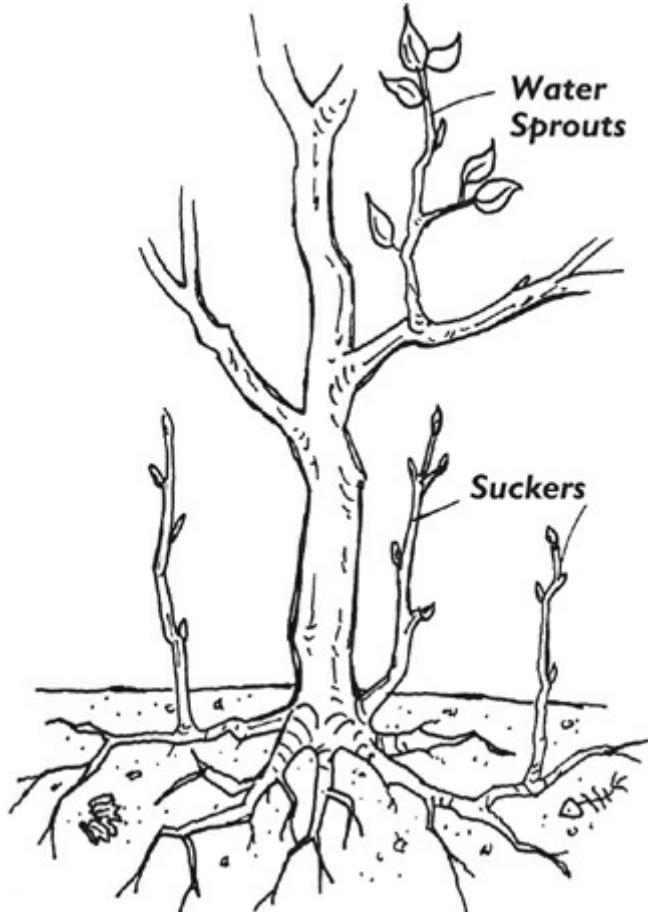

Crotch. This is where a branch connects with the central leader. If a branch is very upright, making quite a narrow angle between it and the trunk (less than 40 degrees), it's called a "bad," or "weak," crotch and is a candidate for pruning because bad crotches are weaker and more likely to break when laden with fruit than branches that leave the tree at a wide angle. The pruner knows that heavy, long, very horizontal limbs, especially when fruit-laden or heavily blown, are more likely to break off than more upright ones, so such branches are also candidates for pruning.

Lateral Scaffolding. The "lateral" or "scaffold" branches are simply the side ones that grow off the central leader. In general you prune a tree in its first few years, allowing only 4 or 5 main branches to come off the leader. You want them to be spaced nicely on the trunk, not to be on exactly opposite sides of each other, and not to have too acute an angle (weak crotch). You do that pruning only once and you're done. A "well-trained" tree is good for climbing. On the other hand, if you want eventually to put a tree house in your tree, train for several branches that grow out near the same spot.

Head Back. To cut off the end of a branch or the top of a central leader is to "head back."

Sucker. Some people use this word to mean both suckers, which grow from the underground or bottom trunk part of a grafted tree, and watersprouts, which grow straight up from higher portions of the tree. (Cass uses it to mean both.)

Apical Dominance. The last bud on the end of a branch is called the "terminal bud." It releases a chemical that travels by gravity and keeps the other buds on down the line rather subdued. It's the boss bud. That's called "apical dominance." When you cut off the terminal bud (or even pull it over), the chemical flow is disturbed. That causes the other buds to begin to grow.

TIMING: Here's Carla's simple system for pruning: Don't prune any the first year. After that, you can prune once in the spring and again in the fall. Prune when the leaves are off the tree. Don't remove the lower branches of dwarf trees; there won't be any higher ones. Here's Cass's much better simple system for pruning!

Pruning of young fruit trees (under 6 years) is done to develop strong, low framework branches and not much else. In fact, it may take a while longer for your tree to fruit. Go easy in the early years. Don't prune too much (no more than $\frac{1}{4}$ total leaf surface) in any year. Old trees can be invigorated by heavy pruning to produce new wood and spur systems, although you may experience a temporary drop in production when you cut off older and lower limbs. But don't try to fix it all in 1 year. If you have a tree of any age that needs a lot of work, do it over several years.

Summer pruning of fruit trees is all right if the tree is vigorous and healthy and well-watered. Summer pruning can be useful for spotting dead wood (no leaves). It can be useful in reducing the spread of fungus-bacterial diseases that like damp weather, and it will help reduce suckering. It generally slows the growth rate and will help restrict the size of your tree. But summer pruning is harder on the plant, so go easy.

NOTE: Never prune during a drought.

BASIC PRUNING

1. First, and always, take out all of the dead wood.
2. Take out the worst crossing, rubbing branches.
3. Take out the worst wrong-way branches. These are the ones that start on one side of the tree, head the wrong way through the center, and come out on the other side.
4. If you have a grafted tree, carefully prune off any suckers growing up from the roots or out from around the base of the main stem below the graft line.
5. Take out some, not all, of the suckers and waterspouts. (Fruit trees can develop a whole bunch of shoots—suckers or watersprouts, reaching for the sky.) Cut some out altogether. Leave some alone (don't cut off the tips), since they will flower and fruit and be pulled over and produce more spurs later. Head back some suckers to thicken them up into second-story branches. Try to head back to another upright side branch and not to a horizontal branch that would sucker back madly. Thinning back some of the branches, especially toward the top (even a few big branches) increases light penetration and lowers your tree. This helps ripen the fruit lower down. It increases air circulation, too, which is important in order to discourage the numerous bacterial and fungal diseases that spoil the fruit.
6. The conventional wisdom for regular pruning is to remove weak crotches. Both horizontal connections and very narrow crotches may be vulnerable. The preferred connection is wider than a 45-degree angle, but less than a 90-degree one.
7. But to encourage more fruiting on your apples and pears, prune for more horizontal branches. Horizontal branches bear more fruit than vertical branches. You can head back laterals to force more spurs to form.
8. Mature fruit and nut trees can be pruned to let more light into the tree. That will make for larger, better harvests.
9. Too much pruning can weaken your fruit tree enough to result in sickness.

Removing a Tree Limb. First find the "branch collar." That's a little doughnut-shaped

bulge at the base of the limb. Don't cut so flush that you cut through the middle of the branch collar. Cut just out from it. That will end up being almost flush, but not quite. The reason it's important not to cut the collar is because cutting it opens up the tree trunk to rot. If you can't see where the collar is, just leave a little space for an assumed presence of one.

Pruning for Fruit Production. Certain kinds of branches make more fruit buds or spurs than others. These are the ones that are situated in a not-too-horizontal position. You can pull or push new branches into such a position, or you can just start cutting out the ones that aren't in the right place and leave the ones that are. Nature makes fruit by sending up a young, straight-up soft branch. It flowers on the tip, and the flower turns into a fruit. The weight of the fruit pulls this supple branch over. As a branch gets older, it stiffens in a more horizontal position. As the branch tips over, the apical dominance of the terminal bud weakens, and buds farther down the branch are released to form nice little side branches (laterals) and on them, teeny, tiny $\frac{1}{4}$ -inch branches called "spurs." These spurs have fat flower buds (fruiting buds) rather than skinny leaf buds. We want the laterals and spurs.

In the winter, it is the fat-budded spurs that you see on trees that make you think what you're looking at might be a fruit tree. You can encourage some, but not all, of your side branches (laterals) to make spurs by heading (also called "tipping back") to 2 or 3 buds. This works on pears and apples, but it doesn't work on cherries.

If your main branch gets pulled too far over—past 90 degrees—apical dominance is diminished, too many buds are released, and those miserable suckers start charging back up. In some senses pruning fruit trees breaks all the rules for ornamental tree pruning. You try to keep your tree small, something that should never be done to other trees. Pruners often reduce fruit trees dramatically, which would be extremely bad pruning on a maple or oak. We also head a lot. We head side branches (laterals) to force them to make spurs. We shorten major scaffold branches with heading, especially young ones, so that they won't swing in the wind and lose fruit. Heading causes these branches to get fatter or stouter. We need stout branches to hold up heavy fruit. On apples and pears, especially, we do a lot of heading. Peaches, nectarines, and Japanese prunes really like it when we whack and whale. However, don't do it to your cherries or European plums.

CASS'S PRUNING CATEGORIES

Prune Hardest: You can, and should, both head a lot and prune most on your peach, apricot, nectarine, and Japanese plum trees.

Prune Medium: Cass suggests that good trees to practice your pruning on are apples and pears "because these trees are so forgiving." Keep young apple and pear trees short, she says, head laterals to encourage fruit spurs, and prune medium.

Prune Least: Cherries and European plums are hard to keep short with pruning. No topping, no heading of lateral is appropriate for these. Love them as they are or train early by bending branches.

PRUNING ERRORS: The most common errors when pruning fruit trees are, first, topping and, second, creating umbrella trees. Topping is bad for any tree, including fruit trees. The suckers that shoot back up from a topped fruit tree not only will be ugly; they are also too busy trying to get enough leaves back in order to feed the tree to make much fruit.

Dealing with Suckers. You may have a forest of suckers that are the result of previous

bad pruning. If you remove all of the suckers, they all come back. So leave some to dominate the rest, shorten some to create a second story up, and thin out the rest. The reason why you “leave some to dominate the rest” has to do with that botanical phenomenon of apical dominance.

Reducing the Height of an Apple or Pear. As you work, keep in mind apical dominance. Thus, it is a good idea to cut back a tall vertical branch to a shorter branch that also faces upward. Basically you are not trying to eliminate all vertical branches; you are simply replacing them with shorter, younger, and fewer vertical branches. This retains some apical dominance and allows the tree to grow a little every year. It’s like a volleyball game—you rotate out a few of the tallest old suckers every year.

Instead of topping, many orchardists choose to reduce the height of apple and pear trees using the “drop-crotch” method of lowering trees. Drop-crotching means you selectively head back to a side branch of a decent size, say one-half the diameter of the parent stem. This is hard on the health of old trees and opens them up to rot. Trees 15 years or younger withstand this height-reduction better. Drop-crotching reduces the amount of sucker growth, as compared to topping, but does not eliminate it.

Umbrella Trees. Don’t create umbrella trees with ugly, sucker-laden crowns. An umbrella tree is made when the pruner cuts to an outside branch year after year, which is called “bench-cutting.” But the typical state of many old fruit trees is an umbrella, which is all right if the umbrella is low down on the tree where you can get the fruit, and if you don’t care how it looks. But often the umbrella occurs high up on the tree, shading out the fruit below. In that case, you’ll want to fix it. The problem is terminal buds that are too low. Gravity prevents the chemical from reaching buds down the line, so a crown of suckers develops at the top. To help keep your old apple tree from excessive crown suckering, thin back low branches to get a branch facing more up and out. To do that, pick out a major (scaffold) branch and follow it with your eyes. Does it dip down quite far, crossing other, lower scaffold branches and cluttering things up? Then you may selectively head back (prune) to one of its side branches that faces more upward and outward (40–60 degrees is ideal). The scaffold branch now ends in a boss bud with greater apical dominance. This will reduce the number of returning crown suckers farther back as well as improve the looks of your tree.

GRAFTING: To learn how, watch a neighbor do it, take a grafting course, hang around at a nursery, or read *Grafting Fruit Trees* (Storey’s: 800-441-5700; www.storey.com); or *Plants-a-Plenty* by Catherine Osgood Foster.

SUGAR TREES

MAPLE VARIETIES: You can gather a sweet sap from just about any maple variety although the sugar maple, *Acer saccharum*, is most frequently tapped. If you live in a state bordering any one of the Great Lakes or in the Northeast, you should be able to grow sugar maples and tap them. You can grow them other places too, but tapping won’t be as successful. Your altitude is an important factor. Between 600 feet and 2,500 feet is best for sugar maples. For good sap production your climate has to have a big difference between day and night temperatures in the spring. Maples don’t produce much sap where winters are mild.

There are other sweet-sapped maple varieties besides the sugar maple that will grow from California on north to Alaska, and they grow over much of the eastern United States

south to Alabama and north to southern Ontario and Quebec. The black maple is almost as good to tap as the sugar maple. The Norway maple comes in right behind the black. The sap of red maples has only half as much sugar as that of the sugar maple, and the syrup isn't as fine, but it can be used. The Rocky Mountain maple, big-leaf maple, silver maple, and big-tooth maple all may also be tapped.

Sugar maples are excellent summer shade trees and glorious in the fall with red, yellow, and orange leaves that make the ground look like it's covered by cool fire. They're hardwoods that grow 50–100 feet tall.

Sugar maples aren't the kind of crop you cash in on in a hurry. They are planted more for your successor than for you because they take so long to grow—about 30 years or more to get large enough for tapping. And if competition for space is tight in your planning, also keep in mind that each maple tree will produce only about 1 or 2 qt. of finished syrup per year. So it may not be worth it to you—or to your successor.

PLANTING AND GROWING: Sugar maple seed is available from William Dam Seeds (905-628-6641; www.damseeds.com), and it's okay to grow them from seed. Or propagate by budding. Country Heritage (PO Box 536, Hartford, MI 45057) sells 4–5 ft. started trees. In the West, Burnt Ridge Nursery sells them. Don't prune your sugar maples much. They produce best if they have lots of branches. Trees spaced 35–45 feet apart produce the most sap, but keep some young ones coming in between there as eventual replacements. One way to thin maples is to use a portable sap tester, which tells you the sugar content of each tree. Then you can thin out the less-sweet trees. Another option is to plant your maples both for tapping and for timber. In that case put them 20 feet apart. Less sap but more trees to tap will add up to the same sugar harvest, and you'll have a bigger eventual timber harvest.

MAPLE SUGARING INFO/SUPPLIES: Storey's offers a booklet, "Making Maple Syrup," and a book, *The Maple Syrup Cookbook* (800-441-5700; www.storey.com). Check out *The Maple Sugar Book* by Helen and Scott Nearing, and *Syrup Trees* by Bruce Thompson (1978). Sugaring supplies of every sort, books, and a free catalog are available from Leader Evaporator Co.: 802-868-5444; fax 802-868-5445; 49 Jonergin Dr., Swanton, VT 05488; www.leaderevaporator.com. A person can spend almost nothing or thousands of dollars on sugaring equipment, depending on your inclination, how many trees you're trying to keep up with, and whether you are producing for home use or for commercial sale. One modern doodad is the reverse osmosis pump that runs the sap water through a preliminary process that dumps half the sap's water content first thing (and eliminates much boiling).

Incidentally, don't expect your homemade syrup to taste just like store syrup, which is merely flavored with the real thing. Maple syrup is the most expensive natural sweetener on the market—because it takes so much sap to make a gallon of syrup (33–40 gal. at 3 percent sugar content), the tapping season is short, and the trees give but not copiously. But if you have maybe 14 or 15 trees to tap, you can have a nice home-sugaring operation.

IDENTIFYING SUGAR MAPLES: Since you're most likely to be tapping from trees that you didn't plant, you may not even be sure if you have sugar maples and which of your trees they are. In yards, you'll have to distinguish the sugar maple from the Norway maple. In the woods you'll have to distinguish it from the red (or soft or swamp maple). In that case get somebody who knows to point them out to you and put a splash of bright paint on each

designated tree so you don't forget. Even an experienced mapler, however, may have difficulty distinguishing sugar maples in winter and spring. Fall is the easiest time. So be sure and get your trees to be tapped marked before fall is over, while their distinctive foliage is still on.

TAPPING MAPLES

When to Tap. You tap your maple trees in early spring, around the first March thaw, generally mid-March to mid-April. Be careful not to tap prematurely. Some old-timers suggest to tap 1 month before your snow is usually gone. You can get some sap in the fall or any warm winter day but not nearly as much as you will during the spring run. The important determinant isn't the calendar; it's the thermometer. The right weather is a freezing night followed by a sunny day, with a temperature of at least 40°F. Take wind-chill into account: more wind requires a higher temperature. It's traditional to try to get all your buckets up in one day.

As soon as you have tapped, the tree goes to work healing the wound and closing off your supply—takes it about 4–6 weeks. If you accidentally tap before the weather has really settled into a spring pattern and the days turn freezing again, your sap supply will temporarily stop and you'll lose some tapping time once it does start to run again.

How to Tap. In addition to tapping the right kind of tree, you need to tap a tree of the right size. Don't tap a maple that is less than 10 inches in diameter. For each 6–8 inches of tree diameter more than 10, you can add 1 tap, as many as 2. (Newest research shows you should limit yourself to 2 taps per tree.) The hole in the tree is bored with a hand drill about 2 feet up from the ground (the lower, the better) and about 2 inches deep. (The hole has to be deep enough and the spout placed in it firmly enough so that even a heavily loaded bucket won't pull the spout out.) If the hole into the tree is angled slightly upward, it will help the sap run out. Sugaring suppliers sell $\frac{7}{16}$ -inch bits, which match the size of most commercial spouts. But a $\frac{3}{8}$ -inch or $\frac{1}{2}$ -inch bit can be made to do. New tapholes are drilled every year.

Ann Moran wrote me: "Sap shows in the end of the twigs, usually in late winter if the winter was mild or in the earliest spring. The hole in the tree is bored with an auger. New tapholes are drilled every year and into each hole you insert a hollow metal spout and from that you hang a bucket. A really big old tree can have as many as four buckets on it. So the sap goes up the tree trunk and out the spout and down into your old-time bucket and then every day you should collect the drippings from each tree and take them to the sugarhouse for boiling down. If you've only got one tree go ahead and tap it. Boil the sap down on your kitchen stove and you'll have about a pint of maple syrup. It takes a lot of sap to make syrup."

Into each hole you hammer in a hollow metal spout with a sequence of light hits, and from that you hang a bucket. Be careful not to hammer so hard you split the bark. Sap would leak out through such a split and be wasted. This spigot can be homemade out of wood or a piece of metal pipe or purchased quite inexpensively from a sugaring-equipment source. Manufactured spouts are made with built-in hooks to hold a bucket firmly on. Your first taps should be on the south and east sides of the tree. Then tap west and north. (North-side taps are last to begin flowing, but they'll also be last to stop.)

If you are tapping from a tree that has been tapped within the previous 10 years, place any new tap holes at least 3 inches to the side of and 6 inches above or below the old holes. That's because a tap hole causes death of the inner bark in an oval pattern around it, the oval being a couple inches to each side of the hole and a few inches above and below it. It takes 10 years for the tree to heal that place completely.

How to Collect. So the sap goes up the tree trunk and out the spout and drips down into your bucket. What can you use for the bucket? A coffee can, plastic milk jug, or a specially designed bucket. (If buying used buckets, beware of beat-up or rusty ones—they probably leak.) A larger container will need to be emptied less often. A commercial bucket will hold 4 or 5 gal. of sap. The bucket needs to be protected from sugar-loving animals, and from rain, snow, and wind-blown debris like dirt, leaves, and bugs. The easiest protection is a lid, which is an attachment you can buy for a commercial bucket, or you can devise your own.

Then every day you should come by each tree with your gathering pail into which you'll empty the spout buckets. Take the full gathering pail to your chosen site for boiling down. You may need to collect more than once a day on the best days.

A modern collection system for trees that are reasonably close together and uphill from the boiling place is plastic pipeline that picks up the sap at the spout and carries it directly down to a holding tank. It's inexpensive and easy to collect with but inconvenient to clean after the season's end. It's also difficult to notice a tree sending in bad sap, and the set-up is attractive to wild critters who'll like to take a bite and help themselves to the sap.

Freezing can shut down a plastic pipeline that has a slack and low place in it. It doesn't hurt the sap at all to freeze, either in the bucket or elsewhere, before you get around to boiling it. An interesting thing about partly frozen sap is that as the sap freezes, the sugar tends to stay in the liquid part. A bucket of sap half frozen would have a sugar concentration in the liquid part of twice the usual, the equivalent of half your boiling time accomplished already. But the frozen lump does have some sugar in it, although a proportionately lesser amount.

WHEN TO STOP TAPPING

1. Before the leaves go into bud (see step 4).
2. If you get tired of boiling sap before that (just pull the spouts out of the trees and

you're done).

3. If the sap stops flowing.
4. If some sap is a pale to bright yellow color (a sign that the tree is ready to bud and no good for syrup-making).
5. If the finished syrup is dark brown rather than amber, with a strong, unpleasant flavor (it's edible, healthy, but not the kind of syrup you can give for a present).

THE BOILING DOWN: At your boiling center all the individual buckets are emptied into a holding tank—maybe a big plastic garbage can. This should be outside in a cold place (north side of a building). Or pour directly into your big kettle, like a canning kettle, or one of the large, flat-bottomed pans specially designed for this process. Galvanized pans are not recommended. You can boil the sap down in any pot and on any source of heat. But if you use your kitchen stove and if you are boiling very much of it, it makes the house damp and steamy. Large producers boil in a “sugarhouse,” which is a separate building—as simple as four corner posts with a roof or as fancy as a wooden building with windows that open and/or a steam vent in the roof. It’s helpful to make it large enough to keep a dry wood supply right in there, too. Holes in a sugarhouse wall help to let the steam out. Either way it’s nice to have a level floor. Another choice could be a fireplace or outdoor stove in your yard, possibly made of cement blocks. It helps if your boiling place is near the maple trees but at a lower elevation.

The sap you’ve collected looks and tastes like sugared water. In fact you can drink it straight, or use it to sweeten other drinks or in cooking.

Beginning the Boiling. Boiling down the sap is a long process, and it takes a lot of sap to make syrup. It takes a 6-gal. kettle of sap 4–5 hours of boiling to turn from sap into syrup—about a quart of it. Thirty to 35 gal. sap would boil down to 1 gal. of syrup. Jean Nance wrote me from Neoga, IL: “We make maple syrup in small batches, from 10 maple trees. If you have 8 qt., you are going to get about 8 oz. of syrup. Until the volume is down to perhaps 16 oz., you are essentially boiling water and don’t have to watch it at all. The last bit of boiling down does have to be watched carefully. The main problem is steaming up the house—everything drips!”

A rule of thumb is that while boiling down from the start to $\frac{1}{10}$ the original volume, you don’t need to watch it. From $\frac{1}{10}$ to the final stage ($\frac{1}{35}$) though, you do have to pay attention. At this stage later sap begins to develop a layer of thick white foam on the top. (Beginning-of-the-season sap is less likely to foam and boil up.) Skim off that foam with a strainer and discard it; wear a leather or rubber glove while skimming. Boiling up (and possibly over) is a problem related to the physics of surface tension; just add a drop of cream and it will go back down. (Without the drop of cream, you won’t be able to boil it as hot and fast for fear of the boiling up.)

Once begun, the boiling-down process should proceed promptly. Sap that stays in the pan too long darkens in color and gets a heavy flavor. But it is fine to add more sap to a batch that is already in the process of boiling down.

Testing the Syrup. You can test your boiling sap for density with the regular sugaring tests or with a hydrometer, sugaring thermometer, or candy thermometer. Boil until your candy thermometer shows 219°F at sea level. For every 550 feet above sea level where you are, add 1 degree Fahrenheit to that temperature. An easy old-time test: Unfinished sap will drop back into the pot off an ordinary spatula that has been dipped into the

boiling sap, but finished syrup will cling to the bottom of it.

If you intend to sell your syrup you need the equipment to get it to exactly the correct density and labeled with its grade, available from a sugaring supplier. For commercial markets maple syrup is graded by established standards for color and density. The lighter amber the better grade. Dark-colored syrups have a caramel flavor rather than a maple flavor.

Maple Sugar. *You will make maple sugar if you don't watch the boiling sap carefully in its last stages.* If allowed to get even slightly too dense, the syrup will gradually, over the succeeding months, precipitate out rock-sugar crystals, which will collect on the bottom of your jar. These crystals are hard and tasteless. It's safer to stop a little short of the ideal density than to let your syrup go a little past it.

On the other hand, if you deliberately want to make a maple candy, then pour some of it onto clean snow. When it's close enough to done it will cool on the snow into a glasslike rock sugar. To make the whole amount into rock sugar candy, heat your syrup to 32°F more than the boiling point of water at your altitude. Then cool slowly back down to 155°F, stirring constantly. Then pour it into molds.

Straining the Syrup. If you skip this step, you'll have debris in the bottom of your syrup that you'll have to discard after the clear syrup above it has been poured off and used. So, after the syrup is completely boiled down, strain it through flannel or a paper coffee filter to remove that debris. Or use a commercial felt strainer.

MAPLE RECIPES

➲ **CANNING MAPLE SYRUP** *If you filtered it, you have to put the syrup back on the heat and bring it back to a boil. Then pour it boiling hot into clean jars or any other sterilized container that you can get a really tight lid on. Pints are a good size for this precious stuff. Fill to very near the top of the container. Then lay the sealed container on its side so the top gets sterilized too. Some people use a paraffin dip. If your syrup isn't carefully canned, it will get moldy. Refrigerate after opening.*

➲ **MAPLE SNOW CANDY** Marlissa Carrion wrote me from New York about her childhood in Ohio: "When Mom and my aunt would be heating maple syrup, we used to run out in the yard in the winter with a big roaster pan and scoop up fresh-fallen snow in it. Then we'd trail ribbons of maple syrup into the cold snow. It would harden to a kind of candy."

➲ **CANNED MAPLE-WALNUT ICE CREAM TOPPING** Mix together in a saucepan 1 c. maple syrup, 1¼ c. corn syrup, ½ c. water, and ½ c. sugar. Boil, stirring once in a while. After it has commenced boiling, add 2 c. walnut pieces, stir in well, reduce heat to a simmer, and let cook 15 minutes or until thick enough to suit you. Then ladle hot syrup into hot jars. Leave ¼-inch head space. Put on lids. Process 10 minutes in a boiling water bath canner.

➲ **MAPLE CREAM SAUCE** Combine 1 c. maple syrup and ½ c. cream. Boil to soft ball. Beat 1 minute. Add 1 t. vanilla.

➲ **MAPLE-HONEY SYRUP** Combine ½ c. maple syrup, 1 c. honey, and ¼ c. butter.

OTHER SUGAR-SAP TREES: Sugar maples are the best known, but not the only sweet-sap trees.

Palm Sap. Palms are the tropical-zone sugar-sap tree. In the blooming stage they send energy to the flowering and soon-to-fruit high part of the plant in the form of a rich, very sweet sap. To tap it, you must climb the trees all the way up to the flower stalk, which is

located high in the palm's crown. Cut it open and establish a drainage arrangement. The flow of sap can be continued for weeks by cutting open the flower stem each time it heals shut. Pounding on the tree can help, too. A palm tree being tapped for sweet sap will not produce nuts as long as it's being tapped for sap.

Butternuts and Birch. Butternut trees can be tapped in the spring just like maple trees and their sap boiled down to make a sweet syrup. Birch trees (even in Alaska!) can be tapped for syrup. Black (sweet) birches give lots of sap. Tap in April, same as for maple. Birch sap is less concentrated than maple sap, but if you boil it patiently enough you get your syrup. Use same directions as for the maples.

NUT TREES

Enter the Wonderful World of Nuts!

If you live where nut trees grow wild, you can bring home bags of nuts for free. But there are fewer and fewer wild nut trees. So consider planting some. Nuts provide fat, protein, and, in the case of acorns, carbohydrates. Most seedling nut trees take 5–10 years, or longer, to bear, but once started they continue producing crops year after year with practically no care—as well as providing a bonus of beauty and shade. Worldwide there are nearly 1,000 kinds of nut trees, but in North America there are relatively few types, each with distinct climate requirements. So what nut varieties you can grow depends above all on where you live.

CLIMATE: If you live in Southern California you can raise macadamia nuts. In North Central California, almonds and Persian or Carpathian walnuts are primarily grown. If you live in the Southwest, you can grow pine nuts; in the Southeast, pecans. California, Oregon, and Washington grow fine filberts, hazelnuts, and Persian or Carpathian walnuts. The Northwest is excellent for chestnuts. Black walnuts can be grown well in the central and eastern United States. Nut tree nurseries, agricultural universities, and individuals are constantly working to develop improved varieties of each nut. Incidentally, peanuts are not technically a nut, but rather a southern-suited legume, a member of the pea family.

NUTS FOR SALE: The best-selling volume market nuts from wild trees are pecans and black walnuts. Statistically, almonds are the number 1 nut grown and sold in the United States in terms of volume produced, followed by Persian walnuts, with pecans coming in third. Chestnuts and pistachio nuts are right up there too. Commercial nut growers must invest in expensive machines that shake trees and other machines that pick up nuts, as well as drying and storage buildings, grading, shelling, and packing equipment. But there are also nut growers who make a living using very old-fashioned production and processing methods.

NUT TIMBER: Some nut varieties, especially black walnut, are grown for their valuable timber. To do that, plant closer than for an orchard and prune to a strong central leader. As they grow taller, every fall cut off several of the lower branches until you have an 18–20 feet trunk or “bole.” Allow at least 2 times as much branched area on the trunk as limb-free trunk. It’s better to cut those lower limbs (making a straight, valuable trunk) while the tree is small and young rather than later when the wound may be larger and may never properly heal over, resulting in a scarred trunk. Butternut, black walnut, chestnut, and

pecan woods are particularly prized for making paneling and furniture.

NUT BOOKS: Look in your library for *Nut Tree Culture in North America* (Richard A. Jaynes, editor), which offers a wealth of information for serious nut growers. "The Annual Report" (1910–present), put out by the Northern Nut Growers Association, contains lots of nut culture info. Other good sources are *Nuts for the Food Gardener* by Louise Riotte (Garden Way, 1975), and *The Improved Nut Trees of North America* by C. A. Reed and J. Davidson (1958).

I'll describe only about 20 nuts in this book, a fraction of the world's nut-bearing plants. Read about the rest of them in *Edible Nuts of the World* by Edwin A. Menninger.

NUTWORKING: These organizations welcome questions from amateurs.

Illinois Nut Tree Association: Robert Adams, Treasurer; 618-475-2448; 7937 Peacock Site Rd., New Athens, IL 62264.

Kansas Nut Growers Association: William Reid, Secretary; 316-597-2972; PO Box 247, Chetopa, KS 67336.

Nebraska Nut Growers Association: www.nebraskanutgrowers.org; NeNGA, 206 West 2nd St., Box 439, Valparaiso, NE 68965.

Northern Nut Growers Association: members include commercial nut growers, nut scientists, and amateurs. Visit their website for nut tree info and to ask questions of an expert: www.nutgrowing.org. NNGA's Membership Directory, quarterly newsletter, *The Nutshell*, "Annual Report," access to the lending library, and an invitation to the annual meeting—all for \$25/yr: Sandra Anagnostakis, Treasurer; PO Box 6216, Hamden, CT 06517-0216

Pennsylvania Nut Growers Association: Tucker Hill, Assistant Secretary, edits PNGA's quarterly newsletter, *The Nut Kernel*, and is the person who answers questions. I am indebted to him for reading this section, painstakingly correcting my errors, and supplying valuable info: call/fax 717-938-6090; 654 Beinhower Rd., Etters, PA 17319-9774; tuckerh@epix.net.

Society of Ontario Nut Growers (SONG) is a Canadian association of nut growers interested in hardy nuts and good publications: Ernie Grimo, Treasurer, RR 3, Niagara-on-the-Lake, Ontario L0S 1J0, CANADA; www.songonline.ca.

Getting Started

PLANTING NUT SEED: Nuts are very perishable and can easily lose their germination ability if they dry out or mold in storage. It works best to plant nuts very soon after you harvest them. Plant in a cold frame or directly into your orchard. But this presents another problem since squirrels and rodents are likely to dig up the nuts and make a meal of them. The answer is to plant with some sort of cage over the seed. A good technique is to put the seeds between layers of sand in a wire-screen covered box. Or to make an individual cover that you can leave until the seedling is developed: a tin or aluminum can with its bottom cut out and its top slit and folded back enough to let in light but not enough that a critter could get through. Push a can fixed like that down on top of each seed you've planted. Seed nuts need time out in the cold outdoors in order to stratify and be able to germinate come spring. It doesn't hurt them to freeze.

NOTE: Grafted trees will produce much sooner than seedlings. Only quality trees are grafted,

so if you buy grafted trees you're guaranteed good nuts.

NUT NURSERIES: These are only a few of many, but all these are recommended. More entries may be at the individual nut listing.

Burnt Ridge Orchards offers hardy almonds, pine nuts, ginkgo nuts, monkey puzzle nut trees, hazelnuts, walnuts, chestnuts, northern pecans, and oaks that grow edible nuts! 432 Burnt Ridge Rd., Onalaska, WA 98570; 360-985-2873; fax 360-985-0882; mail@burntridgenursery.com; www.burntridgenursery.com.

Campberry Farm sells seedlings of hardy pecans, sweet chestnuts, hardy almonds, heartnuts, kingnut hickories, Carpathian walnuts, sweet kernel apricots, persimmons, pawpaws, filberts, hazelnuts, etc. Catalog \$2, payable to R. D. Campbell: 905-262-4927; RR 1, Niagara-on-the-Lake, Ontario L0S 1J0, CANADA.

Exotica Rare Fruit Nursery will send Bunya bunya, cashew, chestnut, ginkgo nut, Italian stone pine, jojoba, macadamia, and Ecuadorian black walnut plants to CA, NV, or AZ only: 760-724-9093; PO Box 160, Vista, CA 92083; www.exoticararefruits.com.

John Gordon Nursery offers a few grafted nut trees and many kinds of seedlings, nut seeds, and scion wood: 716-691-9371; 1385 Campbell Blvd., Amherst, NY 14228-1404; nuttreegordon@hotmail.com; www.nuttreesnorth.com.

Grimo Nut Tree Nursery: John and Lisa Brittain spring-ship grafted and seedling trees—Persian walnuts, black walnuts, heartnuts, butternuts, apricots, Korean pines, hazelnuts, chestnuts, hickories, pecans, and fruits—to the U.S. or Canada: phone/fax 905-934-6887; RR 3 Lakeshore Rd., Niagara-on-the-Lake, Ontario L0S 1J0, CANADA; nuttrees@grimonut.com; www.grimonut.com.

Grinnell Nursery: Sid ships custom-grafted hazel, Persian walnut, and black walnut by UPS or US Postal: 517-625-7176; 14495 Morrice Rd., Perry, MI 48872-9548; www.grinnellnursery.com.

Nolin River Nut Tree Nursery is a small family-owned outfit that offers custom grafting and 200+ varieties of budded or grafted black and Persian walnuts, buartnus, northern pecans, hicams, hickories, butternuts, Chinese chestnuts, heartnuts, pawpaws, and persimmons. Free catalog: 270-369-8551; 797 Port Wooden Rd., Upton, KY 42784; john.brittain@windstream.net; www.nolinnursery.com.

Raintree Nursery: For the backyard grower, they offer Ennis and Butler filberts, filbert hedges, trazels, filazels, beaked hazel (*Corylus cornuta*), Chambers and Spurgeon black walnuts, Layeroka and Colossal chestnut, Titian almond, and the Goldenhorn tree (Chinese edible nut): 800-391-8892; 391 Butts Rd., Morton, WA 98356; www.raintreenursery.com.

Nut Crop Management and Recipes

STORAGE: Nuts need protection from both air and heat to prevent the oil in them from becoming rancid. They keep best in the shell—best of all at 32–36°F, at 60–70 percent humidity. And use them up within a year. If you have shelled nuts, they'll keep better whole than chopped. They'll keep better unroasted than roasted. Shelled nuts, if stored in a tightly closed container in the refrigerator, will keep for several months, which isn't bad if you can spare the refrigerator room. You can also freeze either shelled or unshelled nuts. They'll keep up to 2 years there.

Dry nuts at least 2 weeks before storing. It doesn't hurt nuts to freeze, so they can be

stored outdoors. But don't store nuts where light, heat, mice, or moisture can get at them.

CRACKING: To crack 1 nut or a bushel of nuts, the basic procedure is the same: Lay the nut on a hard surface and hit it with a hammer. Hard shells will be easier to crack and nut meats less fragile and liable to break if you first soak the nuts in warm water. After the soaked nuts are cracked, spread out the nut meats to dry for several hours before you put them away. For very hard-shelled nuts, try freezing them first, then crack them while they're still frozen.

But gadget-makers have invented wonderful aids to this chore, not only the old-time hand-held nutcracker, but also modern techno marvels like the famed Potter Walnut Crackers from 918-224-0567; PO Box 930, Sapulpa, OK 74067. They crack both hard-and thin-shelled nuts (hickories, hazels, pecans, almonds, butternuts, Brazils). Burnt Ridge Nursery offers the Asuite Nutcracker, a hand-cranked tool that cracks more than one nut at a time and is easily adjusted for English walnuts, hazelnuts, pecans, and almonds. The large 10-in. hopper will crack nuts nearly as fast as the hopper is filled, as much as 50 lb. of hazelnuts (90 percent whole) in about 1 hour. Their Top Cracker will shell all your pecans, walnuts, almonds, filberts, even Brazil nuts. Or get the Amish-made "Our Best" nutcracker from Lehman's (it can crack black walnuts): 888-438-5346; www.lehmans.com.

ROASTING: Bob Keene, Amboy, WA, who is also the food columnist "Cousin Grace," sent the following note and recipe: "Carla, the so-called 'roasted' nuts people buy are not roasted, but deep fat (French) fried. That can be avoided."

➲ **ROASTED, UNSALTED NUTS** *Here's his recipe: Place about ½–1 lb. of raw nuts in a 9 × 12-inch cake pan or on a cookie sheet or pizza pan, and place it in the oven. Use a gas oven set on low, which is about 180°F, or an electric oven set on 200°F. "Anything over this temperature is unsafe, as the nuts will burn unless watched carefully," he says. "Keep an eye on them. They'll probably be done within 30 minutes. If not, check again after 5 minutes. Watch them carefully or you risk badly burnt nuts. With dark-colored nuts such as pecans, almonds, walnuts, and filberts (hazelnuts), it is difficult to tell when they are finished."*

➲ **QUICK STOVETOP NUT "ROASTING"** *Roast the nuts in a heavy frying pans or Dutch ovens on top of your stove. It will take 10–15 minutes on very moderate heat. Add 1 t. salad oil per cup nut meats. Mix the oil in well before starting. It will help you get even browning. After the nuts are done, sprinkle salt over them if you want. If oiled, cool on absorbent paper.*

➲ **COUSIN GRACE'S (BOB KEENE'S) TRAIL MIX BALLS** *"Use about 1 part any dried fruit to 3 parts nuts. The fruit—dates, raisins, figs, berries—acts as a binder. The nut portion can be any kind of nuts: pine nuts, sunflower, walnuts, pecans, filberts, peanuts, pumpkin seeds, etc. First chop the fruit and nuts in a food processor or meat grinder. If you don't, the stuff won't stick in balls. After the mixture is run through the food processor, pick some up in a teaspoon and make it into a ball. To prevent the balls from sticking to each other, roll them in sunflower seed meal, rice flour, or whatever. They can be stored and carried in Ziploc bags or empty margarine tubs."*

Thank you, Cousin Grace, for your great recipes, and say "hi" to your wife from me.

➲ **RUTH'S NUT CANDY** *"Grind 2 c. any kind of dried fruit Combine with ¾ c. any kind of nut butter. Optional: add the juice and grated peel of 1 lemon. Mix thoroughly, then form into any sort of shape. Or use cookie cutters. Roll in coconut if you like coconut."*

⇒ **NUT DIP** Blend together 1 c. nuts, 1 c. water, $\frac{1}{4}$ c. chopped green onion, $\frac{1}{4}$ t. paprika, 1 minced garlic clove, 2 T. lemon juice, and 2 T. parsley. Gradually add, while your blender is running, $\frac{1}{4}$ c. olive oil. Optional: dash of soy, or sesame seeds.

⇒ **NUTTY PLUM PUDDING** Sift together 1 c. flour and $\frac{1}{4}$ t. cinnamon. Add 1 c. chopped nuts. Stir $\frac{1}{2}$ c. honey into 1 T. melted butter. Add 1 t. vanilla and 1 c. cooked mashed prunes or 1 c. plum pulp. Mix well. Combine dry ingredients with plum mixture. Add $\frac{3}{4}$ c. yogurt and blend well. Pour into greased 8-inch square pan. Bake at 325°F about 35 minutes, or until firm.

⇒ **BASIC NUT/SEED BUTTER** Blend a cupful of nuts or seeds to produce your butter. If they seem lacking in spreadability, add a little more oil. Sesame seed butter is called "tahini" and is good spread thin on a cracker.

⇒ **MIXED NUT BUTTER** Prepare $\frac{1}{4}$ lb. almonds, $\frac{1}{2}$ lb pecans, $\frac{1}{2}$ lb. filberts (hazelnuts), and $\frac{1}{2}$ lb. roasted peanuts. Put them all through a grinder and then mix well. Pack in a glass or some other straight-sided container and chill. When wanted for use, dip the container in hot water and the contents will more easily slip out. Cut into slices. Good for vegetarians.

ACORN: The little acorn grows on the mighty oak (you knew that). Oaks can grow to be very old, over 200 years! They can reach a very large trunk diameter and a crown spread of up to 50 feet. (Crown spread is measured from branch tip to opposite branch tip.) A wonderful book called *Acorns and Eat 'Em* by Suellen Ocean provides a field guide to 18 kinds of oak trees and their acorns, plus recipes. Yes, it tells how to harvest, prepare, and cook acorns! Contact: ocean@pacific.net; www.pacificsites.com/~oceanhose. Or read *Acorns from Natural Oak Woodlands and their Utilization* by James P. Lassoie (1980).

Oak Varieties. The 2 main categories of the some 300 varieties of oak are the black (and red) oaks and the white oaks. Most unprocessed acorns aren't immediately edible for people—too bitter from the tannin content. (But tannin is used in tanning hides into leather.) Black oak acorns contain so much tannin, they're scarcely worth the effort to make edible. But acorns from the white oaks (they have rounded lobes on the ends of the leaves and no bristles) contain less tannin and what is there can be gotten out by leaching. White oak varieties that are good for acorn-growing are the "white oak," "swamp oak," "bur oak," and "chestnut oak." The bur oak (*Quercus macrocarpa*) grows wild in eastern North America. The Oregon or Garry white oak (*Q. garryana*) is another suitable choice. Burnt Ridge Nursery sells 6 different oak varieties, including the cork oak and ones with good acorns for human or stock feed.

Oak Timber. Among the oaks suitable for the Northwest climate are the cork oak (*Q. suber*), which has an edible acorn plus a bark that is used for cork. In old-time Europe these trees were grown on cork estates in Portugal. Oak timber is valuable. White oak is also considered the world's best wood for holding liquids and is ideal for making barrels because of the reddish-brown "gum" that blocks the wood pores. Varieties vary considerably in growing speed, time to bearing, and acorn production.

Climate. Oaks can grow from Alabama northeast to New England, north to Minnesota, and east to Texas. The Ohio and Missouri areas are fine for oaks.

Harvest. Young oaks typically produce a couple bushels of acorns per tree. Old ones can produce prodigious harvests of acorns, even as much as a ton per mature tree, but more likely about a third of that. Oaks vary hugely in the amount of acorns they will produce from variety to variety, and from year to year. Some oak trees have alternate-year bearing cycles; some give a light harvest one year and then a heavy bounty on the alternate year; or a partial crop for 2 years and a full crop on the third. The ilex (holly) oak bears as much as 900 lb. of acorns on alternate years. Some bear significantly only every third or fourth year but give 500–600 lb. of acorns at that time. The emory oak, however, is said to bear almost every year, at least 4 bushels. One of the reasons for delayed bearing may be acorn crops that are lost to early frosts. But the tree tends to make up for lost time when it does get a crop past the frost risk. The larger the tree, the larger the acorn crop it can bear. Grafted oak trees generally yield at least double the acorn harvest of wild ones.

Acorns for Livestock Feed. Acorns provide food for both humans and their livestock (especially pigs, which will feed themselves off the acorns that drop and get fat on them)—a tradition that goes back to antiquity. Acorns are the best keepers of any of the nuts. They'll lie under the tree for a long time without rotting, which makes them perfect for a forage crop. Pigs will roam happily under the oaks, eating nuts as needed. Chickens love acorns that have been broken up so they can get at the nutmeats.

⇒ **ACORN MEAL** Fortunately, tannin is very soluble in hot water. So, peel the acorns. Grind them up. Soak the “flour” in very hot water. The water will turn brown, because of the tannin coming out. Throw away the water and repeat 4 times. Another way to do this is to line a colander with a straining cloth, put the ground acorns in, and gradually pour a gallon of water, as near boiling hot as you can manage, through. There will still be some dark chocolaty color to the paste, but after exposure to a gallon of hot water, you can be confident that enough tannin has been removed to render the acorn meal edible. Spread the acorn paste on a baking sheet and bake at a low temperature until thoroughly dry. If it has caked, grind again, and you have your acorn flour. You can substitute acorn meal for cornmeal in any recipe, or use part acorn meal and part cornmeal, or $\frac{2}{3}$ acorn meal and $\frac{1}{3}$ oatmeal.

⇒ **ACORN FLOUR RECIPE IDEAS** Mix with sour cream and seasonings (basil, onion, garlic, cumin, paprika, parsley) to make a dip. Or mix with mashed cooked eggplant, mayo, and seasonings to make a dip or sandwich. Or mix leached and cooked acorn paste with mayo and make a sandwich with it (add pickle, sprouts, lettuce). Or mix leached, cooked acorns with macaroni (flavor with tamari, butter, cheese, and hot peppers). Or toast acorn meal, mix with other toppings, use as topping on yogurt or ice cream. Or add to any tomato sauce. Or cook with beets and onion (serve with homemade bread).

ALMONDS: Almond (*Prunus amygdalus* or *Prunus dulcis dulcis*) trees are related to peach and plum trees and are similar in habits. They grow 15–30 feet high with an equal spread of branches. Some varieties are bushy, others more treelike. Almonds start to bear nuts after 3 years of growth, but they don’t achieve full-scale production until they’re about 12 years old. But once your almond is mature and bearing nuts, it will yield for another 50 years, if kindly cared for.

Climate. The sweet almond does best with a long, warm growing season (zones 7–9), plus low humidity. Most almond orchards are on the West Coast, principally in California. Almond’s tendency to bloom a month earlier than peaches means that although the trees can survive in northern areas it’s hard to get a nut crop during any year you have an early frost.

Varieties. Almond extract is made from the bitter almond tree, which grows in Europe and whose nuts contain enough prussic acid that you couldn’t eat more than a few. Bitter almonds are harder than sweets and can be raised anywhere that peaches can. There are dwarf almonds that can be grown in containers. There have to be 2 different cultivars, but the almond is pollinated by bees rather than wind so the pair doesn’t have to be planted really close together. New Halls have received a lot of publicity, but Tucker Hill wrote me, “I’ve spoken to a number of people who were disappointed with this almond.”

Planting. Soak dried seeds a day, then stratify at 40°F. Or simply plant the seed in the fall where you want it to grow. Choose well-drained soil. Protect seed from being dug up by squirrels by placing a “cage” over it until it is well-started. Or bud graft on a seedling rootstock. Good stocks are bitter almond, peach, peach-almond hybrid, plum (if resistant to oak fungus), or any other almonds. Nemaguard and (peach) Lovell are good for waterlogged or irrigated areas. Good scions are Bartre, Nonpareil, and Mission. Plant the smaller (15-foot) varieties 20 feet apart. Avoid unnecessary pruning of the young tree because that will delay nut production. Train like a peach.

Harvesting. Your almonds will be ready for harvest in August or September. *How to Grow Vegetables and Fruits by the Organic Method*, edited by the Rodale staff, available from Rodale Press (see [Chapter 1](#)) has a good description on [this page](#) of how to raise and

harvest this and other nuts grown in the United States: "The outer hulls of the nuts split open in fall when almonds are ripe. When most of the hulls in the center of the tree have split, nuts are shaken or knocked out of the branches and gathered from the ground. Heavy rubber mallets may be used for jarring the nuts loose without injury to the bark. After the harvest, almonds should be shelled and dried to prevent mildew. Kernels are spread for drying in a partially shaded place and are left until the meat is crisp. They are then stored in airtight containers in a cool place until used."

⇒ **BLANCHED ALMONDS** *To blanch an almond means to get the papery outside skin off. Pour boiling water over the nuts. Let them stand 5–10 minutes, or until the skins wrinkle. Drain away the water. You can easily slip off the skins by just squeezing the nut between your thumb and index finger. (If they don't want to give, go with another boiling-water treatment.) Dry.*

⇒ **ALMOND SALAD DRESSING** *From Ruth of Bonaire: "An interesting salad dressing can be made with 2 c. carrot/cucumber juice and 8 oz. fresh almond butter. Blend till smooth."*

⇒ **ROASTED ALMONDS** *"Roast" in a fry pan by pouring the almonds, blanched or unblanched, in with 2–3 T. hot oil. Fry, stirring, until evenly browned. Drain. Sprinkle salt on them. Or do them in the oven by spreading on a baking sheet and roasting at 350°F 5–12 min. Stir them occasionally while baking.*

⇒ **SLIVERED ALMONDS** *Lay the nuts, flat side down, on a cutting board and cut lengthwise with a sharp knife into slivers.*

⇒ **TOasted ALMONDS** *Put on a cookie sheet in a 350°F oven until golden, about 5 minutes. Or mix in 1 T. melted butter and 1 t. salt per 1 lb. almonds and bake until lightly browned and crisp, stirring often. Or you can do it on top of the stove by first blanching, then heating butter in a small pan over low heat, adding nuts, and frying 5 minutes, or until lightly browned. Then drain on absorbent paper.*

⇒ **ALMOND PASTE** *This Victorian gourmet ingredient was used to make macaroons, crescents, and marzipan. To make it yourself, grind in a mortar or in a chopper, or blend in a blender, shelled, skinned, and dried almonds (not roasted). If need be, run through the grinder several times until the nuts are really fine. Then, method 1: For every 2 c. almonds, dissolve 1 c. sugar in ½ c. orange juice and then mix thoroughly with almonds. Method 2: Mix 1 lb. ground almonds with 1 lb. sugar and 1 c. water (sugar and water cooked to the soft-ball stage). Then add ½ c. orange juice. Almond paste improves with some storage. Wait a week at least before using. If you have lots of time and use white sugar, consider taking up the art of marzipan-making. You can buy marzipan molds for making fruit shapes from kitchen specialty outlets.*

⇒ **OLD-TIME MACAROONS** *Blanch ½ lb. almonds and pound them to a paste in a mortar, or put several times through a grinder set on "fine," or blend. Add ½ lb. powdered sugar and 2 stiffly beaten egg whites. Work it all together, then form balls about the size of a whole nutmeg. Bake at 250°F until light brown.*

⇒ **MACAROONS WITH ALMOND PASTE** *Add gradually to ½ lb. of almond paste, ¾ c. sugar and 3 beaten egg whites. Mix well and add ¼ c. powdered sugar and 2 T. flour. Put teaspoonfuls on a paper on your cookie sheet Flatten the shapes a little. Bake at 250–300°F for about 30 minutes.*

⇒ **MARZIPAN** *In the old days marzipan was also known as "toy candy," a traditional holiday treat. To make it, mix 1 c. almond paste, 1 c. powdered sugar, and ½ t. orange or vanilla extract, or rose water (the traditional flavoring). Knead it a long time—20 minutes maybe—*

and then set it on a rack to dry. After drying, it can be shaped into tiny replicas of fruits, or whatever takes the cook's fancy.

Coloring: After drying your molded shapes at least overnight, paint them with food-coloring using a small paintbrush. Or dip them into the color Easter-egg style. Then give them time to dry. You can also give them accessories such as cloves for stems and leaves made of bits of angelica.

Glazing the Figures: Leave them covered with heavy sugar syrup 8 hours. Make the syrup by cooking 5 lb. sugar and 2½ c. water to the soft-ball stage—234–240°F. Remove syrup from heat and let it cool. Add marzipan in a single layer. It is important throughout to avoid disturbing the syrup as much as possible. Then drain your candies and let them dry again.

ARAUCARIA: There are two important nut-producing Araucaria species: Monkey Puzzle and Bunya Bunya.

Bunya Bunya. This Australian native evergreen (*Araucaria bidwillia*) is related to Monkey Puzzle. It grows similar large, thin-shelled, good-tasting nuts, resembling chestnuts. Plant 2 or more for cross-pollination. Bunya Bunya is less hardy than Monkey Puzzle. Plant only in a warmish Zone 8, or U.S. Zone 9, or warmer—or indoors.

Monkey Puzzle. This tall attractive evergreen nut tree comes from Chile. Monkey Puzzle (*Araucaria araucana*), produces large cones with 250 nuts, each about 2 inches long, per cone. The plant is hardy to -10°F. You must plant two or more to get nuts. Available from Burnt Ridge. The nut shell is thin and easily peelable. Roast like chestnuts.

BEECHNUTS: Beech trees can live very long, well over a century, and grow very large. Although the Beech was originally wild, domestic varieties have been developed that yield larger-sized nuts than the wild or seedling trees. Brown beechnuts are good to eat. The American beech grows to 50–75 feet high. Beech trees are very hardy, suitable for zones 4–9, and only rarely lose a crop due to spring frost. They have good disease resistance and no insect problems. They are self-fertile. Plant them 80 feet apart. The tree produces a crop of triangular nuts covered with a burr.

BRAZIL NUTS: This tropical nut grows wild in the Amazon forests of Brazil. It can't be grown unless you have virtually tropical conditions, including heat, lots of rain, and fertile soil. The most southern tip of Florida might be suitable. Mature Brazil nut trees are big and beautiful. Their nuts grow inside hard wooden outer husks about 4 inches across, 18–24 nuts to the husk. They're delicious eating—rich in fat, protein, a little carbohydrate, and a lot of calcium!

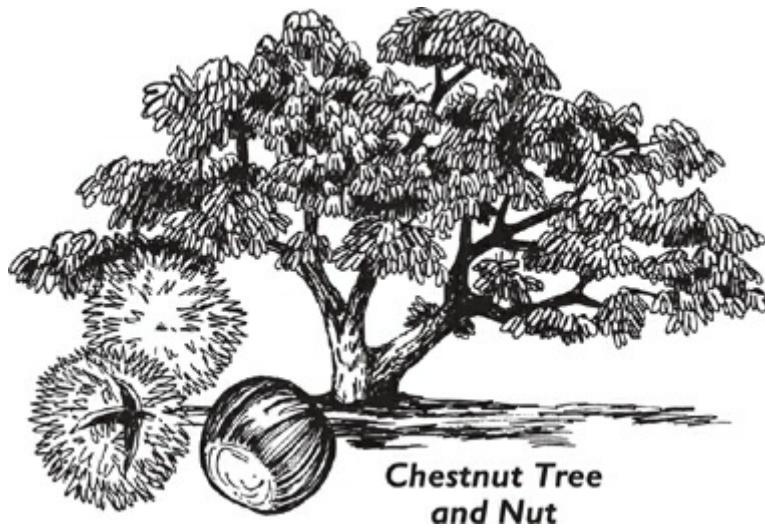

BUTTERNUTS: See "Walnuts."

CASHews: The cashew, *Anacardium occidentale*, is a little evergreen tree that comes from the West Indies and can't grow outside the tropical zone. Trees bear only after 4 or 5 years. You can plant seeds, which grow reasonably soon, or graft.

The fruit, called "cashew apples," is ready to harvest in early summer. Sticking out of the base of each cashew apple is the cashew nut inside an outer shell. But the nut is protected by a substance similar to poison ivy, released to do its damage if the shell is broken by some would-be cashew eater. The solution is to roast the nuts before shelling because that disarms them. The cashew apple has no such problem. You can eat it raw or cooked or juiced or anyway you would a regular apple.

CHESTNUTS: The chestnut (*Castanea*) tree produces abundant flowers from which honeybees love to gather pollen and nectar. A single tree can produce 250 lb. or more of nuts every year. Chestnuts are specialty nuts that are especially popular at Thanksgiving and Christmas time.

Varieties. There are chestnut varieties that bear early (Meiling Chinese chestnut), middle, and late. By planting some of each you can prolong your harvest season. The other big factor to consider is blight resistance.

American. The splendid American chestnut was a relatively fast-growing tree, reaching up to 60 feet tall with trunk diameters of over 3 feet in less than 60 years. And that chestnut timber was an excellent hardwood with many uses. But those native American chestnuts (*Castanea dentata*) of the eastern and southeastern United States all died as a result of the terrible air-borne blight disease that arrived from the Orient in 1904 in a shipment of plants—and still attacks any vulnerable chestnut. Before that, the American chestnut, a superior variety both for timber and nut production, grew huge and wild, making up as much as half of the natural forests in its area. There were also large commercial chestnut orchards, the chestnut being an economical and valued “tree corn.” Although new suckers continue to try to grow from the stumps of some of the old giants, they are struck down by the blight after reaching 20–30 feet.

The chestnut blight, incidentally, presents a very clear example why we should always maintain genetic diversity, even at the cost of supporting some obviously less desirable varieties of a species!

Hybrids. The few American chestnuts that have survived have been propagated and hybridized with European (the Spanish) or Asian (the Chinese) chestnuts. Burnt Ridge offers many chestnut varieties. Chestnut Hill Tree Farm sells bare-root Dunstan seedling chestnuts through the U.S., January to April. Dunstan is a blight-resistant American-Chinese hybrid. (Actually, not one person has ever died of the blight, and this is the most widely planted chestnut in the U.S. today.) They have large nuts, timber tree form. They have been grown successfully from Maine to Florida, west to Illinois and Texas, and on the Pacific Coast from Washington to California: 386-462-2820; 15015 NW 94th Ave., Alachua, FL 32615-6709; www.chestnuthilltreefarm.com.

Chinese Chestnut. *Castanea mollissima*, the most blight-resistant and most popular chestnut variety, grows about 35 feet high and bears tasty nuts. It is hardy as a peach, rarely suffers frost damage, and lives a long time. Most nut trees prefer neutral or slightly

alkaline soil, but this one favors a slightly acidic one. Its wood is very brittle. Head back long branches to avoid breakage.

Chinquapins. These are a small, native-American, Southern chestnut, which is basically resistant to the blight.

Japanese Chestnut. There are several varieties of this one (*Castanea crenata*). Mostly they grow into a large bush or small tree, but some grow into trees as tall as 30 feet. In the past, this tree hasn't been as blight-resistant as the Chinese, but the folks at the Connecticut Experiment Station (New Haven) have managed to create some promising new crosses of the American chestnut with the Japanese that are quite blight-resistant: Essate-Jap and Sleeping Giant. This variety is more suitable for the warmer zones, hardy only in zone 7 or south of it.

Native Northwest Chestnut. The *Castanopsis chrysophylla* species hasn't been hit by the blight. The Northwest is now one of the best areas in which to grow chestnuts because of fertile soil and moderate climate—and because the chestnut blight has not yet found its way into the area.

Planting. Chestnuts are not self-pollinating; plant 2 or more. Open-pollinated European or European-Chinese hybrids are for dual-purpose timber plantings, blight-resistant Layeroka seedlings for nut orchard pollinators, grafted Layeroka and Skookum for nut orcharding, and others. Nanking, Kuling, and Abundance are older favorite varieties.

Fall planting is possible, but chestnut seeds (nuts) must experience at least 3 months at temperatures 40°F or below in order to germinate. They will grow best if planted lying on their sides, in humus-rich soil of pH around 5.5, protected from nut-eating predators. Or you can store your seed in a very cool place. With luck chestnuts retain germination ability for as long as 3 years. Or you can graft or bud. Serious chestnut growers almost all use grafted trees.

Pruning. Chestnut wood is brittle, so prune early for a strong central leader, horizontal crotches, and balanced branch arrangement. Prune only when leaves and nuts have fallen and the tree is dormant. Chestnut pollen is carried by wind or insects.

Harvesting. On the tree, the chestnuts grow inside of burrs. When ready in the fall, the burrs split and spill out the nuts inside onto the ground. You must pick them up before they have a chance to get moldy, wormy, or eaten by squirrels or 4-legged furries.

Storing. If you put chestnuts in water, bad ones will float. When you refrigerate them, give them air by packing them in loosely covered containers or in plastic bags that have holes in them. Unshelled chestnuts will stay fresh for several months if refrigerated, and for much longer in the freezer.

Cooking. Human food for some 6,000 years, chestnuts are an unusual nut because they are mostly starch with only a little fat, so you can do vegetable kinds of things with them. Prepare like a vegetable main dish; grind into a flour; prepare in a soup or sauce; add them to pasta, pastry, or desserts; and, of course, roast them over an open fire.

Shelling by Roasting. Roast in an oven 15–20 minutes at 375°F. Then peel.

Shelling by Boiling. With a sharp knife, cut a crisscross gash on the flat side of the shell of each chestnut. Simmer until they are quite soft, about 15 minutes. Remove nuts from water, shell, and remove brown skins with a sharp knife. Then go ahead with any of the following recipes. It helps to lift the nuts out one at a time and peel off both shell and

inner skin while the nut is still damp.

Freezing. Shelled, blanched chestnuts should be frozen if you won't be using them within a few days. Just pack any chestnut puree recipe in containers that can be closed tightly. Use in cooking without thawing ahead of time.

⇒ **CHESTNUT-MEAT-STOCK PUREE** Cook peeled chestnuts in meat stock, or in a half-and-half mixture of milk and water until they're tender. Puree nuts in a blender or some such. Make a soup by mixing some of the puree with the stock.

⇒ **CHESTNUT-SQUASH PUREE** Mix chestnut puree with squash or pumpkin puree for a special side dish. When freezing this puree, prevent separation by mixing in either 1 T. butter or 1 T. honey to each cup of puree before freezing.

⇒ **PLAIN CHESTNUT PUREE** Boil peeled chestnuts in lightly salted water until tender. Then mash and add a little butter, salt, and pepper.

⇒ **CHESTNUT POULTRY STUFFING** To the puree, add bread crumbs, beaten eggs, and a little of the juice in which the chestnuts were cooked.

⇒ **CHESTNUTS AND SPROUTS** Sliced chestnuts are good with Brussels sprouts.

⇒ **PLAIN CHESTNUT CHICKEN SOUP** Chestnuts go well with chicken soup. Cook 1 c. peeled chestnuts in 2 c. chicken soup until tender. Add about 6 c. more chicken soup. Season with salt and pepper and serve.

⇒ **FANCY CHESTNUT CHICKEN SOUP** Heat ¼ c. butter in pan. Fry a half dozen chopped green onions or 1 small chopped globe onion until golden. Add 1 lb. fresh, simmered, peeled chestnuts. Fry 1 minute, stirring constantly. Add ½ c. chopped celery or celeriac and 2 c. chicken stock, and cook 30 minutes or until chestnuts are quite tender. Strain solids out of the broth and puree them. Then stir back into the broth. Reheat just to a boil. Add salt and pepper to taste, a pinch of nutmeg, and 1 c. light cream (or half-and-half). Do not boil!

⇒ **DIFFERENT CHESTNUT SOUP** Puree 2 lb. fresh chestnuts, or use 1 lb. unsweetened chestnut puree. Heat puree in 1 qt. vegetable stock. Add 1 c. finely grated carrot (or salsify) and cook on low heat about a half hour. Melt 2 T. butter in a separate pan. Add 2 T. flour and cook stirring constantly, until it begins to darken. Add the hot chestnut soup in slowly, stirring to keep it blending. Add ½ c. red wine, ¼ t. nutmeg, ¼ t. cayenne, and salt and pepper to taste. Cook 10 minutes more over low heat (stirring often!). Sprinkle a little paprika over each bowl you serve.

CHINQUAPIN: See "Chestnuts."

COCONUT: There are many different varieties of palms, all tropical species. The beautiful coconut palm (*Cocos nucifera*) grows in both the East and West Indies, the tropical Americas, the South Pacific, Southern California, and Florida. They can grow as high as 100 feet tall. It has no branches, but there's a cluster of large leaves at the very top. Those few leaves are 12–18 feet long and useful for braiding into things or thatching houses. One tree will produce 40–75 coconuts per year (depending on soil fertility), with fruits maturing all year round. Coconuts are salt tolerant. Ocean sprays, wind, flooding, or even an occasional covering with salt water doesn't hurt them. Palms can also be tapped for their sweet sap. But they need lots of humidity, a frost-free climate, 40–60 inches of rain fairly evenly distributed through the year, and a minimum average temp of 72°F.

Planting: A coconut husk high on the beach may have dropped from a tree into the ocean and floated for thousands of miles before washing ashore. Under natural conditions, eventually it will sprout and grow. To plant the seed yourself, place an unopened coconut into a partially shaded nursery bed. Leave the top half of the shell outside the dirt. Keep it moist. If you plant while the nut is still a bit soft it will germinate in only a few weeks. Once the nutshell gets fully hardened, it may take as long as 4 years to germinate.

Harvesting. Dwarf trees bear in 3–5 years, standards in 5–10 years. Once the tree starts, coconuts will continually ripen year round, more every year—from 50, when it's young, increasing to maybe 200 when the tree is fully mature at 15–20 years. The fruit is covered with an outer husk that is made of tough fibers that are very resistant to saltwater. It changes from yellow or green (depends on variety) to brown as it ripens. Those husks are used to make fishing nets, doormats, rope, and brushes. The nutmeat is inside a tough shell, which itself is inside the husk. The shell can be used as a bowl. You can harvest using a knife fastened to the end of a long pole.

Steve Beckman wrote: “I was a Peace Corps volunteer in the South Pacific country of Tuvalu for 3 years and am married to a Tuvaluan ... To harvest brown nuts, just pick them off the ground when they fall. If you harvest green nuts by climbing the tree, give the nut a spin as you drop it down. This causes it to hit upright. If it lands on its side, it will very likely split open. Brown nuts will last a long time just laying in a pile (any making ground contact will eventually become utanu—see recipe below), but green nuts should be refrigerated.”

➲ **HUSKING COCONUTS** Steve says, “Take a stick about 1 inch in diameter and a little longer than waist high and sharpen both ends, making one of the ends a bit flatter than the other. Push the round pointed end into the ground and impale a coconut on the flatter end towards the top of the nut and twist and pry to peel off a small section of the husk. Repeat this going around the nut, taking about $\frac{1}{8}$ of the husk with each impaling. The husk on brown nuts comes off much more easily than those on green nuts, and it is much easier to accidentally break through the shell of a green nut.” The husks are used to make fishing nets, doormats, rope, and brushes.

Opening a Coconut. Pound something sharp through one of the 3 “eyes.” The shell is thinnest there. Then drain the coconut milk into a cup. Next, whack the shell with a mighty hammer blow and it will crack wide open so you can get at the nutmeat. It can be eaten fresh or dried.

Steve corrected me: “You shouldn't have to pound anything through the eyes. Two of the eyes will be solid, but one will penetrate all the way to the meat (this is the eye where the sprout emerges). I used to use the end of a potato peeler for gouging out an eye on green drinking nuts.

“To open a brown nut, hold the nut in your hand. With the eyes as the north pole, whack it along the equator with the back (unsharpened) edge of a large kitchen knife. Rotate it a couple of ‘time zones’ and whack it again. After 3 or 4 whacks, a crack should form along the equator. Insert the knife into the crack and twist while holding it over a bowl to catch the water. The nut will pop apart into two halves.”

➲ **UTANU (GERMINATED COCONUT)** From Steve: “This is one of my favorite treats. When you shake a fresh brown nut, you can hear the water inside. Plant the coconut as per the instructions in your book. As the coconut germinates, you will be able to hear less and less water. When you can't hear any water, it's ready. Open the nut as above. All the water (and most of the meat) will have been converted into a sweet substance with the consistency of

Styrofoam. You can either eat it raw or boil it in coconut cream.”

➲ **LOLO (COCONUT CREAM)** “Open a brown nut and grate the meat. The best tool for this is a coconut grater. We’ve found some crude, but workable, ones at Chinese grocery stores. Put the grated coconut in a mesh of some sort (a couple layers of cheesecloth works, but something stronger is better) and squeeze the cream out of it. Popular in Tuvalu is pieces of the old bait nets from Te Tautai. I suppose a fruit press might work as well.”

➲ **KALEVE (COCONUT TODDY)** “This is a much more involved process than just collecting nuts. Start with the shoot where the coconuts are produced. Get it just before it splits. Earlier, and it will take longer for the toddy to flow. If you wait until after it splits, you won’t get any toddy ... Climb up in the tree (if it’s not a dwarf), remove any coconuts still on other shoots, bend the shoot down to a horizontal position, and tie it down. Next, cut off the end about 4 inches from the end. Cut the husk back about an inch from the end. Now, wrap the shoot as tight as you can from end to end. I used to use twine made from coconut husk, but something like binder’s twine would probably work as well. Every morning and evening you’ll have to climb the tree and shave a paper-thin slice off the end of the shoot to keep the toddy flowing. This requires a very sharp knife—a shaving edge and then some.”

“When the toddy begins flowing, you’ll need a bottle to catch it, and use leaves with the midrib bent over to be a funnel to direct the toddy into the bottle. You can drink the toddy fresh, but strain it through some cloth to filter out the occasional ant. It tastes better chilled. Fresh toddy can be boiled down into a syrup like molasses or maple sap called kaleve kula (red toddy). You can make vinegar from it by letting it ferment through the alcohol stage (toddy contains a natural yeast that will convert itself into a beer in 3 days) and then wait a little longer.”

➲ **MAKING COCONUT MILK** The store product called “coconut milk” or “mix” for making alcoholic drinks is not the real thing and can’t be substituted for genuine coconut milk in tropical cuisine. The clear liquid at the center of the coconut is sometimes called “coconut milk,” but usually coconut milk for cooking is produced by the following method: Cut fresh coconut meat up into cubes about 1 inch on the side. Measure out an equal amount of hot water. Place water and coconut in your blender and blend at a high speed for a couple minutes. Let rest 30 minutes. Set a strainer over a bowl and pour the puree into it. Squeeze out as much “milk” as you can by pressing on the pulp. Giving the coconut milk an extra straining through an even finer mesh makes it nicer. Coconut milk will keep fresh only a few days in the refrigerator. If you need to store it, freeze it. Real coconut milk can be used to make sauces, soups, desserts, and curries.

➲ **SHREDDING COCONUT** Open a hole in your coconut, and pour out the milk. Drink the milk or save it for cooking. Grate the coconut meat or shred it with a vegetable shredder.

➲ **TOASTING SHREDDED COCONUT** Put the shredded coconut in a flat pan and put the pan in the oven at about 200–300°F. Stir occasionally until it is dried. You can also sun-dry coconut. All you have to do is cut the meat into thin slices, spread it on your trays, and put it in the sun to dry. Dried coconut is called “copra.” Store copra in airtight cans or jars. Add copra to pudding, eat it as a sweet, or use it in any recipe in place of nuts.

➲ **COCONUT MILK MADE FROM DRIED COCONUT** Combine 1 c. natural (unsweetened) dried coconut with 1½ c. hot water. Let rest 5 minutes. Puree and strain.

➲ **COCONUT CREPES WITH POLPANI FILLING** Sift together ¼-lb. sorghum flour and ¼-lb. wheat flour 3 times. Place flour in a bowl. Add salt to taste, and the yolks of 6 eggs. Add 3½ c. thick coconut milk. Mix with a wooden spoon. Gradually add 3½ c. more of thick coconut

milk. Beat the whites of the 6 eggs to a very stiff foam and fold them into the batter. Set the crepes batter aside and prepare polpani. (You can substitute any crepe filling for the polpani.)

To prepare polpani (brown sugar and coconut filling): Place 4 oz. unrefined brown sugar in a pan. (The original recipe calls for 4 oz. "jaggery," which is an unrefined brown sugar made from palm sap!) Add 2 T. water and a ½-inch piece of cinnamon stick. Stir and cook over heat until syrup thickens. Add 4 oz. fresh coconut scrapings and a pinch of salt. Keep on low heat a few more minutes, until mixture thickens.

Now put your pancake pan on the heat and melt a little butter, margarine, or coconut oil in it. Pour enough batter into the pan to make a pancake about 5 inches wide and very thin. When it is cooked on one side, turn it over. When both sides are done, slip the crepe onto a plate, put a spoonful of the polpani in the middle of it, and then roll it up.

⇒ **COCONUT BREAD** Combine 2 c. shredded coconut, 1 c. mashed other fruit, and 5 eggs. Mix well. Sift together 2 t. salt, 2 t. baking soda, and 4 c. any flour (doesn't have to be a wheat flour!). Add 1 c. brown sugar and mix all ingredients well. Let rest 20 minutes. Stir once. Pour into a greased pan. Bake at 350°F. Cool, then serve.

⇒ **COCONUT OIL** When dried coconut is pressed, it yields coconut oil.

Green Coconut. You don't have to wait until a coconut is fully ripe to eat it, although that is the proper stage at which to harvest if you want to press from it. The immature coconut flesh is soft: "green coconut." Eat it with a spoon. It's delicious, nourishing food, traditionally given to infants, the elderly, or ill people.

FILBERT FAMILY: Hazelnuts and filberts aren't the same thing, but they are related. The hazelnut (*Corylus americana*) is a native American filbert. It's a small bush that can grow up to 8 feet tall. The filbert (*Corylus avellana*) is a large bush that can be pruned to take the shape of a small tree. Filberts grow up to 15 feet tall. Both filberts and hazelnuts are relatively quick growing and produce nuts early. But both also have a relatively short life span of only about 20 years, so plan for replacement trees as they age. Both prefer neutral soil, have no serious insect pests, and need 2 or more trees for cross-pollination. The hazelnut has the best disease resistance, the best chance of escaping frost damage, and the best general hardiness. There are many other species.

FILBERTS: The filbert is a long-domesticated, much-hybridized, and improved plant, one of the nuts with the distinction of regularly appearing in holiday nut mixes. This nut is popular as a yard-grown tree, being easy to grow, hardy (zones 3–6), and naturally on the small side. In Washington and Oregon filberts are grown commercially. You can grow filberts in colder climates if you get the late-blooming kind. Filberts occasionally lose a crop to frost (again, hazelnuts are harder).

Propagating. You can reproduce filberts easily by layering. To layer, bend a low filbert branch clear to the ground, cover the middle portion with dirt, and put something heavy on top to hold it down like that. Soon that covered (layered) section will have taken root on its own. Eventually you can cut it loose from the parent tree, and later yet you can transplant the new start to wherever you want it. The filbert doesn't have the long taproot of the walnut family, so it's easier to transplant. Grafting and budding are another option. Good stocks: Turkish tree hazel (*C. colurna*); and *C. americana* and *C. cornuta*, both disease-resistant Americans. Good scions: Barcelona and Nonpareil.

Growing from Seed. Growing filberts from seed can be difficult if you're doing it on

purpose. On the other hand, volunteers from careless birds or forgetful squirrels may grow generously. To grow, seeds must have been successfully pollinated, then chilled at 40°F or below for at least 3 months. If your seed doesn't germinate the first spring, don't despair, because sometimes it will after 1 or 2 years or even longer. If you plant numerous seeds in pots, flats, or a nursery bed in your garden, you can hope for better success. In their permanent location, plant filberts 20–25 feet apart.

*Filbert Tree
and Nut*

Pollinating. Barcelona is a good pollinator for Daviana. Filbert trees have unusual blooming patterns. The trees do not have a natural dormant period. They can be loosely classified into early bloomers, mid-bloomers, and late bloomers. Early bloomers start about November and continue into January and February. Mid-bloomers bloom mostly in the winter months. Late bloomers start later and continue until March. To make it even more murky, sexes may bloom at different times. The males of some varieties bloom first; within other varieties, the females bloom first. You're fortunate if you can get them both to bloom at once, which is what you need for fertile seeds.

Pruning. Easterners usually let filberts grow as a large bush (limited to 5 or 6 stems so the center doesn't get too dense), but on the West Coast, they are often pruned to a single main stem to make them look like small trees. Prune mature plants in a way that lets more light into the center of the tree. Prune only during winter.

Cooking with Filberts. Filberts may be toasted, ground, and so forth. For baking they are usually left unblanched, for the pinkish skin adds much to their flavor and food value.

Removing the Skins. Spread the nuts on a cookie sheet or in a shallow baking pan. Bake at 300°F for 15 minutes, stirring occasionally. After they have cooled enough to handle you can rub the skins off with your fingers. If you plan to chop filberts, toast them after chopping. Store toasted nuts in an airtight container. Filberts make a great nut flour.

Harvesting. Filberts that are pollinated in January or February will grow in spring and drop in September and early October. The female flower has already been growing a year and a half when the filbert nut, which has been attached to it almost 8 months, finally drops. Pick up the nuts as soon as possible to prevent mold and to reduce loss to birds and squirrels. Give them the water test—floaters are not good. Dry them by spreading them out in a dry room and stirring them occasionally. Store in the shells in a place where mice and rats won't be tempted.

HAZELNUTS: These trees differ from filberts in that their smaller size allows you to plant them only 10 feet apart. The nutmeats are good-tasting but tend to be smaller than those of the filbert. Winkler is a good variety. Hazelnuts make a nice raw nut butter. You can mix it with vegetable or fruit juices to make a salad dressing.

HEARTNUTS: See “Walnuts.”

HICKORIES: Hickories (*Carya*) grow wild in the central and eastern United States. They naturally grow into straight, very tall trees (maybe 50 feet) and are sold for their unusually strong wood, used to make tool handles. Hickory wood is also a prized firewood, and the bark is excellent for smoking meat. It takes a hickory tree an average 5 years to start bearing nuts. When mature, they’ll produce 4 or 5 bushels per year. They can be stored in the shell for months in a cool dry place.

Hickory Varieties. Hickories include pecans, bitternuts, shagbark, water hickory, mockernut, shellbark, and pignuts. There are still other varieties that are natural hybrids, and more that have been developed by plant breeders for the big commercial pecan market. The value of the nuts depends on the variety.

Bitternut. The bitternut is practically inedible. Bitternut is the hickory that can grow farthest north, even in southern Canada, though the shagbark, shellbark, and mockernut hickories are also very hardy.

Shellbark and Shagbark. The pecan is the prime culinary and market variety; the shellbark and shagbark compete for second-best. The shellbark bears a large, white, 4-cornered nut with a sweet kernel. The shellbark hickory grows wild from Tennessee north to New York and is a good nut tree, especially for northern states (zones 5–8). Hicans are hybrids made by crossing pecans with shellbark hickory. Tucker Hill says the McAllister hican is unreliable for nut production though a good shade tree; the others are good producers. All the hickories have good disease resistance; the shagbark is most free of insect problems. Shellbark nuts have thick shells. One method that helps in cracking them is to freeze them overnight, then crack with a hammer blow on the nut’s edge. You’ll learn to swing with just enough force to crack the nutshell without smashing the nut. Or some readers say a hot-water bath beforehand helps make shelling easier.

Pecans. Pecans (*Carya illinoiensis*) are a hickory variety—a good tree that is easy to grow, does fine in yards, and bears a nut that is easy to shell. Some small varieties have been developed that are more suitable for a small yard. A papershell pecan tree can give you 100 lb. of pecans a year. One way to choose your varieties is between southern early-bearers (Candy, Elliott, Shoshoni, Success, Western, etc.) and southern late-bearers (Curtis, Mahan, Schley). Read ATTRA’s “Sustainable Pecan Production” at www.attra.org/attra-pub/pecan.html.

Climate for Pecans. Big pecan crops are possible all over the southern and southwestern United States and in California. The southern pecan is the least hardy and requires a long growing season, so commercially they are usually grown only from Georgia on south. However, northern pecans are grown in Kansas and Nebraska, as well as Illinois, Indiana, Ohio, and Pennsylvania. The variety you buy needs to be exactly chosen for your climate zone. Tucker Hill warned me to beware of Southern pecan propaganda. “Northern pecans are smaller but higher in flavor. Both Kansas and Nebraska are producing outstanding pecans. We do quite well here in Pennsylvania.”

Planting Pecans. You can plant seeds, graft, or bud. But seeds can't be depended on to breed true. In the South, plant seeds in the ground any time following the nut drop and before the next spring, as long as the contents of the nut haven't dried out. Northern varieties need to be chilled in the ground or in your storage area at just above freezing for about 2½ months in order to germinate. To bud pecans, large varieties should be selected for stock. Seedling trees take years to reveal what you've got—8 or more. Grafted trees usually take about half as long. Plant orchard pecans 30 per acre. Grow 2 different varieties near each other in order to have pollination.

Harvesting. If you have trouble getting your nuts off the tree you can knock them from the branches with a pole. In the shell they will keep best in the refrigerator.

➲ **VEGAN PECAN BURGERS** *From Ruth of Bonaire: "Combine 1 c. ground unroasted pecans, 1 c. wheat germ, 1 c. bran flakes, 1 c. grated onion, ⅓ c. grated carrot, 1 T. tamari, and water enough to moisten, if needed. Shape the mix into patties. Fry on a nonstick or potato-rubbed skillet. Serve on buns together with your favorite toppings."*

➲ **PECAN MACAROONS** *Beat 1 egg white until stiff. Then gradually beat in ⅓ c. pecan nut meats (chopped fine). Drop mixture by teaspoonfuls onto a baking sheet covered with buttered paper. Make smooth rounds of your drops. Sift powdered sugar over the top. Bake at about 350°F.*

➲ **PRALINES** *Combine 1⅓ c. powdered sugar, 1 c. maple syrup, and ½ c. cream. Boil to the soft-ball stage. Remove from heat, and beat until creamy. Add 2 c. chopped pecans (or any other nuts). Pour into a buttered pan and cut into squares.*

Planting Hickories. Plant a nut, or a seedling, or grafted/named variety. But this tree has a long, strong, early-developing taproot, so don't consider transplanting unless it's a very, very small tree and then plan carefully and put that small tree where you'll want to keep it. And if the taproot is cut or bent while transplanting, prune it just above the injured part.

Pruning. Prune after the nuts have fallen, in early fall. Take off a few lower limbs each year while the tree is young until you achieve a 6–8-foot bottom trunk. After that, mature trees don't usually need any pruning.

MACADAMIA: This nut tree is a good-looking evergreen that's native to Australia where it's known as the "Queensland nut." Later grown also in Hawaii, they are now getting started in California and Florida, too. In Australia where the soil is fertile and the moisture abundant enough, they can get 40–50 feet tall.

Planting. Macadamias need to root in deep soil to keep themselves from being blown over, and they seem to do best in an acidic soil. Stratify the seeds during your coldest season; then plant them in individual pots in a greenhouse-type situation. They are slow to germinate. When you transplant be careful not to disturb the root mass. They can be grafted to better cultivars. Warm climates only.

Harvesting. For some reason, only a few of the hundreds of tiny macadamia blossoms produce nuts, but there are so many flowers to start with that your crop can still be generous. The nuts mature inside a husk and require more than half a year's time. The husk ruptures itself when the nuts are mature, allowing them to fall to the ground. During the harvest season (about a month long), go out at least twice a week and gather up all the nuts off the ground. Then dry them thoroughly.

Using Macadamias. You need a special tool (such as vise-grip pliers) to crack the shells because they are so hard. Before you use the nutcracker, spread the nuts on a baking sheet and roast at 200°F for 1 hour. Cool slightly; then shell. Store shelled nuts in the refrigerator in a covered container.

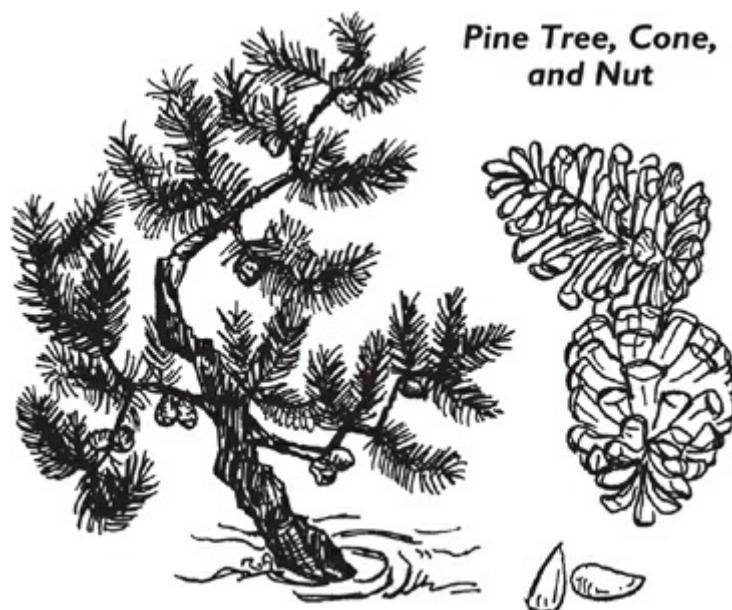

⇒ **MACADAMIA SALAD DRESSING** Ruth of Bonaire combines 1 c. of apple/celery juice or carrot juice with 3 oz. macadamia butter made from unroasted nuts. Or, she suggests using orange juice for a tropical flavor.

⇒ **MACADAMIA WALDORF** Also from Ruth: “Dice 6 tart apples. Pour the juice of 2 oranges and 1 lemon over. Chop 4 stalks celery. Drain the juice off the apples and blend juice with 3 oz. macadamia butter. Mix dressing by hand with apples and celery. Serve in lettuce-lined bowls.”

PEANUTS: These are a variety of the legume, pea family (see [Chapter 4](#)).

PECANS: See “Hickories.”

PINE NUTS: Pine nuts are also called “piñon nuts” or “pignoli.” The evergreen trees (*Pinus*) that bear them are easy to grow and hardy across a wide range (zones 3–10), but all pines are harmed by smog so they don’t belong in the city. Piñons can thrive, however, on dry, rocky hillsides in desert climates. Pine nut trees range in appearance from a large shrub about 10 feet tall to a shade tree up to 100 feet tall. The smallest nut pine can be grown in a pot but won’t produce very many nuts in a container. Being pines, these trees have needles rather than leaves, varying in length from 3 to 12 inches depending on the variety. How much sun is needed also depends on the variety: some can thrive in partial shade. For more information, read Ronald M. Lanner’s book, *The Pinyon Pine: A Natural and Cultural History* (Reno, NV: University of Nevada Press, 1981).

Varieties. The Mexican piñon pine (*P. cembroides*), which tends to be short, grows bonsai-fashion into odd, gnarled shapes and is often planted as an ornamental. The Italian stone pine (*P. pinea*), another good nut-bearer, takes 25 years to get old enough to start its regular and generous production, grows tall (60–75 feet) and straight, is very hardy even to -35°F, and makes a good windbreak. The best variety for the desert is the Mexican piñon. Other species that produce seeds large enough to be called nuts are the

Korean stone pine (*P. koraiensis*), which grows taller than any of the others (up to 100 feet); the Swiss stone pine (*P. cembra*); Siberian stone pine (*P. siberica*); sugar pine (*P. lambertiana*); digger pine (*P. sabiniana*); limber pine (*P. flexilis*); whitebark pine (*P. albicaulis*); piñon pine (*P. edulis*); and single-leaf pinon (*P. monophylla*).

Planting. You can buy started pines from nurseries, collect them from the woods, or plant seed. Plant in well-drained soil (moist is okay). Don't fertilize. This is naturally a desert plant, and once the tree gets going, it doesn't need much watering. It doesn't need pruning either, unless there is dead wood needing to come off or it's growing somewhere that's definitely forbidden.

Harvesting. You'll have to wait 10–20 years for your tree to mature enough to bear nuts. In the meantime you could gather wild ones. In different years your tree may bear very different sizes of crops. You can market pine nuts for a good price, and enjoy them for the rest of your life once the trees get started producing. Pine nut time is the fall. Race the squirrels for them and win by going out and collecting the pine cones after they have ripened, but before they have fully opened. Store them in a big shopping bag, or some such, in a warm place in your house. The pine nuts grow snugly placed at the base of each scale. As the cones open inside the bag, the nuts will fall freely to the bottom of it.

Eating. Pine nuts are hard to crack open. Once you do get the nuts out you have top-notch food. Store them in something airtight, frozen if you want to hold them more than a month. To use: roast, salt, and eat out of hand. Or add to any rice, stuffed cabbage, Italian, or pesto recipe. Pine needles are rich in vitamin C. The tender green tips can be eaten raw or made into a tea.

PISTACHIO: This deciduous nut tree (*Pistacia vera*) can be grown as a single tree or in a group—several make a great hedge because of the tree's tendency to grow densely. But pistachios thrive only within rather narrow climate limitations. They need some winter chilling, about 30 days of cold, but are likely to die if the temp gets below 10°F. They need a hot summer, 100 days of that. They need dry air; high humidity can be a problem. In general, you could try pistachios in zones 7–9, especially if you live where olives grow. California's Sacramento Valley is just right. In southern Turkey, ideal conditions are also present; there, pistachio trees grow wild. Within its climate zone, the pistachio is hardy and able to thrive despite thin soils; they can root even into rock crevices.

Pollination. Pistachios come female or male. You must have both female and male trees in order to have any nuts, although if you absolutely have room for only 1 tree, a length of male branch can be grafted right onto a female tree and will accomplish the job that way! The females grow to be 20–30 feet high, males even higher.

Planting. There are 2 female varieties available: Red Aleppo and Kerman. A male pistachio has got to be Peters. Few nurseries carry them, and then only in containers rather than bare root. The male and female must be planted within 50 yards of each other for pollination to be certain. Plan on planting a few: you want both sexes, and individual plants produce nuts only every other year, so to get annual production you need several plants.

Growing. They grow well from seed, or by bud-grafting, so long as they have the right climate, full sun, well-drained alkaline soil, some pruning, some manure fertilizing, and organic mulching. Once your pistachio pair is well-started it will be quite resistant to water shortages. However, if you give the trees more water, they will bear more nuts.

Pruning. Pistachios crave to be bushes. If you want trees, train to a central leader with a scaffold of 4–5 lateral branches starting 4–5 feet above ground. An unpruned pistachio can grow really dense.

Harvesting. Your pistachio tree won't be mature enough to bear nuts until it's about 10 years old, and it will be 15 years before it's going well. Once bearing, in the fall the fruit will be apparent as heavy bunches of yellow or red nuts hanging prettily from the ends of branches. The color change of the shells to those pretty, bright shades signals that the nuts are getting ripe. When the nuts come away easily when picked and when the shell separates easily from the inside when squeezed, it's time to pick the nuts from your tree. If you don't get right at it, squirrels may do it instead. Expect 10–20 lb. of harvest from a newly producing tree. As a pistachio tree gets older, it steadily increases nut production.

Storing and Using. After picking the nuts, remove their hulls right away, for nuts in a pile in the hull tend to start spoiling almost within hours. Dry the unhulled nuts spread out in a single layer in the sun for a week. In the shell they will keep in a cool place for many months. They're hard work to shell. If you keep running into empty shells, that means your summer was too chilly for this plant, or else that pollen wasn't transported successfully. After shelling, they must be stored tightly covered, preferably in the refrigerator. Eat raw, or roasted. Pistachios are fun to put in ice cream or scatter on top of any other desserts.

SWEET-PIT APRICOTS: These relatives of the apricot (which is related to the almond) can grow in areas that are too cold for almond nut production, if it's moderate enough for apricots. A variety of sweet-pits is the Hunza-cot, a fruit with an edible nut-seed that has been grown and eaten for centuries by the famous long-lived Himalayan Hunza people. Most apricot "nuts" contain cyanide and are bitter at best, potentially fatal at worst. But the sweet-pits don't contain cyanide and taste like almonds. They also can provide fruit and wood. You can order them from Raintree Nursery.

WALNUTS—GENERAL: English walnuts, Carpathian walnuts, black walnuts, butternuts (and the filbert-hazelnut family, too) are all related (*Juglans*). Choose the variety best for your climate. There are suitable walnuts for almost anywhere, from the Gulf of Mexico (*J. nigra*) and California (*Placentia, El Monte*), to the Pacific Northwest (*Eureka*) and Canada (*Carpathian, Broadview, Colby, Gratiot, Hansen, Somers*). The black walnut and butternut are native North Americans.

Planting. Space these trees, when grown for nuts, 30–40 feet apart. The bark of young *Juglans* trees tends to sunburn. Whitewash or use a tree wrap until it is several years old. And either coax rodent-hunting birds to live near your orchard or wrap young walnut trunks with something to keep rodents from chewing on their bark.

Grafting. Grafting any *Juglans* is risky because some crosses of black walnuts (and butternuts) get graft failure after 12–15 years. That's a terribly long time to wait only to learn it didn't succeed. Growing from seed is satisfactory for timber production, but a combination of growing from seed followed by grafting is best for nut production. The grafted tree also produces timber. If you are planting walnuts, check on the sex life of your variety. Some are self-fertile, but some need a partner. It matters, because it's quite likely you don't have space for two of them!

Pruning. Walnut wood is so strong that there is no need to worry about weak crotches.

Basal-prune and train for a strong central leader while very young. If branches are producing so heavily that they are at risk of breaking, prune back some length. Make your pruning at a fork. Prune only after nuts have dropped, in early fall. You may also cut back old unproductive wood to stimulate new fruiting branches. Walnuts pruned in spring bleed severely.

WALNUTS—BLACK WALNUT: Native to North American zone 4, black walnuts do everything slowly and grandly. They bear late, unless grafted, but once started, a mature black walnut tree can produce nuts generously. They grow slowly; it takes them 100 years to get near full growth and 30 more to start feeling middle-aged. They get wonderfully big. The largest of the walnuts are the largest of any nut tree, except maybe the beech or pecan. They are beautiful in your yard. However, keep in mind that roots of both black walnut and butternut defend their space by manufacturing a toxin that is deadly to some other plants. The black walnut is afflicted with few diseases or insect pests. When they do get old enough to die, they're worth a fortune for furniture making. Plant some for your grandchildren! Or great-grandchildren? Read *Black Walnut for Profit* by B. Thompson (1976), for more information on walnut for timber and commercial nut sales.

Planting. Varieties vary as to hardiness and pest resistance. Plant 80 feet apart in neutral soil.

Harvesting. Black walnuts only rarely lose a crop to frost. Commercial walnut growers use mechanical shakers to harvest the nuts and have to prune the trees in such a way that their machines will work, but private parties devise their own shaking systems, or wait for the walnuts to fall naturally off the tree at summer's end. At that time there is a thick yellowish-green husk covering them. Before they fall from the tree, it's a grass-green hull. There are recipes for a ketchup made from those green walnuts in all the old-time recipe books. I never had the nerve to try one. I chomped into a green walnut once and was puckered up for the rest of the day. If they aren't poisonous, I can't understand why not.

Dehulling. Best way to get those hulls off is to gather up all the walnuts in their hulls and transport them to your driveway. Use rubber gloves. The juice in the hulls that have been mashed by being walked on or some such will stain your fingers (it also makes a great home-grown furniture stain). So use rubber gloves to handle them. Spread them out and let the cars run over them for a while. The tires will mash those husks away without harming the nuts. In about a week the job will be done. Get out your rubber gloves again and move the walnuts indoors for stage 2 of their treatment. Don't leave them lie in the sun and wind. It will hurt the nutmeats inside. Don't dawdle around and delay harvesting them until the husks turn black—bad for your walnuts. (Don't be surprised by maggots in black husks. They are there before, just more obvious in the black husks, and a routine, harmless situation.) A cement floor of a sheltered building where you can spread them out and stir them around once in a while will be perfect. A cool, darkish, well-ventilated attic would work very well, too. It's important to dry them not too quickly and not too much.

Cracking. Black walnuts are comparatively difficult to crack and the nut meats are hard to get out whole from all the little chambers. But they sure do produce. (Heartnuts are relatively easy to crack.) The ideal is to hit the walnut hard on that sharp point enough times so that it splits from top to bottom into 4 neat sections. However, Tucker Hill, my nut consultant advises: "This is next to impossible. With a hammer in the hand of an amateur, not smashing the nut to smithereens will be sufficient accomplishment!" Practice helps. Once the shell has been cracked, Tucker advises: "Use a wire cutter to clip away the

shell from the kernel. That is easier than digging out the kernel with a nut pick.”

In the December 1992 issue of *The Nutshell*, Tucker wrote about visiting a gentleman whose system was that he “husks them with a board and a slightly deflated back car tire, cleans them in a wringer washing machine, dries them on 5 × 10-foot wire frames, and hand-cracks enough nuts to pick out roughly 100 lb. of kernels … his homemade nut cracker was of his own design and one of the heaviest crackers I have ever seen … effective, efficient, and easy to use.”

Storing. In the shell, properly cured, walnuts will store until the next fall. You can bake the nutmeats right after cracking in a 215°F oven for 15 minutes, and they’ll keep a good long while. Or you can freeze them, or merely keep them in the refrigerator.

WALNUTS—BUTTERNUTS: These are *Juglans cinerea*, a medium-sized variety of walnut also known as “oilnuts” and “long walnuts.” In addition to bearing nuts, they can be tapped for their sap like maple trees. They are the hardiest of the walnuts, thriving in zone 3, and the least likely to lose a crop to frost damage. Butternuts are one of the most northerly in range of the nut trees, growing well across the northern United States and also throughout southern Canada, zones 4–9. Of all the nut trees, butternut wood is the strongest and lightest in weight, once used to make windmill blades. Butternuts have a shorter life span than any other walnut, a relatively heavy shell on the nut, and somewhat smaller kernels than some other walnuts. They prefer neutral or slightly acidic soil. Their roots give off a poison that kills evergreen trees, so butternuts and evergreens can’t be grown near each other. Keep butternut trees in good health with plenty of compost feeding, mulching, and water during dry seasons.

Planting. Butternuts are self-pollinating, so a single tree can produce a nut crop for you. When planting butternuts for a nut crop, place them 30–40 feet apart. To plant for a timber crop, plant 15 feet apart. You can mail-order them from Vernon Barnes & Son Nursery.

Pruning. Butternuts have a bushing tendency, so if you want a treelike appearance, pinch and prune to a strong central leader during the first few years. Prune a nut-bearing tree only in early fall after all the nuts have fallen off. Don’t worry about weak crotches; butternuts have such strong wood that there is little tendency to break.

Harvesting and Shelling. Your tree will start producing about the third year. The nuts grow in clusters inside a spongy, hairy husk. The husk is easy to get off. Butternuts are really hard to shell. You can wear a glove to protect your hand and stand the butternut on solid iron, like an anvil, then hit the pointed end with a hammer. In half an hour you might have a pint of nut meats. They are a little easier to shell if you first cover them with boiling water and let them soak for 15 minutes. Inside the hard shell that you hammer off, the nut parts are almost, but not quite, separated by woody membranes, like a black walnut. You have to pick the nut meats out, and they break in the process. Butternuts can be stored in a cool dry place for several months (longer if refrigerated).

Cooking with Butternuts. They are the fattiest of all nuts, good in cake or homemade bread. Just add to any recipe and cut back the shortening a trifle.

WALNUTS—ENGLISH (PERSIAN) WALNUT: *Juglans regia* is the botanical name for the Persian walnut—the more correct of the common names since this tree originated in Persia and then arrived in the colonies via English boats. So it originally needed a relatively warm

climate to thrive. But now there is a Carpathian variety from Poland that can grow almost anywhere in the temperate zone up to the northern tier of the United States and even in southern Canadian provinces. English walnuts bear younger than black walnuts. And then there are hybrids in which Persian walnut tops are grafted onto black walnut bases.

Planting. English walnuts are usually self-fertile so you need only one. However, some Carpathian and black walnuts need 2 trees to make nuts. To save seed from English walnuts, harvest nuts while still in the hull. They must be chilled 6–8 weeks at 35°F or so before they'll germinate. Plant 1 inch deep in flats to see which germinate. Transplant only during the dormant season. Or to plant seed directly outside, plant under protection from wild nut-eaters. To graft, cut scions from proven cultivars when they are at least 1 year old. Patch bud in summertime or whip graft. Stocks are best if 2 years old. You'll find the least risk of *Juglans* dying back with these stocks: California black walnut, English walnut, Eastern black walnut, and the Paradox.

WALNUTS—HEARTNUT: *J. sieboldiana*, or heartnut, is the smallest walnut, growing only 35 feet tall. It rarely suffers frost damage, lives long, has good disease resistance, the mildest-tasting kernel of all the walnuts, and nuts that crack unusually easily.

TEMPERATE-ZONE FRUITS

“Fruit” means different things to different people. To a plant scientist, a “fruit” is a plant’s seed container. So acorns, pea pods, apples, and ears of corn are all equally fruits. But to others, fruits mean delicious, soft things that grow on trees, vines, bushes, or brambles—and which usually have seeds inside them somewhere: apples, bananas, grapes, berries, and so on. And fruits are sweet.

Maybe seeing a grumpy, tired, teething baby close its eyes in sleep is really the sweetest thing in the world. Maybe it’s hearing the man you’ve been married to for many years say “I love you,” and mean it. Maybe it’s finding out that something you’ve been worried sick about is going to be all right after all. I’m sure it isn’t anything in the recipes in this chapter.

Most true sweets have their bitter side. The sweet is so sweet because it’s such a relief after what’s come before. When I think of food sweets, my favorite thing to think of is fruits and berries. Those are the best tasting of all to me, never caused a cavity that I know of, and don’t need a thing extra in season to make them a joy to eat.

On the subject of bearing fruit, a reader sent me this quote from a Native American spiritual leader called Black Elk. I taped it to my computer (yes, now I use one and what a help it is!) until I knew it by heart.

A vision without a task is a dream.

A task without a vision is drudgery.

But a vision with a task can change the world!

I do have a vision, and I do have a task—several visions in fact, and thus several tasks. One of them has to be to tell how to grow all the temperate-zone fruits!

INFORMATION AND NETWORKING: *The Harrowsmith Book of Fruit Trees* by Jennifer Bennett is good on temperate zone fruits. Any library has lots more references. The Home Orchard Society is dedicated to promoting the growing of fruit-bearing plants and to preserving historic

fruit varieties. Write for their newsletter and info about pruning workshops, scion exchanges, orchard tours, and rootstock training: PO Box 230192, Tigard, OR 97281-0192; 503-639-6250; www.homeorchardsociety.org.

PEACH TREE BORERS: These are a bad problem for peach, apricot, cherry, and plum trees in places like Pennsylvania, readers tell me. They not only attack peach trees but also wild and cultivated cherry, plum, prune, nectarine, and apricot trees. You've got them if you find masses of tree gum that contain red-brown larval droppings and sawdust on the tree trunks near the ground. The borers eat on the roots and the inner tree bark from below the soil surface to 10 inches above it. The trees first do poorly and the leaves get off-color. Then, often, they die. The borers themselves are about an inch long. They look like worms that have brown heads and cream-colored bodies. They eat in late summer and fall, then winter in their burrows in the tree. In spring they feed again until their pupal stage, which they spend in the top inch of soil around the tree. The adult insects emerge about June. They have long black bodies except for a broad orange band (female) or yellow stripes (male). The female lays eggs on the tree and in the nearby soil. After hatching, the larvae begin boring and feeding.

The best cure is prevention. Paint your newly planted trees with exterior white latex and add a sticking agent for longer-lasting protection. Keep the tree growing at the proper rate with plenty of water and fertilizer. Any tree weakened by injury, drought, hunger, or sunburn will be more susceptible to attack by borers. If your tree does get infected you can worm it by digging up the dirt surrounding it down to 6 inches. Find the wormholes by making cuts around the damaged areas. Use a flexible wire in the burrows to skewer the worms. Do it again in 2 weeks. Fill up the holes and replace the dirt. Put mothballs or lots of ashes on the ground around the tree trunk to discourage a return visit.

Apples

These are the most popular temperate-zone fruit. They grow easily, store well, and have many uses. The modern apple tree is available in a wider range of sizes than that of any other fruit: from 30-foot standards down to 6-foot dwarves. However, the modern apple is also, in apple-growing areas, plagued by many pests and diseases, especially where summers are wet. It's important to choose trees that will be most resistant to whatever pest problems are prevalent in your area. Last I heard, the Liberty was about the most disease-resistant variety available, but the heroic folks who develop trees may have an even better one now.

VARIETIES: There are more than 1,000 apple varieties and many nurseries that specialize in apples, some just in "antique," old-time apple varieties, some in the most modern

cultivars, some that carry both. Both Lawson's and St. Lawrence Nurseries carry 100+ varieties. You can get a free list of "Disease Resistant Apple Varieties" from ATTRA at 800-346-9140. They also offer "Considerations in Organic Apple Production" and "Organic and Low-Spray Apple Production." At Applesource, the wise and wonderful Tom Vorbeck sells not trees, but mail-order apples. His website, www.applesource.com, includes a grower section with Tom's suggested apple varieties for central Illinois backyard growers: 800-588-3854 (LUV-FUJI); 1716 Apples Rd., Chapin, IL 62628. You can choose apple varieties to ripen early, middle, or late in the season; apples with specialized resistance to a particular disease or to all of them; or apples with low-chilling needs suited to southern California and Florida. In fact, there are apple varieties suitable for every temperature through the temperate zone (even to -40°F!). There are apples grown especially for eating out of hand, or for cider, or for cooking, or for winter storage. And green, red, or yellow apples. And short-lived or long-lived apple trees. And tall or "standard" (a large tree that gives a large harvest), shorter standard, semi-dwarf (12–18 feet), or dwarf (6–12 feet) apple trees. The semi-dwarf and dwarf apples will fruit in containers. Standard apple trees are bigger—up to 30 feet—and thus take more room than any other standard fruit tree. And you'll have your choice of trees that are 1, 2, or 3 years old.

Pollinizers. Each variety of apple has its own specifications that you'll learn when you're shopping for it. Suffice it to say that most regular apples need a pollinator, but most crab apples don't. But even the "self-pollinators" will produce better if planted near a pollinating variety. So plan to plant 2 varieties—at least unless your neighbor has an apple tree already.

Crab Apple. This is an apple species distinct from the regular apple. It is unlike any of the others in many ways: It has the smallest fruit and is the only apple that is not comfortably eaten raw because of its extreme tartness. On the plus side, crab apple trees are the hardiest of all apples and thus are a treasure for frigid areas. They have by far the showiest spring blossoms, they are usually self-fruitful, and their fruits make excellent jelly, good pectin, and unforgettable pickled fruit. Crab apples come in both standard and dwarf sizes. When shopping, beware of ornamental varieties; their fruits are as edible as any, but usually smaller. Transcendent is a good edible crab apple. Adams and Robinson are good for disease resistance. Dolgo is the most cold-weather hardy variety. No need to thin crab apple fruits.

SECRETS OF FRUIT PICKING

1. Pick on a dry day because damp fruit is more likely to spoil.
2. Store fruit in a cool place soon after it is picked.
3. For safety's sake, pick into something that leaves your hands free. This could be a bucket hanging from your belt, or a fruit-bag that fastens around your waist and hangs like an apron down your front.
4. For least bruising and best condition, pick each fruit by hand.
5. Bend the fruit upward. Twist gently to free it from the branch. A ripe fruit should easily separate. Keep the stem in the fruit. If pulled out, rot can develop in the

hole.

➲ **SWEET PICKLED CRAB APPLES** Wash the crab apples and remove the blossom ends. You'll need a peck (about 2 gal.) of them. Make a syrup of 1 qt. vinegar, 3 lb. brown sugar, 1 t. whole cloves, and 1 stick cinnamon. Boil. Add apples and cook them in this syrup. Remove apples, put them in a jar, and pour the syrup over them. Seal. Additional good-tasting things to add to your syrup are cider, allspice, ginger, nutmeg, and lemon juice.

➲ **CRAB APPLE PRESERVES** Core the crab apples with a sharp knife through the blossom-end, leaving the stems on. Use 1 lb. granulated sugar and 1 c. water per 1 lb. of prepared fruit. Put sugar and water over the heat, and boil it to dissolve the sugar. Skim, and then drop the apples in. Let them boil gently until clear and the skins begin to break. Take the apples out with a perforated skimmer and pack them in jars. Pour the syrup over them and seal. Optional: slices of lemon boiled with the crab apples, 1 lemon per 3 lb. of fruit.

PLANTING: First the seeds must experience a period of chill. At least 2 months on damp paper, covered with more damp stuff, in a jar in the refrigerator should have them stratified enough to sprout. Then move them to a nursery bed. But most apples grown from seed will bear only small, sour fruit and not be worth the space. That's why apple trees are almost always propagated from cuttings, or by grafting or budding. Standards need to be spaced 40 feet by 40 feet. Dwarfs are spaced 8 feet by 10 feet. Plant in well-drained soil. Allow full sun for strongest disease resistance and sweetest apples.

GROWING: Maintain organic mulch plus a yearly spread of manure or rich compost for feeding. Make sure young trees get regular watering. Once they're several years old, apple trees can make it just with summer rain if your climate provides that reasonably often. Otherwise give them a thorough, deep soaking at least once a month. Prune only while dormant. Some growers do no pruning for 2 years after planting, then prune only minimally to keep the center open. Thinning out to get better air circulation helps combat mildew in your tree. The apples grow on "fruiting spurs"—little branches that grow off bigger ones. When you prune, don't take these out, because in the case of the apples, the fruit is grown year after year on these same spurs rather than on new wood. If you thin the young fruit to get bigger individual fruits, thin to 6–8 inches apart.

HARVESTING: Standard apples take 5–8 years before the first fruiting and take up to 10 years to get into full production, yielding 5–20 bushels per tree per year. Once mature, however, your trees can live and fruit for as many as 30 more years. Dwarf apples fruit in 2–4 years and yield 1–2 bushels per tree. For best storing, pick them before they're dead ripe. Don't pick right after rain; they should be dry. You can use a ladder, but it's safer to use an apple picker, which is a long pole with a stiff wire loop and basket on the end of it. I sort the apples while picking—setting aside bruised, very ripe and soft ones, and ones with wormholes to make into applesauce or give to the animals. When storing green apples, put the very greenest and soundest ones into storage. Don't throw them around. If an apple falls off the tree instead of being picked, put it into a box for quick use since even if it doesn't show, it has been bruised and will spoil more quickly. You can make good cider out of the "windfalls." In fact, if it's cider you're making, harvest by shaking the tree! If wasps are active around your tree, pick late in the day to avoid grabbing a wasp along with the apple.

PRESERVING YOUR APPLE HARVEST

Root Cellar Storage. The keeping qualities of raw apples vary. The best apples for storing are said to be Yellow Newtown, Winesap, Arkansas, and York Imperial. In our orchard we have early apples that come on at the same time as the apricots, and, of course, we don't worry about raw storage for them. What we don't eat we can as applesauce or apple butter. They are better applesauce apples than storing apples anyway. Ditto for the next crop of apples. The last crop consists of apples that don't turn red until fall is really on, and they aren't picked until after the first frost. It is October as I write this, and I have only just begun to harvest these red apples. These are the ones we store for winter. Obviously, the later you put them into storage, the later you have them. They keep better on the tree than in the basement. Only when they really show a determination to fall from the tree do I pick in earnest. We also have a big green late apple. It gets very large, never does turn red, and is very good. These apples are so good we always just eat them up.

Cool storage is vital. It just amazes me how fast the apples start to shrivel, lose that nice crisp texture and flavor, and plain old rot when we bring in a box from the storage shed to the kitchen—literally within a couple days. The secret is keeping them cold but not frozen. In warmish weather they tend to rot first at the bottom of the box. Adjacent apples won't catch the rot very fast but eventually they'll soak up a noxious rotten flavor, so picking over the apples—but carefully not to bruise them—is a good idea once in a while. Apples on top that have been touched by frost will be brown and then bad in the frosted place.

A way to help keep your apples cold is to give the cellar access to frosty night air and then shut it up tight during the daytime. With the best of luck they will even keep until spring. But the apples shouldn't freeze. You could insulate your boxes under straw in the barn, or inside barrels underground, with a straw and dirt covering. Another way to store apples is in a big box lined with crumpled newspaper and then a heavy quilt or some such. My apples are stored in cardboard boxes in the bunkhouse under an old mattress. The children enjoy fresh raw fruit so much when it is out of season. I bring apples into the house as needed. We generally eat them peeled—with breakfast or between meals. Or baked, served with thick cream.

Exactly how long they can last depends on the variety and storage temperature. Eventually, they get softer, then mealy in texture, then hopeless. Keep checking them and shift to another preservation system before that happens.

Invest in an apple peeler, corer, and splitter. You'll be so glad you did (Back to Basics Products; www.backtobasicsproducts.com). If the tree was sprayed, peel the apples.

➲ **CANNING APPLES** Wash, peel, core, and quarter or slice your apples. Drop into a solution of 2 T. salt and 2 T. vinegar per 1 gal. of water. That prevents darkening. Then drain, rinse, and boil them for 5 minutes (in either thin sugar syrup or plain water). Then pack your hot fruit into hot, very clean jars, leaving $\frac{1}{2}$ -inch headspace. Pour boiling liquid from the cooking over up to your headspace limit. Put on lids. Process in boiling water—for either pints or quarts: 20 minutes at altitudes 1,000 feet and lower; 25 minutes at 1,001–3,000 feet; 30 minutes at 3001–6,000 feet; and 35 minutes at above 6,000 feet.

➲ **CANNED APPLESAUCE (AND OTHER FRUIT PUREES)** I make lots of applesauce. It's a good way to preserve apples that wouldn't keep otherwise. Cut large fruit into pieces. Simmer until soft. Add a small amount of water, if needed, to prevent sticking. Put through food strainer or mill. Add sugar to taste. Reheat to simmering (185–210°F) and pack hot into hot

jars, leaving $\frac{1}{2}$ -inch headspace. Adjust lids, and waterbath can. From sea level to 1,000 feet altitude, process pints 15 minutes, quarts 20 minutes; from 1,001 to 3,000 feet, process pints 20 minutes, quarts 25 minutes; from 3,001 to 6,000 feet, process pints 20 minutes, quarts 30 minutes; above 6,000 feet, process pints 25 minutes, quarts 35 minutes.

➲ **FREEZING APPLES FOR PIE** For apples to use in making pies and so on, just wash, peel, core, and slice them. About 50 lb. of apples will make about 35 frozen pints. To keep them from turning dark quarter (or slice) them into a solution of $\frac{1}{2}$ c. salt per 1 gal. water. Or else dunk them into boiling water for $1\frac{1}{2}$ –2 minutes. Then drain the apples, rinse them under cold water, and drain again. Method 1: Scald, drain, chill, cover with a thin syrup (1 c. sugar per quart of water plus $\frac{1}{2}$ t. ascorbic acid), leave headspace, and freeze. Or Method 2: Mix 1 qt. apple slices evenly with 1 t. ascorbic acid and $\frac{1}{2}$ c. sugar. Then put into plastic bags or freezer boxes, seal, and freeze. Or Method 3: No sugar. Just pack 'em plain. The slices break apart quite easily while still frozen for making apple pie or crisp, or you can add a small amount of water and make applesauce. Or Method 4: Freeze whole apples, unpeeled. Just wash, put into plastic bag, seal, and place in freezer. To use frozen whole apples, thaw under cold running water until they can be peeled. Then remove the core and slice. (Work fast; an apple that thaws before peeling darkens.)

➲ **FREEZING APPLESAUCE** Applesauce turns out nicer, I think canned than frozen, but you can freeze it by just making it, then cooling, packaging, and freezing.

➲ **PINK APPLESAUCE** Use red apples and leave the skins on while cooking. Proceed as above. Strain.

➲ **APPLE-RHUBARB SAUCE** A real treat! Make cooked rhubarb sauce in the spring and freeze it. When the apples come on, take it out, combine half and half with applesauce, and enjoy.

➲ **DRYING APPLES** You have to slice them; they aren't dried whole. Fully ripe sweet apples are ideal. Usually they are peeled and cored and what's left is made into doughnut-type rings about $\frac{1}{4}$ -inch thick to oven dry, $\frac{1}{8}$ -inch to sun dry. Let the slices fall into cold water while you are working to prevent "rusting," $\frac{1}{4}$ c. lemon juice or 1 t. ascorbic acid per 2 c. cold water. If your apples are small, wormy, or too mealy to make into doughnut rings, cut into slices of whatever shape you can. Old-timers then strung them on a thread and hung them in the sun, but now we usually just spread them out on a surface. Using an oven or dehydrator, dry them at 140°F on a cookie sheet—turning once in a while—until they are leathery.

➲ **APPLE LEATHER** If apples need sweetening, add it Cinnamon or coconut are good mixed in: $\frac{1}{4}$ t. cinnamon or $\frac{1}{2}$ c. coconut per 2 c. puree. Start by peeling, coring, sectioning, and grinding the apples in your grinder. Be sure and catch the juice that runs out Add $2\frac{1}{2}$ c. cider (juice) per gallon of ground apple, and then cook the whole mixture over low heat. When it is boiling and has cleared some, sweeten it if needed, and then spread it out in sheets to dry.

Cooking. Apples are one fruit that you will have raw for a very considerable time out of season. That gives you so many great possibilities for ways to use them. I like apples in salads, apples in puddings, apples in any dessert, fried apples, and baked apples.

➲ **BAKED APPLES** Peel and core the apples (or don't peel if they're on the small side or never sprayed). Place in a shallow pan with a piece of butter and a dab of honey in the center of each apple. Sprinkle with cinnamon. Add 3 cups water to the pan and bake, covered, at 375°F . until tender and juicy. Or, if you bake uncovered, baste often. The apples will be nearly transparent when done. Serve with whipped cream. Or the traditional "hard sauce" of hot

brandy, butter, and sugar. For a really special dish stuff the apple center before baking with pitted, mashed dates. Or raisins. Or nuts. Or both.

⇒ **“APLETS” CANDY** You’ll need 2 c. cold homemade, unsweetened applesauce, 2 c. sugar, 2 T. unflavored gelatin, ½ c. cold water, 1½ c. chopped nuts, a few drops of orange extract, and some powdered sugar. Sprinkle the gelatin into the cold water and let it stand. Put the applesauce through a sieve to make sure it’s fine, then add the sugar, and cook until it gets very thick. Remove it from the stove and add gelatin. Stir well. Add nuts and flavoring, mix, and pour mixture into a buttered 8-inch-square pan. Let stand overnight but do not refrigerate. Next day cut into squares and roll them in the powdered sugar. This keeps well and can be made a week or more ahead of the holidays.

⇒ **“COTLETS” CANDY** Use the Aplets recipe, substituting the same quantity cooked and sieved dried apricots for the applesauce.

⇒ **APPLE-PLUM BUTTER** Use from 2 to 3 times as many apples as plums. Cut up the fruit and cook in a little water until tender. Then put it through the colander. Add sweetening. Continue cooking until the butter is thick enough to deserve the name. This is Mike’s favorite. He likes it on waffles or pancakes or toast, and so do I and the children.

⇒ **APPLE KETCHUP** Peel and quarter a dozen round, tart apples. Stew until soft in as little water as possible. Sieve them. For every quart of sieved apple, add 1 c. sugar, 1 t. pepper, 1 t. cloves, 1 t. mustard, 2 t. cinnamon, 2 medium-sized onions—chopped very fine, 1 T. salt, and 2 c. vinegar.

MAKING CIDER: You’ll need about a bushel of apples to make each 2–2½ gal. cider (or “juice”). Any kind of apples can be used, and you can try different blends for the sweetness-tartness qualities you prefer. Professional cider makers or serious hobbyists can get really picky about how much of what kind of apple, but hey, it’s all apple juice. The important thing is to find a way to make use of what you have. In general, good eating apples are also the best cider apples. The only apples you seriously shouldn’t use are sprayed apples, partly rotten apples, or apples that have been lying on the ground very long.

⇒ **UNPRESSED CIDER** Even if you don’t have a cider press you can make cider. Clean and cut your apples. Put them through a grinder or chopper, saving all the juice, and then squeeze your grindings through a strong cloth bag.

Cider Presses. In these modern times you may already own an electric, centrifugal juicer, which may be fine if you want to make just an occasional 2-3-gal. batch. It may or may not be heavy-duty enough to make large amounts of cider. And then again a cider press doesn't require electricity. Companies that carry supplies for home wine-making carry fruit presses. The press can also be used for crushing large amounts of other heavy fruits to make juices: grapes, peaches, pears. For larger batches you can get ever-larger sizes of presses, more expensive as they get bigger. Or you can make an apple press out of a screw or small hydraulic jack (a 1-ton jack for a bushel-press). A typical old-time press that holds a bushel of apples produces about 2 or 3 gal. cider for each pressing.

Cider presses come in various sizes. The smallest one may be called a "fruit press" and can be used to make cider only if the apples are preground. The fruit press is also good for juicing berries, cherries, soft fruit, or precrushed fruit. This is often sold as a "cider press." A big cider press has an electric motor that can make 30 gal. of cider an hour. A grinder is part of that machine. Or you can get a manually operated cider press with a grinding attachment (also manual). Pregrind them. Whole apples tend to tear up the press. Happy Valley Ranch specializes in mail-order cider presses; free catalog: 16577 W. 327th St., Paola, KS 66071; 913-849-3103; fax 913-849-3104; hvr@micoks.net; www.happyvalleyranch.com.

Preparing the Apples. Wash (!) your apples and cut out the wormholes. Usually it's handiest to cut all the apples in 2 pieces as you go, in order to get at the wormholes. Cut out rotten spots or scarred places where the apple rubbed against the tree. But it isn't necessary to take out the seeds.

The Pregrinding. The press I have will not extract juice from apples very well if they are whole or even in chunks. If you have a press or pressing system that requires a preground apple, then the apples should be chopped to a fine pulp or mashed before squeezing. You can use a hand food chopper, a meat grinder, a food processor, or a special electric grinder for making large quantities of apple pomace (the ground apple is called "pomace"). Grind it twice if you can't get it fine enough the first time through. Save the juice that results from grinding to add to the cider later. You also need a wooden pestle to use for a follower on the grinder contents rather than risking your fingers. You put the

mashed fruit in a cheesecloth or nylon mesh bag and then put the bag into the press. Or else line the press with that cloth.

Pressing Out the Cider. Put the cleaned and cut apples into the metal cylinder and press. There is a crank device to put the pressure on. Have a nonmetal container ready to catch the juice. This process can't be rushed. Apply pressure, and then wait until the juice stops coming. Now apply still more pressure. The more patient you are about pressing and waiting, the more cider you'll get, and the clearer it will be. You can drink it the moment it comes out of the press if you like. Or heat a cup of freshly pressed cider, and add a dash of powdered spice to it!

The Filtering and Settling. You could use it strained or unstrained. If you don't strain it, the bottom couple inches will collect a visible pulp. If you want to strain it, just pour the juice through a couple thicknesses of cheesecloth. Rinse your cloth whenever the holes clog.

Before canning or freezing cider you can let the freshly pressed juice stand, and the pulp will gradually settle out. To start, pour the juice through a cheesecloth or diaper or such into its settling container. This should be a pan, bowl, jug, or bottle made of crockery, stainless steel, glass, or unchipped enamel—never regular metal because the juice is acidic. Keep the juice below 40°F for 12–36 hours—long enough to get the cider clear enough to suit you. (It takes about 4 days to get it absolutely clear, and by then you're risking some fermentation.) But some people prefer their apple juice with some sediment in it so maybe you won't want to bother with this step at all.

Storing Cider. Cider doesn't need any sweetening. You can drink it fresh. If you keep it refrigerated, below 36°F, it might stay fresh as long as 2 weeks. But store cider is pasteurized, treated with chemicals for preservation, and then canned. If you don't either freeze or can the cider, sooner or later, depending partly on the temperature but maybe as soon as 3 days, you will have first fizzy cider and then "hard cider." You need to preserve it before that stage unless you're making apple wine—and to do that you need more instructions than what I'm providing. You can freeze it, use it as the liquid when canning other fruits, or can it straight. When you can with apple juice, you can reduce or eliminate the sugar.

Freezing Cider. You don't need any heat treatment. Just pour it in containers and put in your freezer. Figure that it will expand about 10 percent when frozen, so you don't break your container. Plastic containers or glass jars with plenty of headspace are all right. You can line tin cans by putting a plastic bag inside them. Twist and tie the bag over the top of the juice and freeze it that way, too. It will keep frozen as long as a year.

Canning Apple Juice in Jars. This recipe is also good for citrus, grape, or pineapple juice. Make your juice. Add 1 c. sugar to 1 gal. juice, if desired. Heat to simmering (185–210° F). Pour hot juice into hot jars. Leave $\frac{1}{2}$ -inch headspace. Process in boiling water bath. Process pints and quarts for 5 minutes at altitudes under 1,000 feet, for 10 minutes at 1,001–6,000 feet, and for 15 minutes above 6,000 feet. If you are packing it in $\frac{1}{2}$ -gal. jars, and that is an option with these fruit juices, then you process 10 minutes at lower than 1,000 feet, 15 minutes at 1,001–6,000 feet, or 20 minutes if above 6,000 feet.

Pasteurizing Apple Juice. Use your dairy thermometer to get the temperature right. Heat it to 170°F and keep it there for 10 minutes. If a scum forms, skim it off. You don't want to get it hotter or keep it hot longer because you'll get a cooked flavor, and it won't be cider to be excited about. Have ready your spotlessly clean bottles, jugs, or whatever, and caps.

Pour the hot cider immediately from your pan into the preheated, sterile bottle and lid or cap at once with scalded lids or caps. Now set the bottle into a hot water bath of 165°F for 5 minutes. Next move the bottles to a tub or sink containing lukewarm water for 5 minutes. Then cool them down some more under cool running water. The reason for such gradual heating and cooling is so your containers won't break. The best caps are screw caps fitted with rubber gaskets rather than cardboard linings. The rubber gaskets give you a much better seal.

⇒ **CIDER TEA** Half cider and half tea, this drink is flavored with lemon juice and sweetened to taste. Or combine 4 c. cider, 2 c. tea, and the juice of 2 oranges and 1 lemon. Sweeten to taste.

⇒ **CIDER BLENDS** Mix cider half and half with plum, pear, cherry, or raspberry juice. Combine before freezing if possible.

⇒ **CIDER ALE** Combine 1 c. orange juice, $\frac{1}{4}$ c. lemon juice, 2 c. cider, and 2 c. ginger ale. Sweeten to taste.

⇒ **CIDER PUNCH** Combine 8 c. cider, 2 c. cranberry juice, the juice of half a lemon, and 4 c. ginger ale. Sweeten to taste.

⇒ **CIDER ICE** Dissolve 1½ c. sugar in 4 c. cider. Add 1 c. orange juice and $\frac{1}{4}$ c. lemon juice. Mix and freeze.

⇒ **OLD-FASHIONED APPLE CIDER BUTTER** This is the traditional apple butter made of pared apples boiled down with cider. Boil 6 c. apple cider in an enamel or stainless-steel pan. (Optional: For extra redness start with 12 c. cider and boil it down to 6 c.) While the cider is boiling down, core and quarter about 10 lb. of apples. Add apples when the cider is ready and continue cooking slowly until they're tender. Put it through your colander. Put your butter back into the pan and add 1½ c. brown sugar (or more to taste—it depends some on the sweetness of your apple variety). Optional: add $\frac{1}{2}$ t. ground cinnamon, $\frac{1}{4}$ t. allspice, $\frac{1}{4}$ t. cloves, and a pinch of salt. Continue cooking over very low heat, stirring a lot, until the cider and sauce do not separate when a spoonful is placed on a plate. Then pour into containers for canning or freezing.

Apple-Pear

See "Oriental Pear."

Apricots

This wonderful fruit tree gives a large harvest of fruits that are somewhat like small, orange-colored peaches. Apricot trees live long; old ones look gnarled and wise.

VARIETIES: Like apples, apricots tend to have disease and pest problems. Plant the most resistant varieties. They come in either standard (20–25 feet), semi-dwarf (12–15 feet), or dwarf (4–8 feet) sizes (which will fruit in containers). The fruits of all varieties are very similar; the differences are in chilling requirements, etc. with one big exception: the edible-kernel apricot or "sweet kernel." All apricot kernels (the nut inside the pit) are high in cyanide and basically poisonous except for these varieties, which have an almond-like edible nut, and are also listed here under nuts.

CLIMATE: There are apricot varieties suited to a range of temperate zones. Because they need winter chilling to break dormancy, no apricot varieties will grow in subtropical

climates. Manchurians are shrubby types that are the most cold-hardy. Choose a type hardy enough for your area and one that blooms late enough that most years your crop will be safe from frost-kill (29°F or lower). Zones 4 and 5 are marginal for apricots unless you use the Manchurian, have an ideally protected planting site, or grow dwarfs in containers, which you can bring in during severe cold or during untimely spring frosts.

PLANTING: Accomplish this by cuttings, budding, or grafting. Planting the seeds just won't pay off. Plant in well-drained soil where each tree can get full sun: standards 20 feet by 20 feet, dwarfs 12 feet by 12 feet. Keep in mind that apricots tend to grow as wide as they are tall. Don't plant on land that has had melons, peppers, potatoes, raspberries, strawberries, or tomatoes growing there for the past 5 years, as the apricot can pick up a disease from those plants. Like other temperate-zone fruit trees, apricots bloom in early spring. Some apricots need a pollinizer tree and some don't, but even the ones that don't usually bear better with cross-pollination, so plant 2 varieties.

GROWING: Apricots can usually make it without many amenities. You can choose not to prune, not to thin, and not to mulch, and probably still get a crop. Moderation is the secret to apricots. An organic mulch including some compost helps keep the roots warm in winter and cool in summer and nourished always, but too rich a diet can result in diseases and splitting. If your summer is dry, they need a monthly deep watering, but too much water if your soil doesn't drain well can make them sickly. Like apples, apricots bear their fruits on "fruiting spurs" that produce for 3–4 years. The conventional wisdom is that some conservative annual pruning will increase harvest, and that hand-thinning will give you larger fruits. I've missed pruning and gotten fruit anyway, and I don't think the thinning is worth the effort if the fruit is for home use rather than competing in a supermarket produce aisle.

Scab. Apricots are subject to a fungal disease called "scab." That's what it looks like, and all unsprayed trees have more or less of it—domestics often more than wild trees for some strange reason. You can trim off the scab to eat the fruit raw. To can it, either trim the blemishes or go ahead and can the fruit, scab and all. Given a good cooking your apricots will be just as delicious as if the scabs weren't there. The scab is not harmful to eat, softens up, and is hardly noticeable for family use. Beats eating poisons. This is called peaceful coexistence.

HARVESTING: Apricots take about 3 years to begin fruiting. Harvest time is a wonderful crisis that usually comes in July. Mature standards yield 3–4 bushels, dwarfs 1–2 bushels. The fruit ripens all at once. You know it's ripe when the color has gotten bright and the fruit is soft. Once ripe, apricots are highly perishable, so the next challenge is a crash effort toward eating up or preservation: by canning, freezing, drying, making jelly or jam, or juicing into "nectar." You can't get ahead of the game by picking green fruit, because apricots won't ripen off the tree (they will just shrivel and get bitter).

CANNING: Wash the apricots, cut them in half, and take the pit out. (If you leave in the pit—which contains cyanide—your syrup will get cloudy and the fruit won't taste good.)

Raw Pack. Pack your halved apricots into overlapping layers, cut side down, in clean jars. Add boiling syrup (or any fruit juice or plain water). Leave $\frac{1}{2}$ -inch headspace. Put on lids. Process in a hot-water bath. At altitudes up to 1,000 feet, process pints for 25 minutes, quarts for 30; at 1,001–3,000 feet, process pints 30 minutes, quarts for 35; at

3,001–6,000 feet, process pints 35 minutes, quarts for 40; at 6,000 feet and higher, process pints 40 minutes, quarts for 45.

Hot Pack. Heat the halved apricots in your chosen liquid thoroughly through to boiling. Boil 5 minutes. Then fill hot jars with the hot fruit, and immediately process in a boiling water bath. At altitudes up to 1,000 feet, process pints for 20 minutes, quarts for 25; at 1,001–3,000 feet, process pints 25 minutes, quarts for 30 minutes; at 3,001–6,000 feet, process pints 30 minutes, quarts for 35; at 6,000 feet and higher, process pints 35 minutes, quarts for 40.

FREEZING: Wash the fruit, cut in half, take out the pit, peel or not as you prefer. Twenty pounds of fresh apricots will make about 25 pt. frozen apricots. Method 1, halves: Cover with syrup (or any fruit juice, or plain water) and freeze. Method 2, mashed: Steam the pitted apricots about 4 minutes, mash, sweeten to taste, pack, and freeze.

DRYING: Wash fruit, cut into halves, remove pits. Do not peel. Optional: Preserve color by dipping into a solution of 1 t. ascorbic acid per 1 c. cold water. Now soak 10–15 minutes in mildly salty water (2–4 T. salt per 1 gal. water). Drain. Lay on tray with the pit side up. They're done when they look and feel leathery and no moisture comes out when you squeeze.

➲ **APRICOT LEATHER** *Wash and pit the fruit. Puree your apricot halves (leaving the skins on). To each cup of mashed apricots, add 1 T. honey and ¼ t. cinnamon (or any other sweetening or spice that suits you, like a dash of nutmeg or nothing at all). Spread the drying tray (or whatever you use) with plastic, or oil it. If you use plastic, make sure some hangs off the edges. Spread your fruit paste on the surface and set it out to dry. When it's done you can just peel the plastic backing away.*

➲ **APRICOT LEATHER AND JUICE** *Steam or cook slightly 1 gal. pitted apricots. Add 1½ c. pineapple juice. Drain off the juice—the more juice you get off, the quicker what's left will dry. Sweeten the pulp that's left if you want. Almond extract is a good flavoring; add 3 t. Can the leftover juice. Spread out your pulp to dry.*

➲ **DRIED APRICOT SAUCE** *Chop 1 c. of dried apricots. Cook with about 2 c. water until tender. Then add 1 t. lemon juice, and sweeten to taste. Add a little more water if it turns out too thick, or cook some more if it's too thin. Or use any other dried fruit.*

➲ **APRICOT JUICE** *Pit and quarter the apricots. Bring to a boil in just enough water to prevent scorching. When tender, mash with a potato masher and then press through a sieve or colander. This is a “puree.” (Optional: add 1 T. lemon juice per 3 c. puree.) For juice, strain again through something finer. Sweeten, if desired. Incidentally, 1 lb. apricots is approximately 10 whole ones or 2 c. chopped or crushed apricots. To can the apricot nectar, use applesauce processing times. Apricot juice dilutes to taste very successfully, same as grape.*

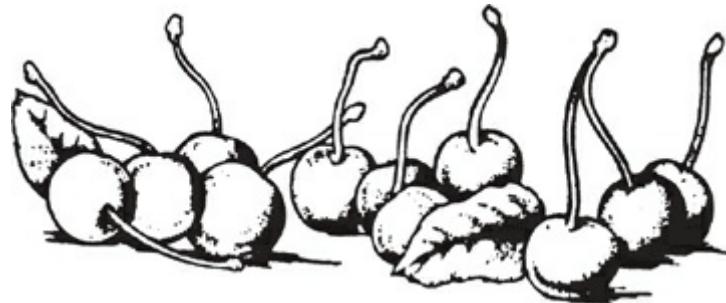

➲ **APRICOT-CITRUS JUICE** *Combine half apricot puree and half orange or grapefruit juice.*

➲ **APRICOT PUNCH** *Combine 1 part apricot juice or puree with 2 parts any other juice.*

➲ **APRICOT NECTAR FROM CANNED APRICOTS** *Blend or puree 1 qt. canned apricots. Add water to thin, if needed. Serve right away.*

Cherries

This fruit in all its varieties is a favorite of mine! Cherries grow in zones 4–9. Sour cherries are harder than sweet, able to handle more cold, and do well in the northern half of the United States. Sweet cherries appreciate a mild, even climate, such as that around the Great Lakes or in the Pacific Northwest. But if you have a bit of sheltered land you can sometimes sneak them into harsher zones. Chokecherries are wonderfully hardy, growing on mountain sides and in Canada where almost no other fruit tree can make it.

VARIETIES: Cherries come in several basic varieties: sweet, sour, and hardy. In general when people say “cherry” they mean sweet or sour. Among the sweets and sours, you can also choose among early, midseason, or late-fruited trees. Better yet, plant a series, and have fresh cherries for months!

The Sweets. These fruits can be black, yellow, or red in color. The standard-sized trees take 6–7 years to first fruit, need 25 feet by 25 feet orchard space, and get 25–35 feet tall (make good shade trees!); semi-dwarfs 10–15 feet tall; dwarfs 6–8 feet tall. Sweet cherry dwarfs take 4–5 years to fruit, and can be grown and will fruit in containers. Sweet cherry trees tend to grow right and need little pruning.

The Sours. Compared to sweets, the sour varieties, also called “pie cherries,” are more disease-resistant, more hardy for cold climates (hardy enough to make it “wild”), fruit a couple years sooner, and require less room. The bad news is that the fruit is sour-tasting, not so pleasant for eating any way except in pies or preserves. Sour standards grow 15–20 feet tall, the dwarfs, 8–10 feet. “Dukes” are hybrid sweet-sour cherries, less sour than the sours, harder than the sweets.

The Hardy Cherries. These are the chokecherry, sand cherry, and bush cherry. The importance of them is that they can be cultivated in places where so few other fruits can. All 3 are very tart. You can use the same recipes interchangeably for any of them. Can and freeze according to sweet or sour cherry recipes. (Recipes follow.) The bush cherry grows on bushes that are 4–5 feet high. Like the other 2 hardy cherries, it can be grown where sweets and sours can’t, even in the Dakotas and Alaska. Sand cherries can grow in Alaska, Canada, and the northern United States.

Chokecherries grew wild where I lived in Montana as a little girl. They’re a native, wild cherry tree. People who haven’t grown up with chokecherries generally don’t appreciate them much at first. They grow on a bushy sort of tree in places cold enough that you really appreciate any kind of fresh fruit. They come on in the fall after the frosts, and for weeks on end on the way to and from school, walking or riding my pony (it was always one or the other for the 2-mile stretch) a pause to refresh at the chokecherry grove was my pleasant stop along the way, for the fruit stays on the tree quite a while. The chokecherry pit is very large in relation to the tiny cherry-like flesh around it. You spit out the pits. *NOTE: The seeds are poisonous (contain a cyanide). Don’t ever grind or use the chokecherry seeds or can chokecherries with the seeds in. The leaves of the tree are also quite poisonous,*

so don't try making tea with them.

The flavor of chokecherries is so sour ("choke") that it will pucker you up, but, once you've learned to endure and even love chokecherries, you eat them anyway, pucker up, spit out all the seeds, and reach for another handful! You can buy started chokecherry trees from some mail-order nurseries and hometown nurseries.

PLANTING CHERRIES: Graft or bud. Cherries need a pollinizer tree except for the sour cherries, which can usually self-pollinate. The pollinizer needs to be a different variety of cherry—and make sure you have 2 that bloom at the same time. But not all varieties will pollinate all other varieties. So before you buy, consult about the pollination aspect! Prune the young cherry once for good shape. Keep in mind that if it's a standard, it needs to be climbable. After that, prune in mid-June, if at all.

HARVESTING: Standard cherries start bearing 3–5 years after their final transplanting, but they'll keep growing and increasing their harvest for another 10–20 years. The yield of a mature standard sweet could be up to 3 bushels; sours, 2–2½ bushels. There's no such thing as a really dwarfed cherry though. So if you raise cherries, you're going to be doing some "cherry picker" picking. Pruning off the top of a cherry tree won't increase cherry production down lower, so don't try it. Let the birds have the high ones and you take the low ones. Harvesting cherries is work, but they're worth it.

Birds. I take my biggest losses to the birds. They love cherries. It helps to have predator birds to keep a balance in your ecosystem; in so many places birds of prey are nearly extinct. And some growers plant mulberry trees around or among their cherries because birds like that fruit even better. Commercial cherry orchards have automatic, periodic "cannon" noisemakers. Private folks sometimes throw bird-proof netting over the cherry tree and that works the best of all if you don't mind the look of it.

PRESERVING: Sweet cherries are wonderful canned, frozen, in jam or jelly, dried, or eaten fresh. Sour cherries are rather sour for raw eating, but they make great pies and jam. The cherry pitter is an excellent invention, especially for those of us who like to dry cherries! A typical pitter can pit a pound of cherries in less than 5 minutes. You can order one from Lehman's, Box 41, Kidron, OH 44636.

CANNING CHERRIES (SWEET OR PIE): Cherries can be canned with or without pits. I used to think it was insane to go to all the work to take out the pits when the kids could spit them out so easily and the flavor was fine with them in. But with those newfangled cherry pitters, it's a more realistic option. I still prefer them whole though. I put up over 100 qt. of cherries last year. They contained an occasional stem or leaf because I put the children to work packing for me, but despite that, they looked very attractive and tasted fine. Cherries can more easily and nicely than any other fruit except maybe peaches. I give canned cherries as gifts sometimes to visitors—I'm that pleased with the product. That's sweet cherries. Canned sour cherries are ... sour and not pleasant unless you do something extra with them, like stick them in a pie.

Hot Pack. Add ½ c. water, juice, or syrup per quart cherries. Bring to a boil in a covered pan. Pack hot cherries into hot jars. Cover with cooking liquid, allowing ½-inch headspace. Process in boiling water bath. At altitudes to 1,000 feet, process pints for 15 minutes, quarts for 20; at 1,001–3,000 feet, process pints 20 minutes, quarts, 25; at 3,001–6,000 feet, process pints 20 minutes, quarts, 30; at 6,000 feet and higher, process pints 25

minutes, quarts, 35.

Raw Pack. Pack cherries into jar. Shake jar to settle them down. Cover with boiling syrup. Process in boiling water bath. At altitudes to 1,000 feet, process pints or quarts for 25 minutes; at 1,001–3,000 feet, process pints or quarts 30 minutes; at 3,001–6,000 feet, process pints or quarts 35 minutes; at 6,000 feet and higher, process pints or quarts 40 minutes.

➲ **MARASCHINO CHERRIES** Wash 2 lb. good ripe, but not overripe, Royal Ann cherries. Combine 1 c. limewater (from a drugstore) and 4 c. cold water, pour it over the cherries, and let them soak 6 hours. Now drain cherries, rinse well, and pit them. Combine 3 c. sugar, 1½ c. hot water, and 2 T. red food-coloring. Heat to boiling and add the pitted cherries. Let them cook on low heat for about 10 minutes. Cool and let rest in the refrigerator until the next day. Now reheat to boiling and stir in 1 T. almond extract. Then hot-pack the cherries in hot, sterilized jars—half-pints only—together with enough syrup to cover. Use cherry canning instructions.

➲ **CHOKECHERRY JELLY** To 3 c. chokecherry juice, add the juice of 2 lemons and 3 c. sugar. Boil at least 25 minutes, or until a drop of juice on a saucer will jell. Pour into jars and seal. Half crab apple, half chokecherry also works nicely. And those are 2 fruits that go together; those and gooseberries will grow in the high mountain country where other fruits won't

➲ **QUICK CHOKECHERRY JELLY** You'll need about 9 half-pint jelly jars for this. Combine 3 c. chokecherry juice and 6½ c. sugar, and bring to a boil, stirring constantly. Stir in 1 bottle liquid fruit pectin. Bring to a boil again and boil hard 1 minute, stirring nonstop. Take off heat. Stir and skim 5 minutes. Now pour into jars. Adjust lids. Process in a waterbath canner for 5 minutes.

➲ **VIRGINIA'S CHOKECHERRY SYRUP** This wonderful, unusual-tasting pancake and waffle syrup was one of my mother's specialties. Here is my friend's recipe for it. Combine equal parts of berries and boiling water. Mash berries thoroughly with a wooden mallet or spoon. Squeeze pulp through a cloth supported by a colander. Combine equal parts juice and sugar. Bring to a boil. If you like it thicker, boil it down to the density you want. Another way is to combine water and berries and cook a few minutes, then mash with a mallet and proceed as above. Some cooks add pectin to the pulp—½ box to 6 c. juice—boil and then add sugar. It hastens the process. Get it thick enough and you'll have jelly.

➲ **CHOKECHERRY-APPLE BUTTER** Combine 4 c. apple pulp and 2 c. (seedless) chokecherry pulp. Mix well and heat to a boil, stirring carefully. Add sugar to taste and ½ t. almond extract. Ladle into hot jars. Put on lids. Process by applesauce times.

➲ **SAND CHERRY JELLY** Use 2 c. sand cherry juice, 1 c. tart apple juice, and 1½ c. sugar. Use the chokecherry jelly directions.

➲ **SAND CHERRY JAM** Cook fruit with water to cover until soft. Put it through a sieve. Measure. Add an equal quantity of sugar. Simmer until thickened.

FREEZING CHERRIES: First wash them. Pit cherries you'll want for salads or cooking. Leave some unpitted for eating. You can even freeze them plain with the stems on! For cherries frozen in a syrup you can freeze covered with apple or pineapple juice, or any sweet syrup (such as 2 c. sugar per 1 qt. water plus ½ t. powdered ascorbic acid), or a sprinkle of sugar. Lemon juice is good in there, too.

FREEZING SOUR CHERRIES FOR PIES: Pack 1 qt. sour cherries with $\frac{3}{4}$ c. sugar, thoroughly mixed until sugar dissolves. Fifty pounds of cherries make about 35 pt. for freezing.

DRYING CHERRIES: Wash, pit, and halve the cherries or chop or leave whole as you prefer. Place halves or sections sticky side up, spread out. Dry at 115°F in your dryer or at 140°F in your oven. Stir once in a while. They don't need to be turned. They will be chewy when dry. Drying cherries takes up to 36 hours in the oven or dehydrator, possibly significantly less, or 1–2 days in the sun. They come out sort of like raisins. And, in fact, you can substitute dried cherries in any recipe that calls for raisins, or add to any baked goods, or stew them up like stewed prunes.

⇒ **CHERRY ICE** Pit 1½ qt. cherries. Mash them with a potato masher as well as you can. Add $\frac{1}{4}$ c. honey and the juice of 1 lemon. Mix well. Freeze, stirring occasionally since it freezes first on the sides of the bowl and you'll want to pull that to the center. Serve with homemade whipped cream, slightly sweetened.

⇒ **CHERRY JUICE** Stem, sort, and wash your cherries. Drain and pit. If the cherries are red, crush them, heat to 165°F (don't boil), and strain the juice through a jelly bag. If they are a white variety, grind and press them for juice without heating them. Cool, let stand overnight, and pour off the juice to be your cherry juice or else strain it through a bag. Sweeten it if you think it's necessary. Sweet cherry juice doesn't have the flavor and tartness of sour cherry juice. Adding some sour cherry juice will improve your product if you are working with sweet cherries.

⇒ **QUICK CHERRY DRINK** Mash through a colander 1 qt. very ripe pitted cherries. Add 1 qt. water and the juice of 1 lemon. Sweeten to taste. Strain and chill. Serve with ice.

⇒ **OLD-TIME CHERRY PUNCH** Combine 9 c. water and 9 mint leaves. Simmer 5 minutes and strain. Add sweetening and cook 5 minutes. Cool. Combine the mint tea, 2 c. orange juice, 2 c. lemon juice, 2 c. cherry juice, 2 c. pineapple juice, and 4 c. regular tea. Mix and let rest an hour. Serve chilled. It makes a lot.

⇒ **SAND CHERRY-RHUBARB PIE** Combine 1½ c. pitted sand cherries and 1½ c. diced rhubarb (or blueberries). Mix in 1 c. sugar and 1 T. flour. Place in pastry-lined pie dish. Dot filling on top with 1 T. butter. Cover with pastry. Bake at 425°F until done.

Elderberries

These resemble chokecherries, only they are even smaller. There are lots of elderberry trees around here. Under natural conditions elderberries grow at lower elevations, chokecherries at higher ones, but they both like mountains and the sides of canyons. Elderberries are on the sour side. They have a lot of seed, which you sort of collect in your mouth until there are enough to bother spitting out. Or go ahead and swallow them. Elderberry blossoms are listed in [Chapter 5](#) for tea-making. There are red elderberries and blue ones. The blue are best. They grow up to 30 feet tall.

NOTE: The sap of the red elderberry is very poisonous. Even the berries taste foul to the point of being inedible. And some varieties of elderberries must be thoroughly cooked or they're poisonous. Consult an old-timer if in doubt.

Here's what Criss Wilhite, from Fresno, CA, wrote me about elderberries: "Another thing we dry is elderberries. We go to the mountains in August and cut bushels of elderberries and elderblow. We dry the elderblow for tea. We dry the berries on their stems. It takes only a few days. Then we remove the woody stems and forget about the smaller ones. The

berries this way are great in home-grown and ground cornmeal mush or muffins or any baked goods. Elderberry juice is great to mix with apple juice or sauce. We also make elderberry-gooseberry juice.” “Elderblow” is the flower petals.

➲ **ELDERBERRY JELLY** Remove large stems from elderberries. Place about 3½ lb. ripe berries in a large pan. Crush, cover with water, and cook on low heat about a quarter hour. Strain to get elderberry juice. Measure juice. For each 3½ c. juice (you can stretch it with apple juice), add ½ c. fresh lemon juice (strained). Heat that combo. Add 7½ c. sugar, and boil, stirring constantly. Add 1 package powdered fruit pectin and boil hard 1 more minute. Take off heat. Skim off foam, pour into hot, clear jars. Cover with paraffin immediately. Or put lids on and process in boiling water bath 5 minutes.

➲ **ELDERBERRY TEA** Use 4 c. fresh ripe berries and 2 c. water. Stir, mash well, and strain, squeezing to get all the juice you can. Freeze or can. When wanted, let simmer a bit. Sweeten with honey. Dilute to taste.

➲ **ELDERFLOWER LEMONADE** Gather elderflowers in June or July when they are in best bloom and remove from the stalks. Slice a whole lemon thinly into a pitcher. Place 4 large heads of elderflowers face down in there, and pour 4 c. boiling water over. Cover with a cloth and let rest and cool about 12 hours. Next day, strain off the solids, add sweetening to taste, and serve.

➲ **ELDERFLOWER TEA** Pick blossoms in full bloom. Use fresh, or dry and store. (See Chapter 5.) At cold or flu time, put 1–2 t. in a cup. Pour boiling water over. Strain. Add honey to sweeten.

➲ **ELDERFLOWER FRITTERS** Start with 10 elderberry blossoms with stems. Dip the blossoms in clean water for a few minutes. Shake off the water. Mix ¾ c. flour, ¼ t. salt, 3 beaten egg yolks, and ½ c. milk. A tablespoon of rum or brandy adds flavor. Heat frying pan with 1 inch of oil. Dip each blossom into the flour and egg mixture, fry, and serve. Good with a green salad.

➲ **ELDERFLOWER CLEANSING CREAM** These flowers have an ancient fame for being good for the skin. You can dry them to have year-round. Drop a few in your bathwater or make this special cleansing cream: In a double boiler heat 1 c. homemade buttermilk with ¼ c. elderberry flowers for half an hour. Remove from heat and let rest for a few hours. Heat again. Strain out the flowers. Add 2 T. honey. Store in a very cool place.

➲ **ELDERFLOWER SOOTHING, PROTECTING, HAND AND FACE CREAM** Melt either 1 lb. pure (clarified) lard or the same of petroleum jelly. Then pack in as many elderflowers (stripped from stems) as you can get in and covered. Maintain the flower-lard mix on a very slight heat (don’t boil!) for 60 minutes. Then strain out the flowers and pack your cream into jars.

Jujube

This fruit tree is hardy in zones 6–10, but it’s filed in this book with “Subtropical and Tropical Fruit.”

Mulberry

There are many species of mulberry growing around the world. *Morus alba* is a shrubby Chinese variety, 6–8 feet tall, whose leaves are relished by silkworms. Commonly called

the “white mulberry” (or often mistakenly called the black), it is common in the South. Its berries can be black or red. *Morus nigra*, the “black mulberry,” is a semi-hardy tree (zones 5–10) that can get 30 feet tall and can survive north to Virginia in the east or Seattle in the west. There are also named varieties that have big, sweet berries in black, red, or white, instead of the rather insipid-tasting old-time tree mulberries. Weeping mulberries are a decorative variety that fruits, but their fruit is of very low quality.

PLANTING: Most “mulberry” trees in nurseries are fruitless ornamentals. You can get edible types from Raintree Nursery, Burnt Ridge, or Hidden Springs. Once started, you can grow more trees from cuttings or from seed. Cuttings transplant easily as long as you keep them moist. Nature plants mulberries via the birds. To grow a mulberry orchard as some old-time pig farmers and chicken farmers did as a source of livestock feed, plant them 25–30 feet apart. They’ll grow on almost any soil, even gravel or rocks. Mulberries don’t need fertilization but will benefit from mulching their first year. Most mulberries are self-fertile. Pests are not a serious problem. Mature plants are able to endure drought quite well.

HARVESTING: Mulberries resemble blackberries in shape and size and also have many seeds. They’re fully ripe when black and soft. The almost-but-not-quite-ripe berries are red and tart and can be used in anything you’ll add sugar to. Late June and July are harvest time for birds, beasts, and people. They are less tart and less pleasant-tasting than blackberries, but are healthy to eat. One way to harvest them is to spread a sheet of cloth or plastic underneath the tree, then shake the branches until the fruit falls. Or let the berries fall naturally and gather them regularly. Mulberries stain something fierce. Pros handle them with thin plastic gloves (order through a beauty shop) on their hands. You can use them in the recipes below ... or grow silkworms! Silkworms eat mulberry leaves. You can buy silkworm eggs and get info about growing them from Karen Emery, Royal Hare; 707-579-2344; 946 Lodi St., Santa Rosa, CA 95401.

PRESERVING: You’ll have to deal with the fruit immediately since it doesn’t keep. Make pies or jelly, or freeze.

⇒ **SPICED MULBERRY JAM** Stem a mixture of ripe and green mulberries until you have a quart. Cover them with cold, salty water ($\frac{1}{4}$ c. salt per quart of water). Let set 5 minutes. Then drain, and rinse in cold water several times. Now crush the berries. Add 3 c. sugar, $\frac{1}{4}$ c. lemon juice (or $\frac{1}{4}$ c. cider vinegar like the old-timers), and $\frac{1}{2}$ t. cinnamon. Cook over low heat, stirring until the sugar dissolves. Then boil hard, stirring constantly, until it arrives at the jelling point. Take off heat. For the next 5 minutes, alternately skim and stir. Have ready clean, hot jars. Ladle your jam into them, and put on lids. Process in a boiling water bath for 5 minutes.

Freezing. Wash and dry the berries, and lay them on a tray for quick freezing. Once hard, move them into freezer containers. If you have both gooseberries and mulberries, try freezing them mixed half and half, unsweetened. They go well together baked in a pie, etc. Or try freezing mulberries with sugar ($\frac{1}{2}$ c. sugar per 4 c. mulberries).

⇒ **(FROZEN) MULBERRY CREAM** To serve, thaw for almost an hour, then prepare sweetened whipped cream and stir the fruit into it.

Drying. Lay mulberries spread thin in a single layer outside on a screen, out of the sunshine, in a warm, dry situation. Don’t let birds rob you. It takes 4–5 days to dry them like that—less in a food dryer.

Nectarines

See “Peaches.”

Pawpaws

This fruit is a North American relative of the South American custard apple (cherimoya). The fruit doesn't survive shipping, so it's not a commercial crop, but for the home gardener this can be a wonderful choice. A deciduous shrub (with leaves up to a foot long), the pawpaw can also be pruned into a single-trunked tree and grow as tall as 20–30 feet high, but it's more naturally inclined to be the sort of plant you'd use as a screen or hedge. They can grow in either full sun or a somewhat shaded location, and they adapt well to being in the middle of a lawn. Once established they are hardy, usually pest-and disease-free, and expand vigorously.

CLIMATE: The wild pawpaw is classified as both a subtropical and temperate-zone plant, for it grows from Florida to Texas and as far north as Michigan. Pawpaws need some winter chilling (they're hardy to -30°F), prefer hot summers, and are suitable to try in zones 5–9, especially in midwestern areas. They need at least 30 inches of rain per year or the equivalent in irrigation.

VARIETIES: There are both inedible and edible varieties, and the edible ones can be hard to find. If the fruit has white flesh it's a bitter, inedible variety. If the fruit has dark-colored flesh, it's an edible one. Most “pawpaw” trees sold by regular nurseries are seedlings intended merely to be ornamentals. For your edible pawpaw look for named varieties that are specifically edible.

PLANTING: The easiest way to get started is to plant a grafted tree from a nursery. If you're transplanting a grafted nursery plant, prune back to just a foot beyond the graft point. Pawpaws do best in well-drained, well-mulched, and well-fertilized, deep and slightly acidic loam, but no matter how good your care they tend to be very slow-growing. Keep their soil slightly moist. Growing wild, a pawpaw prefers a fertile bottomland site along a stream or a hillside. You can use the “cuttings” or “layering” methods, or you can try to bring home a wild one by transplanting, but pawpaws are notoriously hard to get started in those ways.

Transplanting a Wild Pawpaw. Pawpaws are not easily domesticated. They grow wild but are hard to transplant. There's a theory that pawpaws need the action of a symbiotic fungus and that you should add soil from near the base of an already established plant to your planting hole. Surely, you should try transplanting only a very young pawpaw, and try to get the entire root system and keep the roots thoroughly moist during transition (and for the first year after the move).

Pawpaws from Seed. To use your own seed, keep the seeds damp or else plant them immediately after removing from a fruit. To hold pawpaw seeds indoors over winter, store in a plastic bag in the refrigerator. They are very slow to germinate. Your spring-planted seed may not germinate until mid-summer and may even wait a whole year to come up. An alternative, easier method is to do it nature's way and plant the entire pawpaw in the fall. Cover the fruit with only a very thin layer of dirt. When the seedlings come up, remove all but the best-looking ones. Exotica carries pawpaw seeds.

Planting for Pollination. Pawpaws bear lovely maroon flowers in spring. They blossom early enough that the bees may not be active enough for thorough pollination. Old-time pawpaw lore has it that if you lay a hunk of rotten meat close to the blooming trees, the meat will attract flies that will help pollinate. Pawpaw pollination is rather unpredictable, with some needing cross-pollination and others not. Plant more than 1 tree for best results.

Pruning. Once your pawpaw gets going, pruning and cutting off suckers will be necessary every year. If you want a tree, prune away all suckers and lower branches to create a single trunk. If you want a hedge, let the suckers grow that come up in the area where you want the screen to grow; otherwise clip them out. If you have a grafted pawpaw, remove all root suckers, since they're not the part you want to proliferate. An unpruned pawpaw grows into a dense thicket.

HARVESTING: In fall your pawpaw crop gradually turns from green to yellow and on to brown (ripe). Harvest when they're slightly soft. Just exactly when to pick them from the tree depends on how sweet you like them. If you harvest a couple weeks earlier than dead ripe, they will be much less sweet than later, but pleasant in another way. If you leave them on the tree too long, they get mushy and are likely to fall off on their own and be damaged. Look out for late-ripening fruits from late-blooming flowers and leave them on the tree to finish. Handle them gently, and bring them into the house to finish ripening.

EATING OR PRESERVING: The flesh of a ripe pawpaw is yellow-orange with a mild banana-like flavor and a custardlike texture. Pawpaws keep only 1 or 2 days. Use pawpaw fruit in a custard pie recipe, make jam or jelly from it, eat it raw, bake it into bread, make dried fruit sections or a leather, or freeze (eat frozen pawpaw immediately after thawing).

NOTE: *Don't eat pawpaw seeds. They are classified as "mildly poisonous."*

Peaches (and Nectarines)

Peaches and nectarines are my favorite fruits in the world to eat out of hand. I have a little nectarine tree growing in the orchard. Last year a neighbor ran over it with his pickup and practically broke my heart, but one branch survived, and I have hopes for it yet. A nectarine is a variety of smooth-skinned peach. I used to think it was a cross between a peach and a plum, but now I know that's wrong. Nectarines have existed for centuries and sometimes mysteriously appear growing on a peach tree branch. You can sometimes grow a nectarine from a peach tree seed if that peach has some nectarine in its ancestry and was pollinated by a nectarine.

Peach trees are short-lived, bearing only 10–15 years. If you have trouble growing peaches, try genetic dwarf peaches—they are easiest of all. From California to Georgia, in North and South Carolina, Colorado, Utah, these fruits can grow. They're a little more tender, though, than apples or pears. They need well-drained soil. Peach leaf curl is a big problem in damp climates.

VARIETIES: Peaches were grown in China 4,000 years ago. There are hundreds of varieties. When you choose yours, look for disease-resistant kinds whose climate adaptations are a perfect match for your site, such as the very winter-hardy, spring-frost-resistant, and disease-resistant RedGold nectarine if you live in a chilly place. Among peaches, you can get a very early one, such as Harbinger, or a medium one, such as Red Haven, a late one,

such as Loring, or a very late one, such as Stark Autumn Gold—and have peaches constantly coming on from summer through fall. And you can choose between “clingstones” that have a pit to which the peach flesh adheres (best for canning) and “freestones,” easiest to eat raw.

PLANTING: If the soil has lots of clay, add half compost or peat moss. Peach trees need full sun and regular watering (they have shallow roots), freedom from weed competition, and any sucker growth trimmed off. Fertilize in the fall.

Peaches and nectarines are the fruit trees that most benefit from regular pruning and thinning. Do it before February, and cut back up to 50 percent. If you don’t want to climb a ladder to pick fruit, trim back the leader when you prune, and the tree will grow wide rather than tall. For good air circulation and to minimize disease problems, prune to a vase shape. Thin fruits when they’re pea size. Go over and thin again, as needed, when they’re the size of a marble. Thin early ripening kinds to 6–10 inches apart. Thin late ripening varieties to 6 inches apart. A small limb might try to grow 50 peaches. If you don’t thin fruit, a branch might break, or the tree could die.

POLLINATION: Peaches bloom early, before their leaves come out, so the crop is always at risk of early frosts. Nectarines don’t need a pollinizer, but most peaches do. Consult about pollination needs when you buy.

CANNING PEACHES: Wash them and dip them in boiling water, then quickly into cold water. That loosens the skins so you can slip them off. Now cut the peaches in halves and take out the pits. If you’re slow you can drop the fruit into water containing 2 T. each salt and vinegar per gallon water to prevent darkening. But I just work fast.

Raw Pack. Pack your halved peaches into overlapping layers, cut side down, in clean jars. Add hot syrup (or any fruit juice or plain water). Leave $\frac{1}{2}$ -inch headspace. Put on lids. Process quarts in a boiling water bath for 30 minutes at altitudes under 1,000 feet, 35 minutes at 1,000–3,000 feet, 40 minutes for 3,000–6,000 feet, or 45 minutes above 6,000 feet. You can process pints 5 minutes less.

Hot Pack. Heat the halved fruit in your chosen liquid thoroughly through to boiling. Boil 5 minutes. Then fill hot jars with the hot fruit, and immediately process. Process quarts in a boiling water bath for 25 minutes at altitudes under 1,000 feet, 30 minutes at 1,000–3,000 feet, 35 minutes for 3,000–6,000 feet, 40 minutes above 6,000 feet. You can process pints 5 minutes less.

CANNING NECTARINES: Do just as for peaches.

➲ **PEACH KETCHUP** *My husband’s favorite. He likes it with game or ham, as a dipping sauce, or in the gravy. Combine 1 qt. stoned, sectioned peaches, 1 chopped onion, 1 c. sugar, $\frac{1}{2}$ c. vinegar, $\frac{1}{4}$ t. salt, $\frac{1}{4}$ t. allspice, $\frac{1}{2}$ t. cloves, and $\frac{1}{2}$ t. cinnamon. Boil 1 hour. Fill clean, hot jars. Process in water bath 15 minutes and seal.*

➲ **PICKLED PEACHES OR PEARS** *You can easily skin peaches by dipping them quickly into hot water and then sliding the skins off. Pears have to be peeled. For about a gallon of peaches or pears, boil 3 $\frac{1}{2}$ c. sugar with 2 c. vinegar and a $\frac{1}{2}$ -oz. stick cinnamon. Put a few peaches or pears at a time into the syrup and cook until tender. Then pack the fruit into jars, putting a few cloves into each jar. Pour the hot syrup over them and seal.*

FREEZING NECTARINES OR PEACHES: Go through the same preparation as for canning, only you put them in the freezer with cold syrup instead of processing. Or you can freeze whole peaches. Freeze first and then pack in plastic bags for long-term storage. To serve these frozen whole peaches, hold them under running water until the skins will slide off. Slice. You won't need sugar. They'll keep their natural sweetness. Or you can freeze peeled, sliced peaches in pineapple or apple juice with a little ascorbic acid or lemon juice added. Best of all are sliced peaches frozen in orange juice! Don't try to freeze overripe nectarines—they're, well, yucky. Fifty pounds of peaches will make about 35 pt. to freeze.

DRYING NECTARINES: Follow the directions for apricots.

DRYING PEACHES: Freestones are best for drying, and they're best dried if ripe enough for eating, but not dead ripe. Peel, halve, cut again into fourths, or thinner, and remove the pit. Optional: To prevent darkening, dip into a solution of 1 t. ascorbic acid (from a drugstore) per 1 c. cold water. A further option: Now soak 5–15 minutes in a solution of 2–4 T. salt per 1 gal. water. Drain, spread, and dry. Turn occasionally to keep the dampest side up.

➲ **PEACH LEATHER** For general instructions about making fruit leather, see [Chapter 7](#). Get the fuzz off the peaches either by washing or peeling. Cinnamon and nutmeg add a nice touch. Peaches are so sweet you certainly don't need to add any sugar.

➲ **PEACH SAUCE** Use about $\frac{2}{3}$ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

➲ **PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

➲ **PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

➲ **PEACH BUTTER** Scald, peel, stone, and slice 7 lb of whole peaches. Cook in $\frac{1}{2}$ c. water very slowly until soft—about 3 hours. Then sieve. Add $1\frac{1}{2}$ c. brown sugar.

Pears

These trees are less hardy than apples, more so than peaches. You can lose them to a blight, a drought, an early freeze. But when you get them past the pests and diseases and weather problems, pears produce abundant, delicious fruit.

VARIETIES: Pear trees come in many sizes. The standard trees at 30–40 feet are one of the tallest fruit trees. Semi-dwarfs get 15–20 feet tall, dwarfs up to 15 feet. The dwarf pears will fruit in containers. Match your variety carefully to your climate. All need some winter chilling, but the amount varies. Plant varieties resistant to local pests and diseases. There are so many to choose from: early, midseason, late, and very late ripening varieties; various colors: yellow, green, russet, or red; various sizes and shapes. Harvest date varies from August to October, depending on variety. Zones 4–9 are suitable for your familiar, "common," or "European" pear. Zones 5–9 are suitable for the "Oriental" or "pear-apple" or "sand pear."

Oriental Pear. This is very distinct from your familiar pear. It's from Japan, pear-colored and pear-tasting, but apple shaped, crisply apple textured, and very fire blight resistant. It will grow where apples and pears will, is harvested in the fall like them, and stores well.

The remarkable Keiffer pear is an Oriental-common hybrid. It stores well, cooks well, is fire blight immune, and can grow almost anywhere. Available from Raintree Nursery: www.raintreenursery.com.

PLANTING AND PRUNING: Pear seed can't be depended on to produce good fruit. Propagate by grafting a branch or bud onto a young, strong seedling. Remove any root suckers that grow. Prune to shape until the tree begins to bear, after that very little. A northern slope holds back your pear from blooming too soon. A site there in full sun is best. Pear tree branches grow up rather than out, so you can fit a lot of tree into a comparatively small space. Provide organic mulch, but don't fertilize because of fire-blight risk. In dry weather, water mature trees deeply once a month, young ones more often. Pears don't need any special pruning. But if you must prune them, it's better to do an annual light pruning (no more than 10 percent of the branches!) rather than an infrequent heavy one (you'll risk fire blight). Heavy pruning will also reduce your harvest the next year.

POLLINATION: Pears tend to bloom early and so are always at risk from frost. They are pollinated by bees and other insects. Almost all varieties will cross-pollinate and need a pollinator. Some Oriental pears will cross-pollinate with commons. But Seckel and Bartlett won't cross-pollinate each other. Make sure you get same-time bloomers, or at least ones that overlap. *Consult about pollination requirements when buying pears.*

HARVESTING: Pears fruit on long-lived "spurs," which are short special fruiting branches. Oriental pears, like apples, should be left on the tree until ripe. But common pears are always picked green and stored to ripen. If you leave them on the tree to ripen they tend to go bad at the center or fall off and rot on the ground. Standards produce 3–5 bushels per year, dwarfs less than 1. Pick the pears when they are fully grown but still hard and green—when they change from deep green to pale green and a slight tug will separate them from the tree. Once off the tree, they'll ripen best at 65°F and 85 percent humidity. Bartlett pears ripen the quickest—in a couple weeks. Keiffer pears are fast, too. Keep below 75°F. Oriental pears never get truly soft like the common pear will. When the pears get ripe you need to go ahead and eat them or preserve them some other way.

PRESERVING

Root Cellar Storage. Pears will not keep in storage unless picked early and stored then! Don't put any bad ones in the storage box. Box them shallow rather than deep. It helps to wrap them individually in paper (not newsprint unless you're going to peel them). Keep them where it's cool. The ideal is 32–40°F, 80–95 percent humidity. How long they'll keep depends on the temperature and the variety—maybe 2 or 3 months, maybe even 5. Use up or can up because pears stored overly long won't ripen normally when taken out.

Drying. Use sweet pears. Wash, peel, and slice them into halves. (Optional peeling method: Boil the fruit until the skins will slip off. Cool. Remove skins.) Scoop out the core with a teaspoon. Lay out the pear halves, or halves cut into slices, on trays or cookie sheets. In oven or dehydrator, dry at 115–140°F with the oven door propped open $\frac{1}{2}$ inch. Stir or turn once in a while. It takes 12–24 hours, or 2–3 days if drying in the sun. They're done when they're leathery and the center isn't moist (cut to see). Store these dried pears in the refrigerator or freezer.

➲ **STEWED DRIED PEARS** Pour 4 c. boiling water over 2 c. dried pears. Mix in $\frac{1}{4}$ c. sugar or

other sweetening, 4 whole cloves, and 2 t. grated lemon peel. Cook on low heat a half hour. This serves my tribe; divide recipe in half for a smaller family.

⇒ **PEAR LEATHER** *Peel the pears and core them. Don't sweeten. Use usual leather-making procedures, as explained in Chapter 7.*

Canning Pears. It's best to use them while ripe but still quite firm. Wash, peel, cut into halves lengthwise (or quarters), and core. Work fast or else keep them in a salt-vinegar solution (2 T. salt and 2 T. vinegar per 1 gal. water), and then drain well before canning. Use packing process and times for canned peaches. Add syrup, fruit juice, or plain water (a diabetic friend raves about how delicious his pears are canned in just water!). Optional: add 1 t. lemon juice per quart.

⇒ **GINGER PEARS** *To make this "spiced fruit," peel and quarter 2 lb. hard late pears, removing cores. They shouldn't be too ripe for best results. Slice thinly. Grate the rind of 1 lemon, and squeeze it to get its juice. Combine lemon juice, lemon rind, ½ c. water, and 2 lb. sugar in a kettle. Add 2 oz. ginger root or crystallized ginger and simmer about 45 minutes, by which time the fruit should be transparent. When the syrup is thick pour it into jars. Process 10 minutes.*

Freezing. Consider first that pears don't freeze very well. They're much nicer canned or dried than frozen. Fifty pounds of pears will make about 45 pt. to freeze.

⇒ **PEAR JUICE** *Follow directions for apple cider under "Making Cider."*

Persimmons

Diospyros varieties grow over a wide range of temperate climate zones and can handle the competition of a lawn. The tallest kinds can get up to 40 feet tall; the shortest are shrub-like. Persimmons are always ornamental, some for extraordinary leaf coloring (Hachiya), and especially in fall and winter, because the brightly colored fruit stays on the tree long after its leaves have dropped. The plant gives a generous harvest, and its wood is valued by carvers. In the western United States, the persimmon is virtually disease-and pest-free. Borers may go after its trunk in the East, but they can be picked off by hand.

Persimmons are memorably puckering (tannin)—just like biting into a walnut hull, until they ripen; don't even try it. Then they make a sudden, miraculous transformation, and become the sweetest—and one of the most delicious—of all fruits. Some varieties get sweeter than others; some have more tannin, and hold it longer, than others. When the usual persimmon becomes very soft, the stage at which it becomes edible, it will be very high in sugar content.

VARIETIES: Worldwide there are hundreds of persimmon species, varying in every conceivable way. Because of great variation in time of fruit ripeness, you can select to have them ripening in succession. There are 2 basic types, American and Oriental. In either case, it is a good-looking deciduous tree.

American. This is a newly domesticated native (*Diospyros virginiana*), available as a tree or shrub. Its tree form is taller than the Oriental at 30–40 feet. It has a myriad of subspecies varying in size, color of fruit, harvest time, presence/absence of seeds, size, and shape of tree. Its fruits, in general, are smaller, from ½ (wild) to 2½ inches across, and fig-like. It grows suckers that will need to be pruned away regularly unless you want a persimmon thicket.

Oriental. The commercial persimmons (*D. kaki*) are the result of centuries of careful plant selection. They are always a tree, 25–30 feet tall. Hardy to 0°F, they need only 100–200 hours in winter below 45°F to fulfill their genetic chilling requirement and enable fruiting so they do well in southern states. The fruits get large: Fuyu, as wide as 4 inches across and tomato-shaped; Hachiya, 4–5 inches in length. The Fuyu tree is on the small side and is the only type that loses its tannin early enough to be eaten while still crisp, like an apple.

CLIMATE: American persimmons are a little hardier than Orientals, good in zones 5–9, as far north as the Great Lakes and Rhode Island. But persimmons are risky in the more northern areas, because a hard frost that hits before the fruit is ripe can ruin it. In general persimmons can't survive in the northern plains or northern New England. However, once the fruit is ripe, frost, or even freezing, doesn't harm it. So the challenge is to find a variety that will ripen before frost hits in your area, as well as a plant that is itself hardy enough to survive your winters. Wild Americans grow in southern Indiana, Virginia, Alabama, and points between. Orientals are better in hot areas, zones 6–10, for they are only hardy down to around 0°F. In the United States, Orientals are suitable for areas south of Ohio, continuing on down to Florida, and the West Coast.

Mature trees of either category can handle about 10 more degrees of cold than young ones (up to 3 years old). In a marginal area, plant against a south-facing wall. That will help warm your plant in winter and get its fruit ripened. Note that not every young persimmon that looks dead from frost really is. The top growth may be gone, but well-mulched roots can live to come back and thrive.

PLANTING: The persimmon is best propagated by budding, grafting, or cuttings. Start with named varieties if possible. Purchase them as very young trees to avoid problems with the long taproot. It could be a temptation to try to transplant wild persimmon to your garden, but older trees simply cannot be transplanted. To transplant young ones, cut the top way back, and try to get as much of the root as possible. (Some nurseries grow their seed on top of a wire mesh that cuts off the tap root.) Plant allowing a growing space of 20 square feet or what is recommended. Move only during the December to February dormant season.

Seeds. You could plant seeds and make them grow, but their resulting type and harvest would be unpredictable. Or use them as grafting stock. Plant them in the fall in a potting mix (such as part sand, part peat moss). Leave outdoors during the winter for the chilling requirement, in a cold frame if your climate is northern.

Growing. The American persimmon is extraordinary in its ability to make it in poor soil—sand and clay, even in clay where all the topsoil has washed away. Persimmons need good drainage, but some Americans will grow in muck. All appreciate full sun. Prune young trees to 3–5 main branches, widely separated. After that, let it be, except to take out American suckers. All grow on the slow side, 1–4 feet per year the first 2 years, less after that. Mulch lightly to keep the roots warm, but avoid excess nitrogen. Too much may cause premature fruit drop. Water young trees regularly, but once they get going, persimmons are quite drought-resistant and can get along on only an occasional (monthly) deep watering.

Pollination. Persimmon flowers come male, female, or bisexual. An individual tree can have one kind, or another, or any combination. So some female trees will make fruit

without cross-pollination. If they do that, you get seedless fruit. But some trees will not bear fruit without cross-pollination—and their fruit is seedy. Americans are normally sexed trees with males that produce pollen (but no fruit) and females, which will produce the fruit. Unless you see wild trees close to your orchard, plant both. Orientals are usually self-fertile. Find out when you buy just what your persimmon's pollination habits are, and match accordingly.

Harvesting. Persimmon fruit grows on new wood, so it forms on the outer tips of the branches. There's no need to thin the fruit. On the tree, persimmons are first green, then yellow, then, when ripe, orange. Totally ripe persimmons, unless somewhat dried, can be so soft that they're hard to handle.

Harvesting American Persimmons. Fruit from a variety of wild American trees will ripen gradually over a long period of time, storing themselves well on the tree, even after frost has stopped the actual growth. Even lying under the tree, they'll keep a month or longer in cool fall weather. Hanging on the tree, they gradually undergo a natural drying process. Thus the fruit you pick, even in the wintertime, is still delicious and healthful! Just pick it from the tree, even if it's frozen. Thaw it, eat, and enjoy. Persimmons start bearing soon after planting and often bear in abundance (the average tree produces 25 lb. of fruit per year), some types in alternate years, some annually. If you're anxious to harvest, wait at least until after the first frost. Then gather the ripe fruit, sort, wash, and drain it.

Persimmons for Livestock Fodder. Virtually every animal on your place loves persimmons. Old-timers fed them to mules and calves together with grass or good hay for a winter diet. Some pastured their pigs on mulberries in June and July, then let them eat persimmons from September to December, gathering their own as the fruit gradually fell so the animals could get it.

Harvesting Japanese Persimmons. Some grow in clusters, like grapes—only their fruits can be many times larger than a grape. Growers usually pick these about October, before the first frost, then store them in the refrigerator, or at room temperature. Don't eat until they soften, unless you have a Fuyu! They'll ripen around December.

Ripening Persimmons in a Hurry. Put them in a plastic bag together with a few ripe apples. Close the bag so that it is airtight. Leave at room temperature for as long as 4 days. The apples release a gas that has a ripening effect on the persimmons.

Using and Preserving. Low-tannin persimmon varieties can be eaten while still crisp, like an apple. For high-tannin types, wait until the fruit is very soft, then eat it with a spoon; or substitute it in any recipe calling for applesauce or bananas. Persimmons are traditionally eaten either raw, dried, or in a pudding. A dried whole American persimmon resembles a dried fig except there are no seeds inside (if you have a seedless fruit). In modern times, we also freeze them, or even can them.

Drying. Dry the softer kinds of persimmons at that golden moment when they're soft enough to eat but not too soft to handle easily. Firmer kinds can be dried at a riper stage. Peel. With a stainless steel knife, cut in $\frac{1}{4}$ -inch to $\frac{1}{2}$ -inch slices. Spread them out to dry in a single layer, none touching. Dry at 115°F for 18–36 hours (or 3–5 days in the sun)—until there is no more moisture, even in the center. Your dried persimmons will be brown and chewy, leathery. Turn twice during the drying. You can serve dried persimmons as a candy. Or use them to make a homemade trail mix in combination with other dried fruits, plus some nuts and seeds. Or substitute for "raisins" in any recipe, add to any baked goods, or sprinkle over fruit. Persimmon pulp can be made into a good leather (sieve out

the seeds).

⇒ **DRIED PERSIMMON “SUGAR”** You can make a pure fruit sugar out of the highest-sugar kinds, which, when dried, are very sweet! Dry as above. Then chop the dried fruit into sections and dry a second time—until very hard. Then blend or grind in a mortar to a powder. That powder is your persimmon sugar. Use it in place of sugar.

Freezing. Freezing is suitable for the soft, sweet kinds of persimmons. (The crisp Fuyu that lasts and lasts, is best eaten fresh.) Method 1: A thoroughly ripe, seedless persimmon can be frozen unpeeled and whole. To eat, thaw and spoon out of its skin somewhat like a sherbet. Or peel (the skin will slip if you hold the fruit under running water), dice, and serve with cream. The cream freezes as the fruit thaws. Method 2: Blanch your persimmons, peel them, and put them into individual plastic bags. Seal, and freeze. Method 3: For persimmon puddings, mash the soft pulp out of the skin (discard it) or put it through a food mill or colander, package in something moisture-proof, and freeze.

Canning. This is the least popular way to preserve persimmons, but it's possible. Start by making a persimmon pulp, sieving out the seeds. Can the pulp in small jars, no bigger than a pint. Process in a hot water bath for 30 minutes.

⇒ **CANNED PERSIMMON PUDDING** Phyllis Bates, Tangier, IN, invented this, and her husband, Allan, learned how to can it. “It's yummy.” For every 2 c. persimmon pulp, add 2 beaten eggs, 1 c. of either dark or white sugar, $\frac{1}{2}$ t. double-acting baking powder, $\frac{1}{2}$ t. baking soda, $\frac{1}{2}$ t. salt, $\frac{1}{2}$ c. melted butter, 2 c. milk 2 t. cinnamon, 1 t. ginger, and $\frac{1}{2}$ t. nutmeg or allspice. To eat right away, bake the pudding in a 9-inch-square greased baking dish, at 325°F for 1 hour. To can it, fill pint jars only two-thirds full. Can at 15 lb. pressure for 25 minutes.

⇒ **PERSIMMON ROLL CANDY** Start with 2 c. fresh or frozen persimmon puree. Mix in 1 c. sugar, $\frac{1}{2}$ c. brown sugar, 1 lb. smashed graham crackers, 1 c. chopped nuts, and $\frac{1}{2}$ lb. miniature marshmallows. Lay out a sheet of waxed paper and spoon $\frac{1}{3}$ of persimmon mixture onto the paper in a roll shape about 3–4 inches wide. Roll it up in the waxed paper, with a sheet of aluminum foil or plastic wrap on top of that, and freeze it. Do the same with the rest of the mixture. To serve, partially thaw a roll, and cut about 8 slices, each of which will be an individual dessert serving. Top the slice with vanilla ice cream or whipped cream.

⇒ **PERSIMMON FRUIT BARS** Combine 1 c. chopped dried persimmon with $1\frac{1}{2}$ c. of a combination of other chopped, dried fruits (apricots, cherries, peaches, figs, or what have you). Add 1 c. chopped nuts, and $\frac{2}{3}$ c. flour that has been thoroughly mixed with 1 t. baking powder and $\frac{1}{4}$ t. salt. In another bowl cream together $\frac{1}{2}$ c. butter and 1 c. sugar until fluffy. Add 2 eggs and 1 t. vanilla to butter-sugar mix and mix well. Now add the fruit-flour mix to the rest, a cup at a time. Blend thoroughly after each addition (with a spoon, not a mixer). When finished combining, spread it into a greased 9-inch-square pan and bake 45 minutes in a 350°F oven. When done, cool completely before cutting. Slice into 1-inch by 3-inch bars. Roll bars in powdered sugar.

Plums

These are an easy fruit to grow. My family, though, will ask to eat cherries, peaches, nectarines, pears, apricots, or berries before they will plums. Sad but true. Personally, I'm grateful for anything that grows without poisons—and I love Greengages!

VARIETIES: Plums come in so many different colors and sizes—purple, red, green—from as

small as a cherry to almost as big as a peach. Standard plum trees have a height and width of 15–20 feet, dwarves 8–10 feet. Take your choice. “Europeans” bear mostly oval, usually blue fruit, and are hardy in zones 5–7. Damson is a tasty blue European. Greengages are wonderful old-time European plums that are good eaten raw, or in pies and puddings and sherbet. “Japanese” plums are mostly round and red and hardy in zones 5–9, which makes them better for the South. Santa Rosa is a good red Japanese plum; Shiro is an early-ripening yellow one. “American” plums are small, hardy wild natives. But they have been crossed to create better fruiting hybrids that will bear in zone 4. The “plumcot” is a hybrid between the plum and the apricot.

So What's a PRUNE? A prune is a kind of European plum, a freestone. It is blue-black and oval, with firm flesh. The sweetest varieties of plums make the best prunes. Blue Stanleys are the usual commercial choice. So, you dry prune kinds of plums and you have prunes. You dry any other kinds and you have dried plums. There are yet more mysteries to prune production (see “Drying Prunes”).

POLLINATION: Japanese plums and European plums won't cross-pollinate. Most European plums are self-fertile. All Japanese plums need cross-pollination, but they are limited to another variety of Japanese plum to do the job. Consult when you buy.

PRUNING: Japanese plums need heavy pruning with the strong upper wood whacked back to weaker branches. European plums should not be pruned so severely.

HARVESTING: It takes 3–4 years after planting to get your first plum crop. Plums fruit on long-lived spur branches, so don't prune those all away. For bigger plums, you can thin the fruit to 3–4-inches apart, but I don't think it's worth the trouble. Let them ripen on the tree. Pick them when they're soft and they separate easily.

PRESERVING

Canning. Choose ripe, but still firm plums that are only just beginning to get soft. Among the best varieties to can are Greengages and similarly “meaty” kinds. Wash and drain them. Experienced plum canners prick the skins of the plums a couple times with a fork if they're to be canned whole. That helps prevent the fruit from splitting. Freestones are easily halved and pitted and nice that way.

Hot pack: Add plums to hot syrup and boil 2 minutes. Cover pan and let stand 20–30 minutes. Fill jars with hot plums, cover with cooking syrup. Raw pack: Fill jars with raw plums, packing firmly. Cover with hot syrup. For either hot or raw pack, process in a boiling water bath. At altitudes under 1,000 feet, process pints 20 minutes, quarts for 25; at 1,001–3,000 feet, process pints 25 minutes, quarts for 30; at 3,001–6,000 feet, process pints 30 minutes, quarts for 35; at over 6,000 feet, process pints 35 minutes, quarts for 40.

➲ **PLUM JUICE** Tree-ripened plums of deep color are best. Wash and mash. Simmer until soft in just enough water to cover them. Press and strain. Sweeten if the fruit is tart enough to need it. Can by instructions for apple juice (see “Making Cider”).

Freezing. Wash, remove stems and pits, and cut in half. Method 1: Spread out on cookie sheets and freeze like that to get them frozen as quickly as possible. Then move them into freezer bags or boxes, seal, and store in the freezer. To serve the frozen plums, rinse them off and slice them into dishes, letting them defrost enough so you can get your teeth into

them. Or eat them whole like fresh fruit. Method 2: Freeze the plum halves in a fruit juice (white grape or apple are good), or syrup, or plain water. These will be best cooked after thawing. Freeze as quickly as possible. Fifty pounds of plums will make about 40 pt. of fruit for your freezer.

Drying Plums. Cut plums in half and remove the pit. Optional: Now blanch the halves by steam for 15 minutes. Then dry your plum halves (or quarters) the regular way. Some dry them whole, but they're a lot easier to get dry halved than whole. Dry when pliable and leathery. Plums dried without pits are good for pies.

Drying Prunes. For results that look somewhat like store prunes, pick the proper variety of fruit when very ripe, and dry it whole. The first secret of prune making is that "very ripe" part. Some expert prune makers even hang a cloth under the tree to catch the plums at that moment of maximum sweetness when they fall from the branch. Another prune secret is to presoften the skin, either by soaking them 20 minutes in very hot water before drying or by soaking them in a lye bath—a solution of 1 oz. lye crystals in 1 gal. water (in a nonmetal container!)—for several minutes. Then rinse them well in cool water. Then dry them on trays. To oven-dry prunes, start at 120°F for 15 minutes, and very slowly and gradually increase the heat to 160°F. If you raise the temperature too fast they may burst. Turn them occasionally. It takes about 2 days. A last prune secret is to paint them with a honey solution before their final drying.

➲ **PLUM SAUCE** Cook plums in about $\frac{1}{2}$ c. water per 1 lb. plums. They'll need 7–10 minutes. Put through a strainer. Sweeten to taste. Add 1 T. lemon juice.

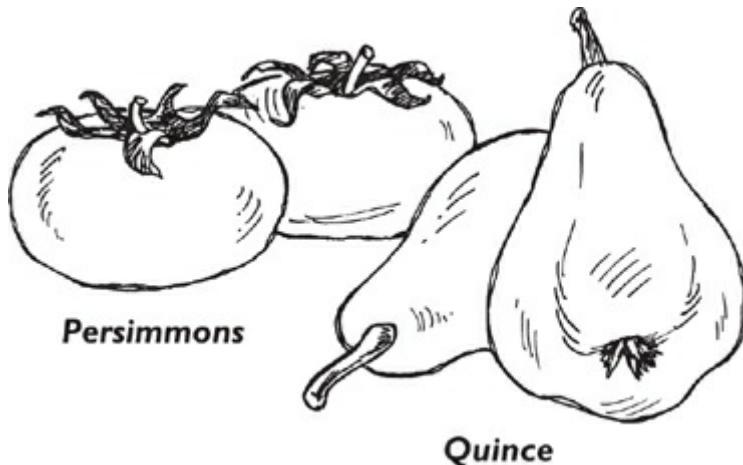

➲ **SPICED PLUMS** Decide how many plums you want to spice and weigh them. For 1 lb. of plums use 1 lb. of sugar ($1\frac{3}{4}$ cups) and $\frac{2}{3}$ cup vinegar. For every gallon of plums use $\frac{1}{2}$ -oz. each of ground cinnamon, cloves, mace, and allspice. Prick each plum in several places with a needle. Add the spices to the syrup and boil it. Pour the boiling mixture over the plums. Let them rest 3 days; then pour off the syrup and reboil it. Boil it down until it's thick but there's still enough to cover your plums. Pour it hot over the plums in the jar in which they are to be kept. Cover the jar well to keep out the dust and insects. Makes plums very special.

➲ **PRUNE RYE BREAD** This is a favorite of mine. The recipe makes 2 small loaves. It is very heavy and moist. It keeps well and my children love it as much as a "sweet." First put your dried prunes on to cook, enough to make 1 c. when they're cooked enough to be able to cut out the pits. Sift together 6 t. baking powder, 2 c. rye flour, 3 c. wheat flour, $\frac{1}{2}$ t. salt, and $\frac{1}{2}$ c. honey. Add 1 egg and $1\frac{3}{4}$ c. milk and mix it well. When your batter is mixed, add the 1 c. chopped prunes, and stir just enough to distribute them. Pour into 2 small (6-inch by 3-inch) greased loaf pans or 1 larger one (11-inch by 3-inch by 3-inch) and bake at about 350°F for about an hour. After baking, when the bread has cooled enough, wrap it in foil, a cloth, or plastic for a tender crust.

Quince

Quince is an ancient, deciduous fruit, Asian in origin, and a distant relative of the pear. The fruits are yellow, hairy, baseball-sized, and come in several varieties, some round, some pear-shaped, ripening in September. Quince naturally grows as a shrub and makes a good hedge because of thorns and that shrubby style of growth. Or you can prune it (in winter only) to a single trunk and make it grow like a small tree, usually only getting to be about 12 feet tall.

CLIMATE: In general, quince is harder than peaches, but a little less hardy than pears. The growing range is wide, from California to the Midwest to the Northeast, zones 5–9. A special cold-zone advantage is quince's blooming time, which is late in spring. In warm, humid areas, quince is more likely to get fire blight and other diseases.

VARIETIES: When ordering plants be sure you get the edible or "orchard" variety (*Cydonia oblonga*). Orange, Pineapple, and Smyrna (probably the best) are good edibles. All quinces are self-pollinating so you need only one. Don't get one of the many ornamental flowering quinces, although they are much harder than the edible. The ornamentals can be deceptive because some produce fruit, but it never ripens and doesn't have the delicious taste, when cooked, of the edible. The fruit of some ornamental quinces will make sauce okay.

PLANTING: Use layering, cuttings, or division rather than planting seed, as seedling quinces are unlikely to grow true. To reproduce by layering, simply force a branch down on the ground in spring and fasten it there somehow. Cover the part that's on the ground with dirt and wait until fall, by which time it will be growing roots. Then cut it off where it connects to the parent plant and transplant to your chosen site.

GROWING: Quince does best in moist, well-drained soil, but it is quite exceptional among the fruits in that it can endure some wet feet from poor drainage. Quinces fruit best in soil of a medium type rather than either very heavy or very light, and they appreciate full sun. If you want your quince to look like a tree, you'll have to sometimes take out suckers. Prune only in the winter and as little as possible because pruning may result in fire blight. Fertilize only with an occasional mulch or helping of manure because excess nitrogen weakens resistance to fire blight. Quince blooms after apples, in late spring.

HARVESTING: The fruit is produced on the tips of current growth. It ripens late in October or even November. Don't harvest until they are almost ripe. You can tell because the quinces turn yellow and smell fragrant when they get ripe. They don't drop from the tree just because cold weather arrived, so you've plenty time to get them. Pick somewhat before full maturation, being careful. They seem firm, but quinces actually bruise easily. Store in a single layer and they'll stay good for 2–3 months. If you store quince in the refrigerator or with apples and pears, everything else will end up smelling like quince!

COOKING: The reason you've probably never seen a quince is because quinces are sour-

tasting and hard, absolutely inedible while still raw. However, when cooked they are good. The Greeks, Romans, and American colonists enjoyed quince dishes: a jelly, or quince blended with other fruit dishes, such as an applesauce made of half-cooked quince and half applesauce (a good choice to can!). Or can quince, or spice or chutney it (use basic fruit recipes), or bake it like an apple, or make quince leather (rolled in sugar). Or make quince-berry or quince-grape jellies (quince is high in pectin). Or quince-orange marmalade.

⇒ **QUINCE SAUCE** From Frances Dallotta, Sacramento, CA: “Cut up quince in small chunks, add sugar, cook, and cool. Never let the chunks lose shape and get mushy! It’s like applesauce, just delicious!” Quince mixed with apples or pears also makes a great sauce.

⇒ **GETTING QUINCE JUICE** Cut out the cores and stem and blossom ends (don’t peel) from 3 lb. quinces. Grind the fruit Combine fruit with 4½ c. water in a nonaluminum pan and heat to boiling, then simmer for quarter hour. Now squeeze out the quince juice in a jelly bag or some such.

⇒ **QUINCE JELLY** Combine 4 c. quince juice, 7½ c. sugar, and ¼ c. lemon juice in a pan. Stir together and then heat to boiling. Don’t stop stirring! Now add in ½ bottle liquid pectin, and boil as hard as possible another minute—still stirring constantly. Then skim off the foam and pour the jelly into your jars. Cover them immediately with ⅛-inch of hot paraffin. Or make jelly using 2 parts apple juice to 1 part quince, or 1 part cranberry juice, 1 part quince, and 1 part apple juice. Use two-thirds as much sugar as juice. In any case, save the pulp for a quince butter. Or make quince jam.

⇒ **QUINCE PASTE** Peel, core, and quarter 3 lb. quinces. Wrap peels and cores in a porous clean cloth and tie. Place cloth bundle, quinces, 2 c. sugar, and 2 T. water in a stainless steel pan. Cook over low heat until quinces are quite soft. Toss the bag and its contents. Puree quince, and move to a small loaf pan (about 8 × 4 inches). Dry in oven at 175°F until firm. (Takes about 18 hours total.) Serve with cheese. Or cut into squares, dust with sugar, and serve as a candy.

⇒ **SPICED PICKLED QUINCES** Peel about 10 large quinces, cure, and cut them into ¾-inch sections. Put fruit in a pot. Pour 2½ c. boiling water over it. Cook around 5 minutes. Drain (save the liquid). Measure 1½ c. of the liquid back into the pot Add about 15 whole cloves, 2 oranges cut into very thin slices, 6 c. sugar, and 2½ c. white vinegar. Boil 10 minutes. Add quinces back in. Boil a half hour more (better stir once in a while). Pour into sterile pint-size canning jars. Process for 15 minutes in a boiling water bath.

⇒ **QUINCE SEED HAND LOTIONS** When quince seeds are soaked in warm water they soften and separate into a “goop” and what’s left of the seed. Good, gooey, soothing hand lotions made from this goop were both homemade and commercially produced by the old-timers.

Country poet Dallas A. Sall got this recipe for me from his mother. Soak 2 oz quince seeds in a pint of warm water for 30 minutes. Strain through a cloth, squeezing well to get the goop off the seeds. To that goop, add 2 oz. bay rum, 2 oz. glycerin, and enough water to make a pint. Add fragrance if you wish.

⇒ **WITCH-HAZEL CREME** Sherry McGuarrie of Pouris, Manitoba, Canada, who does chemistry demonstrations, kindly sent me this old-time commercial recipe plus advice that this author should be “editing your Recipe Book to a more manageable size by deleting most of the chatty bits that don’t add to the helpfulness of the text” So, straight down to business: Soak 4 oz. quince seed in 16 oz. hot water Dissolve 6 oz. boric acid in 128 oz. witch-hazel water. Add

32 oz. glycerin and the witch-hazel water/boric acid solution to the quince seed-water mix. Let that stand for 2 days, stirring occasionally. Then strain and add perfume.

SUBTROPICAL AND TROPICAL FRUITS

That eastern Washington widow Florence Merrifield, who retired in Jalisco, Mexico, keeps sending me tantalizing progress reports: "My banana tree has a bunch of bananas ready and 2 other hands forming. Papayas are getting ripe and some have fallen. And mangos ... there must have been a ton on the seven large trees in my garden. At last they are all about gone. I also have a large vegetable garden. Some green beans and cukes ready now. Planted 5 more banana trees Saturday ..."

In general, "southern" or "subtropical" fruits can't handle freezing or temperatures close to it. Hawaii, southern California, and southern Florida are the most tropical U.S. zones. Northern gardeners can sometimes grow these plants in containers, moving them indoors during cold weather, or in greenhouses, or simply in the house in a sunny window.

TROPICAL FRUIT INFORMATION: *Warm-Climate Gardening* by Barbara Pleasant covers fruits, vegetables, and herbs for the subtropics. *Growing Unusual Fruit* by Alan E. Simmons covers 100 fruits. Other terrific books for subtropical growers include: *All About Citrus & Subtropical Fruits* by Moore and Sweet; *Fruits of Warm Climates* by Morton; *Malaysian Fruits in Colour* by Chin and Yong; *Manual of Subtropical Fruit* by Papenoe; *Tropicals* by Courtright, etc. *Florida Gardening: The Newcomer's Survival Manual* is also good. It's \$11.20 from Betty Mackey, publisher, who also offers *Herbs and Spices for Florida Gardens* (\$15.50), and *Creating and Planting Garden Troughs*: 610-971-9409; PO Box 475, Wayne, PA 19087-0475; www.mackeybooks.com.

Join the Rare Fruit Council International for \$40 and you'll get a subscription to *Tropical Fruit News*, a monthly magazine: PO Box 561914, Miami, FL 33256; www.rarefruit.org. Or subscribe to *Pacific Horticulture: Journal of the Pacific Horticultural Foundation*, \$25/yr; 510-849-1627; PO Box 680, Berkeley, CA 94701; www.pacifichorticulture.org. *The High Value Fruit Crop Newsletter*, put out by Claude Sweet, offers detailed info on individual exotic food crops, plus a computer system to predict specialty crop profitability for you. Sample \$4: RIM Corp., PO Box 370, Carpinteria, CA 93014.

AVOCADO: This is an evergreen tree, 20–40 feet tall in its standard form, 8–10 feet tall as a dwarf. There are 3 basic varieties of avocados. They can be grown in California, Florida, and Hawaii. They need reasonable watering and fertilizing and have a few disease problems. Grafting or budding is far better than planting that big seed. A plant started from the seed will grow foliage, but no fruit.

Preserving. You are going to get an abundant harvest of perishable fruit. Eat it, give it, sell it, or make guacamole and freeze it! Or freeze puree for making guacamole later.

➲ **GUACAMOLE** Peel, remove pit, and mash 4 avocados. Thoroughly mix in 1 chopped tomato, ½ t. garlic powder, 1 T. lime juice, plus hot sauce to taste if you're so inclined (I prefer it without). This is great in almost any sandwich combination or with chips, in a salad, or as a side dish (without the hot sauce). It can be frozen.

➲ **FROZEN AVOCADO PUREE** Choose avocados that are ripe and soft but have no dark blemished places. Peel, slice into halves lengthwise, discard pits, smash pulp. Option 1: Add ⅛ t. powdered ascorbic acid per quart puree; it will taste and keep better. Option 2: Add 3 T.

lemon juice to each quart puree. When thawed, use for sandwich spread, dips, or in salads.

BANANA: Bananas have been a domesticated plant for tens of thousands of years. A dried part of banana root that is planted in a warm, moist place will grow again, even after some time. Over the millenia, human selection developed the banana from a fruit with big seeds into a seedless one. Bananas thrive in Central and South America, Pakistan, India, the Philippines, Thailand, and similar climates. Technically, the banana is not a tree. Its trunk is made up not of wood, but of stalks grown up around each other from the roots in a way that forms a hollow tube. *The Complete Book of Bananas* by W. O. Lessard covers banana history, culture, diseases, cold protection, and recipes.

Planting. The Banana Tree offers a big selection of bananas, plus brief growing instructions (catalog on Internet): 610-253-9589; fax 610-253-4864; 715 Northampton St., Easton, PA 18042; faban@enter.net; www.banana-tree.com. Bananas are planted with pieces of root. Each banana “rootstalk” has buds that resemble potato eyes. Make sure your piece has a bud. Plant about a foot deep. It will soon send up several shoots. By the time a banana plant is about a year old, it will be 15–30 feet tall. Then a purplish flower bud pushes up through the hollow leaf stalk and emerges at the top. It gradually droops and clusters of flowers grow out of it. After the flowers finish blooming and fall off, little fingers of fruit grow from where they were. Each banana is a “finger.” The banana fingers are clustered around the stem in bunches of 10–20, called a “hand.” It takes 3–4 months for the flower bud to evolve from just becoming visible to being a mature bunch of bananas.

Harvesting. Pick them green. If bananas are allowed to ripen on the plants, they spoil. Cutting down a banana bunch is a 2-person job. One person, with a knife on the end of a pole, reaches up and partly cuts the stem several feet below the bottom of the hanging banana bunch. The cutter is careful not to cut all the way through because he wants the cut to be just great enough that the weight of the bananas makes them bend over so his partner can just get under them and catch them on his shoulder. Then the cutter trims the stem off the bananas and cuts the “tree” off at the ground. When the bananas have finished growing the plant dies anyway. A banana “tree” will never grow more than just the 1 bunch of bananas. But after the next good rainfall a new banana plant will grow up from the same roots.

Using. In food value, bananas are very like potatoes. In tropical countries they are typically steamed, boiled, fried, or baked. For cooking, the firm, green ones are preferred. They are peeled, wrapped in banana leaves, and immersed in a pot of boiling water to boil. When cooked, the fruit may be mashed before serving. To bake, the bananas are chosen green, or slightly ripe, and left in their skins. Or the green bananas may be grated, wrapped in a banana leaf, and baked like that. Or grated green banana is mixed with coconut milk into a paste, and then baked. Bananas are fried plain, or mixed with sugar, flour, and a dash salt, and fried. Or a bread pocket is filled with banana and then fried. Banana “figs” are considered a dessert treat. To make “figs,” ripe bananas are dried in the sun and then sliced. They turn out dark-colored, stock, and sweet. A banana flour is made by grinding dried bananas. The big banana leaves have many uses, too: umbrellas, wrapping “paper,” plates, roof thatching. They can also be made into twine and used to weave mats and baskets.

Drying. Perfect bananas for drying are still firm, but flecked on their peels with brown. To prevent darkening, dip sections for drying into pineapple juice (undiluted), ascorbic acid,

or a solution of $\frac{1}{4}$ c. lemon juice in 2 c. water. Method 1: Peel and slice $\frac{1}{4}$ -inch thick onto a drying tray. Method 2: Using a coarse shredder, shred right into your drying pan. Cook 1 minute under the broiler, if you have one. Method 3: Cut in half crosswise, quarter each half and dry.

Spread sections, shreds, or quarters on your drying trays, only 1 layer deep. Dry at 115–125°F in a dehydrator or 140°F in an oven. Turn them over after 3–4 hours, rotate trays occasionally, and stir occasionally. Dry until crisp, about 6–10 hours. Sun-drying bananas takes longer—2 days or more.

Freezing. Put ripe fruit through a food mill or mash very thoroughly. Add powdered ascorbic acid or lemon juice to prevent darkening. Freeze. Thaw your puree to use in banana breads or cakes or for baby food.

➲ **BANANA POPSICLES** Linda Crabtree of Kettering OH, sent me this recipe on February 11, 1976. You'll need firm but ripe bananas and popsicle sticks or popsicle-type sticks; some chilled, strained honey; and chopped salted peanuts. Cut the bananas in half crosswise. Stick a popsicle stick into the end of each banana half as a handle. Coat each one with honey and then roll it in the nuts. Freeze unwrapped until solid.

➲ **GREEN BANANA SOUP** Peel 2–3 lb. green plantains or green bananas. Peel them, boil 10 minutes. Cut into thin slices. Fry a chopped big onion in fat or oil several minutes. Then add 1 c. cooked dry beans, the banana slices, and fry and mix a few more minutes. Then add several pureed tomatoes and water enough to cover all. Simmer until the bananas are fork tender (about a half hour) and serve.

➲ **HEALTHY BANANA CAKE** Puree 6 big bananas. Dissolve 1 T. yeast in 1 c. warm water. After the yeast water has begun foaming, mix it with the banana. Let rest 15 minutes. Mix in 4 c. home-ground flour, 1 t. vanilla extract, and $\frac{1}{2}$ c. bits of dried fruit or raisins. Let rise a half hour. Pour into two cake pans. Bake at 350°F until done. Spread with fruit sauce and decorate with slices of fresh fruit.

➲ **BANANA BREAD** Cream $\frac{1}{2}$ c. butter and $\frac{3}{4}$ c. honey in a bowl. Stir in 2 eggs, $\frac{1}{2}$ t. salt, and 1 t. vanilla. Sift 1 t. soda with 2 c. flour. Add to creamed mix. Add 3 mashed bananas and $\frac{1}{2}$ c. chopped nuts. Pour into greased loaf pan. Bake at 300°F for 1 hour, or until done.

BARBADOS CHERRY: The Barbados cherry, also known as acerola, is a deep-rooting, subtropical bushy tree. It grows 10–15 ft tall, but the trunk is only 2 ft. long and about 4 inches in diameter. Barbados cherry can thrive in poor soil, has no bug problems, and needs little care. What it must have is an abundant water supply. The fruits resemble cherries. Their reddish-orange juice has an agreeably tart taste and an astonishing concentration of vitamin C.

BREADFRUIT: This is the fruit of a very large Polynesian tree *Artocarpus*. Since its juice hardens on contact with air, natives to the tropics have used breadfruit to waterproof canoes. Breadfruit is similar to chestnuts and potatoes in nutritional value; it provides carbohydrates as well as vitamin C. Just 2 or 3 breadfruit trees can keep a shipwrecked sailor alive.

Preparing. Breadfruit is large, as much as 8 inches in diameter, round, with a thick, bumpy outside. *This fruit must be cooked before being eaten.* The fruit's flesh is an off-white color and tastes honestly like bread. It's better when prepared on the unripe side rather than being overripe. You can prepare it by boiling it, then mashing and seasoning it with

herbs and garnishing it with nut slivers. Or cut it into slices; combine it with sliced onions, carrots, or other vegetables; wrap them in an edible leaf; and barbecue it. Or steam breadfruit until cooked, then scoop the flesh out of the rind, mix it with pineapple chunks, flavor it with molasses, and serve with baked squash. Or cut the breadfruit center into chunks and stuff a bird with it and roast them together. Or boil the fruit, then serve with a pasta sauce. Or bake the fruit until very well done, then serve it with an herb butter.

CACTUS: See “Prickly Pear.”

CARAMBOLA: The carambola tree (*Averrhoa carambola*) will grow only in southern Florida, Hawaii, and points south. The leaves are sensitive and fold up when touched. It blooms pink flowers, 3 sets a year: spring, summer, and fall. You can choose between a sweet-fruit or a sour-fruit kind. Or try *Averrhoa bilimbi*, the “cucumber tree.” It’s closely related and similar in needs to carambola, though even less cold-hardy.

Planting. Pacific Tree Farms carries it. You can grow these from seed. Graft good scions to seedlings if you want more control of fruit type. Baby trees are more vulnerable to cold than their elders, which can live at temperatures down to 28°F—provided it doesn’t stay there very long.

Harvesting. The carambola fruits are the size of a large orange, good-tasting, and good for juicing.

CAROB: The carob tree (*Ceratonia siliqua*) is an evergreen leguminous tree that grows 20–40 feet high. Carob is a prized shade tree, windbreak, or screen plant because of its dense foliage. Carobs can't live where temperatures get lower than 20°F. They also don't appreciate high-precipitation climates. They are perfect for mild-wintered Southwestern areas as long as they are away from the coast.

Planting. Carob is easy to grow. If you don't have a full-sun site for it, plant where there's light shade, and it will get along. Carob can be started from seed or by budding, but carob seedlings are unpredictable in their fruiting performance. Many trees offered in nurseries are seedlings intended only for ornamentals with no attention to fruiting and no identification of gender. You can get carob seed from Exotica or from Redwood City. Starts are available from Exotica. Dwight Roberts (3111 Victoria Dr., Alpine, CA 91901-3679) will swap carob seed for your regional seed. (He also has acacia, loquat, and yucca seed.) There are some named varieties, some immune to worms.

Pollination. A few varieties are self-fruitful, but most carobs are not, and you need at least 1 male and 1 female tree to get fruit. It's safest to plant at least 5 if you're growing them from seed because you need good odds to get at least 1 of each sex. You won't know what sex they are until after 3 or maybe even 5 years.

Growing. Carob gets along in any well-drained dirt—sand or clay being equally acceptable. They don't need fertilizing. The mature tree doesn't need watering although some watering will increase your carob bean harvest. Carob can be allowed to grow its natural way into a multi-stemmed shrub or pruned to be a tree (but prune as little as possible). With no pruning it will eventually get about 40 feet high and 40 feet wide. Carob roots are extraordinarily efficient at finding their own water so this plant is a natural for desert homes.

Harvesting. The flat, long (about 10-inch), edible “bean” pods ripen during October and November. When they have turned dark brown, they are ready for harvest. You can eat them right off the tree out-of-hand. If you have a problem with moldy or wormy pods, it means there was too much rain during the pod-ripening time. To deal with the worms, you must pick up and somehow destroy every ground-scattered pod. Carob beans can be fed whole to any of your livestock and will delight them.

Making Carob Powder. You'll find carob pods sweet-tasting and chewy, resembling a date. They contain little black seeds. Commercially, the pods are roasted and then ground to create carob powder, a healthy chocolate substitute. But that kind of processing simply is not possible at the household level. If you want to try making a powder of them, first wash the pods, then pressure-cook 20 minutes at 15 lb. The purpose of the cooking is to soften those pods enough that you can split them open to get the seeds out fairly easily. After the seeds are removed, chop pods into pieces, and put them through a drying process. Once they are good and dry, grind into a powder in a blender or with a mortar and pestle. You'll be able to process only a little at a time. Use your powder in general as a chocolate substitute. For best flavor, dissolve carob powder in water or melted butter before mixing with other ingredients.

⇒ **CAROB SWEETENER** You can substitute carob powder for any sweetening. To make a sweet syrup, dissolve the powder in water and boil it down to a honey thickness.

⇒ **CAROB DRINK** Whisk together 2 T. carob powder, ½ c. water, 2 c. milk and sweetening to taste. Heat it up, but don't boil. Variations: vanilla extract, and/or dash nutmeg.

⇒ **UNCOOKED CAROB/COCONUT FUDGE** Combine 1 c. peanut butter, 1 c. carob powder, 2 c. grated coconut, 1 c. honey, and 1 t. vanilla. Roll into balls.

CHERIMOYA: *Annona cherimoya* is a small tree from the American tropics. Called "cherimoya" or "cherimoyer," it will grow in the south of California and Florida. The fruits are egg-shaped and can weigh more than a pound. The texture is smooth and the flavor is a combination of peach, pineapple, and banana. The tree grows quickly and fruits after only 2 years, but the flowers have to be hand-pollinated (use a paintbrush) in order to get fruit from the flowers. This fruit is delicious fresh and not preserved.

Varieties. The custard apple (*Annona reticulata*) is closely related to cherimoya. These trees are deciduous, frost-tender, and grow up to 20 feet tall. The fruit ripens in late winter. You can plant from seed. Custard apple makes good rootstocks from grafts of cherimoya, soursop, and sweetsop. Its fruit is terribly sweet, best when eaten chilled. Sugar apple is another related variety. They all need high humidity, well-drained soil, and neither too much cold nor too much heat.

CITRUS: All the citrus varieties are evergreens with dark green glossy leaves, and nice flowers. These trees grow easily in a back or front yard, so long as you're in a subtropical climate and have any well-drained soil. Southern California, the Gulf Coast, and from central Florida on south is good citrus country where groupings of citrus varieties make great shade trees around the house. For more information, read *Citrus—How to Select, Grow, and Enjoy* (Tucson, AZ: H. P. Books, 1980)—very thorough.

Calamondin. This tiny citrus fruit looks like a miniature orange. You can grow it in a bucket or a peat pot in a sunny room of your house, and enjoy the sweet scent of citrus blossoms. Take seeds out and puree it and add to cake batter for a delicious flavor.

Citron. There is a "citron" fruit that looks like a large lemon and grows on a small shrubby citrus tree (*Citrus medica*). The preserved rind is used to flavor cakes and puddings. (Don't confuse with the "citron" that is a small hard-fleshed watermelon variety that is made into pickles and preserves.)

Grapefruit. *Citrus paradisi* is the largest of the citrus family, both in tree size and in fruit size. A Red Flame grapefruit tree can live to be at least 40 years old! Grapefruit thrives in the home garden. It comes from the West Indies and is grown commercially in Florida, Texas, California, and Arizona. It is better able to endure cold than most other citrus varieties. Use basic citrus care. Pink Marsh and Ruby are pink-fleshed. Wait until the fruit falls off the tree to eat it; only then is it perfectly ripe, and so much sweeter than store grapefruit! Triumph is a good old-time variety.

Key Lime. These were at one time a secret of the English navy. They were salt fermented. (Two t. salt per 8 oz. and corked loosely because it'll pop its cap.) It was used as a sauce and prevented scurvy. The modern lime came from this plant. But the old-time key lime is still a favorite. It produces large amounts of fruit, several crops a year. It's useful in cooking. Any recipe that calls for lemon juice will be even tastier if you substitute key lime juice. There are both thornless and thorny key limes.

Kumquat. This Chinese evergreen tree is a close relative of the orange and has similar blossoms and care. The Meiwa kumquat (*Fortunella crassifolia*) gets 8–15 ft. tall. For a

cookbook with 100+ recipes for kumquats, send \$6.50 (postpaid) to Stephanie McGraw, 28403 Meadow Mesa Lane, Escondido, CA 92026. Kumquats are delicious stuffed with guava paste or with nuts and dates.

Lemon. Ah, the lore of lemon juice. To bleach linen or muslin, just moisten the cloth with lemon juice. Spread it out flat in direct summer sunshine. Use lemon juice full strength (or diluted equally with water) for a sore throat gargle. Use lemon juice to remove strong odors from the hands. To get out ink, rust, or fruit stains, rub with lemon juice, cover with salt, and set in the sun.

The lemon (*Citrus limonia*) is a small evergreen tree with a delightfully acid fruit that grows well in Florida and California, hardy only down to about 26°F. The trees are everbearing, seldom without either flowers or fruit. Seedlings can be planted, but grafting to the stock of the sour orange is the usual choice. The Lisbon is hardy, disease resistant, and vigorous. The Perrine is a hybrid that's resistant to citrus scab. The Meyer lemon is the hardiest variety, able to endure down to 10–15°F without being killed. It reaches 10–15 ft tall, and bears abundantly.

Orange. The common orange (*Citrus sinensis*) has many varieties. There are early, midseason, and late ripening varieties. The Seville orange (*C. aurantium*) is a sour orange, often used for root stock. Use the seed to make pectin. Use the fruit to make an old-time marmalade.

The Navel orange is a quick-growing, generously bearing tree. They begin bearing in November and end in January (in Florida, of course). Navel oranges are great eating but don't make good juice for canning or bottling. The Red Navel (Cara Cara) has bright red flesh. The Ortenique orange tree produces from December to May. The bergamot orange (*C. bergamia*) is related to the lemon. Valencia is a late-maturing type that requires high heat and ripens during the second summer after flowering. Some varieties of orange are riper and sweeter if the peeling is slightly green, because when ripe on the tree it "regreens," pulling chlorophyll back into itself from the tree.

Panama Orange. This small tree is hardier than most citrus and will grow in the deep South. The fruits are an inch in diameter and used like the orange.

Tangerine. These are also called the "mandarin orange." A favorite variety is the Ponkan (Chinese Honey Tangerine). They are large, easy to peel, very sweet, and tasty. They ripen earlier than most oranges, around the first of December. The Honey Murcott is a smaller, but more hardy tangerine, which fruits in January and February. Tangerine is a very beautiful citrus tree, with dark green, glossy leaves and richly colored fruit.

General Citrus Planting. Plant citrus in direct sunlight. Partial shade weakens them. Soils should be enriched with organic material and deeply cultivated before planting. They do best in sandy loam (pH 5.5 to 6.2). Citrus trees grow about 1 ft. per year in both height and spread of foliage. So use adequate space between trees: 25 × 25 ft. for most oranges, 25 × 30 ft. for grapefruit, 20 × 20 ft. for mandarins, and 15 × 15 ft. for lime or lemon trees. The lime grows 10–15 ft. high; lemon 10–20 ft.; orange 15–40 ft.; and grapefruit 30–50 ft.

Plant in March, April, or May as the plants do not grow when the weather is chilly. Citrus trees begin bearing at about age 6, and are long-lived. Avoid pruning citrus unnecessarily because leaf removal holds back tree growth and delays bearing. Trim only to remove dead wood and rootstock suckers. Keep the ground constantly moist for a few weeks after planting. After that give a citrus tree at least 20 gal. of water a month. Compost is good, but don't let mulch touch the tree trunk as disease may result.

Harvesting. Citrus fruits are harvested during winter. The biggest crisis for a grower of tender citrus is a cold snap. Citrus can often survive if warmed by a fire, whose warm air is propelled toward the plants by a fan. The trunks of young trees may be protected by heaping soil high enough to protect the bud union. Remove dirt when danger is over.

If citrus is left on the tree too long the tree reabsorbs its juice and the fruit shrivels. Some growers believe this is good for the tree and suggest that you always leave at least 10 percent of the crop unpicked. For those who buy their citrus: Smear a thin amount of Vaseline on the outside of citrus fruits, and they'll keep 9 months or so, even without refrigeration.

Citrus Juice. Tree-ripened citrus fruit (oranges, grapefruits, lemons, limes), if you can get it, makes the best juice. Don't heat citrus juice and don't strain it. Just halve your fruit and extract the juice on a juicer or what-have-you. Don't press the oil from the rind, and do remove the seeds. Don't sweeten the juice unless it is for lemonade and limeade. I've heard that navel oranges don't make good juice for canning or bottling but I don't know why. Cut away the navel ends before you juice them. If you want to strain the juice use something with big holes. To get the maximum juice from the fruit, quickly heat it in hot water for several minutes before squeezing or roll it to soften.

⇒ **JUICING ORANGES** You can figure that a dozen large oranges will give you 7 or 8 (8-oz.) glasses of juice. A dozen medium-sized ones would give you 6 or more glasses, and a dozen small ones would give you 4½–5 glasses. It's a good idea to work as rapidly as possible to preserve nutritive values.

⇒ **LIMES** These are more acidic than lemons. They can be substituted in almost any recipe calling for lemons, using two-thirds as much lime juice as lemon juice.

⇒ **CITRUS COMBO** Two-thirds grapefruit or orange juice combined with one-third other juice: it can be apricot, peach, nectarine juice or purees, or any other juice you want to experiment with.

⇒ **GRAPEFRUIT-GRAPE** Combine half grapefruit juice and half grape juice. Serve over ice cubes.

⇒ **ORANGEADE** Combine 2 T. sugar or other sweetener, 1 c. water, and the grated rind of 1 orange in a saucepan. Boil 5 minutes. Cool. Add 2 c. orange juice and 2 c. cold water. Serve chilled over ice.

⇒ **LEMONADE** For each serving mix 4 T. lemon juice, 2 T. sugar or other sweetener, and 1 glass ice water. For a batch, juice 5 lemons. Add 5 c. water and sweeten to taste. Serve with a slice of lemon in each glass.

⇒ **PINK LEMONADE** Add to a pint of lemonade prepared in the usual way, 1 c. or less of strawberry, red raspberry, currant, or cranberry juice. (A little cranberry juice goes a long way.)

⇒ **LIMEADE** For each glass use 3 T. lime juice, fill with water, and sweeten to taste. Serve a slice of the lime in each glass.

⇒ **ORANGE SYRUP** Strain the juice of 24 oranges and 6 lemons. For each pint of juice add 1¾ c. sugar. Boil the juice-sugar mixture, skim, strain and chill.

⇒ **IRENE'S LEMONADE SYRUP** Combine 2 c. sugar, 1 c. water, and 2 lemon peels cut into small pieces. Boil 5 minutes. Add the juice of 6 lemons. You can either strain the syrup or just leave the cooked peel in it. Keep it refrigerated.

⇒ **ORANGE FLOWER WATER** Combine 1 lb. orange flowers and 1 oz. grated orange peel (no white pulp) with 4 c. water. Let soak 24 hours. Concentrate to 2 cups. Or dissolve 1 oz. orange essence from an herbal supplier in 1 gal. distilled water.

⇒ **SIMPLE ORANGE MARMALADE** Cut 6 oranges into quarters and then cut each quarter into thin slices. Discard the seeds. Measure your resulting fruit and then add 3 c. water per cup fruit and let soak overnight. The next day simmer until the rind is tender. Then add 1 c. sugar for each cup of fruit. Cook until fruit is clear and the syrup sheets from a spoon (222°F). Pour into glasses and seal.

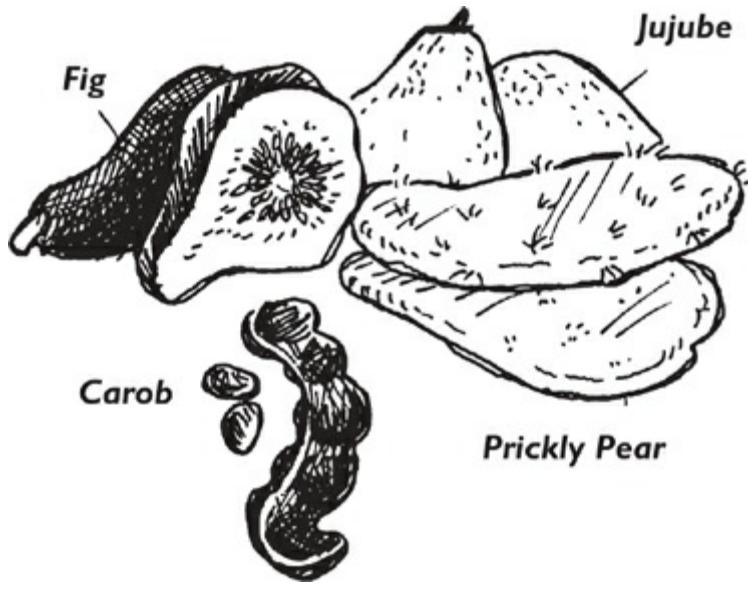

Rinds. If your rinds are unparaffined save a reasonable amount, grate, and store tightly covered in the refrigerator for appropriate dishes. It's called "zest." Don't include the white inner pulp!

COCONUT: See "Nut Trees."

DATES: The date palm is one of the oldest food-bearing trees to have been cultivated and also is one of the most useful. Dates grow on a palm with feathery foliage that light passes through easily, so beneath the branches of a 100-foot palm there is enough sun to support another layer of plants. Cultivating a date palm takes a lot of effort, but dates are so healthy and delicious that it's worth it. Date palms are very particular about where they will grow. They require a hot climate with little rainfall (as in Southern California or Arizona).

Figs: Commercial fig orchards are grown in Southern California and Texas. In the tropics the fig tree can get 40 feet tall. But individuals grow figs farther north. A woman in Seattle has one. Northern figs tend to be shorter, 25–30 feet tall. Southern-growing figs sometimes have pest and pestilence problems. Once established, fig trees are long-lived.

Varieties. Careful selection of figs is constantly extending their growing range north. They come in several varieties, most best suited for subtropical and tropical zones, but at least 1 type can be grown as far north as New Jersey or Michigan, and several do well in greenhouses or containers. The fig family is a large one, and the different types of fig can be extremely unlike. Not all are even edible. Pollination is totally different and sometimes very complex and difficult, depending on the variety. Some figs are self-fertile, some are not. Plants are available from Burnt Ridge. The California Fig Advisory Board offers lots more info: PO Box 709, Fresno, CA 93712; 559-440-5400; fax 559-438-5405; www.californiafigs.com.

Common Fig. These varieties bear both male and female flowers, so can mature fruit without a second plant.

Caprifigs. These are inedible “wild” figs, but they have both sexes of flowers and thus are pollinators for edible figs, and provide a home for fig wasps.

Smyrna Figs. These types bear only females. To grow Smyrnas you also have to grow the fig wasp (which actually develops inside the caprifig!), their only possible pollinating agent, which means, of course, that you must grow the caprifig; otherwise the Smyrnas won’t get pollinated and their fruits won’t mature. Smyrnas figs are large and delicious, and they dry well (they’re familiar commercial dried figs).

Others. Dwarf figs are sold in tubs from nurseries. This is one of the best varieties for container planting. Kadota figs are the best to can. Mission and Kassaba figs dry well. Turkey figs are good eaten fresh off the tree.

Planting. Don’t start from seed; you may get a plant, but you’re taking a chance on its fruiting capacity. Propagate by buddings, cuttings, grafting, or layering.

Planting from a Cutting. Cut off a 10–24-inch length of previous season’s growth. Don’t cut it off until the fig is thoroughly dormant, its leaves all dropped. Bury the cutting in sand and store it in a cool place for the winter. In the spring, plant the cutting half underground and half above, in well-drained soil of any type in the place you intend for its permanent home, since transplanting is risky. Plant it where it can get plenty of sun, since less light results in less fruit.

Planting in a Container. Start your cutting in a 4-inch pot. When the roots have filled that size, move the plant to a 6-inch one. But if you started your fig in the garden in the spring, but want to shift it to a container in the fall for safety, it will need a still larger pot or a small “tub.” A wonderful thing about figs in pots is that when winter comes you can simply take them inside and store them until spring. They’ll be fine in a cellar, or a basement. To winter a fig that is growing in the ground in a marginal area or to get it through a cold snap, you can wrap and/or bury it; bend the branches over and heap dirt over them and the trunk. Your bundled/buried fig can survive the cold fine that way, too.

Growing. Fig roots grow unusually close to the surface, and mulch helps keep them moist. Avoid soil cultivation around fig trees. Don’t fertilize excessively. Figs in too rich a soil tend to grow branches rather than fruit. Be careful of the bark while you’re picking fruit or

doing anything else to a fig, as it's fragile and easily damaged. Don't prune it unless the leaves have dropped and the tree is fully dormant, since otherwise figs tend to bleed severely. Brown and white figs bear fruit only on new wood, so every year each branch needs to be pruned back extensively for best fruit production. This is not true of black figs.

Harvesting. Figs grown from cuttings sometimes bear fruit as soon as the second year. They don't blossom. The fruit just appears along the branches; that's because the fruit actually is an enlarged stem end that contains the flowers. Temperate-zone fig trees bear 2 crops, usually the first in June and the second in August. The second crop is usually larger. Farther south, you can pick figs longer, usually from June to November. Leave figs on the tree until they're thoroughly ripe because they won't ripen any more once picked. While picking, wear gloves to protect your hands because the fig tree's white sap will irritate them. When picking the fresh fruit, handle it with care; the skin is delicate and any tiny tear in the fruit's skin is likely to result in its spoiling. Depending on the variety and which crop, ripe figs may be yellow, brown, purple, black, or anything in between. If you are planning on drying the figs and your weather is suitable, leave them unpicked to dry on the tree until they naturally drop off. The important thing to keep in mind when harvesting figs is that they don't keep well fresh and need to be preserved somehow as soon as possible.

Preserving. You can candy, pickle, or spice figs, make them into jam, freeze, can, or dry them. Substitute dried small fig pieces for raisins in any recipe.

Drying. Gather tree-dried figs that have dropped and continue their drying process in the sun. Stir them once in a while, covering them with cheesecloth if insects are a problem, and take them into the house at night. Or, for indoor drying, gather figs that are a few days short of dead ripe, and cut off the stem and blossom ends. Steam them for 20 minutes or dip them into boiling water for just 30 seconds. Drain and dry. For quickest drying, poke holes in each fig using a fork, or even cut them in half—or chop them into small pieces. In a dehydrator or oven, dry at 120°F, 36–48 hours for whole figs, 12 hours for pieces. To store dried figs, brush outside lightly with honey. Pack in plastic and keep in refrigerator or freeze.

Freezing. Black Mission and Kadota figs freeze well. Wash them in ice water, take off the stems, and peel. Pack unsweetened, simply stacked in your container or with water poured over. (Add $\frac{3}{4}$ t. ascorbic acid per 1 qt. water.) Or pack covered with a light syrup with ascorbic acid added. Leave head space. Or put fully ripe figs into food-grade plastic bags and freeze. After thawing they must be used immediately.

Canning. Black Mission, Celeste, Kadota, and Brown Turkey figs all can well. Select firm, ripe, uncracked figs. *Do not can overripe fruit with very soft flesh. Figs have very low acid anyway.* Wash thoroughly. Drain. Do not peel or remove stems. Hot pack only. Cover figs with water or syrup and bring to a boil. Let rest a few minutes. Pack into jars hot. Add 2 T. bottled lemon juice per quart, or 1 T. per pint to the jars. Cover as needed with more hot water or syrup. Leave $\frac{1}{4}$ -inch head space. Adjust the lid. Fill jars with hot figs and cooking syrup. Process in boiling water bath: At altitudes to 1,000 feet, process pints 45 minutes, quarts 50 minutes; at 1,001–3,000 feet, process pints 50 minutes, quarts 55 minutes; at 3,001–6,000 feet, process pints 55 minutes, quarts 60 minutes; above 6,000 feet, process pints 60 minutes, quarts 65 minutes.

➲ **BAKED FRESH FIGS** Wash about 2 dozen large figs and cut off both ends. Set them in a glass baking pan and pour a nice fruit juice over the top—apple is best. While they are baking

(in a moderate oven) stir the juice every once in a while to moisten the figs and roll them over occasionally Cook them at least 40 minutes. Good with whipped cream.

⇒ **SPECIAL FIGS** Put in the oven as for baked figs (350°F) with the contents of a 16-ounce can apple juice concentrate. After 40 minutes, turn the heat down to 150°F and dry them for 30 minutes more. They come out “candied.”

For more info contact the California Fig Advisory Board, PO Box 709, Fresno, CA 93712; 559-440-5400; fax 559-438-5405; www.californiafigs.com/. Or Valley Fig Growers, www.valleyfig.com/. Or read *Organic Gardening*, “Discover Figs for Your World,” Sept./Oct. 1991, pp. 30–34. Or *National Gardening Magazine*, July/Aug. 1996, pp. 35–40, “Fabulous Figs.”

GUAVA: This tropical American native, *Psidium guajava*, a.k.a. the “Florida peach,” is an evergreen shrub or small multi-stemmed tree (about 20 feet high) that is now grown in subtropical and tropical areas all over the world. To grow guava you need a frost-free zone and warm weather. The fruit has a strong smell that some people don’t like. Guavas easily freeze out, but then resprout from the old roots and will be fruiting again in a few years. These trees handle soils that are unusually acid or alkaline but need lots of fertilizer.

Varieties. The common guava belongs to the Myrtle family. For eating out-of-hand, people prefer the uncommon guavas such as the “white” guavas, popular in California and Florida. And there are others:

Strawberry Guava. This close relative, *P. cattleianum*, a.k.a. “Cattley guava,” has round, purplish-red, 1-inch-long fruit. It actually does taste like a strawberry. This one is a little hardier than the common guava and, once fully grown, can survive down to 22°F for a bit.

Pineapple Guava. *Feijoa sellowiana* is another close relative with similar characteristics—hardy to 15–20°F—but it prefers a cool summer and won’t set fruit in a desert, or in the deep south of Florida. It does tolerate some salt in the soil, is disease-resistant, and thrives wild in Hawaii. Pineapple guava is exceptionally good eaten raw. Let it get entirely ripe though; the flavor improves much with the final ripening. The basic rule is that they aren’t completely ripe until they actually fall off the tree. To serve, cut in half and spoon the fruit flesh out of the skin like you do a cantaloupe. Good in any fruit mixture.

Planting and Growing. Modern orchard guava trees are the result of extensive selection for commercial quality. Make sure you start with a type bred for good fruiting rather than ornamental talents. Don’t plant from seed; they will grow but you could end up with anything. (If you must plant seeds, plant straight from the fruit into your planting site; germination will be in a few weeks.) Plant just before your rainiest season. Most varieties are self-pollinating, but a few are not. Find out when you buy. Guavas do best in deep sandy loam and need good drainage. You can propagate by layering, root cuttings, or grafting. Full sun or partial shade is okay. Pinch to thin. Guavas start to fruit as soon as 2 years after planting. Starting then, fertilize with organic manure or compost 4 or 5 times a year, as long as fruiting continues, and it may do so year around. Weeding is best done by mulching. Winter pruning of old branches will stimulate fruiting. If you have a dry season, you’ll have to irrigate then.

Harvesting and Using. Guava fruits are a true berry, and the tree bears a lot of them. The shape of the fruit varies with variety from round to pear-like; size varies from walnut-

to apple-size. Harvest season is about a month and a half in the summer. Unripe guavas are literally green. As they ripen they turn yellow, perhaps with some red. Inside the thick outer skin, the pulp contains many seeds. Fresh guava has a musky quality, but improves greatly when cooked. Guava fruit can be eaten fresh—they’re rich in minerals and vitamins, especially C, but they are more often used to make jelly (guavas are high in pectin) or conserve.

Freezing. Peel the fruit, cut off the portion between the peel and the seeds. Freeze that.

JUJUBES: The jujube is an Asian fruit tree with weeping-willow-type drooping branches. They are thorny, beautiful plants with shiny deep-green leaves.

Climate. Jujubes are very hardy trees that will survive in almost any climate (zones 6 to 10), but they require long hot summers to bear fruit and cannot do without full sun. They also like dryness.

Varieties. There are both shrub-like and tree varieties—15–30 feet tall—and both evergreen and deciduous varieties. But the Lang and Li varieties are the only 2 kinds of jujubes generally available in the United States, though the Mu Shing Hong and Sui Mon can sometimes be found, too. These are all Chinese jujubes, deciduous trees with clumps of thorns. There are also, if you look hard enough, Indian or Malay jujubes (*Ziziphus mauritania*). They are evergreen trees with broad thorns along the undersides of their branches; they are hardier plants with a smaller fruit than the Chinese jujubes. They need cross-pollination, so plant 2 different varieties. Jujube starters can be difficult to find, but Pacific Tree Farms lists both Chinese and Indian/Malay varieties in its catalog.

Planting. These can be planted from seeds or propagated by grafting. Jujubes do best in high-quality, well-drained soil, but will make do with almost anything. They don’t require fertilizing or special care, and are resistant to most diseases, although in very wet climates they may catch funguses. They have suckers that can break through pavement, though. To discourage those powerful wandering roots, water the plants infrequently and deeply.

Harvesting. The fruit is harvested in the fall. Jujubes are shaped like huge roundish olives, reddish-brown in color, and crisp to bite into and mild when just coming ripe, but softer and much sweeter when dead ripe.

Drying. Jujubes can be eaten fresh, dried, or candied. For drying, harvest very ripe, riper than you would usually eat them fresh. Dried jujubes resemble dates in taste.

Loquats: This fruit, also known as “Japanese medlar,” *Eriobotrya japonica*, grows on an evergreen tree. Some people like the taste, some don’t. They do well on a beach and near the ocean, full sun to some shade. “Champagne” has a big fruit with the best flavor. The leaves are large. Loquat is an evergreen of the rose family! The fruit is juicy with an acid-sweet flavor and yellow flesh, and it contains a few dark seeds—sort of like eating super-sized rose hips.

Climate. Loquats come from southeastern China and are grown in quantity in Japan and Taiwan. There are loquat orchards in California and some grown also in Florida. They’re semi-hardy, okay down to 15–20°F, but the fruit crop is ruined by a freeze so they do best in California or the Gulf states. Loquats are harmed if the temperature falls below 32°F. Loquats grow 15–25 feet tall where it’s warm and wet, 20–40 feet under the best conditions, shorter than 15 under least favorable conditions. They can handle drought once well-started, but you won’t get much of a fruit crop unless you water.

Planting. Make sure you get a grafted, named variety, not an ornamental whose fruits would not be as good. But most nurseries just have seedlings rather than the grafteds. You need only one; they're self-pollinating. Plant them where the drainage is good because they can't handle wet feet. They do best in gravelly loam or clay on slopes. If you prune, a modified vase form or hollow round headed form is traditional. This tree can get fire blight. Organic manures are considered essential for a good crop in the Orient, applied at a very young stage of the fruit and again after harvesting. Flowers and fruits are both thinned. You can do your own propagation by aerial layering.

Harvesting. Loquat flowers appear in September and October. The fruit ripens from January to April of the following year, depending on your variety. The variety called "Early Red" is ready to eat in January. "Advance" ripens March to May. (Loquats are the earliest fruiting fruit in their areas.) The fruits are small, loosely clustered, and yellow. They have top flavor when fully ripe but make better jelly and preserves when somewhat on the green side. They're ripe when fully colored and somewhat soft.

➲ **CANNED LOQUATS** Remove stem and blossom ends Cut fruit in half and take out seeds. Cook about 5 minutes in water or syrup. Pack hot. Cover with the hot liquid you cooked them in. Leave $\frac{1}{4}$ -inch head space. Put on lids. Process pints 15 minutes, quarts 20 minutes in a boiling water bath.

➲ **LOQUAT JELLY** Remove blossom ends from about 10 lb. loquat fruit and cut fruit in half. Add 2 c. water and 1 c. lemon juice. Simmer until tender. Strain and measure juice. Add $\frac{1}{2}$ c. more lemon juice. Boil juice 5 minutes, then add 5 c. sugar. Cook until jelly test works, or add 1 package powdered pectin. Then pour into jars, adjust lids, and process in a water bath for 5 minutes.

➲ **TROPICAL FRUIT CUP** Mix $\frac{1}{2}$ c. sugar and 1 c. water, boil 5 minutes, chill, and add $\frac{1}{4}$ c. lemon juice. Gently mix 3 peeled, sliced kiwi fruits; 3 peeled, sectioned sweet citrus fruits; and 3 c. fresh, sliced loquats (or 1 c. canned). Pour syrup over fruit Chill and serve. Fancy: Add some sliced ginger root to syrup before boiling. Remove the ginger before adding fruit.

LYCHEE NUTS: The following was written by my son Jacob at age 16: "My mother spent a year and a half in Taiwan (although it seemed like forever), and according to her, lychee nuts were one of the best features of her stay. However, my friend Ross described them as being 'Disgusting. Like a grape, except really gross,' so it would be best to be sure that you like the fruit before you commit yourself to growing it. Lychee nuts can be found canned or dried in Chinese specialty stores and in many supermarkets. The trees are tall, beautiful, rounded evergreens and are practically free from care. They originate in southern China, and the fruit is shaped like an eyeball with a pebbled, paper-thin shell and a grapelike flavor. To preserve, dry or make into preserves."

Growing. The lychee nut will grow only in areas with cool, dry winters and cannot withstand extremes of temperature. In the United States it's grown in Southern California and Florida. It will grow easily in loamy, fertile soil, especially if it is given compost or manure in early spring. It has almost no problems with insects or diseases, though you may wish to spray it with Malathion if it becomes infested with aphids.

Planting. The lychee nut can be planted from seed, air layer, cuttings in sand, or grafting. Air layers work best because the plants reach maturity much more quickly. Transplanting is best done in winter, though you can get away with it in any season.

Varieties. There are a number of Taiwanese varieties, the most popular of them being

“Black-Leaf.” None of them vary widely from each other. But you may wish to consider the Longan, which is a close relative of the lychee nut. Its skin is yellowish-brown rather than red, and it is a hardier, shorter (35 meters) tree—those are the only real differences.

MANGO: Mango trees are ancient residents of Southeast Asia with more than 30 varieties. The common mango (*Mangifera indica*) is grown in the tropics, worldwide. This attractive, large (90 ft. tall) tree, round-topped, grows leaves 8–14 inches long. It’s useful for ornament and shade as well as fruit. It can’t survive much frost. Mangos grow in southern Florida and California. They can endure poor, sandy soil. They produce better with richer soil, but too much nitrogen causes more vegetative growth and less fruit. Plant large varieties 30 ft. apart. They begin to bear fruit 5 to 7 years after planting and are long lived. Mangos are often planted from seed. Seed from Philippine varieties breeds true, but shield budding and crown grafting are also used to propagate.

Fruits begin to mature in May; some varieties continue harvest into mid-fall. The mango fruit is large, yellow-orange, and oval, fleshy and juicy, rich in sucrose and vitamins A and C. It has one big central seed. It works well to gnaw the delicious fruit off that seed rather than try to cut it off.

MESQUITE: This multiple-trunked desert native, *Prosopis juliflora*, is a nitrogen-fixing legume, a distant relative of carob, and is amazingly well-adapted to desert survival. The long, sugar-rich bean pods provide a food both humans and animals can eat. Stock also enjoys munching on young mesquite. Mesquite roots go amazingly deep and far and are a good source of wood in the desert.

➲ **MESQUITE (OR CAROB) BEAN DRINK** Soak the seeds in water for several hours to get a sweet lemon-flavored drink. Or grind the seeds and mix that powder with water to get your beverage.

OLIVES: The mango and *Olea europaea*, the olive, are the most long-lived of domesticated fruit trees. They both can live to 600 years! Despite its age, an olive grows only 15–35 feet high. It’s an evergreen with pretty silvery leaves and abundant, fragrant flowers in May and June.

Climate. Olives will grow in the interior valleys of California, southern Arizona, New Mexico, and Texas.

THE OLIVE CLIMATE

1. Zones 9–10. (See the planting zone map in [Chapter 2](#).)
2. No spring or summer temperatures of 28°F or lower. Those damage blossoms and fruit.
3. Preferably no temperatures below 15°F; those damage the tree itself. At 10°F or below the tree will die.
4. Altitude not above 2,000 feet. Olives won’t grow at higher elevations.
5. Winter is cool enough that there are at least 2 months of chilling when temperatures average 50°F.

6. Pollination doesn't go well in high humidity.
7. A long summer with high heat is needed for fruit to mature.
8. The tree can handle drought (8–10 inches water per year), but will fruit better with deep watering once during blooming and once again in early fruiting. Its long taproot is made to pull up water from the water table. Too much rain and humidity above ground makes it more disease-prone.

Planting and Growing. Olives need good drainage and fairly fertile soil (not very alkaline!), and *full sun*. Give the tree about 30 square feet of its own. The fruit drop is messy so the trees are best situated over a lawn or other ground cover or mulched ground rather than a patio, walkway, or driveway. These are the kinds in order of size of fruit, smallest to biggest: Sevillano, Manzanillo, and Mission. *Buy a fruiting, rather than ornamental, variety. Ornamentals do fruit some, but not nearly as much.*

Most, but not all, olives are self-fertile, but cross-pollination gives you more fruit. They tend to bear every other year, so plant more than one. Plant bare-root nursery trees in winter months only. This tree has a long taproot. Coat or paint trunks of your newly planted olive to protect it against sunburn. Keep strawberries away from your trees since they may carry verticillium wilt, a risk for olives. Don't fertilize until fruiting starts, and if then not much.

Olives will grow from ripe (black olive) seeds if you chill the seeds first (3 weeks in the ice-cube tray freezer), but seedlings are genetically unpredictable. So plant from cuttings: just cut off and stick in the ground. Or graft cuttings onto seedling roots.

Olives naturally drop their leaves every 2 or 3 years, in the spring.

Harvesting. The tree takes 4 years to bear. The fruit develops on new wood from the previous year's growth. Thinning gives you larger fruit. Olives are easy to grow but the harvesting and curing is work. *Don't harvest olives from public ornamental plants unless you're sure pesticides and herbicides haven't been applied.* Olives are first light green, a pale straw color, or rosy red. When fully ripe they're black. Pick green for a "green-ripe" curing. Pick reddish-black for a Greek cure. Pick fruit for curing off the trees gently so it isn't bruised or skinned. You can hold the olives for curing in a salt brine ($\frac{3}{4}$ c. salt per 1 gal. water) in a cool place for just a few days. But if you haven't started curing by then, they'll be too soft. To harvest olives for oil pressing you can leave them on the tree as long as desired, and hit the branches to bring them down onto tarps or plastic you've spread under the tree.

Curing Olives. You can't eat olives straight off the tree. When fresh they're loaded with tannin and, so, very bitter. They have to be "cured" before eating. Lye neutralizes the acid as part of one curing process, but that lye is even more of a risk to you than uncured olives so be very careful when using it.

Green-Ripe Cured Olives. These instructions are from the University of California, Agricultural Sciences Department.

This process will produce straw-yellow to green or brown olives. Choose fruit that is green, straw-colored, or cherry-red. Do not use black-ripe fruit because it is likely to become soft when pickled. *Start early in the morning. This is going to be a 12-hour work day.*

1. Prepare a solution of 2 oz. (about 4 T.) of lye to each gallon of water. (An easy way

to do this is to dissolve a 12-oz. can of flake lye—household lye—in 6 gal. water.) Use a wooden, glass, heavy plastic, or stoneware container. Never use an aluminum container because the zinc will dissolve and may make the olives poisonous. Stir the solution until the lye is well-dissolved. Then let the solution cool to a maximum of 65–70°F.

2. Cover the olives with the lye solution early in the morning. Place a towel or cloth over them and push it down tightly to keep the olives submerged. Stir the olives with a lath or a wooden or stainless steel spoon every 2 or 3 hours until the lye reaches the pits. This usually takes 10–12 hours. You can judge the amount of penetration by cutting sample olives to the pit with a sharp knife at intervals of 1 or 2 hours. The lye solution discolors the flesh to a yellowish-green color. Test the biggest ones. The olive's inside will be a yellowish-green color where the lye has penetrated, but it's hard to see the line of separation between that which has been penetrated and that which has not. Keep an uncured olive handy to compare colors. How long it takes the lye to reach the pit depends in part on the weather and the temperature. It can be from 8 to 48 hours.

If the lye has not reached the pits by bedtime, remove the lye solution and cover the olives with water. The reason for such caution is that if the lye gets into the olive pits, it's next to impossible to get it out again. Next morning, pour off the water and cover the olives with a solution of 1 oz. (about 2 level T.) of lye per 1 gal. water and let stand until the lye reaches the pits completely. This may take as long as 30 hours if the fruit is quite green.

Frequently, this lye treatment is insufficient. Some olives neutralize most of the lye so that it fails to penetrate to the pits. In such cases, prepare a fresh solution of 1½ oz. (3 level T.) of lye per 1 gal. water and allow it to cool. Then discard the used solution and pour in the fresh. Let the olives stand until the solution reaches the pits, then follow the procedure in steps 3 to 5.

3. Pour the lye solution off the olives and throw it away. After the lye stage, you have a long rinsing stage. Then comes the brining period. And then you eat or can them.
4. Rinse the olives twice in cold water, then cover them with cold water. Change the water 4 times each day until you can no longer taste the lye in the olives. This may take as long as 7 or 8 days. (For commercial packers, it takes about 4 days.) *Expose the olives to the air as little as possible during the lye treatment or this rinsing.*
5. Prepare a salt brine containing 4 oz. (about 6½ level T.) of salt per gallon of water. (If the solution seems too salty, reduce the amount of salt to 3½ oz.) Dissolve the salt thoroughly, and cover the olives with the solution. Let stand for 2 days.
The olives are now ready to use. Store them in a cold place, preferably in a refrigerator. They are susceptible to spoilage. Refrigerate and use within a short period of time (2 weeks). Or you can make them last longer by brining.
6. If you do not plan to use the olives within 2 weeks, prepare a brine using 8 oz. (about 13 level T. or slightly more than ¾ c.) of salt per gallon of water. Store the olives in this brine for 1 week. Then replace the brine with a solution of 1 lb. (26 level T. or about 1⅔ c.) salt per gallon of water. After 10–12 days, put the olives in a fresh brine of 1 lb. of salt per gallon of water. In this strong brine, it may be 2 months before your olives begin to deteriorate.

ANTIDOTES FOR LYÉ BURNS

Be extremely careful when working with lye. If lye comes in contact with human skin, it causes a chemical burn. Flush immediately with water. If it is not flushed, it will continue to burn. If possible, add a little salt to the water. If water is not available, use soda water or soda pop—they're better than nothing. If after 5 to 10 minutes your skin is still red and painful, seek burn care in a hospital emergency room.

If lye is swallowed, call 911. Swallowing lye can be fatal. When swallowed, it burns the esophagus, so vomiting (which may be inevitable) should be avoided. Take milk or ice cream to help neutralize the lye's chemical reaction. Although vinegar, orange juice, and so forth also neutralize lye, they should *not* be ingested because the combination creates heat. This rise in temperature will burn physically in addition to the chemical burn.

If lye gets into the eye, call 911. Flush the eye immediately with water; add salt to the water if possible. Again, use milk if available, to neutralize the chemical reaction. Most likely you should get to an emergency room as soon as possible. Do *not* use vinegar or boric acid solution.

But the best advice is: Be Careful!

Freshening from Holding Solution. Remove olives from holding solution and soak them overnight in fresh, non-salted water. By then they should be nice. They won't keep now. Use them up within 3 days. *If at any time your olives seem mushy, moldy, or bad smelling, don't even taste them. Throw them out.*

Canning Olives? Since green olives will keep for months simply refrigerated, it makes sense not to can them. Olives are quite low in acid. A food specialist told me that in California the 2 most common sources of botulism poisoning are home-canned taco sauce and home-canned olives.

Anonymous Olives. This letter wasn't signed. "Home-cured olives are such a treat. They are easily done, but you have to follow instructions closely or you will fail. First have everything you're going to use ready and clean. The olives should be freshly picked and I always make the green ones. I worked in an olive curing plant and the black ones are more difficult to get just right. The olives should be graded so all are the same size so as to cure at the same rate. Throw away all bruised or cut ones. This recipe is to cure 40 or 50 lb. of olives. A wooden keg is best but you can use a crock jar. Only you need a drain hole at the bottom and you do not naturally have that in a crock. I used to use an old wooden washing machine. Dissolve 1 can of lye in 5 gal. cold water. (Soft water works better. Do not use fluoridated water.) Stir with a long wooden stick so the lye fumes don't burn your hands. Now gently pour olives into lye solution. Water will cover olives. Stir gently every few hours to get them all well soaked in the solution. Keep them in there until the lye almost reaches the pit. The water turns lighter. You can cut one in half and see if it is still bitter. You can taste it but do not let it stay in your mouth. Spit it out and rinse your mouth. When the lye has almost reached the pit, drain and cover with fresh water. Change the water every 12 hours for 2 days and be careful not to bruise any of the olives. If you

see slick or cut ones take them out.

"Now place your olives in a second lye solution using 1 lb. lye to 6 gal. water. Always use cold water. Allow olives to remain in this solution for 4 to 5 hours, or until the lye reaches the pit. You will know when you cut them open."

"Drain off the lye and cover with cold water. Change water every 12 hours for a week. Then cover with brine. To make the first brine, use 2 T. salt per 1 gal. water and let stand 1 day. For a second brine, use 2 T. salt to 4 gal. cold water. Allow to stand 1 day. For your third brine, use 2 T. salt to 6 gal. water and allow to stand 2 days. For your fourth brine, use 2 T. salt to 8 gal. water and allow to stand 3 days. Now make a final brine using 10 T. salt to 10 gal. water. Bring this to a rolling boil. Skim scum, let cool, and cover the olives. Have the last brine ready to go over the olives right after you drain them of the next to last brine."

Keep these olives in a holding solution, same as step 6 in the method above.

Process for Dark-Ripe Olives. This process is more complex than the one for green-ripe olives. The purpose of it is to make the olives dark-brown or black. Start with green, straw-colored, or cherry-red olives. It is best to use fruit that is all the same color (the same degree of ripeness) and nearly the same size.

1. First Lye Treatment: Prepare a solution containing $1\frac{1}{2}$ oz. (about 3 level T.) lye per gallon of water. (Follow above directions for preparing the lye.) Pour the solution over the olives and let stand until it penetrates the skins. (Start checking the olives after 3 hours, and then check them every 30 minutes.) Remove the lye solution and expose the olives to the air in the container in which they were treated. This helps give the olives their dark color. Stir the olives 3 times during the first day they are exposed to the air.
2. Second Lye Treatment: Prepare a lye solution of the same strength as for the first lye treatment. Pour this over the olives and let stand until the solution penetrates $\frac{1}{32}$ - $\frac{1}{16}$ -inch into the flesh. Remove the lye and expose the olives to the air for 1 day, stirring as before.
3. Third Lye Treatment: Use a lye solution that is the same strength as the first lye treatment. Pour it over the olives and let stand until it penetrates $\frac{1}{8}$ - $\frac{3}{16}$ -inch into

the flesh. Pour off the solution and expose the olives to the air for 1 day, stirring as before.

4. Fourth Lye Treatment: Make a solution of the same strength as for the first lye treatment. Pour it over the olives and let it stand until it penetrates $\frac{3}{16}$ – $\frac{5}{16}$ -inch into the flesh. Pour off the solution and expose the olives to the air for 1 day, stirring as before.
5. Fifth Lye Treatment: Make a lye solution using 2 oz. (about 4 level T.) of lye to 1 gal. water. Pour this over the olives and let stand until it penetrates thoroughly to the pits. Pour off the solution and expose the olives to the air for 1 day, stirring as before.
6. Rinsing: Cover the olives with cold water. Change the water 4 times daily until the olives no longer taste of lye (up to 7 or 8 days).
7. Holding Solution: Cover the olives with a holding solution and store as described for green-ripe olives.

Freezing Ripe Mission Olives. You can preserve pickled ripe Mission olives by freezing, but other olive varieties soften badly when frozen and thawed. You can freeze Mission olives processed either by the green-ripe or dark-ripe method. Cover them with a brine made with 4 oz. (about $6\frac{1}{2}$ T.) of salt per gallon of water. Boil for 10–15 minutes. This will lessen the softening from freezing. Discard the brine and chill the olives in cold water.

Pack the olives without brine in rigid cartons, glass jars, cans, or used coffee cans. The package should be moisture-vapor resistant to prevent drying out. Seal coffee cans with freezer tape. Tightly seal other types of containers in the usual manner. Quick-freeze the packaged olives and store in the freezer.

Before serving, let the olives thaw thoroughly. If desired, roll the thawed olives in olive or salad oil mixed with chopped garlic or other seasoning and let stand overnight.

Drying Ripe-Processed Olives. You can dry processed green-ripe or black-ripe olives in a home dehydrator or in the sun until bone dry. If you use a dehydrator, dry at 145–150°F. The dried olives will keep well in airtight food-grade plastic bags, glass jars, or metal containers. However, they keep best when refrigerated or stored in a home freezer. You can eat the olives out-of-hand without soaking, or use them in cooking. Do not prepare more olives by this method than you can use within 3–4 months because they'll become very rancid during storage.

Brined Greek-Style Olives. Always use mature, full-colored (dark-red to purplish-black) fruit to prepare this style of olive. You can use any variety, but be sure the fruit is firm and harvested before frost. It is most common to use the Manzanilla and Mission varieties. The cured olives may be more or less shriveled because of the high salt brine used to preserve them. Some of the olives may fade in color during curing. In general, they tend to darken again when exposed to air.

How to Prepare Greek-Style Olives

1. Sort out defective fruits.
2. Place good olives in a container that can be made airtight. A 1-qt. glass jar is the smallest size recommended.
3. Cover the olives with a brine containing 8 oz. of salt per gallon of water (see step 6 under Spanish-Style Green Olives, below). Fasten the lids loosely. Store the olives at 60–80°F.

4. At the end of 1 week, replace the original brine with one containing 1 lb. of salt per gallon of water, again leaving the covers loose.
5. After 15 days, replace the brine with one containing the same concentration—1 lb. of salt—and seat the covers firmly.
6. If pressure forms, carefully loosen the cover to release the gas. Then close it firmly.
7. If brine spews out, replace it with more containing 1 lb. salt per 1 gal. water.
8. If you prefer less bitter olives, you can replace the brine at 1 month intervals for 2 or 3 months after step 4.
9. If you keep the olives airtight in brine, you can store them for at least 1 year, if the container cover does not corrode. There is no danger of spoilage or possible toxicity because of the high salt concentration of the brine.
10. You can eat the olives within 2 months after preparation if you like fairly bitter olives. In any event, after 2 months in the strong brine, you can use them for cooking in tamale pies and similar dishes. It is desirable to soak the olives in water overnight to reduce the saltiness before eating them out-of-hand.

Store any desalted, uneaten olives made by this method in the refrigerator, in a solution containing 1 part red wine and 1 part red wine vinegar, with a layer of olive oil floating on the surface. Before serving, since the olive oil may congeal in the refrigerator, allow the olives to sit at room temperature until the oil has melted.

Black Olives. The black olive procedure takes longer. The big difference is that the olives have to be exposed to the air as part of the process.

1. Mix 3 level T. lye per gallon of water and soak your olives in it until it merely penetrates the skins. As little as 3 hours may do it. Check often so you don't have an overdose.
2. When the lye has just penetrated the skin and not the flesh, pour off the lye solution and let the olives lay out in the air for a day. Stir them every few hours.
3. Now give your olives another lye bath until the lye has soaked in another $\frac{1}{36}$ – $\frac{1}{16}$ of an inch. Then pour off the lye water and let the olives lie in the air again, stirring every few hours.
4. Again lye bathe them until the lye has gone in $\frac{1}{8}$ – $\frac{3}{16}$ inch. (No wonder everybody thinks this procedure is too hard!)
5. Now give them a new solution of 4 level T. lye per gallon water. Leave them in there until it soaks to the pits. Pour off the solution and give the olives another day of fresh air.
6. Now cover them with fresh water, changing every few hours all day long until the lye taste is gone. Freshening will take about a week.
7. Now give them the brining treatment and can them like green olives.

Oil-Cured Greek-Style Olives. Make Greek-style olives from mature olives that are dark-red to black. Mission olives are commonly used, but any variety will do. Use smaller olives because larger ones get soft. The olives will become shriveled since they are salt-cured. These olives are salty and slightly bitter, and you may have to acquire a taste for them.

1. Cover the bottom of a wooden box with burlap. Weigh out 1 lb. salt for each 2 lb. olives. Mix the salt and olives well in the box to prevent mold from developing. Pour a layer of salt over the olives to a depth of 1 inch. *Place the box outdoors so the brine that forms won't ruin the floor.*
2. After 1 week, pour olives and salt into another box, then back into the first box to mix them. Repeat this mixing process once every 3 days until the olives are cured and edible. This usually takes about 30–35 days. Stir things up as gently as possible. Remove any olives that have gotten soft or broken.
3. Sift out most of the salt through a screen. Dip olives in a colander into boiling water for a few seconds, drain, and let dry overnight.
4. For storage, add 1 lb. salt to each 10 lb. olives. Mix olives and salt and put the olives in a cool place. Use within 1 month, or store in a refrigerator (they'll keep up to 6 months) or home freezer (they'll keep up to a year) until used.

Just before using, coat the olives with olive oil by dipping into olive oil. Or put them in a large pan or box and sprinkle a little olive oil over them. Work the olives with your hands to coat them with oil. But don't oil if you plan to use the olives for cooking. Don't worry because they look all shriveled up and wrinkled. That's how Greek olives always look! This type of olive is useful for flavoring stews, tamale pie, spaghetti, and as a relish eaten out-of-hand.

Using Olives. Use olives to decorate main dishes or eat as finger food. Add to pasta sauce, chopped, to salads, or any meat soup, or baked meat, or omelet mix.

⇒ **STUFFED OLIVES** Remove the seed. In its place put a strip of pickled pimiento, a nut, or some other tasty morsel.

Homemade Olive Oil. Many people have asked me how they can make their own cooking oils. This is the only system I've ever been able to find that seems halfway possible for people to do on their own. The recipe was written by the late W.V. Cruess, who was Professor of Food Technology at the College of Agriculture, University of California, Berkeley, CA.

There are 2 ways you can make homemade olive (or any other) oil: by grating, simmering, and skimming, or by pressing it out. By these processes, you get only two-thirds as much oil as from a commercial press. Still that isn't bad for homemade.

Grate/Simmer/Skim Extraction. Ordinary lye will be needed. Make up a solution of $\frac{1}{2}$ lb. lye per 1 gal. water, using an agate-ware or iron pot (not aluminum!). A small basket of wire screen such as is used for making French-fried potatoes will be needed, or a piece of cheesecloth can be used. Heat the lye solution to boiling and while it is boiling, dip the olives in it for about 20 seconds. The time needed will vary with the toughness of the skins. Leave the olives in the lye until the skins are softened—that is, practically dissolved. Then plunge them into cold water for a few seconds to stop the action of the lye. Place the lye-treated olives on a piece of fly screen tacked to a frame over a large dishpan. Rub them on the screen until the flesh has separated from the pits and dropped through the screen into the pan. A heavy pair of rubber gloves is necessary in this process to prevent your hands from becoming badly stained and roughened by the lye and olive juice.

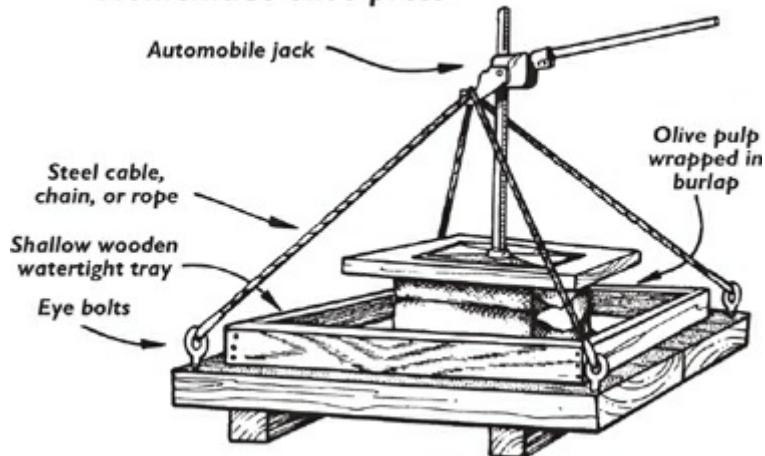

Place the pulp, which should now be of a pasty or mushy consistency, into a pot with about 2 or 3 times its own volume of water. Heat to simmering, stirring constantly, for about $\frac{1}{2}$ hour. Set it aside for several days to permit the oil to rise to the surface. Usually a

fair yield of oil can be obtained by skimming it from the surface of the pulp. The pulp may then be boiled a few minutes with more water and allowed to stand again. The process should be repeated several times. The secrets of success are to rub the olive flesh to a fine-grained pulp and always use a large excess of water with the pulp. The yield of oil is also sometimes increased by adding about $\frac{1}{4}$ lb. salt per gallon of water used with the pulp.

Oil obtained by this process must be washed and should be filtered as described later.

Pressure Extraction. The simplest way to prepare olives for pressing is to place them in a strong sack, then hammer the sack with the broad side of an ax or with a heavy board until they are thoroughly crushed and broken up. The olives will crush even better if boiled a short time beforehand to soften them. Now press them in your store-bought or homemade olive press.

Homemade olive press

Making a Homemade Olive Press. Materials needed: a heavy auto jack, 2 lengths of steel cable or chain or heavy rope, 1 shallow wooden watertight tray, 1 piece heavy burlap material to hold the crushed fruit, a pair of 2-inch by 10-inch by 16-inch boards for the bottom, a pair of 2-inch by 4-inch by 20-inch boards for braces, and 4 threaded eyebolts with nuts. Start by nailing the bottom together. Put the 2-inch by 10-inch boards side by side and nail them onto the edge of the 2-inch by 4-inch boards as shown. Next build a tray or simple box and caulk all joints to insure watertightness. And set this on the bottom. Then drill holes for eyebolts in the 4 corners of the bottom as shown, and insert eyebolts. All that is left is to set the jack up and measure and attach the cable.

The Pressing. You can press either green or black olives for oil. Green makes the best quality oil, but less of it. *For kitchen oil, don't press hard enough to crack the pits. There's oil in them, but it's good enough only to make soap with.* The oil from a first pressing is highest quality and called the "virgin oil." Green olives press best if first dried a week out of direct sun.

Place the crushed fruit and pits in a piece of heavy burlap and fold the edge of the burlap in to give a pressed cake about 10 inches square and about 4 inches thick. Make 2 of these and place them in the press. Press slowly until no more juice can be obtained. Save all juice and oil pressed from the fruit. The pressed pulp should now be boiled with an equal volume of water and pressed a second time. Repeat boiling and pressing again. Usually a fourth heating and pressing will pay. Combine all of this pressed liquid and allow it to stand in a tub or barrel overnight. The oil can then be skimmed off.

Clearing the Oil. Oil obtained by either of the above methods will be bitter and not clear. Use any of the following methods to clear it.

Method 1, Water Washing. Prepare a bucket or a 5-gal. can with a hole and faucet or cork near the bottom. Place the oil in this container and add an equal quantity, or more, of warm water. Mix oil and water by stirring for several minutes. Allow water and remaining solids to settle for several hours. Draw off the water and replace it with fresh warm water. Stir, let it settle, and draw off water and solids again after several hours. Repeat until the oil no longer has a bitter taste. Usually 2 days' washing will be sufficient.

The oil will be cloudy and mixed with a little water. Now pour it through filter paper from the drugstore or a coffee filter placed in a funnel over a bottle or jar. Oil filters slowly. Do not become discouraged if it requires several days for it to run through the filter. A way to hurry it would be to filter it through several layers of cheesecloth—again and again. Then bottle as below. Some oil makers swear that the oil needs aging for several months to have the proper flavor. Method 2 has aging built-in. For method 1, age in bottles away from bright light. Too much light will cause it to lose color and flavor. But a warm room will help it age more rapidly. The oil will also age faster if the bottles are only $\frac{3}{4}$ full, and if a small piece of cotton is used to close the bottle.

Method 2, Siphon System. In this case you take the oil off the top instead of the water off the bottom. Start by straining the oil through several layers of cheesecloth into glass containers (the glass is an advantage of this system). Let it settle a couple weeks. Then siphon the oil off the top, stopping before you get near the sediment. (Plastic tubing works well.) Strain again, settle again, siphon again. Five such cycles will give you quality oil. Now pour into sterile jars (don't heat), and add lids or cork to seal.

Once you break the seal on a jar of your olive oil, refrigerate it to prevent rancidity.

PAPAYA: The papaya is the most tropical of tropical fruits. Even the tree has an exotic look of the jungle about it. It isn't actually a tree. It is more of an overgrown 20-foot herb. It produces vast amounts of a delicious fruit that is also very nutritious. In appearance and taste it is much like a melon.

Varieties. There are a number of papaya varieties, different in sweetness, hardiness, and pollination requirements. Mexican varieties are less sweet and more hardy. If you're going to grow only a few, I'd recommend the Solo Papaya, which is small and sweet and will pollinate itself.

Growing. The most important factor in growing a papaya is climate: they cannot abide chill. In the United States, the only suitable climates are in Hawaii, along the Southern Californian coast, and the Gulf coast. Temperatures below 30°F, even for only a few hours, will damage the plant and/or prevent fruiting. Luckily, the plants can be grown in containers and brought indoors for cold spells. Most types of papayas need both male and female plants to fruit, and only the females bear papayas. The soil should always be kept moist but never wet. Fertilize frequently. Plant from well-washed seeds, 2 or 3 of them in a pot filled with a mixture of manure, sand, and loam.

➲ **DRIED PAPAYA** Wash the outside and peel the fruit. Cut in half and take out the seeds (pea-sized and black). Cut lengthwise into $\frac{1}{4}$ -in. slices. Dry at 135°F until pliable. Eat as a snack or add to any dessert. Dry the seeds separately. Powder them to make into a meat tenderizer (papayas contain papain, an enzyme that not only helps your body digest food but also tenderizes meat). Grind the seeds for a pepperlike seasoning.

PINEAPPLE: Pineapple (*Ananas*) is a strange fruit that comes from northern South America but does well in tropical regions throughout the world. Pineapple contains an enzyme,

bromelin, that helps digestion.

Planting and Growing. It is never grown from seeds, but propagated from slips cut from the base of the fruit or its crown (at the top of the fruit). Or it can be propagated from suckers that grow off the lower part of the stem. There are seed-producing varieties, but when seeds develop it causes the pineapple's flesh to be spoiled for any canning use. Red Spanish and Smooth Cayenne are popular kinds. Pineapple is like strawberry in that it has a pitiful root system and must have lots of well-rotted compost in the top several inches of well-cultivated soil. Planting is done in spring or fall in rows divided by mulch paper, which suppresses weeds, retains moisture, and warms the soil.

Harvesting and Use. Fruiting begins with a flowering, called a red bud, in the plant's center. The flower cluster has about 150 flowers, in a spiral array, with pale blue petals. Each flower blooms for only one day. Then the petals shrivel and fall off. The base of the flower grows into one part of the multiple fruit. It takes about 20 months for the planted slip or sucker to produce a mature fruit, ready for harvest. After the pineapple is cut away, prune the plant, removing all but one or two suckers. Those suckers will each produce a pineapple that will be ready for harvest in about 12 more months.

Harvest yellowish-brown pineapples that are completely ripe and have fresh-looking, healthy leaves. A fruit with a decayed bottom or dark, wet spots on its sides is overripe. To prepare more than a few pineapples, wear gloves, or rinse your hands in cool water once in a while, because the fruit has a very high acid content. Rinse the pineapple. Cut off its leafy top, and peel it (a good job for an electric knife.) Remove any fibrous areas or "thorns" that remain after peeling. Remove core. Don't add raw pineapple to a gelatin dish because its enzyme prevents jelling.

➲ **CANNED PINEAPPLE** Peel, core, and cut in rings or chunks. Pack into jars. Cover with a thin boiling syrup. Leave $\frac{1}{2}$ -in. headspace. Process pints or quarts 30 minutes in a boiling water bath.

➲ **DRIED PINEAPPLE** Choose ripe, but not overripe fruits. Cut peeled, cored fruit into $\frac{1}{4}$ – $\frac{1}{2}$ inch slices or wedges. Dry at 135°F until pliable. Dried pineapple is very sweet Add it, as the sweetener, to cereals, desserts, and baked goods.

POMEGRANATES: These can be grown from seed, by cuttings, or layering. Or order them from a nursery. They look like small trees. They are hardy in the Las Vegas area and have no insect problems. They flower beautifully for a good 2 months—brilliant coral trumpet-shaped blooms. The pomegranate is ripe for sure when it starts to split. (You can't tell by the outside color.) Pomegranate juice will severely stain your kids' clothes. Rosalind Creasy, in *The Complete Book of Edible Landscaping*, has recipes for pomegranate jelly, grenadine syrup, and pomegranate juice.

PRICKLY PEAR: *Opuntia ficus-indica*, prickly pear cactus or "Indian fig," is the best known cactus fruit, but there are numerous edible cacti in the *Opuntia* and *Nopalea* cacti species. In general they will grow from zones 5 to 10. They grow well in containers so you can bring more-tender ones inside for cold weather if your weather gets below 20°F .

Varieties. Choose your species thoughtfully. Some are more hardy than others; *O. opuntia* is the hardest. (See *Cactus and Succulents*, published by Sunset.) Edible types include *N. chamaecuera* (fruit and pads), *N. dejuncta* (fruit and pads), *N. cochenillifera* (fruit), *O. engelmannii* (pads eaten fried), *O. leucotricha* (pads and fruit), *O. ficus-indica* (pads and

fruits), and *O. basilaris* (flowers can be steamed and eaten).

There are new spineless varieties available, which cattle like to eat and which can grow in deserts where little else thrives, doing well in a well-drained rocky or sandy soil. Starts are available from Jim and Electra Elliott at Arizona Cactus Sales, 1619 S. Arizona Ave., Chandler, AZ 85248; 480-963-1061; www.arizonacactussales.com. John and Vickie Dicus offer a “nearly spineless” *Opuntia ficus-indica* var. *Burbanks Spineless*, a rapidly growing variety called *Opuntia ficus-indica* var. *Santa Maria*, and the “Dinner Plate” cactus (*Opuntia robusta*), whose edible “almost spineless” leaves can grow as large as 16 in. across: Rivenrock Gardens, PO Box 196, Nipomo, CA 93444; www.rivenrock.com. Or shop at GreenDealer: 502-459-9054; PO Box 37328, Louisville, KY 40233-7328; greendealer@insighbb.com; www.greendealer-exotic-seeds.com

Planting. You can start a plant from either seeds or pads. If you live where cactus grows wild, just broadcast seed, cover with ¼-inch sand, and wait. Otherwise, plant in flats. It takes the seed months of a little dampness and a little sun to get going. Planting a pad goes faster. Let it cure a few days in sunshine, then plant right-side-up in moist sand. No fertilizer is needed, but they do need water at least once a month their first year. Not too much water, though; excess results in mildew or rot of these desert naturals.

Harvesting. It takes several years for the plant to get big enough to fruit. In spring, nice yellow (or orange) flowers bloom. The leaves are thorny, thick green extensions called “pads.” They’re edible and taken in spring. The flowers are followed by fruits, ready in the fall. The pads and fruits both have needles. Be careful not to get punctured. Old-timers pick fruit and pads with leather gloves.

Nopales. “Nopales” is the Mexican name for prickly pear pads served as a vegetable. To use, first get rid of the bristles on the pads by scraping them off completely or singeing or cutting them off like you’re cutting out “eyes” from a potato. Then peel and cut into large chunks, then boil in water. (Cooked nopales are still firm.) Drain and serve with salt, pepper, and butter. Or serve raw and sliced. Or add to a basic meat and vegetable soup or stew. Or fry sections.

Prickly Pear Fruits. These can be eaten fresh if you’re willing to spit out the seeds. Marion Stick is a woman of Native American descent who lives in Phoenix, AZ. Marion says Native Americans pick the fruit from cactus and make jelly and candy. The following recipes tell you how.

⇒ **CACTUS CANDY** Marion makes this from the small barrel cactus. Take off spines and outer skin. Cut pulp across in 1-inch slices. Soak overnight in cold water. In the morning cut into 1-inch pieces and boil until tender. Drain and cook slowly in a syrup until syrup is almost gone. Watch so the pieces do not scorch. To make syrup for about 2 qt. cactus pieces, combine 3 c. sugar, 1 c. water, 2 T. orange juice, and 1 T. lemon juice. Bring to a boil and add cactus. When syrup is almost gone, remove cactus pieces. You may cover with powdered or granulated sugar.

⇒ **PRICKLY PEAR JELLY** Pick prickly pears with leather gloves. Take off spines. Rinse the fruit and place in kettle, adding enough water to cover. Boil until quite tender, then squeeze through a jelly bag or jelly press. To every 2½ c. of juice add 1 (1¾ oz.) package powdered pectin and boil for couple of minutes. Then add 3 T. lemon juice and 3½ c. sugar. Stir often and boil hard for 5 minutes. Pour in jelly glasses. Adjust lids. Process 5 minutes.

Roselle: This attractive, tall (4–5-foot) annual, *Hibiscus sabdariffa*, also called “Florida

cranberry" or "sorrell," is grown for the fleshy cranberry-flavored red calyces that develop from the bases of its yellow flowers. It needs subtropical or greenhouse conditions with a long, hot summer. It grows fast and can be used in the South as an annual hedge. Plant like tomatoes, spaced 1½–2 feet apart.

Harvesting and Use. The plants are triggered to begin flowering when the days shorten, but too soon a frost will prevent the roselles from maturing. The roselles will be ready for harvest around 15 days after the flowers bloom. To harvest, just snap them off. The red calyces, called "roselles," can be used fresh or made into a fruit sauce, or used to flavor jelly, iced drinks, or hot teas. Roselle juice is like cranberry in color and taste, but lacks cranberry's bitterness. Dried roselles, or "Jamaica flowers," can also be used as flavoring. Young roselle leaves and stems can be cooked and eaten same as spinach.

⇒ **ROSELLE JELLY** Cover the roselles with water and cook them until tender. Strain through a jelly bag. Measure the juice. Boil it 5 minutes. Add 1½ c. sugar and 2 t. lemon juice per 2 c. roselle juice. Cook until it sheets from the spoon. Skim. Pour into your jelly jars and seal.

SAPOTE: Sapote (*Sapotaceae*) is also known as sapota, sapodilla, and the "chocolate pudding fruit." Mamey Sapota, var. "Pantin" (*Pouteria sapota*) is a grafted plant that needs tropical conditions such as a heated greenhouse, available from Pacific Tree Farms.

TAMARILLO: The tamarillo (*Cyphomandra betacea*), or "tree tomato," is grown in subtropical areas around the world. It's a beautiful plant with large leaves and a sweet smell that grows only about 8 feet tall.

Planting. Choose a wind-protected, warm site and well-drained, light soil. Provide reasonable watering. Tamarillo will grow from seeds (available from Southern Seeds).

Harvesting and Use. Your plants start bearing smooth, bright fruits in 2 years. They are sweet and acid and make good preserves and sauces, or can be cooked as a vegetable—good stewed or baked with any meat. They have tough outer skins that help them store well, but they must be peeled before eating.

UMKOKOLO: The umkokolo, or kei-apple (*Dovyalis caffra*), is a 10–20 ft. thorny tree that grows well in Florida and California, if on sandy soil. Its fruits are pulpy and yellow, an inch wide, edible if cooked, and resemble cranberries in flavor. A related plant is the Ceylon gooseberry, a.k.a. kitambilla (*Dovyalis hebecarpa*). It is hardy enough to be grown in the deep South. The fruits are purplish and sweeter than umkokolo. Both umkokolo and the Ceylon gooseberry are unisexual (like kiwi), and you must plant one of each sex near each other to get fruit. Propagation is usually by seeds. Read more about them at www.hort.purdue.edu/newcrop/morton/kei_apple_ars.html.

VINE, BUSH, AND BRAMBLE FRUITS

The Complete Guide to Growing Berries and Grapes by Louise Riotte (Garden Way) pulls together most of the basic details about small fruits. For good readable advice on grapes see *Organic Gardening*, February 1972, p. 72. You can also get a lot of useful information on grapes out of the Henry Field Seed Company catalog.

This section is divided into 2 parts: the vine fruits are listed first.

Grapes

(For information in this section I am heavily indebted to Cass Turnbull, who knows so much more about grapes, their training, and their pruning, than I do.) Quite likely you can get started with grapes with cuttings from a neighbor who has them. You cut in the early spring before the sap has started to run, when it looks all dead. Don't prune grapes after the sap is running because they'll bleed like crazy. Cut off a length of stem with at least 5 bud spots on it. This is where the leaves will develop later. Stick it in your chosen place with 2 or 3 spots underground and the other 3 above. Roots will grow from those underground, and leaves from those above. Keep the ground soaked around them all that first summer. You may have grapes from them even the first year. If you're planting in a row, set cuttings about 2 feet apart. They can be by the side of a building if you want, but pick a sunny side. Supply a pole for climbing. When choosing grape starts, be careful to take slips off a good productive plant rather than just anything.

VARIETIES AND PRODUCTION: Green grapes make nice table grapes, but purple salad grapes are better for preserves and juice. Ours are some little green kind with seeds. Don't get in a hurry for production. Generally you'll have no grapes the first year you plant, very few the second, more the third, and then in the fourth year you'll start to get into real production—depending on how you prune. That's true of cold-weather grape types. You see, there are 2 basic kinds of grapes. One is your vinifera or California wine type. They are most common in warm climates. Thompson Seedless, also this type, is a good table grape. With these warm-climate grapes you can have grapes growing by the second year after planting. The labrusca varieties have slip-skins and are cold-weather kinds of grapes. Concord is one. The Concord grape is a good producer. These do better in cold climates where they will give you a heavier production than warm-weather types will. Cold-weather types will do fine in New York. But they take at least 3 years to bear fruit. They bear fruit from the third, fourth, and fifth buds from the base of the vine. When you are pruning you have to be careful you don't cut away that fruiting wood. You'll find lots more info on commercial aspects under "Organic Grape Production," at www.attra.ncat.org and search for grape.

GRAPE PRUNING: Cass wrote up this subject to help me: Grape pruning is daunting to the novice, especially to one who has inherited someone else's old, overgrown vine. Don't worry. In grape pruning, as with most pruning, there is a large margin of error. If you avoid the big mistakes you can do a decent job until time and experience teach you the rest. The 2 most frequent mistakes I see are not pruning at all and simply shearing or whacking all canes back to the arbor or trellis and leaving a big, tangled clump.

A Grapevine Story. An early settler planted a grape vineyard. It grew fine for several years, but eventually the settler moved on and the vines were left unpruned and neglected. Eventually they grew out of site and rambled along the ground. The grapes were poor in quality and out of reach. A new owner bought the property with the intent of raising livestock and pack animals in the forgotten fields. A year or two later the animals had nibbled back all of the vines. Thereafter the vines returned and fruited magnificently. The moral: Any ass can prune a grapevine.

Controlling Grapevine Size. If you have planted or acquired grapevines, you will soon have a lot of experience pruning them. That's because the primary reason for pruning grapevines is to keep these "rampant plants" from growing up and covering nearby houses and trees. This extensive annual growth is the *modus operandi* of most vines. Don't take it personally. Furthermore, if you neglect to prune, you will find that all the grape

clusters appear way out of reach at the ends of your enormous vine.

Maximizing Production. On old, let-go vines, you will find many, many clusters of grapes, but they will be small and of poor quality. Shortening and thinning allows more energy and light to reach fewer buds, making the fruit bigger and bigger.

How Much Grape Pruning Is Enough? Take off between 60 and 80 percent of the foliage and old canes every year. That looks like a lot, but really it isn't for a grapevine. Yes, it is possible to overprune. The plant won't die, it will simply stimulate rapid and rampant regrowth. Such growth has bigger than normal leaves and fewer fruiting buds, meaning fewer grape clusters. This is one reason that severe pruning, which is commonly done to renovate an old vine, is often spread over several years.

When to Prune. Most grape pruning is done in the dormant season, meaning mid-winter. If you prune too late (late February or March, in Seattle), your grapevine will "bleed." This means it will ooze sap from every cut end. Bleeding doesn't hurt the grapevine, but it will scare you. If you have a bleeding grape, don't put on a tourniquet. Just wait. It will stop once the leaves have emerged.

Thinning Grape Clusters. Early in the growing season, you may want to thin out clusters of young grapes. Just cut some clusters off, or parts of clusters off, to channel more energy into what's left. Here again this is not essential, but it will make the remaining grapes bigger and better. I like to do a little touch-up pruning in the summer to get more light to the grape clusters.

GRAPE-PRUNING DEFINITIONS

Shoot. New supple, 1-year-old, green growth.

Cane. A 1-or 2-year-old shoot. On it are buds that never grow out unless they are pruned back, buds that become new shoots, and buds that become flowers and fruit. A good, young cane is about pencil thickness and is smooth and tan, not brown and shaggy.

Spur. A cane shortened to 1 or 2 buds, about 3 inches long.

Fruiting Arm. An older spur that is cut a little farther out each year until it becomes a thicker, older, more permanent feature a few inches long. When a fruiting arm becomes too old, pick a new cane originating on the truck or scaffold and train it as a replacement (spur prune). Then cut back the old arm.

Scaffold. Main side branches. Originally these were the canes arising from the trunk that you trained along the wires or across the arbor. They have been cut back to be 6–10 feet long and kept year after year as framework. They are now fatter, browner, and shaggy.

Head Prune. A system of pruning in which canes are cut back to the trunk, not scaffolds.

Trunk. The main trunk. Wood is thick and shaggy.

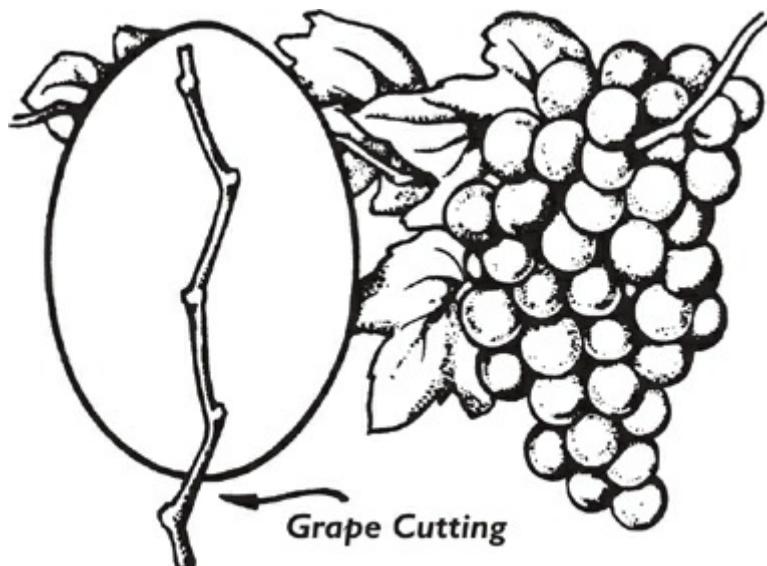

TRAINING A NEW GRAPEVINE

Support for a New Vine. The first 4 years of pruning are done to create a strong, compact framework for your vine. Too commonly I see grapevines being trained on thin posts with wire trellises. Be sure your main framework is sturdy: Use 4 × 4 posts or 3-inch pine buried deeply in the ground (or perhaps even set in concrete). Remember that it will eventually support the weight of a large, old, heavily grape-laden (as in, "oops, it got

away from me") vine. Unless the vine rests on top of an overhead arbor (using a system of 2×4 s), it will also need wires around which to wrap its tendrils and onto which you tie canes.

Space for a Grapevine. Give your vine a lot of room. Even with annual pruning they require at least 6–10 feet in which to grow. Early training of grapes doesn't make sense to the logical mind. The first winter after planting you cut the poor tiny thing down to as few as 2 buds from the ground (3–6 inches). This is done to force rapid regrowth and a strong trunk. The next spring it zooms up and sends out side branches. In the spring or summer you cut off the side branches and keep tying the main stem (or sometimes 2 stems) onto the stake to hold it up. Don't tie too tightly, or the ties might girdle the vine.

During the next winter, whack it back to half of its present size (about 2 feet). Really this is the way it's done! Let it grow through the summer. Gently tie it every 6 inches or so, as it grows up the post or stake. Again, remove side branches (shoots) and basal shoots (those coming from the base or ground level). When the vine finally reaches the lowest of the wire supports, allow 2 shoots (one on either side) to grow along the wire, tying them in place temporarily if need be.

You now have a "trunk" and 2 scaffolds. They are the main framework for your plant. You will need to cut back your scaffolds the first year to about 10 buds (2 feet or so) just like you did the trunk. This forces them to become thick and sturdy and causes them to set up more buds close to where you'll want them. The shoots arising from the scaffolds are similarly cut back, becoming "fruiting arms" an inch or so long. Arms should be spaced about 6 inches to a foot apart on the scaffolds.

SYSTEMS OF PRUNING

Spur Pruning: When you spur prune, you cut back a cane until it has only 2 or 3 buds from the scaffold or fruiting arm. Do this in the winter. Spur prune canes, which are spaced every 6 inches or so apart along the scaffold, and cut off all other shoots and canes entirely. This keeps crowding down. The 2 buds will grow into new canes and set fruit next year. The next winter cut off the outer one of the 2 canes and shorten the other cane to 2 buds. Repeat annually.

This is the method used for most European varieties except Thompson Seedless (the most common supermarket grape). European grapes are Red Malaga, Ribier, Perlette, Muscat, Cardinal, Tokay, and California wine-type varieties.

Cane Pruning. This is also known as “renewal pruning.” Some varieties won’t set fruit if you spur prune all canes annually. These are the American grapes such as Delaware, Concord, Niagra, and Pierce, as well as the Thompson Seedless. These fruit form growth farther out on the cane. Therefore, you cut back half your canes (the newest ones) about 2–4-foot lengths (8 to 14 buds) every year. Wrap or tie the canes gently around the support wires. Cut the other half (meaning the older canes that bore fruit this last summer) way back, making them into spurs. This type of spurring is done to ensure a continued supply of canes that are close to the trunk or scaffolds.

The Shotgun Method. If you’re like me, you are probably faced with an old tangled mop of a grapevine monster, and you have no idea what type it is. Try the shotgun method. Cut out 60 percent (or more) of the shoots and canes entirely back to bigger scaffolds or to the trunk. You follow each chosen victim with your eyes, cutting it in many places and unthreading it from the tangled mass. Keep an eye out for old, dead canes and cut them out too. Dead canes look, well ... they look dead and dry. They have no live, plump buds along them, and they are light-weight.

What’s left is the big fat trunk, the scaffolds you wish to keep, and many (but now far, far fewer) canes. Shorten some canes to 2 bud spurs (3 inches) and shorten most of the rest to 10 or 14 buds (2–6 feet). If it’s on an overhead arbor, you may care to leave some canes longer as framework.

Repeat this procedure annually. By careful observation you may be able to tell which type of grape you’ve got. Otherwise this method should suffice to keep your grapevine producing and in check.

PRESERVING GRAPES

Raw Storage. Grapes, like pears, are a late summer crop—at least around here. If you pick only good ones and keep them in a cold, moderately moist place, they will keep a month or more. Catawba keep the best.

Drying. When grapes dry you have raisins. I used to think that raisins were some kind of tropical fruit that grew in California. It was a real surprise to me to learn that raisins are dried grapes and prunes are dried plums! Grapes are one of the harder fruits to dry—more difficult than any of the large pitted sorts, which are the easiest. Any sweet grape can be dried. Seedless varieties are obviously preferable. Good raisin varieties are the Thompson Seedless, Black Malaga, Black Thompson Seedless, and Muscat.

Making Raisins. Let your grapes ripen on the vines until they are sweet as you’d expect them to be before they start going bad. Then pick the branches, cluster by cluster. Spread them out in the sun to dry and turn them over occasionally. It may take a couple of weeks or so. Once the raisins are dried you can remove them from the stems for storage or store them on the stems as you prefer. Or you can dry seedless green grapes at 170°F for at least 24 hours in an oven.

Criss Wilhite, of Fresno, CA (the “raisin capital of the world”), wrote me: “We cut the grapes, lay them on [a lead-and dioxin-free] paper next to the vines. Then, days later, we turn them over. Then days after that, we roll them up in the paper. Since there is no dew here in summer, we don’t have to cover them up. The hard part is stemming them! Last summer, we dried so many grapes that we ended up with 100 lb. of raisins. I put the raisins in baskets and sorted them out from the big stems and stuff. Then I bagged them in 2-lb. bags and stuck them in the freezer. (Since this is the agribusiness and grape center of the country, every grape-loving, pesticide-resistant bug imaginable winters over in

raisins. Freezing is easier than oven-heating.) Whenever we need raisins I spill a bag out and empty it into a colander. I sort of knead the raisins around in it and the stems rub off and fall out. I do this until about 70 percent are stemmed. Then, I put them in a damp terry cloth towel, roll them up, and rub them around a bit. I do that twice. It gets a few more stems out, washes, and moistens the fruit. It all takes 20 minutes maximum. We eat 3 or 4 lb. a week! A hundred pounds a year isn't enough for us."

⇒ **RAISIN SAUCE** Cook $\frac{1}{2}$ c. raisins in a little over $\frac{1}{4}$ c. water. When the raisins are soft, strain and reserve $\frac{1}{4}$ c. water drained from them. Combine $\frac{3}{4}$ c. brown sugar and the raisin water and cook together 5 minutes. Then add 2 t. butter and $\frac{1}{2}$ t. vanilla. Mix, add raisins or not as you prefer, and serve warm.

⇒ **GRAPE JUICE** The Concord and Catawba varieties are especially fine for juice, but you can make it from others, too. The key to enjoying homemade grape juice is knowing that you want to dilute your juice with water to taste when you serve it. The floating crystals are tartrate (cream of tartar). In grape juice you have a natural concentrate. If the grapes are ripe and sweet you don't need to add sugar. If you add more sugar to your grape juice you get the equivalent of a syrup.

Use only sound, ripe grapes. Let them ripen on the vine, and after you pick them keep them out of the sun until you have a chance to pick off the stems and wash them. Mash the grapes with a potato masher or in a press. Cover the red grapes and Concord grapes with water and heat to 145°F. Don't heat white grapes. Put the pan contents in a cloth or fruit press. Work the sack gently so that you extract all the juice or just let it hang all night. If you want clearer juice let the extracted juice stand overnight in a cool place. Then pour off the top. The pulp will have settled to the bottom. If you have white grapes be careful not to crush the seeds. To can grape juice, use the recipe for canning apple juice. When serving the juice I dilute half and half with water. Early in the season the children don't care much for grape juice, but by about February when the apples are gone they really start to relish it, and I do too.

⇒ **HOMEMADE FRUIT COCKTAIL** Green grapes can be made into homemade fruit cocktail. Just cut your fruits small. Use whatever you have—strawberries, peaches and so on. Combine with a honey syrup and can or freeze. Although you never see grapes listed in regular canning lists they can be canned.

Canning Grapes. Just remove the stems, pack in your jars, pour over hot syrup or even plain water. Process in a hot-water bath 15 minutes. I have a friend who has no freezer and whose family lives off their own produce. She cans quarts and quarts of whole grapes, strawberries, and raspberries every year.

⇒ **SIMPLE CANNED GRAPES** Into a clean sterile quart jar put 1 c. any kind of grape. Add 1 c. sugar or $\frac{1}{2}$ c. hot honey. Fill the jar on up with boiling hot water and seal it. Takes about a month to be ready. Tastes good.

Freezing Grapes. I used to think you couldn't freeze grapes because that's what I'd read, and I'd never tried different. Then a friend told me he freezes grapes and they freeze very well. He said he takes the grapes off the stem, washes them, and bags them up with no other treatment in plastic bags. He said that they were practically like fresh when thawed.

⇒ **GRAPE PUNCH** Combine the juice of 2 lemons and 1 orange, 2 c. grape juice, and 2 c. water. Sweeten to taste.

⇒ **GRAPE ICE** Pulp 3 lb. grapes. I like the little green seedless ones. Then you can keep the pulps and skins in the syrup. If you are using seeded grapes you'll have to pick the seeds out

and put the grapes through a sieve, in which case you'll lose a lot of good stuff and good time, too. Add ¼ c. (or more) honey and mash well. Freeze, stirring occasionally. It takes quite a while to freeze. Serve when it is barely beyond the "slush" stage. This is nice with a whipped cream topping, or plain.

Grape Leaves. Grape leaves are the ultimate health food. If you can't grow them, you can buy them. How to work them into the menu? Add several fresh grape leaves to each jar of pickles. When making crock pickles, cover the bottom of the crock with a layer of grape leaves. (On top of that place a layer of dill flowers. Then put in the cucumbers.) Use grape leaves as a wrapper for steamed veggie/meat mixes. Or add to a smoothie.

Kiwis

These have also been called "Chinese gooseberries." Kiwis started out in China, then got to New Zealand, and finally to California. Commercial size and quality patches can grow even in northern Washington. Kiwis grow on a grape-type vine, are large as a lemon, and have no connection with the regular gooseberry. The first importers of the fruit renamed them "kiwi fruit," and that's what they are called in American supermarkets.

Here's Cass's wisdom again: An interesting thing about kiwis is that most varieties are dioecious, meaning male and female flowers are on different plants. You need 1 male plant to service about 7 females. Of course, only the females will fruit. (Some newer cultivars are self-fruitful. Finding and planting one of these may save you a lot of room.) It may take from 2 to 8 years for a vine to begin producing. Kiwis also need a long summer to ripen on the vine. In short season climates like mine [Pacific Northwest], we pick the fruit after the first frost and ripen it inside in a cool storage area.

PRUNING KIWI VINES: Kiwis are like grapes in many respects—only more so. Their growth is so extensive that summer pruning is essential, as often as once a month, to keep the vine from running down the block and covering your neighbor's house and trees. They need even more room to live than grapes (10 by 16 feet on an arbor, 3 by 16 feet as an espalier). Prune them in the winter as well. Early training for kiwis is similar to that for grapes. Prevent the main stem from twisting around its support stake. Once mature, kiwis are pruned a lot like "spur-type" grapes. In the winter cut back all of the new rampant growth to the original spur system, only a little farther out. This means that you will cut to 2 or 3 buds beyond where it last fruited. However, your spur system will eventually get old and crowded. You will need to renew it by cutting it back severely or starting it over by cutting back to the scaffolds.

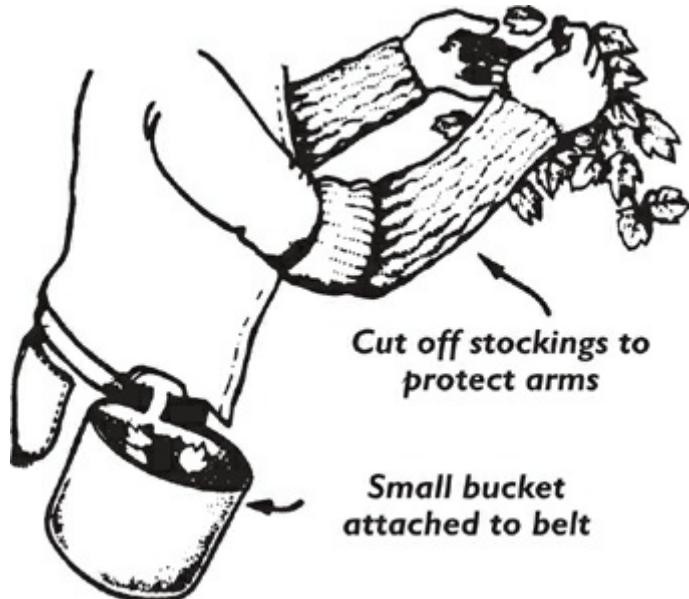

Passion Fruit

This wonderful perennial and evergreen vine from Brazil will grow only in a hot, humid subtropical zone. It can endure a brief light frost, but that's it. Because it will grow in a container you have that option also, pruning to keep it the size you need. The flowers are unusual and very beautiful. It grows quickly and generously produces fruit in 2 years. The vine can climb as high as 30 feet. There are several varieties, some better for flowers, others for fruit. The fruit will be mature about 3 months after the flower bloomed. *Passiflora edulis* fruits from summer through fall. Passion fruit has an outer juicy orange pulp and seeds in the middle. You can juice it for any juice use: punch, syrup, jelly. Seeds are available from Southern Seeds. Several varieties, guaranteed down to 25 or 26°F, are offered by Pacific Tree Farms.

Bramble, Bush, and Other Tiny Fruits

It's a good idea to have several varieties of berries, as well as a good orchard. Your first strawberries will bear in June. Raspberries mature in July. Blackberries and wild berries are on in August and September. You will have berries all summer long.

BERRY PICKING: When you pick berries that have thorns, wear long stockings with the feet whacked off—not nylons—or some similar heavy protection on your arms so you won't get too badly scratched. A leather belt around your waist with a half-gallon can hanging on it is handy, and then you can empty the berries into a big bucket when the little one is full. Don't worry about leaves and such when you're picking. You can put the berries in water when you get home, and leaves will float to the top; you can just scoop them away.

RUNNER REPRODUCTION: Strawberries and many other berries reproduce by "runner." Strawberry runners travel on top of the ground, then stop about a foot away from the parent plant, put down roots and become a new, independent strawberry plant. You just whack the connection, dig up the independent plant, and reset it in your ground where you want it.

BERRIES FOR FREE: When gardening neighbors are cleaning out unwanted berry runners in the spring and cutting back perennials, they can give you all the good starts you'll need if you just give them advance notice that you would like to have them. They have to dig them out anyway from between their rows, and if they didn't give them to you then they would throw the starts away. Berry plants planted from suckers bear no fruit the first year; they will bear fruit the second year.

NURSERY STARTS: If you can't get berry and grape starts from neighbors, buy from your local nurseryman rather than by mailorder, unless you live someplace where there are no plant nurseries and mailorder is the only answer. Almost all the big catalog seed houses carry a wide selection of berry cuttings, but some specialize in them.

BASIC BERRY AND TINY FRUIT RECIPES: If you have some unusual kind of berries or small fruit for which you can't find specific recipes (there are umpteen different kinds of berries), just substitute in recipes that call for a similar fruit because they are very similar except for the

sweetness/tartness, which you can taste-test and add more or less sweetening as needed. For preservation methods, experiment! It may be better to freeze or can. Or make leather. You have to find out.

DRYING BERRIES: Dried berries may not be as agreeable to eat out of hand as the larger fruits, especially seeded berries. Even unseeded ones may turn out quite tough, dry, and full of seeds. But there's an old man who lives near here who dries lots of berries just like his mother did before him when they wintered mostly on dried food. He soaks his dried berries in water and then they make fine pies!

➲ **BERRY LEATHER** Puree your berries some way or another. Putting them in a blender works. Add 1 T. honey per 1½ c. berry puree and proceed with drying.

Freezing Berries. For nicest taste and texture, I like my larger fruits canned, and my berries frozen. I just pick, bag, and freeze—no syrup or liquid at all. Same for any berry or tiny fruit. It saves work and mess too.

Canning Berries. Process them as soon as possible after picking. Get them ready by hulling or stemming. *Can only firm berries with no mold.* Put in a sieve and wash by swishing them through a pan of cold water several times. Strawberries tend to lose their color and aren't as nice canned as frozen, but it can be done. Blackberries, blueberries, gooseberries, and huckleberries can nicely.

To hot pack, bring berries and sugar (½ c. per quart) to boil in covered pan. Shake pan to prevent sticking. Pack hot berries and their juice. Process in boiling water. Times for pints or quarts are: 15 minutes at elevations lower than 1,000 feet; 20 minutes at 1,001–6,000 feet; and 25 minutes above 6,000 feet.

To raw pack, pack berries into jars. Shake jar gently to obtain full pack. Cover with boiling syrup. Process in a boiling water bath: At elevations lower than 1,000 feet, 15 minutes for pints, 20 for quarts; at 1,001–3,000 feet, 20 minutes for pints, 25 for quarts; at 3,001–6,000 feet, 25 minutes for pints, 30 for quarts; at 6,000 feet or higher, 30 minutes for pints, 35 for quarts.

➲ **BASIC BERRY JUICE** The general rule—except for strawberries (which aren't heated)—is to wash, crush, heat to 175°F and extract the juice. Can by instructions for apple juice.

➲ **BASIC BERRY JAM** Weigh hulled and washed berries. Weigh out an equal amount of sugar. Mash berries and set to cook over low heat—but not in an aluminum pan. Bring to boil slowly with frequent stirring. Add sugar. Simmer until thick stirring often enough so jam doesn't start to stick and burn on the bottom. Pour into hot clean jars. Process in a boiling water bath 5 minutes.

➲ **OMELETS WITH BERRIES** Beat up 2 or 3 eggs until just blended but not frothy. Melt 1 t. butter in a clean frying pan. Pour half the egg mixture into skillet for your first omelet. Stir around once and then stir by shaking the pan. When the omelet is done put it on a serving dish. Pour ½ c. fresh berries onto it. Fold over. Top with whipped cream and a few more berries, and do your other omelet with another ½ c. berries and whipped cream.

➲ **BASIC BERRY SYRUP** In a nonaluminum pan, mix together 2 c. berry juice and 3 c. sugar. Cook over low heat until all the sugar is in solution. In a separate small saucepan combine ½ c. water with ½ bottle liquid pectin or ½ box pectin. Boil 3–5 minutes, stirring constantly. Stir pectin mixture into the juice mixture and refrigerate until ready to use. Your result will be a basic pancake-type syrup.

➲ **BUSY WOMAN'S BERRY JUICE** (*Blackberry, raspberry, gooseberry, and the like.*) This stretches the berries as far as possible. Put your berries in a kettle. Cover with water and boil 5 minutes. Drain off the juice and save it. Cover the berries again with water, boil 5 minutes. Drain off the juice and save it. Cover the berries again with water, boil 5 minutes more, drain again and save the juice. Squeeze the seeds and stuff left if you want. Boil again if you think it would help. You can use your busy woman's berry juice as a base for jelly or for juice. Each successive boiling will make a lighter-colored juice. Sweeten to taste.

➲ **WONDERFUL BERRY DRINK** Boil 2 qt. water with 1½ c. sugar or ¾ c. honey for 3 minutes. Then crush 2 qt. raspberries, blackberries, or strawberries and pour the hot syrup over the fruit. Cool. Strain. Add 1 c. lemon juice and ice cubes, and serve.

Brambles: Red and Black Raspberries and Blackberries

PRUNING BRAMBLES: The pruning of brambles is different from that of trees. Since new fruit grows on new canes yearly, you do a fair amount of complete pruning: that is, removing entire canes that have already produced their crop. Every year blackberries send up new shoots from their root systems. The size of these canes by the end of the summer depends on local conditions: soil, moisture, and light. But fruit is borne on these canes only in the following year, largely on lateral branches, which grow during the spring of the second season before flowering. In the wild, after these canes finish bearing, their leaves die and discolor, and the dead canes stand in place until they slowly fall over, decay, and rot. If a stand is particularly thick, it will soon become choked with those used up canes. If you keep the berry patch clean of dead and dying canes, you can significantly extend the life of a good stand. And the amount of fruiting wood available can be increased significantly by pruning. If you head back the top of the canes the first spring, the plant will put all its energy during the second season into the lateral branches, the ones that produce the fruit. Furthermore, blackberries under cultivation can be spaced and trained in such a way that a careful picker will not be so scratched up by the thorns. When pruning out at the end of a season, cut the canes on the ground, but do not pull them down to remove them. Cut them all off in an area at once, then stand up and lift out the canes—less tearing of leaves on the new canes that will bear next year's fruit.

BLACKBERRIES: They grow wild and they grow tame. They are called "blackberries" and they are called umpteen other names like "dewberry" and "thimbleberry," "black raspberry," "flymboy," "wineberry," "nagoonberry," "cloudberry," "wild raspberry," "salmonberry," "blackcap," and "bake-apple." The line of distinction between blackberries and raspberries in the wild isn't very clear, and there are so many different varieties with so many different sizes and colors—suffice it to say they are all good to eat. If you live where they grow abundantly you have a wonderful ready-made free source of small fruit. Blackberries make good out-of-hand eating and good jam and jelly. You can make a hedge of blackberries. If you pick them prematurely they won't be as sweet as later on. Let them stay on the bush until they are really, really ripe, and then they will be sweet and not sour tasting. The "dewberry" variety of blackberry has huge beautiful berries but it isn't as winter hardy as some others. You can propagate blackberries by the volunteer suckers that grow or by root cuttings. Vine-type blackberries like youngberries, boysenberries, dewberries, and loganberries seldom sucker but can be propagated by leaf bud cuttings, except for some fancy thornless varieties. If you took a root cutting of an improved thornless variety, the new plant would revert to the old thorny kind. A 2-inch

segment is enough of a root cutting to plant.

➲ **BLACKBERRY SYRUP** *Crush well-ripened blackberries and add one-fourth as much boiling water as you have berries. Let stand 24 hours, stirring frequently. Strain. Add 1 c. sugar for each quart of juice and boil slowly for 15 minutes or until you have the density you want, and then can it.*

➲ **LOGANBERRY ALE** *Combine 1 c. loganberry juice, the juice and grated rind of 4 lemons, 1 c. sugar, 2 c. ginger ale, and 3 c. water. Let stand a couple hours to mellow. Garnish each glass with a mint sprig and a lemon slice.*

➲ **LOGANBERRY SPECIAL** *Combine 2 c. loganberry juice, 1 c. raspberry juice, 1 c. lemon juice, and 3 crushed mint leaves. Mix and serve over crushed ice.*

RASPBERRIES: These, like blackberries, are a very soft berry. The soft berries do better frozen than canned because they cook up so easily. They make good jam, jelly, sauce, and juice, too, but are nicest of all fresh. Raspberry plants don't last forever. A started raspberry row will last 7–10 years. So after the fifth year start a new row so it will be growing berries when the old one starts slowing up. Raspberries now come in black, red, or yellow. Most varieties will bear only once on a cane so you prune by cutting out old canes after they have fruited. But there is one kind of raspberry now that will bear fruit 2 years in a row before stopping on any particular cane.

➲ **RASPBERRY JUICE** *Use fully ripe, juicy berries. Wash in cold water and drain. Crush and heat the berries slightly to start the flow of juice. Strain in a jelly bag to get the juice.*

➲ **RASPBERRY-APPLE JUICE** *Combine half raspberry juice and half apple juice.*

➲ **RASPBERRY-MINT DRINK** *Combine 1 c. sugar or ½ c. honey, 1 c. water, and the grated rind of 2 lemons. Cook, stirring over low heat until your sweetening is dissolved. Boil 5 minutes more. Cool. Add 2 c. crushed raspberries, 1 c. lemon juice, and 4 c. water. Serve with some mint leaves in the bottom of the glass (and in the pitcher) and a mint leaf on top.*

The Non-Bramble Berries

BARBERRIES

➲ **BARBERRY JUICE** *Use cranberry juice recipe.*

BLUEBERRIES: These need an acidic soil. If they have that, you have a wonderful berry that may bear fruit the first year and for the next 50, but if they don't have that soil they will die and that's all there is to it. St. Lawrence Nurseries offers numerous varieties of half-high blueberries. You can prune blueberries only very lightly. Blueberries don't really have "canes," just twigs. In all but the far north, do what judicious cutting you must in late winter. You'll find lots more resources in ATTRA's "Organic Blueberry Production" at www.attra.org/attra-pub/blueberry.html.

➲ **BLUEBERRY SAUCE** *Start with 1 c. blueberries. Put half the blueberries and ½ c. water into a pan. Simmer 3 minutes. Add 1 t. cornstarch and stir thoroughly. Continue cooking, stirring constantly, until thick. Then add the other half of the berries and cook 3 minutes more. Add 2 T. lemon juice.*

➲ **BLUEBERRY SYRUP** *Combine 1 c. fresh (or frozen or canned) blueberries, ½ c. water, and ¼ c. sugar, and bring to a boil. Crush berries. Simmer 2 or 3 minutes more. Serve this*

syrup hot.

Drying. Dry blueberries out of doors 2 sunny days in a row, then in the oven at low heat until they are rubbery and look like raisins.

CRANBERRIES

Cranberries grow wild in peaty bogs and semi-marshy areas from Nova Scotia to North Carolina and west to Minnesota. They're rarely grown in gardens because they're so picky about conditions—requiring lots of acid water, a pH 4.5 peaty, sandy bog to live in, and a flooded condition when temperatures are below 26°F. It's called a "cranberry bog" for good reason. Yet good drainage is required, because cranberries are grown on dry ground except when flooded to protect them from frost. Cranberries do well in Cape Cod, Massachusetts, in the pine barren area of New Jersey, and in Wisconsin.

Plant cuttings in spring. The best soil for them is a 3–4 inch layer of sand over peat. Plant in April with cuttings, in rows 8 inches apart. After rooting, the cuttings send out runners (like strawberries). The plants will be killed by frost if they're not protected; their natural protection is flooding. Cranberries are not harmed by being under water, even all winter long. But if the water turns to thick ice and stays frozen for too long it can smother them, and so it is better broken and drained off some. It takes 3 years of watering, weeding, and waiting before they begin to bear fruit.

Add a cup of cranberries to applesauce makings to get a tasty pink applesauce. Add cranberry juice to lemonade to make pink lemonade.

➲ **CRANBERRY JUICE** Cook 1 lb. cranberries in 1 qt. water until soft. Crush and drain through cheesecloth for a nice clear juice.

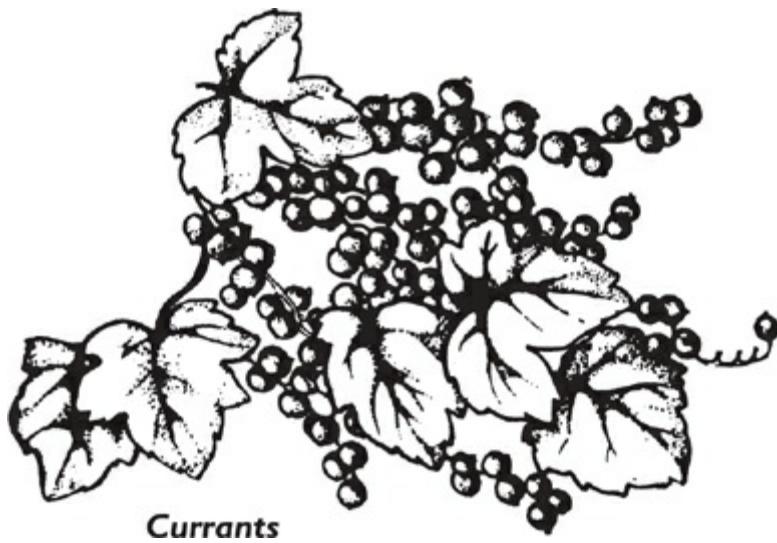

➲ **CRANBERRY COCKTAIL** Grind 4 c. cranberries in your food chopper. Add 1 c. sugar to 6 c. water. Add the ground cranberries and their juice and boil all for 5 minutes. Cool and strain. Add 1 c. orange juice and the juice of 1 lemon. Chill.

➲ **CRANBERRY ICE** Heat 1 qt. cranberries and 2 c. water together, boiling until the cranberries are soft. Run through a sieve. Add 2 c. brown sugar to puree. Heat again, stirring until the sugar is dissolved. Add the juice of 1 orange. Remove from heat. Cool. Pour into tray and freeze firm. Remove to chilled bowl and beat until light. Return to tray and finish freezing without stirring. Serve at slush stage.

➲ **CRANBERRY KETCHUP** Wash and pick over 2½ lb. cranberries. Cover with vinegar and cook until they burst. Force through a sieve. Add 2⅔ c. sugar, 1 T. cinnamon, and 1 t. ground cloves. Return to heat and simmer until thick. Pour into hot sterilized jars and seal.

➲ **SWEET CRANBERRY "RAISINS"** Saute cranberries in brown sugar and butter until the skins break. Add a little honey and stir. The secret is the broken skin that allows the sweetness from the brown sugar and honey to get inside the cranberry. Then dehydrate. It takes a lot of cranberries to make a little bag of cranberry raisins.

CURRENTS: This small fruit went through a time of trouble in the 1920s when bushes were uprooted and became very rare as a result. Certain varieties of currants and gooseberries were supposed to carry white-pine blister rust, a disease that destroyed white pine trees. Many states passed laws banning currants and gooseberries, and seed catalogs stopped carrying them. Now currants are making a comeback. Legal restrictions on them are being lifted, and increasing numbers of nurseries are carrying them again.

That's good news, because currants and gooseberries are among the hardiest of the berries and are important to folks who live on mountainsides. Currants are a firm berry as compared to the blackberry. They are easy to propagate by stem cuttings, and I know people who have raised them from seed. Take cuttings about 8 inches long anytime during the fall, winter, or very early spring. They won't do quite as well if you start them after growth has got going in the spring. They do well in a clay soil. It's still a good idea not to plant currants if there are white pines (pines with needles growing in clusters of 5) within 300 yards. And check your local laws to make sure you aren't in an area where it's still illegal to plant them.

Drying. Put your currants into a large bowl and add some flour (about $\frac{1}{2}$ c. per 1 lb. of currants). Mix the flour with the currants and then rub the currants between your hands to get the stems off. After the stems are off, put the currants in a colander and let water stream through them until you have nothing left but currants. Then scald them a half minute, and chill by drenching again with cold water. Drain. Spread on pie dishes, trays, and so on, and put out in the sun or on your screen or into the oven to dry. They are like little raisins when done.

➲ **CURRENT JUICE** Choose fully ripe, bright red currants. Wash in cold water and remove stems. Crush the currants and warm to 165°F to start the flow of juice. Don't boil. Press the hot fruit in a jelly bag to extract juice. Sweeten to taste.

➲ **BLACK CURRENT PUNCH** To each cup of currant juice add 2 c. weak green tea. Sweeten to taste. Serve in glasses half filled with chopped ice and garnish with a sprig of mint.

➲ **CURRENT SYRUP** Boil 3 c. sugar with 4 c. water until the sugar is dissolved, then add 4 c. cooked, strained currant juice and the juice of 6 lemons. Cool and bottle. This is nice to add color to other drinks.

➲ **CURRENT KETCHUP** Combine 4 lb. ripe currants, 2 c. vinegar, 1 T. cinnamon, 1 t. salt, 3½ c. sugar, 1 T. cloves, and 1 t. pepper. Mix, boil down to a thick sauce, and bottle.

GOOSEBERRIES: These went through the same thing as currants and became very uncommon. Berry gooseberries grow on a low berry-type bush. For "Chinese gooseberries," see "Kiwi" in the vines section. Regular gooseberries are another tiny berry-type fruit.

Harvesting. When gooseberries are green they are still underripe. They turn kind of purple red at the moment of ripeness. There is a wide variety of sizes, from tiny on up. In my experience they either have to be picked before the berries get too ripe or you have to

cope with worms in them. It's the same as with peas. The insects "sting" them—make black spots on the outside, which, if left long enough, hatch into worms. If you have a sturdy stomach you can use the wormy gooseberries. I set them on to cook in plenty of water. As the berries heat, the worms rise to the top and can be skimmed off.

➲ **GOOSEBERRY SAUCE** Stew $\frac{1}{2}$ lb. gooseberries in $\frac{1}{2}$ c. water until soft. Rub through a sieve. Return to pan. Add sweetening to taste and 1 T. butter if you are planning to serve it as a relish with roast goose, duck, or mutton.

➲ **GOOSEBERRY FOOL** Simmer green gooseberries, starting with cold water, until tender, adding a little salt (optional) to preserve the color. Strain and puree. Put the puree on the heat with sugar to taste and cook until sugar is dissolved. To serve, mix with cream.

➲ **GOOSEBERRY JAM** Cook $4\frac{1}{2}$ c. gooseberries in 2 T. water over medium low heat until yellow. Add 2 c. sugar. Bring to a boil again and boil 5 minutes. Pour in jars and seal. You'll get 2 pt. jam.

➲ **GOOSEBERRY PIE** Cook 3 c. fresh gooseberries just long enough so they pop. Add $1\frac{1}{2}$ c. sugar, $\frac{1}{2}$ t. ground nutmeg, and 4 T. flour. Pour onto a prepared unbaked piecrust. Put second crust on and seal well to keep from boiling over. Put slits on top. Brush top with cream and sprinkle sugar on it. Bake about 45 minutes at 425°F , or until it looks cooked. Good with plain cream.

HUCKLEBERRIES: These are cousins of the blueberry—a small, firm berry.

Canning. These can nicely. Use basic canned berry recipe. If you can huckleberries, make sure your jars are sealed and you wash the outsides because they tend to give off an odor that other foods pick up.

➲ **BASIC HUCKLEBERRY SAUCE** You'll need 1 c. huckleberries, $\frac{1}{4}$ c. sugar, 1 t. water, 2 T. light corn syrup, 2 T. berry juice, 1 T. cornstarch, and 2 t. lemon juice. Place berries in a pan. Add sugar, water, and corn syrup. Bring to a boil. Blend berry juice and cornstarch and add to berries, stirring constantly. Cook until thickened. Stir in lemon juice and remove from heat. Chill. Good for jelly roll, open-face pie, cooked pie shell, or topping for ice cream.

➲ **HUCKLEBERRY PIE** Make dough for a 2-crust pie. Boil, drain, and rinse 2 c. huckleberries, then cook again with a very little water until tender. Add sweetening to taste and 2 T. flour. Bake in a 425°F oven.

➲ **HUCKLEBERRY CAKE** Barbara Stone, Stites, ID, wrote me: "I don't care for huckleberries raw but in a cake is something else. Separate 3 eggs. Beat the whites until stiff and set aside. Beat the egg yolks and blend with $\frac{1}{4}$ cup milk. Blend in 1 cup sugar and $\frac{1}{2}$ cup butter or other shortening. Sift $1\frac{1}{2}$ cups flour with 1 teaspoon baking powder, $\frac{1}{4}$ t. nutmeg, $\frac{1}{2}$ t. cinnamon and add to egg yolk mixture. The batter will be unusually stiff. Put berries into flat dish and roll in flour. Up to this point an electric beater can be used, but now the berries are folded into the batter with a spoon. Then fold in the beaten egg whites. Bake in a greased and floured [8-inch square] pan. A loaf pan is better so the batter doesn't spread too thin. Sprinkle the entire top of the cake with a thin coating of sugar. This will form a glaze. No frosting is necessary. Bake in a moderate oven (350°F) until done. Depending on the oven it usually takes 50–60 minutes."

SALAL: This Pacific Coast native, *Gaultheria shallon*, is an evergreen shrub, 2–6 feet high, and can thrive in either sun or shade. It can grow from mid-California to British Columbia. It needs moist soil.

Planting. Plant seeds, cuttings, or divisions. You can get plants from Raintree Nursery, 391 Butts Rd, Morton, WA 98356.

Harvesting. Pick the small bluish-black berries in the fall when the whole cluster has finished ripening. You can substitute in any blueberry recipe or use to make a jelly.

⇒ **SALAL JELLY** You'll need 1 c. salal juice, 1 c. tart apple juice, and 1 c. sugar. (See "Jelly-Making" in [Chapter 7](#).)

SARVIS BERRIES OR SASKATOON BERRIES: Eaten fresh, these are bland and flavorless, but put them in pancakes. When the heat hits them, the flavor comes out. Or use them as a filler with other berries. Or add lots of grated orange and orange juice to add flavor.

STRAWBERRIES: Strawberries are the first fruit to arrive in spring and a much loved one. They do well in short-season areas, for they like cool nights and warm days. If you're interested in growing them for sale, you'll find much more info in "Strawberries: Organic Production" at www.attra.org/attra-pub/strawberry.html.

Varieties. Strawberries do best in cool, moist regions and in acid soil. But they can be grown in hot dry places with irrigation. Strawberries grown up north produce in the summer. The best quality berries are picked in the coolest months. Growers in the subtropics grow kinds that produce in short days. They plant in October, start picking by Christmas, and their harvest lasts through April. If you, as a home gardener, find it hard to get hold of a winter-bearer, grow them from seed from store berries. In the Tennessee area, you'd like Ozark Beauty, Cardinal, or Tennessee Beauty. Krohne Plant Farms is a mail order strawberry specialist: 269-424-5423; fax 269-424-3126; 65295 CR 342, Hartford, MI 49057; www.krohneplantfarms.com.

Planting. These plants want lots of moisture and a semi-shady location such as on the side of your house. They prefer slightly acid (pH 5.5–6.5) soil. The ground should be tilled 6 inches deep, but no deeper is needed. Make sure there's no lurking grass or persistent weeds. Mix a layer of about 2 inches of aged manure, compost, or peat into the soil where they'll go. Keep the food near the surface because their roots don't go down deep. If you have alkaline soil, plant the strawberries in almost pure potting soil or compost, and add heavy doses of iron. In Hawaii and states on the southern edge of the United States, plant strawberries in mid-fall. In northern states, plant in the spring. How many? Figure a yield of $\frac{1}{2}$ lb. strawberries per plant. Plant only healthy-looking plants. You might want them to be certified nematode and virus free. Costs a little more, but this is a long-term investment.

There are various ways to arrange the strawberry plants. For home gardens the best choices are a raised bed if you have very alkaline soil or a wide row if you have limited space, good soil, and a busy life. Commercial growers may prefer the spaced row system because it makes bigger berries, but it's a lot more work to maintain.

1. **Raised Bed:** If planted in raised beds, strawberries do best in sandy loam with compost or aged manure. Place them 12 inches apart, 6 inches from the edge of the bed.
2. **Wide Row (Matted Bed):** Set the mother plants out 18–36 inches apart in rows 36–54 inches apart. The transplants will make runners. Let them make all the runners they want within a width of about 24 inches. That 24 inches is your "wide row." The remaining 12–20 inches becomes your aisle between the wide rows from which you'll work to weed and harvest. Soon the mother plants will have established plants every 3

to 4 inches in the wide row. This planting system yields lots of berries. You don't ever have to replant. Every 6 years, you hoe out the original mother plants, add an inch of compost, and let the children live on and do their thing. Mowing all the plants at 3 inches can be done at the same time you hoe out the mothers. That process, called "rejuvenation," stimulates new growth.

3. Row: If you're going to use this system, buy a strawberry variety that doesn't grow many runners (because you have to pinch them all off!). Plant 10–12 inches apart with rows spaced about 12 inches apart. Make 2 or 3 rows that close together. Then make a wider aisle, 18 inches to 3 ft. across, for you to get in and water and weed. Cut off all runners. Only the original plants are allowed to survive.

About Runners. Strawberries reproduce by "runner." They begin to grow in June, creeping across the top of the ground. They stop about 1 ft. away from the parent plant, put down roots, and become a new, independent strawberry plant. If you cut the connection between plants, dig up the independent plant (with plenty of dirt around the roots to lessen the shock of transplanting), and replant it elsewhere in the garden, you're making a new strawberry bed.

About Blossoms. You will have strawberries about 30 days after the flowers appear. In warm weather, you may have them sooner. The plants will produce flowers (and therefore fruit) the first year. Compulsives pinch off all blossoms the first year in the belief that the plant will then develop a stronger root system and more foliage and make more and larger strawberries the next year. It's probably true. But homesteaders usually just let them do what they want and are happy to collect what fruit appears. Strawberry plants can endure hard frosts, but their flowers cannot. If they bloom, and then the temperature plunges, try covering or sprinkling to protect the blossoms.

General Care. Fertilize after you have finished picking the crop; use compost or aged manure. Don't fertilize in the spring because that holds back fruiting. Hoe and weed faithfully. Since strawberry roots are shallow, no more than 6–8 inches down, they can suffer when their soil dries. So irrigate faithfully by drip or sprinkler system if it doesn't rain. Mulch them when the temperatures get hot. Mulch them also when it gets very cold. Remove that winter protection in about March so the soil can warm up. Strawberries love mulch so much they got their name from the grower's practice of spreading some 4 inches of straw before hard frosts begin.

Replacement and Rotation. Gardeners generally let their strawberries fruit up to 4 to 5 years, then replace them. If you establish a small new bed every year by digging up and resetting some strong runners, you'll have a constant supply of new plants. Or plant a new bed a couple years before you're going to plow under the old one. Planting in a new place breaks disease, weed, and bug cycles. If you've been having disease problems, don't plant eggplants, peppers, potatoes, or tomatoes where you had the strawberries because they're afflicted with the same problems. Growing broccoli for two years plus tilling broccoli residue into the soil before planting strawberries can suppress 95 percent of the critters that cause the soil-borne disease verticillium wilt.

Harvest. As a strawberry ripens, its color changes from white to pink to red. The darker the color, the sweeter the berry. Because they are so perishable, pick strawberries often, at least every two or three days. For best-tasting berries, pick early in the morning. Leave a bit of stem attached to each berry to retard spoiling. If you see any rotting berries in the garden, remove them! Get berries into the fridge as soon after picking as possible, the cooler the better. At 32°F, they'll last up to 10 days.

Preserving. Imogene says, "Just let them boil up once, then pour into jars and seal." That's Imogene's way and she cans umpteen quarts every summer. To can strawberries the regular way, pack them hot, cover with hot juice, and process 15 minutes. I freeze them. Dried strawberries are delicious tasting, despite the fact that they turn very dark and look terrible.

➲ **STRAWBERRY JUICE** Use fully ripe berries. Wash in cold water Drain. Remove anything green. Crush and strain the juice through a jelly bag.

➲ **STRAWBERRY PUNCH** Mash 1 qt. strawberries. Add the juice of 1 lemon, 2 T. orange juice, and 6 c. water, and let the mixture stand 3 hours. Strain. Sweeten to taste. Serve with ice.

➲ **STRAWBERRY-PINEAPPLE JUICE** Combine 2 c. strawberry juice, 1 c. pineapple juice, 4 c. water, $\frac{1}{2}$ c. lemon juice, and $\frac{1}{3}$ c. honey. Mix well and serve with ice.

➲ **OVERNIGHT STRAWBERRY PRESERVES** Wash and hull firm, choice berries. Combine 2 c. sugar with 1 c. water and boil until you can spin a thread when you hold a spoon up that has been dipped into the liquid. Now gently add 4 c. strawberries, $\frac{1}{4}$ c. lemon juice, and 2 c. more sugar. Boil 12 minutes without stirring. If you get a scum, skim it off. Pour the mixture out into a shallow pan and let set 24 hours. Put into jars cold and seal with paraffin. The berries keep their shape and color.

➲ **MODERN PRESERVES** Prepare 4 half pint jars. Heat 1 c. of your juice to boiling. Then pour it over $\frac{1}{4}$ c. fresh herb (or $1\frac{1}{2}$ T. dried herb) or 2 T. whole spice. Let soak for half hour. Strain it into a nonaluminum pan. Add 2 c. more of juice, 2 T. vinegar, and 3 c. sugar, mix, and boil (stirring constantly). Now mix in $\frac{1}{2}$ bottle pectin, and boil another minute, still stirring. Remove from heat, and stir in food coloring at this point if you want it. Pour immediately into sterilized jelly glasses. Adjust lids. Process 5 minutes.

➲ **OLD-TIME PRESERVES** Prepare jars to hold 10 cups. Coarsely chop 6 lb. tart apples, put into nonaluminum pan, add just enough water to cover, and cook a half an hour, or to softness. Then pour into jelly bag over bowl and let it drain overnight. Next day, measure the juice. Per $2\frac{1}{2}$ c. juice, add 2 c. sugar. Stir sugar into solution over low heat. Add herbs or spices, or a mixture of them, tied into a porous bag, and simmer until jelling point is reached. Remove bag and pour into jars.

⇒ **STRAWBERRY SHERBET** Soften 1 envelope unfavored gelatin in 1 c. orange juice in a small pan. Combine 1 qt. washed, hulled, and crushed strawberries with ½ c. sugar, and then stir in gelatin-orange-juice mixture. Pour into your freezer tray. Freeze, stirring once or twice, until almost firm. Remove to chilled bowl, break up with a fork and then beat until smooth but not melted. Fold in 2 stiffly beaten egg whites, blend, and return to refrigerator. Freeze, stirring once in a while with a fork, until firm.

SYMPHORICARPOS: These hardy shrubs of the honeysuckle family are from China. The tasty fruits are usually paired or clustered berries. They do well in any soil, in part shade, and in urban areas. The best known are the snowberry (*S. albus*), and the Indian currant, or coralberry (*S. orbiculatus*).

WOOD HEAT

Managing an Existing Stand of Trees

If you are starting your forest or orchard management career with an existing stand of trees, the first thing to do is to get acquainted with them. What kind are they? What are their uses? You may choose to leave them exactly as is. Or, to do some tree weeding, taking out some in order to replace them with more needed ones, yet retaining a mixture of trees for many different purposes and products. Or you may want to take the existing trees out and start over, specializing and growing a plantation of all the same kind of tree. When you are planting a tree crop, you're usually planting for a maturity date or a market year one or more decades away, so think long-term.

Horse logging does the least environmental damage to big tracts. Read *Work Horse Tales: Adventures in the Forests of Appalachia* by Anita G. Mannon for glimpses of the life-style of folks working with draft horse partners in the forests of the Blue Ridge Mountains today: 888-795-4274; International Plaza II, Ste. 340, Philadelphia, PA 19113-1513; www.xlibris.com/bookstore.

Reforestation

You don't have to prepare the soil by cultivation to plant forest-type trees. If trees are planted 5 feet apart (right for a 6-foot-high tree), you can grow 1,000–1,300 per acre. Each tree needs sunlight to live, so plant in the open spots. Two people can plant a huge number of trees in just a single long, hard-working day, using no more equipment than a spade. (There is such a thing, however, as a mechanical tree planter.) But don't expect all of them to survive; a percentage won't make it and will need to be replaced (maybe up to 30 percent, but probably much less).

MULCH COLLARS: You can raise the survival rate dramatically (up to 90 percent) by installing a heavy cardboard circle (available from printing-press shops) at least 36 inches in diameter, with a center cut out plenty wide for the tree, around the tree base. Or make a mulch out of newspaper or weed-block mats. But the heavy cardboard circles do the best job of protecting seedlings from competition from weeds and brush. Just make sure that what you install isn't in a position to girdle the tree (cut a seedling hole in the middle), is of a material that will eventually decompose (cardboard or paper), and has a system to let water through (cut slots for that). The mulch mat must be anchored using wood slash or rocks heavy enough to keep it from blowing off or slipping over on top of the baby tree. If

the mulch protection lasts 3 years, by the fourth the tree is usually far enough developed to survive no matter what. Shaded lower branches may wither, die, and eventually fall off. That's okay. Actually, a long "clean" trunk is desirable for lumber.

WOODLOT GROWING INFORMATION: To grow enough wood to stay even with the appetite of a wood-burning stove is a grand achievement in itself. For more help, read *The Earth Manual* by Malcolm Margolin, an inspiring book about how to work with wild land without taming it. It covers tree-felling, tree-doctoring (why not to), erosion control, seed collecting and planting, pruning, etc. You can order the pamphlets "Woodlot Management" and "Fast-Growing Firewood" from Storey's, 800-441-5700; www.storey.com. *Working with Your Woodlot* by Mollie Beattie, Lynn Levine, and Charles Thompson covers hardwood forests in the northern United States and mountainous South. Read about Merve Wilkinson's long-term woodlot management philosophy in *Wildwood: A Forest for the Future*.

GROWING CHRISTMAS TREES OR TIMBER EVERGREENS: If you don't need pasture and your land is on the poor side but still gets enough rainfall or can be irrigated for evergreens, a market option is to plant Christmas trees. They'll grow on cool, north-facing hillsides that fruit trees might not do so well on. They'll be harvested while still reasonably small so no big equipment is necessary. And your investment can be quite reasonable. Plan to space your Christmas trees an average 5 feet apart for a 6–7-foot harvest size. (If you will harvest smaller, plant closer.) To make more efficient use of your space, plant small trees between each pair of large trees 2 years before harvest time for the big ones.

GATHERING TREE SEED: You can gather cones, dry them, shake the seeds out, freeze them for conditioning, plant in seedling pots, then transplant them when they're bigger. Or you can plant seedlings ...

COLLECTING SEEDLINGS: You could collect these from forests (but don't steal). Gather in early spring when they are 5–15 inches high. Dig or pull out (only when the ground is very moist), being careful to preserve their root system. Bundle, transport, and replant in your field. It's best if you can pull and replant them in the same day. You may want to save space and grow them for a couple years in a nursery bed before setting them out in the field.

NURSERY SEEDLINGS: Or you can buy seedling trees from a nursery. Buy locally if possible, or from a nursery in your same climate zone. Trees grown in a warmer climate than yours will tend to start growing in the spring by their old calendar rather than your new one and possibly be killed by frosts. To buy seedlings, learn what kind of trees are available, how much they cost, and how many years they've grown in the seed bed and then in the transplant bed. Some states have tree nurseries and sell seedlings reasonably from them. (A state extension agent can inform you on this.) Here are nurseries that specialize in woodsy seedling trees:

Carino Nurseries specializes in seedling Christmas trees and other evergreens: 800-223-7075; fax 724-463-3350; Box 538, Indiana, PA 15701; www.carinonurseries.com.

Musser Forests: 800-643-8319; fax 724-465-9893; PO Box 340, Indiana, PA 15701-0340; www.musserforests.com.

Pikes Peak Nurseries: 800-787-6730; R.D. 1, Box 75, Penn Run, PA 15765;

Why they're all in Pennsylvania is a mystery to me.

Harvesting Wood

Foresters harvest trees for their wood before they become over-mature or die. Plain folks find good uses for dead wood in the stove. Either way, every block of wood represents a concentration of sunlight's energy ready to be released by fire.

February is an awful time to be out scouting for wood. The wood is best gotten during the fine dry days of midsummer and early fall. Old-timers say that if you fell the tree while the sap is still in the leaves, the trunk will be dryer and easier to cut.

Finding Your Wood. Any tree is owned by somebody—a rancher, a homesteader, a corporation, or a government agency and, by extension, the public. Anywhere outside your own property, you need permission before you cut firewood. The U.S. Forest Service and the Bureau of Land Management look after a lot of the public woods and will, in many areas, readily grant you a permit to cut 10 cords or so, if you give them \$10. You can get your permit at any Forest Service District Office or at any B.L.M. office. Some states (e.g., Montana) will give you a free permit to cut firewood on land managed by them. Be sure you know exactly where the state-owned trees are before cutting it. To cut wood on privately owned land, ask permission first. Owners can become very angry, and justifiably so, if you enter and cut without permission. That's trespassing and theft. If you can't find the owner, leave the wood alone. Large corporate landowners often offer paid permits available at the corporations' offices. There will be a strict set of guidelines you must follow when cutting their wood. On the other hand, be cautious of timber-buying offers. Many landowners have been misled. So often their trees are gone, their land is uglified, and they didn't get the money they expected.

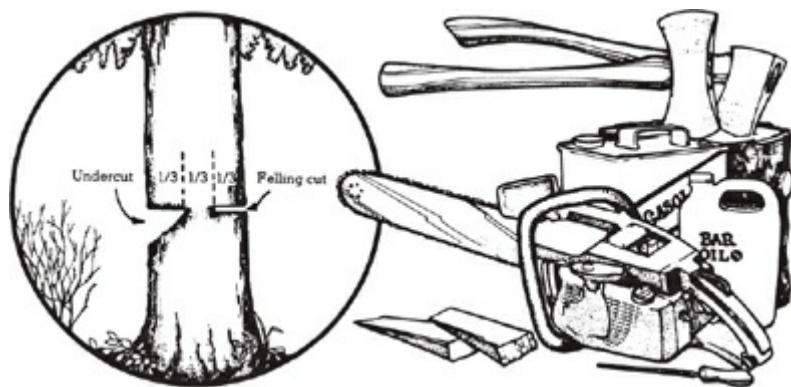

Choosing the Tree. Every variety of tree is different. They look different and are of differing hardness, burning style, sawing and splitting quality, even aroma in the forest and in the fire. Softwoods, such as pine and cedar, have a coarse fiber that burns quickly. They make good kindling. Pine is very pitchy. You can tell a pitchy wood in the fire because it does a lot of noisy popping. For a long-term steady fire, especially for oven-baking, hardwood (or coal) are nicest. It really depends on what trees are available to you. Some woods provide you with beech, yellow-birch, maple, and black-cherry, and those all make fine wood, too. Another consideration might be ease of sawing if you're working by handsaw rather than chain saw. Balsam is especially hard to handsaw. Yellow birch takes less effort to saw than maple. Or consider ease of splitting; maple splits cleaner than the birch. Or whether it will burn green or has to be well dried; yellow birch will burn green.

Take a walk with somebody who knows trees during the spring, summer, or fall. Trees are most easily identified by their leaves and fruit. Or use a tree identification book: *Trees of Eastern and Central United States and Canada*, or *Manual of the Trees of North America* (both volumes), or *Guide to Southern Trees, Forest Trees of the Western Slopes*, or the *Audubon Society Field Guide to North American Trees* by Elbert L. Little.

Tree felling is dangerous if you aren't experienced, so proceed cautiously. First find the one you want. Standing dead tamarack, red fir, or black pine are the best in this part of the country. White and yellow pine are fairly good. Cedar's good for a hot quick fire to set off harder woods but it doesn't last. Bull pine, white fir, or any spruce are not very good firewood but will do if you can't find anything else. It's ideal to find a snag (dead tree)

that still has bark and branches on it. The bark and branches show that it hasn't been dead too long and hasn't had time to rot. Or a blow-down with bark and branches will be all right if it's not too wet. Use green wood (live wood) only if you have cut it and let it season at least 6 months to dry out well.

Chain Saws. To cut down a tree it's most convenient to use a chain saw. You can do it with an ax, but if your tree is big enough to bother cutting down at all that's a pretty big struggle. A 12-inch chain saw is cheaper, lighter, and easier to handle than a 16-inch one, but it won't cut as big a tree. In general, a chain saw can handle a tree with a diameter almost twice the length of its blade, though if you really know what you're doing you can stretch that. You've got to oil it all the time you're sawing by a squirt attachment. You get a round file that is the same size as the teeth on your saw and file them sharp between sawings. The rakers on the chain also have to be filed down regularly. Different wood conditions require different heights for the rakers. Sawing frozen wood is different, too.

You need a manual or somebody who knows what he's doing to help you get started with a chain saw. Hang on to your chain-saw warranty. They break down a lot, especially the cheaper brands. The big ones are used by sawyers who are felling trees on a professional scale. The chain saw runs by a gasoline motor. Once in a while you can get a new one on sale for as low as \$125. The lighter saws are cheaper and won't wear you out near as fast. For more information, see *Chainsaw Savvy* by Neil Soderstrom, which covers cutting, sharpening, and repairing a chain saw. Great on safety, cutting form, kickback protection, safest refueling, felling, limbing, bucking, and moving logs. Also read *The Good Woodcutter's Guide*, by Johnson, which covers chain saws, portable sawmills, and woodlots (Chelsea Green). Log splitters, chain saws, heaters, and more are available from Northern Tool & Equipment Co.: 800-221-0516; fax 952-894-1020; PO Box 1219, 2800 Southcross Dr., Burnsville, MN 55337; www.northerntool.com. A portable sawmill can cut a tree into 2×4 s or 4×6 s. Cost is about \$12,000. I know four families who each put in \$3,000 to buy one and soon earned their money back.

Cutting Down the Tree. A personal safety guideline for you to hold is to never go into the woods to fell trees alone, no matter how good you are. People get killed that way, or they get hurt and have nobody to help them. If you've never cut firewood before, the best way to learn how is to go out together with somebody who has done it a lot.

Decide which way you want the tree to fall. You'll have to take into consideration which way it's leaning already. I don't know any way to make a tree fall uphill from a decided lean. If possible, you want to knock it down toward the road so you won't have to haul the pieces so far. Try not to fell it uphill because it might bounce back downhill when it hits and hurt somebody. Cut a wedge from the side of the tree where you want it to fall, sawing up toward the center of the tree from the ground angle and down toward the

center of the tree from the sky direction. The V-shaped cut should have its point one-third of the way into the tree. That's important. The wedge should be about a 30° angle. Remove the wedge of wood.

Now saw from the opposite side of the tree with your cut on a line to meet the point of the "V." Go slowly the last few inches and when things start to creak and clatter get the heck out of there. The tree should be starting to topple over toward the "V."

You'll be about one-third of the way in from the other side when it starts to go. On trees over a couple feet in diameter you should use a wedge. Hammer the wedge in after you get the cut deep enough to take it. As you saw deeper, hammer the wedge in deeper. When you get one-third of the way in, take the saw out and keep hammering the wedge in until the tree falls. Usually the fellows here use a regular "felling" plastic wedge. You can buy them at a saw shop.

Bucking. Once the tree is on the ground you can finish wherever you want to. First you take off the limbs—"limb" it. Sawing it up into chopping-size segments is the next step, and that's called "bucking." If you have a big logging truck you can load the whole log up and take it home, or you can saw it up on the spot and take chunks home. Know how long a piece your stove takes (a little shorter than the length of the firebox). That's how long your segments should be. You can buck with a roaring chain saw and it'll be done in a jiff. Or you can do it with an old-time 2-man crosscut saw together with a friend, spend a little more time, and have a pleasant conversation while you work. The rhythm of working with a 2-man crosscut saw is something you learn with experience. After the bucking, folks usually leave the chunks in a big heap to dry some more before chopping.

Chopping. Before the wood is stove-ready, the segments have to be split with an ax—double-bladed or single. Save a couple of blocks of really good hard wood with wide diameter to be chopping blocks. They're indispensable for woodmaking and for slaughtering poultry, too, if you do it the old-time way. Maybe taking such an interest in ax technique is unwomanly; I don't have to chop wood now much, thank heavens—there's plenty else. But I was the only kid at home all my adolescence, and I chopped it aplenty for my mother (as well as hauled water by the bucketful up the creek bank to keep the porch tank full).

Chopping Safety. Strive for accuracy before you strive for force—at least enough so that you don't hit your foot. Then, once you're sure you can put the blade onto the wood, you want to give it all the power you can. Use a good big ax, a heavy one, because you can get a lot more force with it. *Wear heavy boots in case you miss.* Chips can fly up into an eye or the ax blade can hit a knot and be deflected, so *don't let children, or anybody, stand near when you're chopping.* My little boy got an ax blade in his forehead when he got too close behind another boy who was chopping. No harm remains than a little scar, but it's a lesson. If you want to be really safe, wear goggles, a hard hat, and steel-toed boots!

Chopping Technique. Everybody's got his or her own way of chopping. A friend of ours only lifts the ax to shoulder height, then brings it down with a big grunt and the wood splits. Another friend raises it straight over his head. Mike holds the ax strong in his left hand, loose in his right hand, and then brings it down kind of pulling with the left hand and pushing with the right hand. The best stroke for me uses both hands on the ax—as if you were holding a baseball bat, only farther apart. To do it my way, if you're right-handed, start the ax out back of your right shoulder behind your head with your back arched backwards just a trifle (or you can alternate shoulders with every swing) and then bring it forward and down, moving your shoulder and chest forward at the same time.

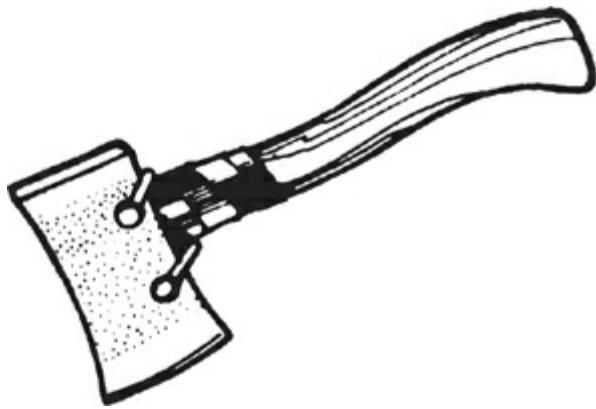

Try to hit your block of wood right in the center. Mike says you don't want the ax absolutely perpendicular to the stump when it strikes. I aim to get it square on. If your wood doesn't split from the center you can try taking slabs off the edge awhile before you tackle the heart. If you can get your ax into the tree but not out the other side, pull it out and try again. Look for a natural crack to strike into. There usually is one in old wood. If you're still finding it hard, use wedges and a wood-splitting maul or sledgehammer instead of the ax.

Knots. A "knot" is where a branch grew out of the trunk. That branch extends like a holding pin all the way through the trunk to the center. It prevents the trunk from splitting naturally. With tamarack or red fir you won't have too much trouble with knots. With cedar they're impossible. Split away from the knot and just throw the knot away unless it's small enough to burn by itself. But big cedar knots are too huge for anything but a bonfire. Cedar blocks make dandy furniture though, so if you see a knot in the block you could just reserve it for a stool or something.

Kindling. Some of the wood has to be split and re-split into very slender sticks called "kindling" for starting fires. You need really dry wood for kindling. Wood on the green side burns okay in a big fire, but it makes terrible kindling because it is so damp. To make kindling out of it you have to split it into small kindling-size sticks and then dry them out some place like in your warming ovens—and then it will work to start a fire.

Kindling is made with a hatchet because those little sticks won't stand up by themselves. You have to hold them up with your left hand and chop up with your right hand using the short-handled hatchet. The thing with using a hatchet is not to cut your fingers off. Either learn unbelievably good aim or learn to let go just before the hatchet blade strikes, so the fingers are out of harm's way. I keep the hatchet back of the wood range, hanging on the wall by its neck—a nail on each side, high out of reach of the children. That's where the other woodstove implements are kept too.

WOOD STORAGE: Cut and store under shelter inside a shed or at least under a tarp. If you have 2 buildings close together you can roof over the gap with tin sheets or something cheap, put a back on it, and have a very adequate woodshed. Or you can have an open woodpile for the blocks outside somewhere and a large area for drying and storing wood on your porch. I carried wood to our porch from my chopping station in the yard by the woodpile. But we lived in a relatively dry climate. A wet one would need covered outside storage too.

My father always insisted on a very neatly arranged stack of wood inside our front porch. The wood supply on my parents' porch was enough to last about 10 days and was arranged by graduated sizes with the real small kindling on the left end and the wood pieces getting bigger as it moved to the right. That way my mother could easily find whatever size sticks she wanted. Now my husband and I have a similar system: a pile of tree chunks outside by the chopping block, a porch storage area for chopped wood, and a kitchen wood box near the stove. It has to be filled once a day in cold weather. It's $2\frac{1}{2}$ feet wide, 4 feet long, 3 feet high, and bottomless so I can pick it up and sweep up the sawdust come spring. I toss all the paper-type garbage in it in wintertime for starting fires.

The Technology of Wood Piling. Split your wood before stacking; this increases the exposed surface area and reduces drying time. Stacking the wood in alternate directions row by row further helps the drying process. Protect your wood supply from rain and snow by keeping it in a woodshed if possible. That's better than stacking it against the side of the house or under trees in the yard. If you must store wood on the ground, stack at least 6 inches off the ground to protect the lower part of the woodpile from ground moisture. Simply lay 3 parallel poles under the pile and then set the wood on top of them.

A Cord of Wood. A standard cord of seasoned (air-dried) dense hardwood weighs about 2 tons. It yields about the same amount of heat as 24,000 cu. ft. of natural gas, 175 gal. of No. 2 fuel oil, 1 ton of coal, or 5,000 kilowatt-hours of electricity. To heat a small dwelling for a moderate winter, 2 cords of wood in a modern stove will be plenty.

A cord of wood measures $4 \times 4 \times 8$ ft (128 cu. ft). A cord of a good kind of hardwood (apple, American beech, rock elm, bitternut hickory, shagbark hickory, ironwood, black locust, white oak, white ash, yellow birch, sugar maple, red oak), seasoned, equals a ton of anthracite coal in heating power. The cord of wood will leave 60 lb. of ashes. (The ton of coal would have left 200–300 lb. of ashes.) A cord of the poorest woods will still yield the same heat as a little more than a half ton of anthracite coal. It takes 5–8 cords a year to heat a house, depending on how efficient your stove is, how cold your climate is, and how well insulated and large your house is. The weight per cubic ft. (lb./cu. ft.) of firewood depends on the variety of the tree and its moisture content. As the density, or the moisture content, of the wood increases, so does its weight per cord. The heat-producing

capacity of the wood is directly proportionate to its weight if that weight is wood density rather than moisture.

Tava Bonnell, Newman Lake, WA, wrote: "As for measuring wood, a true cord of wood, packed as tightly as possible so that there are minimal air spaces between the pieces, is 128 cu. ft. It's generally measured as $4 \times 4 \times 8$ ft, but it can be any shape that totals 128 cu. ft. Don't confuse this with a 'face cord,' pawned off by a lot of wood sellers on unsuspecting folks every winter." A face cord measures 4 ft high \times 8 ft. long, but can be just about any width.

SHARPENING HAND TOOLS: It takes practice to master tool-sharpening. Find someone in your area who regularly sharpens tools and watch how it is done. No edge remains sharp after being used. The edge dulls as the metal wears. The sharper the edge to start, the more quickly it wears and the more often you'll have to sharpen if you want to keep such a sharp edge. Corrosion caused by rust or fruit juices also dulls blades. If you cut something acidic (even with stainless steel), it helps preserve your blade's sharpness to wipe the knife dry afterwards.

COAL: Bituminous coal doesn't make as hot a fire as anthracite, and it's dirtier and smokier. If you are using coal, it has to be stored where it won't get wet. Coal requires more shelter than wood. To bring the coal to the stove from its storage place in your woodshed, or a corner of the garage or cellar, the coal scuttle (a strong bucket with a wide pouring spout on the end and a bale handle, about as big as what a person can stand to carry) is traditional. Any bucket will do, though. You usually need only a bucket at a time in the kitchen if you're mostly using wood. The coal is to get a hotter fire than wood will give you and a longer-lasting one; you put in the coal the last thing before going to bed. Tamarack holds a fire about as well, though.

Burning Wood

Burning wood seems easy and natural to me. But I live in a timber-producing area, have timber here on the farm, and a sawmill and wood products plant both just down the road. Correspondents tell me that in the East, wood is very scarce and very high-priced, that wood stoves are hard to come by, and that insurance companies won't insure a home that is heated with wood. Anyway, if you haven't got dead trees around then a wood cookstove isn't necessarily right for you.

You want the wood just dry enough at burning time. It takes 6 months to a year to dry wood for burning. So spring-cut wood could be burned the next winter. Freshly cut (green) wood is about 50 percent water. It's heavy and burns "cold" (because of all the energy it takes to evaporate that water). It also deposits a lot of flammable creosote in the chimney. Even well-dried wood is still 12–20 percent water. That's just right for burning. It's still damp enough to be a calm and manageable fire. If the water content is under 10 percent, you have "tinder-dry" wood. This makes great kindling because it burns fast and hot. To burn tinder-dry wood you may have to damp down the airflow regulators to reduce the oxygen supply to keep from overheating the stove, or your home, and that lack of oxygen for the fire also tends to deposit creosote.

WOOD HEAT REFERENCES: I have been urged to position the references at the very end of the topic. I know that's how other people do it, but I prefer to put them right after my introduction to a subject. That's because I believe the references are potentially more

important to you than what I have to say. They're written by specialists in the field who have spent years experimenting and gathering information on just a single topic. By putting them up front I'm urging you to start with them and maybe even skip what I have to say, or heavily supplement my material.

When it comes to using chain saws, felling trees, and installing a stove, you need more expert and in-depth advice than mine! Get *The Wood Burning Stove*, by Geri Harrington. Older classics on this subject are *Solid-Fuel Furnaces and Boilers* by John W. Bartok; and *The Wood Stove Handbook* by Wilburn W. Newcomb (1978). *Solid Fuels Encyclopedia* by Jay Shelton is encyclopedic on this subject. *Mother Earth News* often ran articles on wood heat (Sept./Oct. 1982; Sept./Oct. 1985). Storey's has 32-pg pamphlets (\$3.95) on these subjects: "Curing Smoky Fireplaces," "Buying & Installing a Wood Stove," "Build Attractive Hearths," "Catalytic Combustors for Your Woodstove," and "Chimney & Stove Cleaning." The cutting edge of research these days is into clean combustion and efficient woodlot management.

THE ECONOMICS OF WOOD HEATING: If you are considering switching to wood heat, calculate your total fuel bill for last year and then figure your bill for next year. If you install a wood stove, how much of your previous fuel do you still expect to use, either for supplemental heat or for uses other than space heating (water heating, cooking)? What do you expect to pay per cord of wood? If you don't know, look in the classified section of the local newspaper. Multiply the price per cord by the number of cords you will need per year. A cord of dried softwood such as pine, larch, or Douglas fir provides about the same amount of heat as 19.3 thousand cubic feet of natural gas, or 5,276 kilowatt hours of electricity. So, if you now heat with gas, divide the number of MCF of natural gas by 19.3 to estimate equivalent cords of wood. If you heat with electricity, divide kwh by 5,276 to estimate equivalent cords of wood.

I've seen numbers suggesting that you might save only, for example, \$75 per year by switching from gas to wood if you got your wood for \$50 a cord. However, if you are switching from electric heat to wood, your savings might be \$700 or more a year. If you cut the wood yourself, you could save more money. But there would still be expenses involved. Is it your wood? And how far do you have to drive to get to it? On average, you'll spend \$12.50 a cord on gasoline for cutting and hauling, plus the wear and tear on your truck and chain saw and you. And don't forget the cost of your wood stove and its installation, and the chimney, and the chimney-cleaning. Some states offer state tax credits for switching to wood, but only if you buy a clean-burning stove that meets their standards.

BUYING FIREWOOD: Sometimes firewood is sold by the ton rather than by the cord. A ton of seasoned (about 20 percent moisture content) hardwood (maple, hickory, oak, etc.) equals about $\frac{1}{2}$ cord. When buying wood by weight rather than volume, choose the driest wood so you aren't paying for water. Learn to recognize dry wood by sight and sound. If there are cracks in the wood, it's dry. If it gives a high-pitched ring from a thump, it's dry (wet wood gives a low-pitched thudding sound).

Wood density also matters. A cord of oak weighs a lot more than a cord of aspen (and holds a fire longer). Firewood is sold in various lengths and thicknesses. A mixture of wood species and diameter sizes will be helpful. Small pockets of rotten wood are not a problem. Choose a size that will fit into your fireplace or stove with about 4 inches to spare. Wood whose diameter is over 8 inches will need to be split. Wood that is too long for your firebox will need to be sawed in half.

Tava says, "Generally, you can't fit a full cord of wood on a half-ton pickup truck. I know that our half-ton, '63 Ford pickup with an 8-foot bed, which has those heavy-duty, leaf-spring overloads as well as shocks, can safely only haul a half cord, or maybe a little more (of pine or fir usually) at a time. Much more would be so heavy that the front end would be light (it actually starts to lift off the ground) and your steering can be compromised."

OF WOOD BURNING AND AIR POLLUTION: This is a problem with wood stoves, both for the individual homeowner and for the environment in general. Wood stoves make a considerable contribution to an area's smog if there are lots of them in a small area. Air inversions and still air can keep that pollution hovering right over you. Or your next door neighbor, an elderly asthmatic, may literally be dying from your burning. So, if you want to burn wood, be considerate of others. And if you're in an area with regulations, obey the laws. Oregon regulations began in July 1986 and national standards patterned after Oregon's went into effect in July 1988. The stoves that I've described down below wouldn't pass the emission laws in Oregon.

FIRE PREVENTION: How would you cool your fire quickly if a pipe or your box gets red hot and you become worried about a fire? In an emergency you could just pour water on it. On the other hand, that could cause cracking of the stove parts! During the winter months chimney fires in the northern Idaho community of Coeur d'Alene averaged 1 a day between November 1 and January 1. In Coeur d'Alene about half of the homeowners heat with wood. Fires from wood heat devices make up almost 60 percent of the residential fires in the nation. You have to install these devices, use them, and maintain them correctly. Many fire departments will make a courtesy inspection of your wood heater.

Wood Stove Safety Products. You might also want to buy a special chimney fire extinguisher and keep it handy. And any wood-heated home needs a smoke detector. The smoke detector will warn you if your stove develops a back draft during the night or if there's a fire out of control. Installing and operating a wood stove in a mobile home requires special vigilance. Other things that can put out a fire are salt, sand, baking soda, a heavy blanket (to smother the fire), diatomaceous earth, and water. A new biodegradable fire-fighting product called Flamestop comes in a spray can. You can order numerous products that assist in woodstove safety from Lehman's Hardware (888-438-5346; www.lehmans.com), such as Soot Destroyer, a stove and stovepipe thermometer, and a chimney fire extinguisher.

Creosote. The primary danger is creosote, a waste product that collects on the surfaces of the stove and pipes. Anything over $\frac{1}{4}$ -inch thick of creosote build-up is dangerous. Creosote burns at about 2,300°F, hot enough to melt stainless steel. If you simply knock the creosote off the smoke shelf and down into the chimney, you can ruin your catalytic converter. A common problem is buying a stove that's too large for your house size, then letting the fire burn low inside it to save money. One last log smoldering is what makes the chimney thick with creosote. A good way to clean up is once or twice a day, when you first build your fire, let it free burn freely and cook for a few minutes. The intense heat will clean out the pipes. You can also slow down the build-up of creosote by burning only well-seasoned wood, being sure your fire has an adequate supply of oxygen, inspecting your flue often, and cleaning your chimney at least once a year. If you do this yourself, you need a metal brush with a long extension rod, designed for the job. Your stove-dealer can provide these.

Chimney Fires

NOTE: Read this if you see a cherry-red stovepipe and hear the roar of a chimney fire! Shut off the air supply to the stove and get everyone out of the house. Call the fire department. Then use your hose to cool the roof but don't spray water directly into the chimney. That could result in even more damage, by causing the overheated flue to contract too quickly. Once the fire is out, have the chimney thoroughly cleaned and closely inspected before using it again.

Wood-Stove SHOPPING: When I first started writing this book, there were no such things as stores specializing in wood stoves. And stove design was traditional and hadn't evolved for a hundred years. Then there was a burst of attention to woodstove technology coming from alternative energy scientists, and now wonderful stores are scattered all over the areas where wood is convenient to burn, selling these much improved stoves. The new stoves are cleaner, safer, more efficient, and bewildering in number—some 450 different models to choose from. So many of the modern wood stoves are amazingly high-tech. Some are computerized, many are the result of thousands—tens of thousands—of dollars spent on research and development. They're more efficient: efficient at combustion and efficient at heat transfer capability. You need both kinds of efficiency.

So check in your yellow pages to find stores that specialize in wood-burning stoves and related products. A door/stovepipe/legs kit for a barrel stove is available from Lehman's (888-438-5346) for \$59 or \$79, and from some hardware stores.

The next cheapest wood stove is a small "outdoor" or "camping" type. It can heat one room. The largest size can heat a house. They usually have flat tops you can cook on. A Chinese import in this category is the Boxwood Heater/Stove, \$170: 800-423-2567; international 805-388-3000; toll-free 800-444-3353 or 800-237-4444; www.harborfreight.com. Cabela's, a camping mailorder outlet, offers one brand of this stove type, made in Utah, for \$150 to \$639 (depending on size); free catalog: 800-237-4444; One Cabela Dr., Sidney, NE 69160; www.cabelas.com.

For nicer stoves, prices go up ... to \$4,000 and anything in between. How about an outdoor wood furnace? Central Boiler Classic is installed away from your home. It has thermostatically controlled heat to a possible several buildings. A water jacket surrounds the furnace firebox, and heated water is pumped to the buildings through insulated underground pipes: 800-248-4681; www.centralboiler.com.

A mailorder wood heat specialist is Vermont Castings: 800-668-5323; fax 877-565-2929; 410 Admiral Blvd., Mississauga, Ontario L5T 2N6 CANADA; www.vermontcastings.com. Or check out Energy House, 3902 S. Main, Salt Lake City, UT 84107; 801-261-3210; 877-440-6481; www.transoceanltd.com. You can find a local dealer for the Norwegian manufactured wood stove, Jotul, at their website: www.jotulflame.com. These specialists routinely carry woodstove accessories, books, and pamphlets, as well as stoves. And they'll give you good advice on what to buy. You need guidance in your woodstove shopping now because the Environmental Protection Agency has adopted regulations that strictly limit emissions from all wood stoves. Your stove dealer is probably certified by the Hearth Education Association and has worked hard to become knowledgeable on this subject.

Fireplace? A fireplace fire can make you warm if you're sitting within 6 feet or so of the radiated heat, but it's not an efficient way to heat the entire room. A fireplace can be modified with fireplace screens and tubular grates or fireplace inserts or stove-like inserts to improve its efficiency.

Stove Material Choices. You'll buy a stove made of cast iron, plate steel, or sheet metal

(or even soapstone or porcelain). In general, the thicker the metal, the more it costs, but the longer the stove will last. Plate steel and cast iron are about equal in their heat retention ability and cost about the same. A sheet metal stove is cheaper, but will burn out faster and need to be replaced sooner than a heavier one. A sheet metal stove with reinforcement from firebrick or metal plates in the firebox will last longer than one without.

Stove Designs. Radiant stoves have a single-walled firebox. These stoves heat by simply radiating the heat out into the room. A convection stove has a firebox to contain the fire and another metal layer surrounding the firebox, with an air space in between. This stove heats by circulating the air from this space, thus heating the room with warm air. There may be an electric fan to circulate the heat away from the stove. You can position a circulating stove at about half the distance from combustible materials as that required for the radiants.

Some think that wood-pellet stoves are the wave of the future as wood gets scarcer and more expensive and air-quality regulations on emissions of wood-burning stoves increase. Pellets burn cleaner, and there are special stoves designed for them such as Welenco. A ton of pellets costs about \$125 and will last 6–8 weeks of average winter weather. Pellets are made not only from wood, but also from corn, walnut, and almond shells.

Catalytic Combustor. This isn't a wood stove but is used to increase the overall efficiency (it can help up to 20 percent) of almost any wood stove it's attached to. But the combustor is a rather fragile item and not cheap. Also you'll have to be careful not to burn anything but wood in your stove, since the lead found in nails and in the newsprint on magazines and newspapers can destroy the converter.

You are likely to need professional help installing one of these sophisticated stoves.

Wood Stoves and Air Pollution: Anytime you burn something, you're putting more carbon dioxide into the atmosphere, exacerbating the Greenhouse Effect. Wood fires also produce dozens of different gases, particles, and other airborne odds and ends, many of which, if inhaled too much, are even carcinogenic. Cigarette smoke and wood smoke are identical in many ways. The wood-smoke particles are small enough to get deep into your lungs and accumulate there, aggravating asthma and bronchitis, making you cough, or giving you a sore throat, runny nose, or headache. A hot, clean fire produces some pollution; every wood stove—even the airtights—let some pollutants escape into your house. If you have a chronic heart or lung problem of any sort, wood-heating can be a health problem. From that point of view, solar, geothermal, wind, and hydroelectric are the winners of the clean-energy-source contest. Ah, if only more of us individual homeowners could be users of them—and not of environmentally damaging energy sources.

Of Wood Cookstoves

I remember the wood stove we had when I was a little girl. It was our only heat and a much-appreciated presence on winter days. Mother raised bread behind the stovepipe. The spring chickens first lived in a box on the floor back of the stove before they graduated to the bathtub. Hot water came from a tank attached to the right-hand side of it with a circulating pipe rigged up to pass near the firebox. I started out cold mornings sitting on top of the stove. As it got warmer I scooched away from the firebox. Then I leaned on the stove. When it got hot enough so I couldn't lean on it anymore I was thawed out enough to function anyway. I never could understand how my mother

managed to get up in that icy house leaving my father and me in our warm beds and make the fire. Now I understand better. Necessity is the progenitor of toughness. I mean, when you have to, you can.

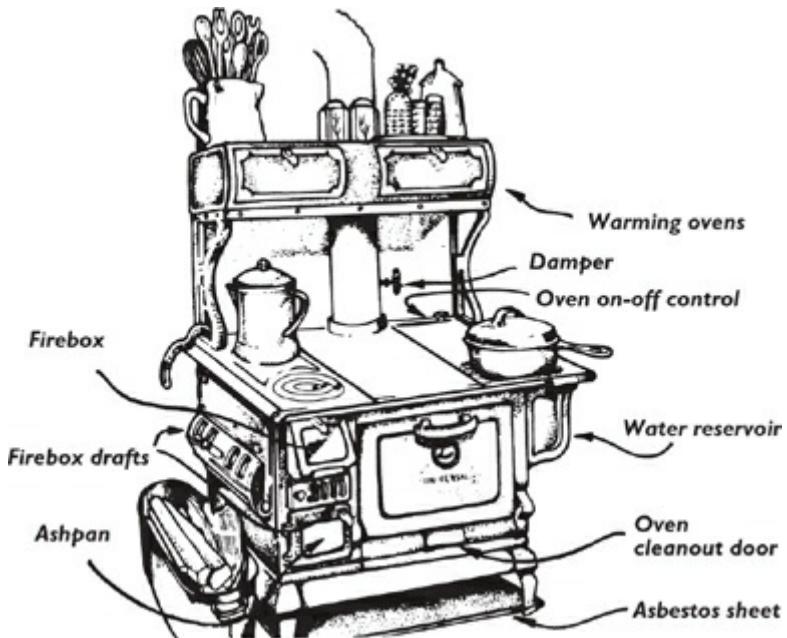

Now I have an electric stove and 2 old-fashioned wood ranges in my kitchen. I use my younger Montag Duchess white-enameled stove in winter as a cupboard and the top as a work area. In summer it moves to the backyard under a canopy to be my canning stove. I like to bake in the electric stove, and it's a blessing on hot summer days because I can cook a meal on it without heating up the kitchen too much. But I prefer the wood stove for frying, stewing, such delicate businesses as making cottage cheese and cream cheese, and for its friendly and practical warmth on cold days since it heats the kitchen area. That stove is a big black box with the name "Monarch" on it in 9 places, warming ovens on top, and lots of fancy metalwork. It's a good stove too.

INSTALLING A STOVE: The old-style wood-and-coal range is a large iron box, which may or may not be on legs. It should be placed well enough out from the wall not to be a fire hazard and set on a fire-retardant sheet to protect your wooden floor. Stove pipes need to be assembled carefully and cleaned regularly. Chimneys must be insulated properly. A spark arrestor on top of the chimney will protect your roof. You may be concerned about how to keep squirrels and birds out of a fireplace chimney and about creosote build-up.

Leveling a Stove. When you first set up a wood cookstove it's important to get it level. Put a frying pan on top with a few drops of water in it for an indicator. The drops of water should go to the center of the pan.

GETTING ACQUAINTED WITH YOUR STOVE: The firebox is usually on the left. At the bottom of the burning area is a movable grate—an iron grill with interlocking fingers—which is opened by a special handle to let ashes fall down into the ash pan, a trap that occupies the lowest level under the firebox. You can keep the grate shaker hung near the stove along with the scraper, poker, pot holders, hatchet, and lid lifter. The poker is a long metal rod with a handle used to move chunks of wood away from the sides of the firebox, or to do whatever poking you need to in the fire without burning your hand.

About Dampers and Drafts: In addition to fuel, fires have to have oxygen to burn. The range is connected with the chimney vent by means of the stovepipe. There is a damper in the pipe and probably another at the front of the grate and another at the back or side of the firebox. Technically, the ones that are above the fire are "dampers," the ones in front of it are "drafts." The dampers and drafts are used to control the amount of air flow. A new fire needs lots of air. The 2 lower dampers are probably shifted by metal handles to open or close air holes into the firebox. The stovepipe damper is a plate just the diameter of the pipe with an outside handle. It may be adjusted to obstruct the pipe and slow (dampen) the fire by limiting the airflow (draft). The "flue" is the hole inside the chimney or stovepipe through which your draft flows. If you let your fire get big and roaring a little bit before you damp down, it will help burn up and blow out the cinders in the stove and stovepipe that can't be reached so easily any other way.

Of Stoves, Air, and Weatherization. No matter what you burn for heat, you'll save money and the environment if you burn less, and you'll burn less if you insulate your house. Find out where you're losing heat and try to stop those leaks. Drafts are a major culprit. You can buy a helpful pamphlet ("Cut Those Energy Bills") from Storey's or Vermont Castings. But don't cut off your oxygen supply completely! Keep in mind that if your house is very tightly sealed, there may not be enough natural leakage into it to provide adequate air for your stove. That would result in a weak draft, smoking, difficult starting, and poor performance. (Test to see if cracking open a nearby window solves the problem.)

Here's another problem with weatherization in a woodstove-heated home: in a home that is just leaky enough to provide a good, fresh draft for the stove and a frequent exchange of room air, the pollutants that leak from the stove can't stay around long enough to concentrate in the room air. But as you tighten your house against drafts, air exchange from outside air happens less often; indoor pollutants have time to accumulate, and this can be a health problem. Not all the pollutants—notably carbon monoxide—can be smelled or seen. So, if you are burning wood, the room where you keep your stove has to have a conscious system to vent and renew the air with an air-intake system that will feed your fire with outside air instead of recirculated room air. And always burn a hot, clean fire to minimize the amount of pollutants produced in the first place.

STARTING A FIRE: On very cold mornings, if there is no other heat, I let the children build the fire. It keeps them occupied while the house is warming up. Otherwise, they just stand around the cold stove and complain. The basic idea is this: You strike a match to get heat enough to light paper, which will burn and create heat enough to light kindling, which will burn and create heat enough to ignite bigger, and then bigger, hunks of wood, which will burn with enough heat to kindle coal. That's because each thing has its "kindling point," meaning the lowest possible temperature at which it will catch on fire. So you start with the thing that has the lowest kindling point (the match) and work your way up.

Starting Clean. Before starting a new fire, you first need to clean out the ashes from the previous day's burning. Shake the grate with the shaker to get all the old cold ashes down into the ash pan. Take the pan out and empty it onto the garden or into the lye barrel, compost heap, or garbage. If you were using coal yesterday, be thrifty and pick out any half-burned chunks to save and finishing burning later. Having all those old ashes out

helps the new fire get air. Besides if you don't empty your ash pan now it will be overflowing by noon with ashes and hot cinders. Then you will have to empty it and the tray will be burning hot and very unwieldy to carry anywhere.

Laying Burnables into the Stove. Separate sheets of newspaper. Wad them up individually and put them into the firebox. Or use any discarded papers or paper containers. Add some of your most finely cut kindling on top of the paper, then a few bigger chunks of wood on top of that, then a couple of yet larger sticks on top of that. Arrange all the wood in as open a style as possible, not pressed together so that lots of air can get in there. Not only does the fire in general need air, but at first every individual stick needs an air supply. I carefully arrange them log cabin or teepee style to ensure this. Once it gets going you needn't be so particular. And start with plenty of sticks. One stick of wood never burns well alone. (There's some profound philosophy there if I ever get time to ponder it—a sermon even.) Now light the paper with a match as near the bottom as you can.

Adjusting the Dampers. Fire travels up. Always start your fire with all the dampers wide open. As the fire gets going, keep it supplied with fuel of the appropriate size for the stage it's at. As it gets going better you can gradually cut back on the draft. You will waste fuel and have a hard time heating your stove and oven if you let all your hot air go directly up the chimney, which is what it will do with all the dampers left open. So when your fire is going really well, cut back the draft—by turning the damper in the stovepipe—until it starts smoking. Then turn it back enough so you have no smoke. If the chimney damper is shut too tight, you'll have smoke all over the place. If it's open too wide, the fire will roar and consume like crazy—but it won't make the room warm. Close the damper at the back or to the side of the firebox, shut or almost shut. Adjust your front damper to the point that the fire's health seems to require. The hotter your fire the more dampening it can stand. If your fire is too slow, give it more air. If your fire still isn't burning well, try loosening up the pile of fuel.

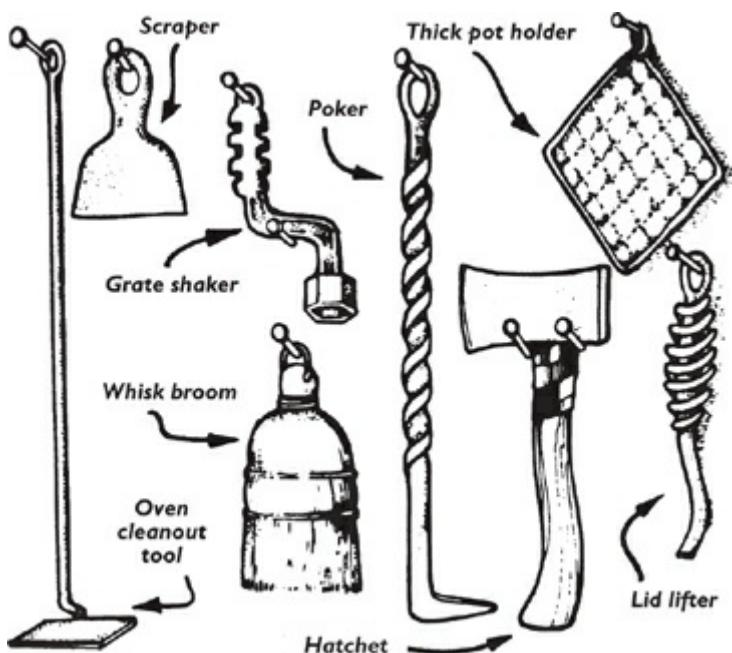

COOKING ON A WOOD STOVE

Shopping for a Wood Stove's Needs. Lehman's carries an excellent line of woodstove items: cast iron (enamel-lined) or stainless steel tea kettles, enameled frontier coffee-makers, old-time flat irons that heat on the stovetop, pokers, lid lifters, scrapers, lids, books ... and stoves themselves; 888-438-5346; www.lehmans.com.

The Top of the Stove. The oven of a wood stove is hard to work with but the top more than makes up for it. The heat on top of a wood stove is more even and potentially milder than that on an electric or gas stove. You will be delighted with your fried eggs because the texture of eggs cooked alone or in mixtures is directly affected by the temperature at which they are cooked. Cooked below the boiling point of water the egg white is firm but tender, and the egg yolk is tender and like a salve. Eggs cooked at too high a temperature are first tough, then leathery, then crispy. Fry your eggs in a little butter in a cast-iron pan on the right-hand side of the wood range.

It's basic knowledge that the different parts of the stove top have different temperatures. The hottest area is usually just to the right of the firebox. (If the draft isn't good, the hottest may be right over the firebox.) You can adjust your cooking temperature just by moving the pan to a suitable place on the stove top. Start it boiling over the hot part, then settle it down to the rate you like by moving it over some distance to the right. The far right is the traditional place for making cottage cheese and keeping dishes warm

when a meal is waiting for the eaters.

Pot Handles and Holders. This kind of stove is hard on perishable pot handles—wooden or plastic ones. The stove top is hot all around the pan as well as under it and a wooden handle such as that on a coffeepot may even catch fire. The traditional handles are metal and you pick them up with a pot holder. You can make a pot holder by folding an old washrag in half and the folding it in half again and sewing down all around the edges. Or you can sew down enough layers of cotton rags to get a manageable thickness and then attach a loop to hang it up by. It can be round or square, about 7 inches across is nice. Crocheted ones burn you through the holes unless they have an extra cloth filling or you use them several at a time stacked like pancakes. Keep the pot holders hanging on nails handy to your stove. You'll be using them a lot.

Stirring on a Wood Stove Top. You need long-handled wooden spoons. You can use a clean stick if you haven't wooden spoons. Wood doesn't conduct heat. The long handle helps you keep your arm away from the heat. Any metal spoon will quickly heat up and burn your fingers. Then you'll drop it in the pot. The old-fashioned flat irons, griddles, waffle pans, and other "hot air" pans—including the kugelhupf (apple-dumpling pan)—are meant to be put right on the hot range top. (If you want to use these pans on an electric burner, put a metal pie pan over the burner—otherwise they'll get too hot in one spot.)

➲ **POTATO LEFSE** *This Scandinavian dish was traditionally baked right on top of a wood range although you can use a pancake griddle. Boil 5 large, peeled potatoes, then mash them and add $\frac{1}{3}$ c. cream, 3 T. butter, and 1 t. salt. Beat until the mixture is fluffy. After it has cooled, add enough flour to roll out thinly, as for pie crust, or even thinner, using your rolling pin. Start with walnut-sized balls. Roll out to tortilla-sized pancakes. Use the center panel of the stove or you can bake on a grill or in a heavy skillet. Clean and oil it and then bake there, turning as often as you need to keep from scorching.*

➲ **WHEAT LEFSE** *Mix $\frac{1}{2}$ t. salt with 3 c. whole wheat flour. Add $\frac{1}{4}$ c. oil and 1 c. water; mix and knead. Roll dough thin as for Potato Lefse. If your dough is sticky, add a little more flour. Cook like the Potato Lefse. You can eat plain, or buttered, or like pancakes, or like tacos with a filling rolled up inside (keep them hot) like mashed dry beans, green onion, and tomato.*

⇒ **WELSH STOVETOP COOKIE** Jennet Gray, age 10, Fruitvale, ID, gave me this recipe. It was passed down from her namesake, Jennet Havard, born November 30, 1875, in Wales—Jen's great-great grandmother. Mix 4 c. whole wheat flour, 1 c. brown sugar, 1 T. baking powder, 1 T. freshly ground nutmeg, and $\frac{1}{2}$ t. salt Cut in 1 c. butter. Add 1 c. raisins or currants. Add 2 eggs mixed with $\frac{1}{4}$ c. milk. Roll out $\frac{1}{4}$ -inch thick and cut into large circles. Cook them on the stovetop in a frying pan (or in an electric fry pan at 350°F). Brown one side. Flip over and brown the other. Jen's mother is a remarkable lady who worked every summer for years out in the woods for the U.S. Forest Service—until she got so disturbed about timber overcutting that she went back to college for an M.A. in political science and guidance about finding a way to influence and limit the unfortunate industry-dictated policies she knew so well.

The Oven. The oven of a good wood range is beside the firebox and is heated by hot air circulating from the firebox over, down the far side and under the oven. If your oven is not heating or is heating unevenly, the problem may be accumulated soot in those areas. My mother taught me to clean them out once a week. You can lift off the top of the range to clean the top area and sides. The bottom is reached through a little door under the oven. There is a special tool for cleaning there called a "stove scraper."

Ovens vary among stoves and with the kind of fuel you are using and the weather. You'll have to get to know your individual oven and fuel. Throw away your former standards for baking. Just be grateful if it isn't raw and isn't burnt. Disregard suggested cooking times. Your oven may be faster or slower or both. Keep an eye on what's happening in there. If the oven doesn't have a built-in thermometer, by all means go out and buy one of those little portable oven thermometers that you can hang or set inside. That way you'll never have to bother with the famous flour or paper tests. The problem isn't finding out the temperature—it's controlling it!

If your oven is too cool, stoke up the fire with more fuel. If the oven is too hot, leave the door open a crack and ease up on feeding the fire. If one side is obviously getting more heat than the others, the oven is hotter there and you will need to rotate your baking pan occasionally during the baking. If you have several pans in the oven, rotate them all to take turns in the hot spot. If the top is browning too fast, cover it with greased or wetted brown paper or aluminum foil. You can put a whole pie into a paper bag. Old fashioned cast-iron frying pans, Dutch ovens, and gem (iron muffin) pans are helpful, since the cast-iron absorbs heat and distributes it evenly throughout the surface of the pan.

Wood Cookstove Repair: Assuming you don't lose a lid lifter, or, worst yet, one of your stovetop lids, the first problem likely to come up is that the stove liner (the firebrick material that lines the inside of the firebox and protects the metal) will first crack and then gradually crumble away. This takes years, but it eventually happens.

I didn't know how you could replace these worn-out firebox parts. Barbara Ingram told me of a way to reline any stove that has a firebrick-type liner using something called "refractory cement." Buy a can of it and a small putty knife. Apply a very thin layer to the part to be relined. Let it dry until hard. Then apply another very thin coat. Keep it up until that area is built up to match the rest. Refractory cement will resist temperatures up to 8,500°F and is the stuff they use in blast furnaces. Katya Morrison, Mount Airy, MD, shared her experience too. "After using our wood stove a while, the lining of the firebox cracked. We tried plain cement made with just sand and it has lasted beautifully and was easy to do."

Karen Prahl, Washington Island, WI ("an island 7 miles out in Lake Michigan off the NE

tip of Wisconsin"), says: "Some brick and block companies sell a dry powder mix that, when mixed with water, can be used to lay a liner to protect the metal surfaces. We have not had a chance to pursue this item and see how it works."

Now that's really putting our heads together!

I wrote the above paragraphs 20 years ago. Now (2002), you can go to your local woodstove store. Or mailorder furnace cement, firebox inserts, or obsolete stove parts from Lehman's (888-438-5346; www.lehmans.com) or The Cumberland General Store (#1 Highway 68, Crossville, TN 38555; \$4 for their 289 Pg catalog; 800-334-4640; fax 678-240-0410; www.cumberlandgeneral.com).

Of Green Leaves, Courage, and Foolishness

In my front yard, outside my front door, there's a foolish little almond tree. Perhaps it's appropriate—this foolish little almond tree living outside my door. Because this is the same winter that so many people are calling me foolish. Again.

I bought the tree for 6 dollars down in Lewiston at Garden Square Nursery. And maybe it was a foolish thing that I bought it because almonds don't belong in cold climates. Some people have managed to raise them at Lewiston, but I'm about 500 feet higher. I'm always trying to grow things that can't be grown (my nectarines are doing well though the fig tree died), so I bought and set out 2 little almond trees. They were practically alike—about 4 feet high with 8 twiggy branches. We pruned them both when we set them out, cutting off the tip of each branch. I winced when we did that. I hate to hurt anything, but the nurseryman said it would help them—that there wouldn't be so much tree for the roots to support while they were just getting started. They both grew nice green leaves and made a fine start for themselves this summer. Then I had to go away and spend months traveling and selling books. While I was gone fall came. Then winter.

I'm back. I've been back 6 weeks. And here in my yard is this foolish almond tree. Right outside my front door. I don't know whether to laugh over it or weep. Time and again I jump up and run to the window to look at it—can it be real? Yet it is; all my visitors have seen it too. Right this moment, in December, I am in my kitchen and my wood cookstove is burning with the hearty fire inside that we need to keep warm. Outside snowflakes float steadily down, piling up on the ground where the little almond trees stand rooted. And there is the one tree, looking just the way it ought to in a December snowstorm: its leaves long since shriveled, changed color, and fallen away, the narrow whip of its lean young trunk waiting patiently for spring to come and transform winter's boredom into another frenetic season of growth like all sensible farmers and plants alike must accomplish. And then there is that other, foolish, tree.

I just got up and looked out the window again. There is the foolish tree, there in the snow, in the snowstorm. Its branches aren't 6 inches long like those of the wise tree. They are over 2 feet, though there aren't quite so many of them. And there are 47 lovely, spring-like, green leaves on that foolish almond tree. I went out and counted them. I stood shivering without my coat in the storm and gently touched the smooth green perfection of each one. Snow and ice were clinging to some so I gave the little tree a gentle shake to try to free it of that chilling burden. Then I looked down and saw 3 of those perfect leaves lying on the snow. Had I done that by shaking it, even so gently? I hurt for them. I felt so guilty for what I'd done. Yet, even on the snow and separated from their tree, they didn't look in the least wounded, not in the least dead.

I've been watching that foolish tree ever since I got home from my months on the road selling books. I've been waiting for it to give up and cut off the flowing sap to those green

leaves like all the other deciduous trees in the orchard have, but it doesn't do it. And I'm starting to cling to the image of those green leaves in my heart as a symbol of Hope.

Has God given me a mutation? Or a miracle? An accident? Or a promise? Or just a foolish almond tree? Is the tree going to make it through the winter? Are 47 leaves enough if 3 fall each snowstorm? So many times God has pruned me, and I've lost green leaves and whole branches, but I knew He was shaping me for better things. That little tree is mocking the annual death we all accept so calmly: out there being summer in winter. Is it some genetic freak, lacking the inner knowledge to accept a winter's hibernation? Will it die completely after having made such a magnificent struggle not to sleep at all?

I'm the foolish one. Because I get weary. Discouraged. Because I consider, just for a moment, that maybe it would be possible to agree with everyone else and say, "Yes, it's too hard—it can't be done" about all the things I dream of, that I work and struggle to make happen. It would be kind of a relief to agree with them. Or am I foolish? Because I believe that life can be full of wonderful joyous miracles ... if we only stretch out our arms, our living branches, and let life flow through us unceasingly, no matter what the weather report.

God has set a foolish almond tree outside my front door. My beloved, wonderful, foolish almond tree isn't a figment of literary imagination. Nothing in this book is. Sometimes I have wild thoughts of running out and wrapping it in my big warm winter coat and in my arms till spring. Or I get up on a new morning and go to the window thinking: Now, finally, it will have accepted the inevitable and dropped those leaves. But no, there it stands. Green. I remember my pastor saying that he will die only at God's appointed hour for him to do so and no mere disease will change that fact. Oh, foolish tree. God's perfect thing. Reminding me that the Valley of the Shadow of Death is just that, only the valley of the shadow of death.

LARDING

INTRODUCTION

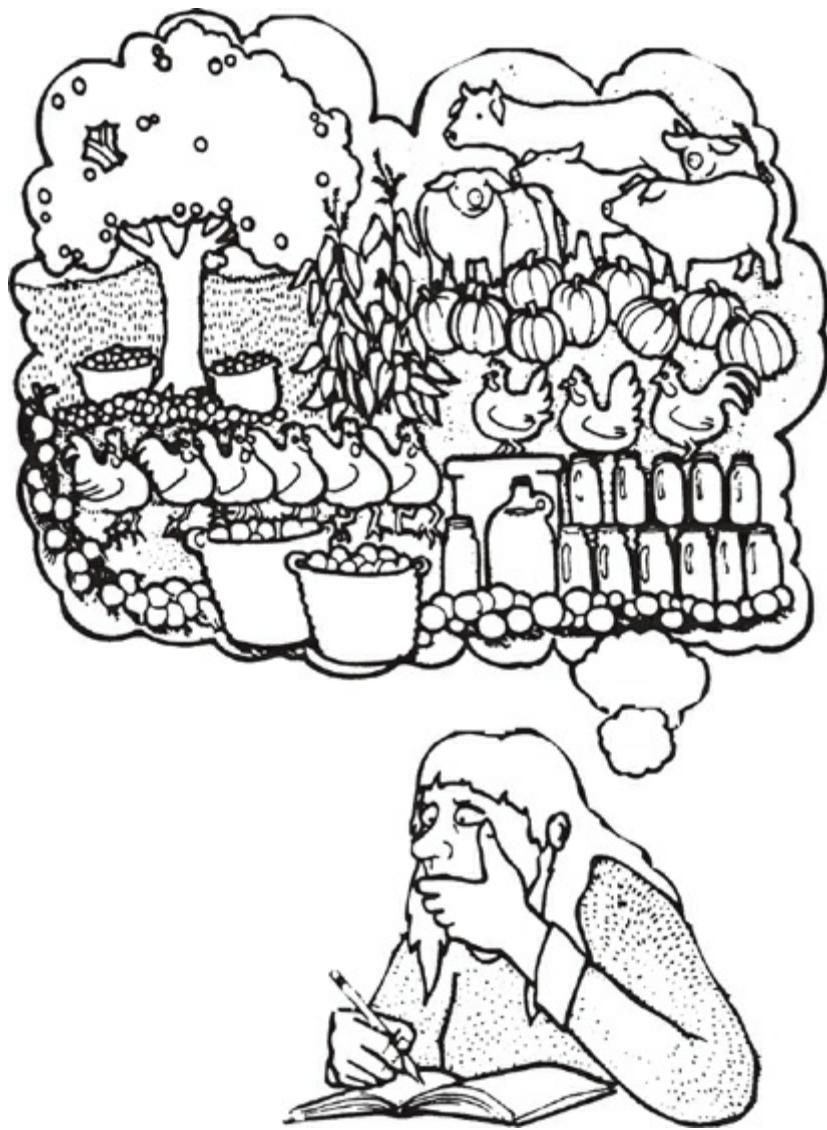

⇒ **HOW TO PRESERVE A HUSBAND** Be careful in your selection; do not choose too young and take only such as have been reared in a good moral atmosphere. Some wives insist on keeping husbands in a pickle, while others put them in hot water. This only makes them sour, hard, and sometimes bitter. Even poor varieties may be made sweet and good by garnishing them with patience, well-sweetened with smiles and flavored with kisses to taste. Keep warm in a steady fire of domestic devotion and serve with peaches and cream. When thus preserved, they will keep for years.

⇒ **PRESERVED CHILDREN** Take 1 large field, a dozen children, 2–3 small dogs, a pinch of brook, and some pebbles. Mix together children and dogs; sprinkle the field with flowers; spread over all a sky of deep blue and bake in the sun. When brown, set away to cool in the bathtub.

Once upon a time, in the bad old days when the Communists and the Western countries were poised on the brink of mutual nuclear annihilation, many of us in the back-to-the-land movement were poised to repopulate the barren earth by managing to be the only survivors of that holocaust. I built a fallout shelter in the backyard. It was very carefully designed, for I'd studied the subject thoroughly—enough to understand that the shelter could solve only part of the problem. But I had children to worry about, and although I couldn't do anything about nuclear proliferation, I could, at least, build a concrete hole. And I managed to do it quite economically for the quality of concrete I used. Thank God it was never put to the test.

All we have to worry about now are local nuclear conflicts, and nuclear power plants blowing up one at a time, and forever-deadly nuclear wastes piling up and leaking away into the planet's circulatory systems.

Another critical issue back then for would-be survivors was how to be self-sufficient, foodwise, if normal supply systems broke down and the grocery stores were empty. Unlike building a fallout shelter, growing your own food and having a good backup supply in storage is still a worthwhile endeavor. The one thing that does not change is the fact that there will be changes. You can be certain there will be more crises. Most prophets of doom are right ... if you wait long enough. How long? Centuries? Millennia? Which crisis will be next? Which will be worst? My bet is on some sort of “environmental” disaster.

In 1991 the United States imported more than half its oil, which accounted for 65 percent of our trade deficit. I recently saw a news item about how Cuba couldn't get any oil and was suddenly having to harvest sugar cane by hand and with oxen. We had a few generations to make the switch away from animal power to petroleum power. It is likely the switch back would happen as it did in Cuba—suddenly, unexpectedly, in an atmosphere of crisis. If what I've heard is true about the oil supply being expected to run out in 50 years, or 100, or 150, there are some big adjustments—or reversals—ahead. Even though it seems inconceivable, we may have to remember how to do things the other way, the way we did them before "progress" happened. (In some ways I would consider that a huge blessing.) But it's more complicated than that.

Modern nations almost literally sow oil to produce food. If there were no oil, there would be no artificial fertilizers, no herbicides, no pesticides, no gas for the \$50,000 (\$150,000?) tractors that help us grow our food supply. If there were no petroleum, there would be no crop—except for what the organic farmers could produce without mechanized equipment.

Our modern food supply is also utterly dependent on the petroleum products used to create the electricity that runs milking machines and electric egg incubators.

Other things have changed too. In the old days, there were no seed catalogs; people saved their own seed from year to year. There was no artificial insemination; farmers knew where to find a bull for their cows, because otherwise there would be no milk and no calf for meat the next year. There were no electric egg incubators; poultry species

brooded, hatched, and reared their own young. Preserving food didn't require electricity or metal. If people's labors were fruitful, they put away a long-term food supply as a matter of common sense. And their food was wholesome, hearty, and free of carcinogens.

Thus, until about 70 (or fewer) years ago, families harvested in the fall and stored enough food to get them and their livestock through until the next harvest. Milk, butter, and cheese from dairy animals, along with meat and the stored foods, were important winter foods. Old-timers stored food mainly by root cellaring, drying, salting—or feeding to livestock, which returned the food as milk, meat, or work. The old-timers never let anything go to waste. After canning came along, most country families canned many, many jars of fruit, vegetables, and meats every year. When freezers were invented, some preserving, especially of fruits and meats, was shifted to that system.

ORGANIZING FOOD PRODUCTION, STORAGE, AND USE

City Food Preservers

You don't have to have your own orchard and garden to reap the benefits of home food preservation. You can make an arrangement at a roadside stand, farmer's market, or U-pick to get organically grown food in bulk. It's best if you make arrangements the previous fall, so the grower can make sure to plant enough for your needs.

Plan Ahead

If you haven't previously raised your own food, I would guess it will take more food to keep your family going than you now realize. In general, can or freeze only the amount your family will use up before the next harvest season. In your first year, you may have trouble figuring out how much. But by your second, you'll know what ran out fast and what was left over. With that info you can fine-tune your plan.

Do you know how many cows, goats, chickens, sheep, etc., you need for one year's supply of milk and meat? How many bushels (or acres) of grain? How many heads of cabbage and sacks of potatoes? You can find out to a certain extent by keeping records and then by experience. You'll need a lot of food, because people doing hard outdoor work have bigger appetites, because you have animals to feed too, and because you have to allow for loss by crop failure or spoilage in storage.

With pumpkins and fruit, you have to figure from harvest to harvest—a full 12 months. You store greens from fall to spring because you'll have them fresh the rest of the time, from dandelion greens in the spring to your last cutting of Swiss chard or mustard greens in the fall. Meat is a crop you can harvest in winter but not in summer—except for very small animals like poultry and goats. Milk is available fresh year-round—providing you have more than one animal milking and stagger the time they come fresh. You have to store enough winter feed for them. A hungry cow won't just loyally grow lean. She'll either go way down on the milk, or she'll go through the fence and range onto the neighbors' land. (She is also likely to leave in search of a bull when she needs one—fences hold only contented cows.)

All spring I try to plant something every day—from late February, when the early peas and spinach and garlic can go in, on up to midsummer, when the main potato crop and the late beans and lettuce go in. Then I switch over and make it my rule to try to get something put away for the winter every single day. That lasts until the pumpkins and sunflowers and late squash and green tomatoes are in. Then comes the struggle to get the

most out of the stored food—all winter long. It has to be checked regularly, and you'll need to add to that day's menu anything that's on the verge of spoiling, wilting, or otherwise soon becoming useless. Or preserve it a new way. If a squash gets a soft spot, I can gut it out and cook, mash, can, or freeze the rest for a supper vegetable or pie, or add it to the bread dough.

You have to ration. You have all the good food you can eat right at arm's reach and no money to pay ... until you run out. You're likely to have either no elk at all or a lot of it (meatwise, an elk is about as much as a whole cow). Rotate when you have a variety. If you have elk, beef, and some odds and ends of chicken, trout and ham, eat elk on one night, beef on the next night, and alternately chicken, trout, and ham on the night after that. Garden crops have a tendency to either fail completely or overwhelm you with abundance. Fruit comes by the barrel but for only a short time—unless you can preserve it.

A MEASURE OF YOUR FOOD SELF-SUFFICIENCY

See how your ability to feed yourself and your family measures up by the old-timers' standards. There are no right or wrong answers to this "test." Its purpose is just to help you evaluate where you are right now—and think about what direction you might want to expand in.

Do you grow your own vegetables?

Yes No Percent

Do you grow your own dairy foods (milk, butter, cheese, yogurt, etc.)?

By root cellar storage?

Yes No Percent

Do you use cloches, a cold frame, or a greenhouse to prolong your growing season?

Yes No

Do you have enough food on hand to feed the family 1 week? 2 weeks? 1 month? 3 months? 6 months? 9 months? 1 year? Longer? How long?

Do you have enough seeds on hand to grow your food supply next year?

Yes No Percent

Plan ahead. Breed your milker 9 months before the time you'll want milk. If you butcher 30 chickens in June and have chicken every Sunday, you'll have no more after Christmas until next summer. And did you save layers? They may not lay in the winter, but hens that have rested will make up for it in May. Did you preserve eggs during that period when the hens lay like crazy—from May to October (or sooner)—just in case you don't see another egg until spring? I'll confess that I never manage to do all the food preserving correctly. But we keep struggling toward the ideal.

For information about planning a garden, see [Chapter 2](#); planning an orchard, see [Chapter 6](#); planning your meat supply, see [Chapter 8](#); planning your dairy supply, see [Chapter 10](#).

PRESERVING NOTEBOOK: Keeping one makes it possible to learn from experience. If you've the time and the patience, you can put down even more detail than this. Record in the notebook:

1. When you butchered what and about how many pounds of meat you put into the deep freeze.
2. How many chickens you have and how many eggs you get.
3. How many goats you're milking and how much milk you get, and the same for cows

or other dairy animals.

4. How many seed packets of what you planted, or how many pounds of potatoes. At harvest time write down how many bushels of spuds, etc. you had to go into storage.
5. How much you're spending every week on store-bought food and where you're spending it.
6. See if you can bring that down by using more homegrown ingredients.
7. How many mouths you're feeding and what age they are.
8. How much you preserved of what and in what way.
9. When you ran out.

A very organized reader named Lin Shoemaker, Pullman, WA, even records what recipes she used in her food preserving, and if she added to or subtracted from the basic recipe. She refers back to that the next year to see if she wants to change or to do the same.

You'll get used to planning ahead for an entire year—from garden to garden, from slaughter to slaughter—in order to avoid a feast-and-famine cycle. Then in the long winter evenings when you're planning for next summer, adjust where needed. Not enough eggs? Save more hens from the chopping block this year. Couldn't eat all those pickles? Don't give so much garden space to cucumbers next year.

Menu Making: 365 Independence Days

For supper tonight we had kidney beans, helped along with some head meat fished out of the kettle where I'm cooking up some from a pig we butchered last weekend. With the meal I served milk and a dessert made of whipped cream, crumbled heels of homemade bread loaves, and some home-canned cherries and apricots.

It put me to thinking. Certainly wasn't a gourmet dinner. People have sometimes eaten at our home and really gone away raving—for instance, when they happened onto us when we were having sirloin steaks, or homemade ice cream made the old-fashioned way (mostly whipping cream and fruit), or homemade bread with so much applesauce in it that it was about half "cake" (only no sugar). But I imagine most folks would turn up their noses at a meal of kidney beans, head meat, and recycled bread dessert. Yet it was really special to me because all the ingredients came from our farm.

Just this afternoon I read an article in the women's section of the newspaper about a lady who grew much of her own food. I was impressed. But then it went on to give her recipes, and only one ingredient per recipe could possibly have been homegrown. The others were things like margarine, brown sugar, vanilla, baking powder, exotic nuts, cake mix, confectioners' sugar, miniature marshmallows, cocoa, and so on.

This noon for lunch we had a soup made of carrots, potatoes, onions, and milk, along with hamburgers (homemade bread and cut-up onion added to homegrown beef). Breakfast was homemade bread and butter and an eggnog (eggs from our chickens, milk from our cow) flavored with store-bought molasses. My grocery bill for the last few months has been averaging around \$20 a month [1974], and that's not bad for a family of 7. (We rack up other expenses in producing the food, of course.) It's that cheap when everything on the farm is producing just perfectly—corn, chickens, garden, orchard, cow. Any slip sends the bill soaring—for instance, if the cow dries up, then I'm short on dairy products. None of us can stand reconstituted powdered milk, so suddenly I'm spending for dairy products.

If you have to buy all your food at the store now [1993], the USDA figures it will cost a

family of 2 adults \$220–400 per month, and a family of 2 adults and 2 children \$365–700 a month. Gardening, if you have a place to do it, is one of the best ways to save money.

My favorite month, foodwise, is June: new potatoes and peas, turnips and lettuce, fresh strawberries, raspberries, and cherries, lots of milk and eggs. The winter food bill depends precisely on how much food is in the deep freeze and other forms of storage.

People have to choose what they're going to struggle for. Life is always a struggle, whether or not you're struggling for anything worthwhile, so it might as well be for something worthwhile. Independence days are worth struggling for. They're good for me, good for the country, and good for growing children. I think being married to a fine man, raising children, and raising food are the most important worldly things there are. And the most rewarding.

I think the best food product is the one you grow or make yourself, starting with ingredients that are as natural as possible (or, if you're stuck in the city, the ones in your grocery store labeled "organic"). The results may not look or even taste the best, but they really are the best. That's what I believe. When it comes to believing, you just have to believe whatever you believe and let it go at that without more fuss.

My ideal woman milks a cow or goats, gardens, and cares for her children herself. She hasn't got time for fancy cake decorating and vegetable dishes with 10 ingredients. And my ideal woman wants to use as few store-bought ingredients and gadgets as possible. She's looking for from-scratch recipes or making up her own.

USE WHAT YOU HAVE: There are a few basics to cooking in any food category. Some cooks use a recipe only to guide them through the first few times. Then they know the recipe by heart—or, better yet, know the principles involved and can strike off on their own to do variations on the theme. I don't want to be a slave to recipes with ingredients that are unreasonable, inappropriate, and expensive—recipes that would have me running to the store way too often to search for strange ingredients. On the other hand, it's interesting to learn about new foods, new seasonings, new cuisines. But ingredients are most exciting to me if I might be able to grow them.

The wonderful magic at the heart of a food-growing household is the magic that turns your home-produced turnips and cream, apples and meat into your meals. The moment of triumph is when you say to the family: "Here's what we worked so hard to grow, and isn't it good!" I think you cook most happily, freely, and independently when you make good things out of what the Lord is giving you!

Lane Morgan, author of the *Winter Harvest Cookbook* (Seattle: Sasquatch Books, 1990), says, "I agree entirely that cooks are spending too much time and money at the supermarket and the gourmet supply store. But I think we would profit by spending more time looking at cuisines of other cultures, to help us better use what our particular gardens can grow. Country people around here will eat canned green beans and carrots all winter, which are considerable work to put up, because that's good American garden food. Meanwhile they could be eating fresh kale and leeks and Japanese mustards from that same garden, which would be tastier, more nutritious, and easier all around, but they don't because that's foreign stuff and they don't know the Greek or Indian or Japanese techniques to make them wonderful. They'll make clam dip from a package, but they won't consider an Indian chutney made of garden mint and garlic, served with garden spinach and potatoes. Too strange."

Making menus out of what you can grow is the way Great-Grandmother did it. Each week she looked in the larder and the cellar and took a walk through the garden to see what she had to work with. Then she made menus. When she had eggs and milk aplenty,

a little honey, and some stale bread, the family had a bread pudding. In May she served rhubarb in it, in June strawberries over it, and in September peaches—because that's the way they grew.

To have 365 days of independent eating, you've got to learn to eat what you can grow, and you've got to learn to grow what you want to eat. At first it will be hard, but stick to it. If you don't like what you have, eat it anyway and use the energy of your distaste to figure how to get what you'll like better. If your only meat is elk, eat elk until you can raise something else. If you miss bacon, get four little pigs. In six months they'll be 200-pounders, and you'll have a year's supply of bacon plus a sow to breed and keep the bacon coming. If you're still living in the city and you don't have anything but dreams, try for fun buying only what you imagine you could grow—in a natural unprocessed state—like whole grains, and see if you can learn to live off it.

When lettuce is in season, have a salad every day—you can't preserve it. If you miss it in the off-season, contrive a way to raise winter lettuce in the house. If you miss sweets, learn beekeeping. If you have barley and corn, make your bread, pancakes, and pie crust out of barley flour, cornmeal crust, and a bear-meat filling. If you have some tough old hens past their laying prime, 3 extra male goats, and 100 rabbits, then learn good ways to cook tough old hens, goat meat, and rabbit.

SEASONAL EATING: At any particular time of year you'll have a different set of fresh foods coming out of the garden and root cellar to complement what you have frozen and canned. Winter, cloche, cold frame, and greenhouse gardening enable you to have at least a few varieties of garden-fresh vegetables year-round. Even in chilly November, in a basic temperate-zone garden and with some attention to protection, you might be able to harvest broccoli, brussels sprouts, cauliflower, collards, cabbage, Chinese cabbage, carrots, escarole, kale, leeks, lettuce, parsnips, salsify, spinach, rutabagas, turnips, and winter radishes.

HOMESTEAD MENUS THROUGH THE YEAR: Here are some menus from back in '72 and '73. Those were my banner years for home growing and good cooking. It wasn't "gourmet" or "health food" cooking. But we raised it ourselves without poisons and had plenty of food and plenty of variety. We dried fruit in our front yard. Mayonnaise was homemade. Butter was from our own churn and bread from our oven. Bacon or ham was home-cured, and sauerkraut was out of our crock, as were pickles. The root beer and ginger ale were homemade, too. We always had milk and usually an herb tea on the table.

Breakfasts. If your chickens aren't laying, leave out the eggs.

1. Cornmeal mush; bread, butter, honey; soft-boiled eggs
2. Toasted sourdough bread; pork chops; applesauce; scrambled eggs
3. Homemade grape nuts with cream; sliced fresh peaches; poached eggs
4. Cornmeal mush; home-canned fruit; elk sausage ($\frac{1}{3}$ pork meat); fried eggs
5. Leftover boiled potatoes (sliced and fried); elk sausage; home-canned tomato juice; fried eggs
6. French toast (bread sliced and dipped in an egg-milk mixture and fried); honey and butter to go on the toast; fried pork side meat; wild plums
7. For a summer breakfast cooked outdoors: pancakes; goat's butter, honey; stewed wild apples; fried pork side meat

Lunches

1. May lunch: scrambled eggs; leftover boiled potatoes fried with chopped green top-set onions; cooked, buttered asparagus spears
2. Fried leftover cornmeal mush with butter, molasses, or honey; blackberries; fried meat; bread and butter
3. Hamburger; sliced fried leftover boiled potatoes; tomato ketchup; bread, butter, jelly
4. Leftover stew, extended with some fresh vegetables; bread, butter, wild plum sauce; mint tea with honey
5. Ground leftover ham and pickle sandwiches; cottage cheese (we eat it with milk and honey—except Mike, who prefers it with salt and pepper)
6. Sandwiches of herb bread and sliced cold venison roast; canned juice; pickles
7. A special lunch: cold leftover steak sliced in strips; fried potatoes and onions; hardboiled eggs; canned applesauce; bread and butter; iced wild strawberry leaf tea

Spring and Summer Suppers

1. Potatoes; bread; creamed onions; stewed dandelion greens; raw fresh asparagus
2. Dandelion greens and (real) bacon bits; roast ham and gravy; potatoes; stewed rhubarb; radishes
3. Leaf lettuce salad; radish roses; potatoes; fried meat and milk gravy; strawberries on leftover bread with cream
4. Leftover sliced cold roast; bread and apple pudding (crumbled bread crust baked with milk, sliced cored apples, beaten egg, honey, cinnamon); warmed-up leftover gravy extended with milk (to go on the meat); boiled Swiss chard
5. Chicken stew (made from an old layer, with carrots, potatoes, onions, turnips) and dumplings; blackberry-apple bread pudding (berries, apples, milk, bread crust, and honey, baked and served with cream); iced herb tea
6. Corn on the cob; sliced fresh fruit; roast; mustard greens; potatoes; half-cured crock pickles
7. Carrot sticks; boiled peas; boiled new potatoes; fried chicken and gravy
8. When you're hot and tired: potato salad (made ahead and chilled); barbecued meat (cooked by husband); tossed green salad (made by children); raspberry ice (made ahead); bread and butter
9. Picnic: Fried chicken; potato salad; leaf lettuce salad; raspberries in whipped cream; ginger ale

Winter Suppers

1. Boiled sliced turnips; roast and gravy; baked potatoes; pickles; bread and butter; junket pudding
2. Elk roast and gravy; sage dressing; baked squash; spinach; mashed potatoes; mincemeat cookies
3. Pork chops; gravy; boiled peas; yeast biscuits; boiled potatoes
4. Steak and gravy; mashed potatoes; cole slaw with homemade dressing; cream-style corn; crumb bread and cherry jelly; canned apricots
5. Stew made with meat, tomatoes, carrots, cabbage; raw turnip slices dipped in herbed sour cream
6. Leftover sliced cold roast; bread and apple pudding; mashed boiled turnips

Snacks. Snacks are for company, for husband or children famished between meals, for an afternoon tea break or a bedtime family treat. Lots of old-time farm families have a regular midmorning and midafternoon mini-meal for the working men in summer, when they are putting in long days. Maybe we take sandwiches and a gallon of cold tea out to the field and the work stops for a few minutes.

I blacklisted store-bought cookies, potato chips, pop, and candy. But I don't fight snacks that are homegrown and home-prepared: fresh, canned, or frozen fruit; dried fruit; pickles; popcorn; homemade popsicles; homemade crackers; jerky; bread with homemade jam or honey.

Leftovers like cold sliced roast or cold boiled potatoes are good with some salt or butter. My husband Mike doesn't like to eat leftovers, except potatoes and meat, so if somebody doesn't snack them up, the chickens or pigs get them—except for bread, which metamorphoses into bread pudding or lunch dishes that I serve when it's just me and the children.

Feasts. Holiday feasts are wonderful rituals that bring a family closer, a time to pull out all the stops and load the table with everything good you can think of.

Thanksgiving 1972. Gander (the one that bit our son Danny twice) stuffed with sage dressing; sliced tomatoes (last of the fresh ones—picked green just before frost and stored to ripen gradually); cooked pumpkin mashed with butter; boiled green beans with onion and bacon; boiled potatoes with griblet gravy; sweet crock pickles; bread and cheese; brandied peaches (buried in September and dug up for Thanksgiving); root beer.

Thanksgiving 1973. Roast goose stuffed with sauerkraut; griblet gravy; mashed potatoes; baked acorn squash halves (a dab of butter and honey cooked in the heart); boiled Swiss chard; brandied peaches; mincemeat pie.

Christmas Dinner. Turkey and dressing; peach ketchup; potatoes and griblet gravy; boiled green beans; carrot and dried fruit salad (grated carrot tossed with chopped dried fruit and mayo); bread and butter; pumpkin pie.

A SYSTEM FOR MENU PLANNING: My mother taught me the following basics of menu planning. I've heard of other systems, but this is the one I grew up with. It has served me well enough that I'll pass it on. To me, if something works, then it was obviously made in Heaven. This worked for me and my mother and, for all I know, for Great-Grandmother, too. But it's sort of like Infinite Goodness; I'm always striving after it and often falling short. Still, if you're striving after a good thing, usually even your failure will be a sort of success.

Breakfast. My mother's rule was to include a fruit or fruit product, a meat, a starch, eggs, and a beverage. That was a huge country-style breakfast for men who were going to do hard physical labor all day. Modern, more sedentary and health-conscious folks are cutting back on cured meats and high-fat and high-sodium foods. So I now suggest you omit the meat or eggs—or both! Anyway ...

A "fruit" can be a glass of fruit juice, sliced orange sections (cut orange on the equator; then get about four sections out of each hemisphere and eat with fingers), a grapefruit half, a half-cantaloupe or muskmelon, stewed or canned fruit, fresh sliced fruit on cereal or in pancakes, berry syrup hot for breakfast bread, or preserved fruit on bread.

CHOOSING FOODS TO REDUCE HEART DISEASE AND CANCER RISK

Heart disease is this nation's Number 1 killer. Cancer is next. Here are my 11 guidelines for healthy eating.

1. Eat a variety of foods.
2. Maintain a healthy weight.
3. Choose a diet low in fat, saturated fat, and cholesterol. Drink nonfat milk. Avoid fatty meat and fried foods.
4. Eat plenty of vegetables and fruits. Eat strawberries, tomatoes, or cauliflower daily; eat citrus fruits and juices, green peppers, and broccoli 3–5 times a week.
5. Eat brown rice, pasta, whole grain cereals, and legumes generously. Grain products and legumes provide lots of fiber, which protects you from some kinds of cancer.
6. Use sugars only in moderation.
7. Use salt and sodium only in moderation. Avoid salt-and pickle-cured foods.
8. Avoid cured and smoked foods.
9. Avoid seafood and fish that might have come from polluted waters.
10. Avoid alcohol. Or, if you drink alcoholic beverages, do so only in moderation.

11. Always eat organically grown foods whenever you have the choice.

A “meat” can be bacon, link sausage, patty sausage, ham slices, breakfast steak, pork chops, or fried trout.

A “starch” can be leftover boiled potatoes, maybe fried in butter with a little chopped green onion or green pepper added (saute first), or grated and fried (that makes hash browns). For potato pancakes, make patties with leftover mashed potatoes mixed with egg and milk (chopped onion optional), and fry in a little butter. Or have homemade bread, plain or toasted, or biscuits, pancakes, waffles, crepes, or corn bread. Or any hot cereal, or a cold one like homemade grape nuts. Or leftover rice warmed with hot milk and honey.

“Eggs” can be an ingredient in the breakfast bread, or they can be fried slowly over low heat in butter or boiled, poached, scrambled, souffled, or used in an eggnog.

Lunch. This varies so much depending on who is eating. If you feed a man who works near enough home to eat lunch with you, then you may even want to reverse the lunch and supper menus. If your man can’t get home for lunch, lunchtime is handy for using up leftovers for you and the toddlers—or the cat. That’s what I do. Mike takes a packed lunch to work. It usually consists of two sandwiches of leftover sliced meat on homemade bread plus some variety of extras such as hardboiled eggs, pickles, a ripe tomato, or carrot sticks. In the winter he takes Postum (made with milk), soup, or tea in his thermos; in the summer, cold tea, root beer, or ginger ale. On weekends we often grind leftover meat to make sandwich spreads. Then we have sandwiches, milk, and fruit.

Supper. Your menu should include a meat, a starch, and 2 vegetables. One of the vegetables should be raw. One should be green and the other should be a yellow, red, or white one. For a special dinner, have 3 vegetables—one green, one otherwise, and one raw—and add something sweet (jam? dessert?) and something sour (pickles? relish?) to the menu.

A “meat” can be any kind of meat prepared any way.

In my meals, a “starch” usually means bread, dumplings, noodles, or boiled, baked, or mashed potatoes. In Taiwan it would mean rice.

A “green vegetable” can be peas, beans, Brussels sprouts, broccoli, cabbage, collards, spinach, lettuce or any of the many other leafy greens, green onions, green peppers, and so forth. A “yellow, red or white vegetable” can be carrots, turnips, squash, sweet potatoes, cauliflower, parsnips, pumpkin, corn, radishes, beets, tomato, eggplant, and the like.

“Something sour” can be anything of the pickle, relish, spiced fruit, or vinegar family. “Something sweet” to me usually means fruit or a pudding sweetened with honey.

The “beverage” in summer is homemade root beer or ginger ale, cold water, iced tea and milk for the small children. In winter it’s tea or honey and lemon with hot water, a mulled beverage, eggnog, or milk lassie made with hot milk.

Food Preservation Methods

This section describes general methods of food preservation. For detailed canning, freezing, drying, or root cellar storage procedures, look in the chapter that covers that food—for grains, [Chapter 3](#); for herbs, [Chapter 5](#); for fruits, [Chapter 6](#); meats, [Chapter 8](#). For vegetables, look in [Chapter 4](#); pickles are mostly discussed under “Cucumbers” and

sauerkraut making under “Cabbage” in that chapter.

IN-GROUND STORAGE: Some people say you should leave most of the root vegetables in the garden during the winter, even after they’re grown, rather than using other preserving methods. Parsnips and salsify are about the best for that; they’re often left in the ground over winter with a mulch over them. But I tried that and despaired. Every time I wanted something out of the garden, the ground was either frozen so solid that I couldn’t dig it up, or it was so wet and muddy that I could barely manage to pull my legs back out of the garden soil, much less bring an armload of vegetables with me. If the ground freezes down far enough to freeze your vegetables, they will get soft and be no good anyway (except for leeks). I guess it depends a lot on where you live or what your garden storage system is. For more information, see “Extended Season Gardening” in [Chapter 2](#).

DETERIORATION IN STORAGE: We share this wonderful world with myriad invisible but ravenous little critters who love to eat exactly the same things we do. The food preservation game is to get a move ahead of them and “enzymes,” which are chemicals contained in the food itself that can cause undesirable changes. Salt, sugar, alcohol, sodium benzoate, and sulfurous acid are “chemical” preservatives that, in effect, poison or make the food yucky to the beasties. Drying food makes it impossible for them to grow and reproduce in it. Freezing puts them into hibernation except for the most cold-hardy, which can then double their number only in months, perhaps, rather than in hours. Canning, when you do it right, kills every last beast in the food and seals it up tight so that no more can get in. Cellar storage takes advantage of certain living foods’ natural defenses against spoilage.

All stored foods, no matter how they are stored, slowly but steadily lose quality and nutritional value as time goes by. Some foods deteriorate faster than others. If a food was on the verge of spoiling when you started, it may lose quality more quickly in storage. Some storage methods, such as canning and drying, hold the food better than others. The biggest single risk factor for most stored foods is warmth, which causes the loss of both nutrition and palatability. With few exceptions, the cooler it is (above freezing for nonfrozen foods), the better they keep. For every 20 degrees' increase in storage temperature, you lose one half of the possible shelf life of most stored foods. The ideal storage temperature is 38–40°F.

THE BASIC METHODS: There are 6 basic methods of food preservation: canning, freezing, drying, pickling (for salt, vinegar, and spices), sugaring (for jams and jellies), and root cellaring—underground or even in the garden (live storage). Root cellaring is the oldest method, but not all foods store well using that method; in fact, most don't. Freezing is the most popular method and the next easiest, but it's also the most expensive, and you have to own a freezer and have electricity. Canning takes the most time and effort, but the food can be safely kept (if you carefully follow the rules) and stay delicious.

PRESERVING MEAT: Our family of 7 (and very often extras) can use 2 big calves, 4 pigs, maybe half an elk, and 50 or more chickens a year. The pigs supply cooking grease as well, which can be canned or stored in the deep freeze. Without electricity to run a deep freeze, you can't keep meat frozen, except if you live where there is a really bad winter—and even then, only during that winter. In most places, your outside temperature will be below freezing sometimes, but you'll also get off-season thaws that could spoil the meat. So, without electricity, you'll have to either rent a locker in a nearby town, which doesn't cost much, or can most of your meat right after butchering. That's what the old-timers did, and they ate well. You can also dry the lean meat in small strips—jerky. But that isn't as tasty or chewable as canned meat. You can can the meat from any kind of animal; just bone it out first. Another food preservation system for meat is making mincemeat at the beginning of the cool season. It will keep during the winter months in a cold, outdoor place.

COST COMPARISON: Another way of comparing preserving systems is by their cost. From that point of view, in-the-ground in your garden is cheapest. Root-cellар storage is next, because you build the cellar and then have no additional expense. However, drying can be cheaper than root-cellar storage if you have to factor in the cost of a root cellar, for if you're drying with simple sunshine, drying is free. If you're using an oven or dehydrator, it isn't.

Canning is a bit cheaper than freezing—even taking into account the cost of new jars, some sugar to add to your fruit, and the electricity it takes to heat your canner. If you live where electricity is expensive, the cost of canning can be as little as half the cost of freezing. On average, the electricity to keep 2 cubic feet of freezer space cold for 1 year in the Northwest will cost \$7.68. On the other hand, electricity to can the equivalent amount of food (assuming peaches here) on high heat for 1½ hours would be only 13 cents. But electric costs vary wildly depending on where you live. Here in the Northwest, we have just about the cheapest rates in the country. If you're canning on a wood stove and have your own wood supply, then you don't even pay for electricity, and once you have your basic jar collection, new lids are your only expense. Electricity to dry that amount of fruit would cost about 40 cents. Freezing is the most costly method because you have to buy a

freezer and pay for electricity and wrapping material or containers to freeze the food in.

NUTRITION LOSS IN STORAGE: But also consider, according to the USDA, that foods lose 60–80 percent of their nutritional value when they are canned, because of the high canning temperatures and water soaking. (Storing canned goods in a dark place minimizes the loss of riboflavin, which is caused by exposure to light.) Canned goods also lose vitamins from exposure to warmth. Frozen foods lose only vitamins E and B6, but if stored above 0°F, they can also lose a considerable amount of vitamin C and other nutrients, up to 40–60 percent of their food value. Blanching before dehydrating helps hold vitamins. Dehydrating using very low heat levels is less destructive of nutritional value than sun drying. However, dehydration results in more nutrition loss than any other form of food preservation. Live storage (in a root cellar) is the best of all for holding nutritional value, so long as the food doesn't freeze, the storage is cool, and the food is an appropriate one for this method. Heat, oxygen presence, and passage of time all cause losses.

Nutritionists are most concerned about what happens to vitamins A and C. Vitamin C is totally lost after sun drying foods (80–90 percent is lost after drying in a dehydrator) but is 100 percent retained in freezing. In canning, 25 percent of C is lost from fruits and 50–90 percent from vegetables. So they recommend that you dry or can high-vitamin A foods but freeze high-vitamin C foods.

SUMMING UP NON-FOOD FACTORS: Root cellar storage is cheapest of all and will retain most of the nutritional value. Of canning, freezing, and drying, freezing is quick and easy, but the most expensive; drying and canning are both cheap, but drying is by far the worst in terms of loss of nutritional value.

THE FOOD TO BE STORED: Yet another factor is that there are one or two best methods of keeping any single type of food. Sometimes even a particular variety of plant will keep better by one method than another. In my opinion, tomatoes, large fruits, syrups, fruit butters, and juices are all best kept canned. Cucumbers and cabbage are best pickled (preserved in salt). Green beans are good either canned or frozen. Corn, greens, peas, baby turnips, baby carrots, extra bread, meat, and hides waiting to be tanned are in my freezer. Berries are better frozen than canned. Fruits, except berries, are also very good dried. Apples are good made into sauce or butter and canned. Or you can dry apple rings or freeze slices in syrup for pie making. Onions, beets, green tomatoes, potatoes, winter squash, pumpkins, big turnips, big carrots, and celery will keep best in the root cellar. I didn't include drying in this list, but if you live where there's lots of dry, hot sunshine, this is also a wonderful option. Even if you don't and have to use an oven or dehydrator, it still may be a great option!

Books, Containers, and Equipment

Food PRESERVATION Books: *Stocking Up III: The All-New Edition of America's Classic Preserving Guide* by Carol Hupping covers canning, drying, freezing, root cellaring, plus preserving meat and dairy products. A similar, good, big, conservative, encyclopedic book on food preserving is *Putting Food By*, by Ruth Hertzberg, Beatrice Vaughan, and Janet Greene; it also covers making sausage, cheese, lard, and grits. *The Busy Person's Guide to Preserving Food* by Janet Bachand Chadwick (1982) and *The Big Book of Preserving the Harvest* by Carol W. Constenbader would also be helpful. For commercial level postharvest technology, see the *Wiley Encyclopedia of Food Science and Technology* (4 vols., John

Wiley & Sons, NY, 2000).

NOTE: The USDA says be careful of any canning recipes published before 1990! Before then, all canning recipes were based on research completed in 1942, but USDA studies completed in 1990 found numerous errors in the old research.

EQUIPMENT: If you are preserving foods gathered from your garden, orchard, and home butchering, you are periodically faced with preserving large amounts of the same thing—a mountain of apples, tomatoes, peaches, beans, etc. There are gadgets for sale that can make almost any food preserving process easier: cherry pitters, bean splitters, pear corers. And then there are the larger slicing, dicing, squeezing, and juicing types of machines. A “food mill” purees food and can also separate pulp and liquid; it’s good for making sauces, fruit butters, and leathers. An electric blender or food processor is great for making smooth-textured sauces and spreads, and for chopping finely. These are all wonderful if you can afford them, but are not absolutely necessary if you can’t. Everybody can afford some gadgets, though, even a humble one like a paring knife! A kitchen scale that weighs amounts up to 5 lb. is nice for making old-time recipes given in pounds. For heavier weights, use your bathroom scale.

C. F. Resources offers all kinds of food preservation stuff: vegetable strainers and juicers; canning funnels; a wide choice of pressure canners; American Harvest dehydrator; gamma seal lid to go on grain/bean storage buckets; opener for plastic pails; pasta makers; sprouting trays; grain grinders; 1-lb. dry yeast packages; and much more. Free catalog: 719-962-3228; www.cfamlyresources.com.

Over the years you’ll find ways to acquire such gadgets. They save you time and energy and make food preserving more fun. Make sure you have a special place to keep directions for use, parts ordering info, and warranties—an envelope in a special drawer, maybe, or a photo-type album kept with your cookbooks.

PLACES TO BUY CONTAINERS

Basco, 2595 Palmer Ave., University Park, IL 60466; 800-776-3786; www.bascousa.com; food and water storage containers and seals.

Container Store, Melvin Selcer, 314 S. Main, PO Box 263, Agra, OK 74824; 918-375-2601.

Drumco/WaterTanks.com, PO Box 340, Windsor, CA 95492; 901-396-6484; 877-655-1100; sales@watertanks.com; www.watertanks.com.

Major Surplus & Survival, 435 W. Alondra Blvd., Gardena, CA 90248; 800-441-8855; www.majorsurplus.com; offers gamma seal lids, etc.

NITRO-PAK Preparedness Center, 475 W. 900 S., Heber City, UT 84032; 800-866-4876; www.nitro-pak.com.

USING SAVED CONTAINERS: Back when I first wrote this book, public recycling was barely getting started. Back then thrifty housewives saved things like containers and found good uses for them at home. That principle can still apply.

NOTE: Polyvinyl plastic may cause cancer, so do not use plastic garbage cans, wastebaskets, or garbage bags that are not “food-grade” to hold food.

Cans. The 46-oz. juice cans are good lard holders. You can just fit a baggie over the top to make a fairly tight cover before putting it away in the freezer. Or put the right size “food-

safe" baggie inside to line the can and fill it with liquid or food. Then tie, or wire shut, the baggie at the top and use it as a freezer container. One-gallon cans are good lard containers, too, and good grain holders to feed the chickens. Punch a few little holes in the bottom of your small cans, and you can start plants in them indoors. Cans make the best plant pots I know—except for peat pots, which aren't reusable or as sturdy, and you have to buy them.

Glass. Any gallon jar (glass or plastic) is good for many things—holding milk, pickling, anything you need a "crock" for. Widemouthed jars can be used as drinking glasses, or to hold seeds, crayons, Scrabble letters, or other odd things. In the summer, the children need jars with holes punched in the lid for grasshoppers, spiders, and so on. Small jars can hold dried herbs and spices, dried jerky, dried fruits, and crackers.

Paper. I wouldn't store (or eat off, or wipe with) white paper, because much white paper is bleached and has traces of carcinogenic dioxins in it. But brown paper bags are healthy to store in, as long as the food is dry and you don't heat the bag.

NOTE: Don't ever put a paper bag in a microwave or regular oven though, because bad chemicals will leach out of the paper when it gets hot.

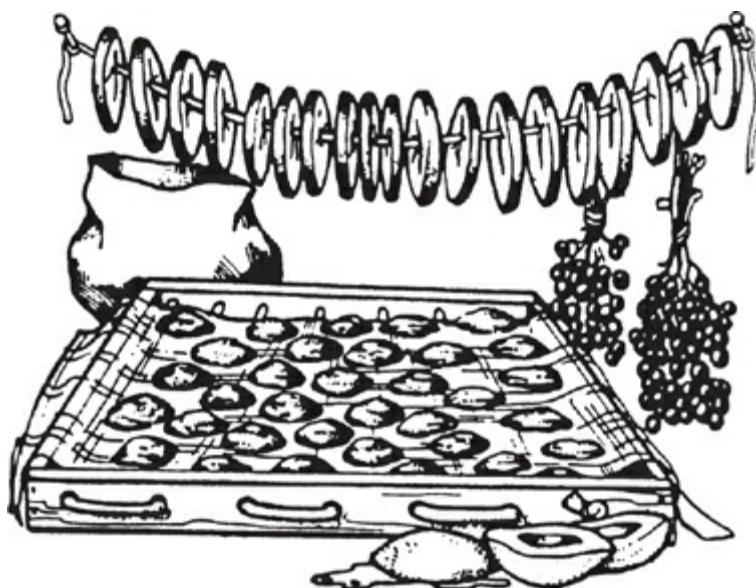

Found Toys. There are 3 places in my kitchen where children are especially welcome. One is the box that holds their toys, coloring books, and so on. The second is the special drawer where I keep my collection of lids, which double as toys. They think of their own games to play with the lids, and the possibilities are practically infinite. Toddlers love the chunky bright metals, especially the doughnut-shaped canning screw-tops. Bigger children make up matching games. The woodbox is their other favorite kitchen toy box. All kinds of forts, houses, barns, highways, railroads, and towers go up on my kitchen floor. They all end up in the stove, of course, but then the children are very willing to haul in more wood for me.

DRYING

Sun drying is the oldest method of food preservation. Nowadays it is the least common form. Too bad, because drying is a cheap, easy way to preserve, and everybody loves the results. You can dry fruits, vegetables, meats, fish, herbs, berries, edible flowers, nuts, and eggs. For directions, look in the entry in this book that tells you how to grow them. Small, thin, leafy herbs are the easiest foods to dry. Apples, apricots, cherries, and coconuts are the easiest fruits. Easy vegetables are mature kidney, mongo, pinto, red, black, and soybeans; green lentils; chili peppers; parsley; celery tops; mature sugar, cow, chick, pigeon, and other peas; sweet corn; sweet potatoes; and onions. You can make jerked meats, vegetable chips (corn, potato, zucchini, etc.), and much more. Dried foods require less space and weigh less than foods preserved in any other manner.

Low Moisture: Dried foods are preserved by their very low moisture content, so if in doubt, it's better to get them too dry rather than leave them too moist. The moisture content of a well-dried food varies with the food, from as little as 5 percent for leafy vegetables up to 25 percent for acid fruits. Most microscopic beasties won't grow in a low-moisture environment. The beasties aren't dead, however—they're just waiting. Research on drying and dehydrators is going forward at a marvelous speed, so your drying results can be better all the time. Recent problems with canning lids, shortages of jars, and threats to public power have really impressed on me the importance of knowing how and being equipped to dry. Friends who fed me their home-dried foods eliminated my last shred of

prejudice against dried vegetables. They were delicious!

DRYING INFO AND SUPPLIES: Get the latest extension service bulletins on home drying, probably free or at least cheap. Horizon Publishers (801-295-9451) specializes in dehydration books. They offer *The ABCs of Home Food Dehydration* and *New Concepts in Dehydrated Food Cookery—Hundreds of New Ideas and Tested Recipes for Enjoying Home Dehydrated Foods*, both by Barbara Densley; *Fun with Fruit Preservation—Leather, Drying and Other Methods* by Dora D. Flack; *Home Food Dehydrating—Economical Do It-Yourself Methods for Preserving, Storing, and Cooking* by Jay and Shirley Bills; and *Just Add Water—How to Use Dehydrated Foods and TVP* by Barbara G. Salsbury. There's also *Making and Using Dried Foods* by Phyllis Hobson; *Food Drying at Home* by Bee Beyer (300+ recipes for dried foods); and *How to Dry Foods* by Deanna DeLong. ATTRA's booklet, "Options for Food Dehydration," is at www.attra.ncat.org/attra-pub/dehydrate.html.

Dry It—You'll Like It by Gen MacManiman (75 pp., \$10) is a fun drying book—the first of them, and still a good one! Gen, now 86 and still going strong, offers her book, her personal line of Living Foods Dehydrators (your choice of three sizes, plus kits for those three sizes, plus they sell parts to make your own), and a free basic catalog of drying supplies: Living Foods Dehydrators; 425-222-6753; 3023-365nd SE, Fall City, WA 98024; www.dryit.com. From Gen's catalog you can order heat-fused polypropylene tray screening that is nonstick, absolutely food-safe, and easy to clean. You can get dryer thermometers and an electric food grinder specially adapted to powder dried herbs and vegetables, which you can then use to make your own instant soups and teas. (Powdered dried vegetables and meats are also nutritious additions to pet food or baked goods.) She also sells guar gum, a natural, excellent thickener for fruit leathers. Her growbox attachment turns a food dryer into a little hothouse for germinating seeds or sprouts. She offers Teflon sheeting—a permanent, nonstick, wipe-clean base for drying fruit leathers.

"FREEZE DRYING": This isn't something you can do at home. Food is freeze-dried by being spread on trays and then frozen there. Then the tray is put into a vacuum chamber. All the air is pumped out and the chamber is heated. The heat melts the ice, which turns directly into water vapor in the vacuum and is then pumped out of the chamber. Freeze-drying gets food drier than other drying systems; moisture is below 2 percent. So freeze-dried food stores longer and more safely.

Detailed Step-by-Step Drying Instructions

1. HARVEST: Harvest your fruit or vegetables at the peak of flavor. They'll taste better when slightly immature than when overripe—unless you're making leather. You can make fruit leather out of overripe fruits, but you're better off raising chickens and pigs on the overripe vegetables. Get started on the drying as soon as possible after picking the harvest. For sun-dried foods, start early in the morning. Then you've got the entire first day to get them started drying. Start on a day that promises to be dry and hot.

2. CLEAN AND SLICE: Wash off any dirt. Scrub if necessary. Dry off. Do the necessary shelling, peeling, slicing, or what-not. Vegetables to be dried are generally first cut up very thin, unless they are already small, like peas. Slice about $\frac{1}{4}$ inch thick—a little thicker for peaches, tomatoes, and zucchini. An important rule of drying is that smaller pieces dry faster and have better color and taste. If you slice peaches rather than merely halve and pit them, it takes more time at the start, but it saves time and struggle later on. The same goes for your other foods, especially vegetables.

Because vegetables are low in acid and spoil more easily, they need to be cut thinner than fruits so they will dry quickly enough that no microscopic beasties can get going. On the other hand, you've got a point of diminishing return on the thin slicing. Carrots, zucchini, pumpkin, sweet potatoes, squash, and turnips, thinly sliced and dried, make wonderful snack chips—good plain or with a dip. But if you slice them too thin, some foods, such as tomatoes and zucchini, tend to stick to the tray. (Unless you're using Gen MacManiman's wonderful nonstick liners.) But then again, almost everything sticks to some degree or other, and that cures itself as the food continues drying.

3. PRE-DRYING TREATMENTS FOR FRUITS: Fruits do not get blanched, but some people believe that the larger, lighter ones are improved by dipping in ascorbic acid, salt water, fruit juice, or honey solution before drying. The dips are useful for apples, pears, apricots, peaches, and other light-colored fruits that turn brown (an oxidation reaction) if exposed to air. A mere change of color would be no big deal, but oxidation also damages flavor and destroys some of the vitamins A and C. Most dark-colored fruits, such as figs, prunes, and grapes, don't oxidize. For those that do, here are harmless ways (unlike sulfuring, which is harmful) to prevent or minimize oxidation. The ingredients for these solutions are available in various places; try your grocery store—or your drugstore.

Salt-Water Dip. To keep fruits from darkening, you can slice or chop them directly into a gallon of water that contains 6 T. flaked pickling salt. Soak no more than 5 minutes so it doesn't get mushy with water content or too salty-tasting.

Ascorbic Acid Dip. Ascorbic acid is a form of Vitamin C. To make it, crush 5 one-gram Vitamin C tablets, or add 1 or 2 T. ascorbic acid crystals or powder to 1 qt. lukewarm water. Slice or chop your fruit right into this solution. Remove the fruit from the dip before it gets soggy. Drain and dry.

Commercial Fruit Preservative. This is a powdered mixture of Lascorbate, sugar, and maybe also citric acid. Just follow directions on package.

Sulfuring (or Not). The “sulfur” used for this purpose isn’t usually pure sulfur. It’s one of several preservative compounds containing sulfur that prevent darkening of light-colored fruits and repel insects. I don’t give a hoot or a howl what color things are—dark skins are just as good as light ones, and vice versa. And I think that what insects would consider inedible probably wouldn’t be healthy for my kids either. And I hate using chemicals unnecessarily. And unsulfured food tastes much better to me and digests easier. And 5 percent of asthmatics are sensitive to sulfites (some nonasthmatics may be also). The USDA says, “Those persons who are sensitive to sulfur dioxide and sulfiting agents have experienced sudden attacks of asthma, difficult breathing, nausea, diarrhea, and even death” after eating sulfured food.

NOTE: Sulfur fumes are injurious. If you sulfur, you must do so outside and avoid breathing the fumes! But I’m not going to tell you how to do it. Gerald Lehman, supplier of food dryers to the Amish, gets the last word here: “There is no need for chemicals or additives. Dried and properly stored dried foods will last as much as five years. Simply slice, dry, place in jar, and store in cool, dark area.”

4. PRE-DRYING TREATMENTS FOR VEGETABLES: Blanching is a hot water “dip” or a period in steam. It is used for vegetables to be dried or frozen. Vegetables should be blanched to reduce the risk of spoilage of low-acid vegetables; to halt enzyme action, especially the enzyme that causes first ripening and then over-ripening; and to tenderize them. However, drying slows the enzyme action anyway. Those who research in this field say that most vegetables will retain more flavor, color—and possibly also nutrients—if they are blanched before drying. Not everybody blanches, but many do, especially if the veggies are old, have been gathered too long, or were grown under very dry conditions. Chili peppers, onions, celery, zucchini slices, thinly sliced mushrooms, and garlic need not be blanched.

The Non-Blanchers. Crystal Glenn (beautiful name!) of Aspen, CO, has lived on a farm most of her 52 years and made soap, bread, butter, cottage cheese—and raised chickens and dried foods too. She wrote me that she has never steamed her fruit before drying it, nor has she blanched her vegetables. She said, “I’ve never had anything spoil or get wormy.” Catherine Humes wrote me that the only food she ever steams before drying is potatoes, “so they won’t turn black.” Farmers’ Bulletin 841, put out by the USDA in 1917, agrees: “Blanching of vegetables is considered desirable by some housekeepers, but it is not strictly essential to successful drying.”

Steam Blanching. You need a heavy pot or double boiler that has a tight-fitting lid, plus a wire basket that can be suspended over about 2 inches of hardboiling water. The chopped or sliced vegetable in the wire basket shouldn’t be more than 2 or 2½ inches deep. That way the steam flow will stay strong enough for all the food to blanch properly. Put the vegetable in over the boiling water, and cover tightly so your steam doesn’t escape. If you don’t have a steamer, put a sieve in the pan (hanging over the boiling water) or suspend a bag with the food in it over the edge of the pan. The important thing is to keep the food out of the boiling water so you actually steam rather than boil it. Blanch for the suggested number of minutes. Or just estimate: leave veggies in there until they are heated clear through and wilted, or until they look translucent when cut, tender but not completely cooked.

Boiling-Water Blanching. Start out with the kettle, but use lots more water. Put the food in the wire basket, but in this case you dunk the basket right down until the vegetable is

all covered by the boiling water. Start counting as soon as the water starts boiling again and leave it in there for the recommended amount of time. You can use the same water over and over. Use at least 1 gal. water per 1 lb. food. You need plenty of water so water will boil again soon after immersion and for best heat distribution into the food mass.

After Blanching. Pull out the vegetable, drain, chill by plunging into ice water or under cold running water, and drain again. Merely draining doesn't get it dry enough to go into a dehydrator. Blot vegetable dry with cloth or paper towels.

5. SPREAD ON TRAY: Spread your vegetables or fruit on the drying trays, one layer only in thickness, except for leafy stuff like parsley or herbs, which can be loosely mounded a couple inches deep. Don't dry very moist foods together with almost-dry ones. Dry strong-flavored (or -odored) foods by themselves. Set each piece separately (not touching) with air space between it and the next one. When drying lookalike herbs and fruit leathers, label them before drying.

6. SET TRAYS IN HEAT: Set them out in the sun, in your attic, or in your solar or oven or electric drying situation. Dry at a low temperature for better flavor and color, safer storage, and no risk of burning. *The drying temperature must be high enough that the food will dry before it spoils, but low enough that the food doesn't cook or get hard on the outside while damp inside.* Within those limits, the faster a food dries, the better its final quality.

7. STIR OR TURN FOOD: Turn the food often enough to keep it from sticking. Turn big-hunk kinds of food at least 2 or 3 times a day to speed drying and prevent sticking. Stir small pieces of food. Using a dehydrator, move most-nearly-dry foods to the bottom trays and put new and moist ones into the top. As foods shrink, you can consolidate to save tray space.

8. DONE WHEN? Fairly dry food may last a month or two. For longer storage, it needs to be completely dry. When is that?

Dry vegetables until they are brittle and will shatter when struck by a hammer, or until the dried slices crumble or break when bent. Fruits are dry enough when between leathery and brittle. Some fruits such as figs, cherries, raisins, and dates, are always sticky, no matter how dry. But even though still pliable, fruits must not produce any beads of moisture when squeezed.

Drying Methods

SUN DRYING: You can dry either by sunshine, in an oven, or in a dryer ("dehydrator"). I prefer sunshine drying over oven drying. Taste is good, there's no expense or risk of burning or scorching. Sun drying is the basic commercial method too. Most apricots, raisins, figs, peaches, etc.—your grocery-store-dried fruits—were sun dried. Read Stella Andrassy's 1978 classic, *The Solar Food Dryer Book*, and Joseph Radabaugh's exciting updates in *Heaven's Flame: A Guide to Solar Cookers* (www.homepower.com or www.backwoodshome.com/articles/radabaugh30.html).

Climate. For sun drying, your climate matters a lot. I live in a region where the days are very dry and very hot when fruit is in season. Hot days when the sun shines brightly all day long are perfect for sun drying. So outdoor drying is easy here in northern Idaho and in the dry Midwest and Southwest. It's harder in the rainy, humid, coastal Northwest.

Nights. Bring trays indoors at night because cool nights put moisture back into the food. Drying in the daytime but re-moisturizing at night can result in moldy food.

Bugs. If the sunshine holds, insects are the biggest threat in open-air drying. If you are drying early in the season before the flies and wasps are about, you can simply put the food out on trays. Sun drying works best if the wasps aren't around yet. Once August arrives, we are afflicted by wasps, with some child or other getting stung almost every day. I intensely dislike wasps, as does everyone else. Wasps especially eat meat and fruit. Fruit set out to dry not only attracts hordes of them, which is dangerous for the children, but the wasps actually will eat it up themselves. Cherries and apricots usually come before the wasps, so I can just lay them out plain with at most a porous cloth over the top. They'll go ahead and dry underneath it. Once the bugs are about, you must dry under a cheesecloth or nylon net, using something to raise it so that there's no chance of it blowing onto the food, especially into a sticky leather. Or else put the food outside in a screened bug-proof setup.

Flies are the other possible problem. A fly now can mean a maggot later in some types of food, especially meats. That's the real advantage of drying inside the house in a sunny window spot, or up in your attic, which is probably warm, dry, and bug-free. Another good spot is in the rear window of your car with the windows rolled down only $\frac{1}{2}$ inch.

You can make a screened-in sun dryer by starting with something wooden with four legs and a vaguely box-like structure, such as an unused rabbit hutch. I have a neighbor who did this. He replaced the top and bottom of the hutch with screen. He hinged the top and, just like that, he had a wonderful dryer in which to put the food trays. You can even design it so that more than one level of trays can be loaded in at once. Mike made me an outdoor dryer from an old wooden table: a screen on the top replacing the original tabletop and a screen on the bottom. The top was hinged to lift up, and the food trays went inside. But I have to confess that this nice dryer made from a table later evolved in the other direction and ended up becoming a rabbit hutch for Becca's two Christmas bunnies.

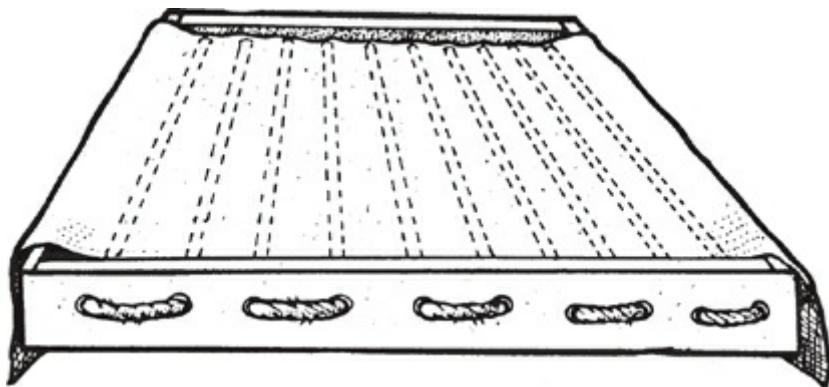

Secrets of Sun Drying

1. Don't dry outdoors where there is traffic pollution to avoid possible airborne lead contamination!
2. Don't ever lay food to dry directly on galvanized screen. The screen contains zinc and cadmium and will contaminate food.
3. Fruits can be dried nicely at 85°F or higher, but a temperature of 100°F or more is best for drying vegetables.
4. Always dry in full sun in a place where the air is moving as freely as possible.
5. Begin your drying with the trays covered with cheesecloth or some gauzy cloth (proped up to keep it from touching the fruit) in order to protect it from insects.
6. Fruits can get dry enough to store in a couple days. Vegetables may need as long as 3 or 4 days. It usually takes about 3 times as long to sun-dry as to dry in a dehydrator or oven.
7. Researchers have discovered that if you keep the drying process continuous by using an artificial drying system during the night, your food dries much faster and there is better quality, less loss of nutrients, and less risk of mold.
8. At the end of each day, turn your drying pieces and take your trays inside the house for the night to avoid dew. Set them out again the next sunny morning until the

drying is done.

9. If insect eggs may have been laid on your food, “pasteurize” before storing (discussed later in this chapter).

Homemade Drying Trays and Outdoor Dryer. You can make portable drying trays by making square (more or less) frames of soft lumber. Across the top, staple or thumbtack a single thickness of curtain netting or some other strong but very porous cloth or Gen MacManiman’s plastic screening—*not metal, which may badly contaminate your food*. The drying rack will resemble a window screen with a wooden frame. If you make your frame at least a couple inches smaller than the inside of your oven, you can also use these trays for oven drying. If the cloth sags, reinforce it underneath with string stretched from side to side. These screens are best when set up on posts or some such outside, so that air circulates through the mesh and all around your food. Inside the house, you can arrange a stack, with 3 or 4 inches between each tray, over the rear of your wood cookstove or heater, and dry food that way too. Allen Dong offers plans for a farm-scale food dehydrator at PO Box 413, Veneta, OR 97487. John Vivian published “How to Build a Food Dryer” in *Mother Earth News*, Feb./Mar. 1993.

DRYING IN AN OVEN OR DEHYDRATOR: Food dried in an oven or dehydrator generally has more color, flavor, and nutrients than sun-dried ones (except for leather). And there’s no bug problem.

Any very hot, dry area such as your attic, your car’s rear window, or around your heater or cookstove is a good drying environment. So is your oven, but oven drying, unlike sun drying, means you have to be on hand to keep an eye on what’s going on. Using a dehydrator is more like sun drying in that it’s usually foolproof; you can walk away and forget about it. Low-wattage dehydrators work well on electricity from alternative power sources and are still cheaper than canning. Dehydrators are the easiest to dry in. In your oven or dehydrator, you can dry year-round. Most, of course, during harvest, but ...

More Dehydrator Uses. A dehydrator is good for more than dehydrating fruit! In a dehydrator, you can make fruit leathers, jerky, and crackers; dry vegetables and herbs; rejuvenate limp crackers or chips; dry bread sticks to use with dip; and dry homemade pasta. It’s also good for raising bread and decrystallizing honey. Use it to dry flowers, dyed wool or wool sweaters, and lingerie. In some you can start seedlings, grow sprouts, and make yogurt.

You can dehydrate food leftovers (remove and discard all fat) to later toss into a stew, soup, or casserole or munch for a snack: peas, sliced carrots, even leftover spaghetti casserole! Dry the food you salvage from your root cellar storage, such as half a squash whose other half spoiled and went to the pigs, chickens, worm bed, or compost heap.

Temperature. The biggest problem with oven drying is that it is often hard to get a steady enough heat at a low enough temperature. The ideal drying temperature is 120–150°F. Over 150°F is potentially disastrous. Judging temperature can be a problem. Some ovens don't have a thermometer. If you don't have an oven thermometer, you can buy a portable one and put it in there; toward the rear of your top tray is best. If you can't get an oven thermometer, you can judge temperature by feel. The food should feel cooler than the air in the oven. If it feels warmer to you, either you need less heat or the oven door should be open wider.

Disengage, remove, or do not light the top heating element of the oven. Preheat it at its lowest setting.

Air Circulation. This is also a problem in the oven if you have a tight-fitting door. You want the air to circulate around the food to absorb the moisture and carry it away. So prop the oven door open at least $\frac{1}{2}$ inch. Gas ovens need to be open at least 4 to 8 inches. It helps to put a fan at one side of the open door to drive the air through the oven. While drying, occasionally change the fan's placement from one side of the oven door to the other.

Food Placement. Don't overload trays, and don't arrange your trays solid wall to wall, or the air won't circulate properly. Use trays that are at least $1\frac{1}{2}$ inches smaller than the width and depth of the oven. Separate trays by about $2\frac{1}{2}$ inches. Allow at least a 3-inch clearance from the top and bottom of the oven. Don't load an oven with more than 6 lb. of food to dry at one time; the food nearest the heat will scorch and that farthest from it won't dry. Every couple hours or so, swap tray positions around in the oven. And stir small pieces of food on the tray so they are more evenly distributed. This also exposes any wetness to the heat. Turn over large chunks individually.

Done? Oven drying is much quicker than attic, on-a-string, or outside drying. Vegetables may be done in as little as 5 to 12 hours, fruits in 6 hours or so. Pieces around the tray edges tend to dry first. Remove them first. Watch carefully near the end of the drying; it's easy to scorch food that overheats at the end. When drying is almost done, it's safest to turn off the heat and open the oven door wide.

Homemade Dehydrator. There are plans for making an electrical dehydrator in *Dry It—You'll Like It* and in Gen MacManiman's catalog.

Ready-Made Dehydrators. Among the many brands of electric dryers available, the Excalibur is very popular. It comes in three sizes, including a "family size." It's a real workhorse. For a free color catalog with recipes and drying tips, write: 6083 Power Inn Rd., Sacramento, CA 95824-2381; 800-875-4254; www.excaliburdehydrator.com. Look for a dehydrator that has a thermostat and is made of something better than the cheapie plastic that tends to break off after a few years. Magic Mill is of middling quality. Gen MacManiman sells a good one, the Living Foods Dehydrator. The American Harvest dehydrator has useful side venting.

Fruit Leathers

Another way to dry fruit, as well as certain vegetables, is to leather them. Leathers are lightweight, high in nutrition, and easy to store and pack for hikes and camping. They are a good way to make use of overripe fruits, a good healthful "candy" for the kids, and a good liner for a cobbler. Apricots and peaches make the nicest leathers, but you can make good ones from pears, plums, rhubarb, unseeded berries, and many other foods or

combinations of foods.

OVERRIPE FRUIT LEATHER: All the rule books advise starting with only the best produce when preserving, but fruit leather is a blessed exception to that. If fruit is too ripe or bruised but not yet rotten, you can still make it into wonderful leather. In fact, slightly overripe fruit actually makes a sweeter, better-tasting leather! You just wash it, cut out the worst, mash, and dry. Bananas, even if almost brown, make fine fruit leather.

STEPS TO “LEATHER” MAKING

1. For any fruit, basically you just rinse it off and grind or force it through a sieve, mash with a potato masher, put through a food mill, or blend. Remove the peels, especially with pears, or you'll get a disagreeably grainy leather. Take pits and seeds out at whatever stage is appropriate. Too many seeds can really spoil a leather. You can store the mashed fruit in the freezer until you get around to making leather, and it will be all right. Even if it has started a wine-type fermentation, it will still make good fruit leather!
2. To make vegetables (squash, sweet potato, pumpkin, etc.) into leather, you have to pre-cook and then sweeten and/or spice them to taste. You may like the final results of your fruit leathering better if you add 1 or 2 T. of sweetener per batch, and 1 t. lemon juice to light-colored fruits. You can vary sweetening and spices as you please, but you don't need to sweeten as much as you might think because as the leather dries and gets more concentrated, it gets sweeter and a chemical change occurs that causes the creation of more sugar.
3. The fruit or vegetables need to have the consistency of a smooth puree that is thin enough to pour. Add more fruit juice (any fruit juice will be great) or water if thinning is needed. (Apple and pumpkin tend to need thinning.) But too much water makes a puree that's too thin; thin puree tend to make a leather that sticks to the drying surface. (Grape and berry purees tend to be too thin.) If the puree is too thin, thicken by combining with a thicker sort of fruit puree; by slowly cooking it down over low heat to evaporate some of that water before you start drying; or by adding a thickener. There are lots of possible thickeners out there: guar gum (1 t. guar gum per 1 c. juice; let rest 10 minutes before you proceed); psyllium seed husks (1 T. per 1 c. juice; let soak 5 minutes before proceeding); slippery elm (2 T. per 1 c. juice; let soak 5 minutes); wheat or oat bran; or chia or flax seeds.
4. If you're making leather from light fruits (apple, apricot, peach, or pear), heat puree to almost boiling (about 180°F) before drying. That will retard the browning.
5. Line a drying rack or cookie tray with food-safe plastic. *Don't dry leather on wax paper or foil. The leather will hopelessly stick to them.* Low-pectin fruits naturally stick more than high-pectin fruits. Combine with apple if you want to raise the pectin amount. If you're expecting a sticking problem, lightly coat the drying surface with a nonstick vegetable spray or vegetable oil. If your plastic is flimsy stuff and likely to blow into the leather, tape or clothespin the loose edges to each side of the pan. A 12 × 17-inch cookie sheet will be just right for about 2 cups of puree. For larger quantities, one system is to cover the top of an outdoor table with plastic wrap fastened at the sides and ends with tape. Pour your puree onto that. To ward off bugs, you can make a cheesecloth tent over it.
6. Pour your puree in and get it spread an equal depth by carefully tilting the tray one

way and then another. The thinner your layer is, the quicker and easier it will dry. I recommend $\frac{1}{8}$ to $\frac{1}{4}$ inch. Get it too thick and you'll have trouble with spoiling, or you'll just plain get tired of having it around before it finally dries. If you get it thicker in the center than at the edges, you'll end up with leather that's brittle around the edges while still sticky in the middle.

7. You can dry by sun, oven, or dehydrator. Even home economists say that sun drying makes the best fruit leathers! They taste better and keep longer. When oven drying, try not to get the heat above 130°F and definitely not over 140°F! Oven drying with insufficient air circulation or excessively high heat tends to make a brittle leather. High heat also runs the risk of scorching the fruit or even melting the plastic! It takes longer to oven-dry fruit leather than plain fruit, but your leather could be done within 6 hours. In a dehydrator, dry at 120°F. Rotate pan or shelves often. When top side is dry, pull fruit off its backing. Dry with the down side up for about an equal time, and then you're done. Drying time in the sunshine depends on how hot and how humid it is. As few as 8 hours is possible.
8. Fruit leathers that are still slightly sticky to the touch but peel readily from the plastic are dried enough if they'll be eaten within a month or so, or frozen. They're nicer for finger food, but will store only up to 3 months or so at room temperature; if dried until no longer sticky, they'll store indefinitely (a year or more). Leather that is completely dried is mold-proof but tends to crack, crumble, and not roll. Pear, pineapple, and rhubarb leathers just naturally get more brittle during drying and storage than other kinds.
9. When your fruit leather is dry, cut it in strips about $1\frac{1}{4} \times 2$ inches, or into squares. If you made strips, roll each one up, tightly layered between waxed paper or plastic wrap. Wrap with plastic or paper on the outside. Or store in flat sheets with something between them. Enclose in a tightly covered moisture-and bug-proof container. Or you can just bag them up in plastic and store in the freezer. If the leather is not adequately protected from light, air, warmth, and moisture during storage, it will tend to darken and deteriorate.
10. To serve, you can cook up the leather like dried fruit, but children enjoy snacking on hand-held chunks so much that's generally the way mine goes. Children love them as much as candy. Other options are to dissolve the leather in water and use as a pie filling, serve as a dessert topping over a pudding or ice cream, or stir in yogurt to flavor it.

⇒ **APPLESAUCE LEATHER COMBOS** Mix applesauce with berries, or any strong-flavored or scarce fruit, to stretch it. Then use this mixture to make the leather, following the leather-making instructions above.

⇒ **CRISP FRUIT WAFERS** Add $\frac{1}{2}$ c. wheat bran per 1 c. thin fruit puree. Mix well, and proceed immediately as if to make a fruit leather. What you'll get is a delicious snack wafer. You can use oat bran the same way (especially good with tropical fruit juices), only it needs to soak for several hours before drying.

⇒ **FRUIT LEATHER "CANDY"** Sprinkle a breadboard with powdered sugar and work the leather strips on it, patting and rolling until about $\frac{1}{8}$ inch thick and powdered.

⇒ **LEATHER-JUICE COMBO** The essence of this method is that you steam or pre-cook your pitted fruit, then pour the panful into a sieve. What stays in the sieve gets made into fruit leather by the above recipes. What runs through (without a struggle) gets made into juice. The more juice you get, the quicker what's left will dry. This is really a great way to make your fruit juice without struggle and without waste!

⇒ **FRUIT PASTE CANDY** The pulp of two or more kinds of fruit can be combined for this. You can start from scratch with fresh, or use canned fruit. Just put the pulp through a fine strainer. Then measure it. For each pint of pulp, add $1\frac{1}{3}$ c. sugar. Cook stirring constantly, until thick and clear. Then turn out on an oiled platter. Let dry until a good tough film is formed on the top. Then turn it out onto a plastic screen to finish drying. Dry until it loses its stickiness. The sooner you can get it dried, the better. I recommend open air and sunshine for the job.

⇒ **SUNSHINE PRESERVES** This is actually a partially dried leather. This is the way to proceed if you want to keep the shape of the individual fruit sections in the preserves rather than work with a pulp. Dry fruit only until it has a "jam" consistency; then stop. Try this with apricot halves, nectarine or peach slices, or whole berries. The fruits keep their shape and color well. Use 3 c. sugar and 2 T. lemon juice to 4 c. fruit. Combine fruit, lemon juice, and sugar in a pan. Stir gently to blend the ingredients. Now cover and let set at room temperature 1 hour. This is to extract some juice to cook it in. Now put it on the heat and stir until it boils. Then let it boil hard 4 minutes without stirring. Now cool, uncovered. Pour your preserves out into glass or plastic pans or trays, $\frac{1}{3}$ – $\frac{3}{4}$ inch deep. Set out in direct sunlight. If bugs or dust are a problem, cover with a pane of glass or clear plastic, leaving a 1-inch opening along the side. Once every hour stir a little bit. They are done when the fruit is plump (turn as needed) and the juice is about as thick as corn syrup. Your preserves will get thicker when cold.

⇒ **UNCOOKED SUGAR-DRIED FRUITS** To make this half-dried crock preserve, pit, peel, and cut up peaches, apples, sliced pineapple, or whatever. Dry partly. Then pack in a crock with sugar spread thickly between each layer. Another way is to halve peaches, remove the pits, sprinkle the cavities with granulated sugar, and dry in an oven. Currants and cherries can be boiled with $\frac{1}{2}$ lb. sugar per 1 lb. fruit for 15 minutes and then spread out to dry.

Storing Dried Food

CONDITIONING: The Number 1 problem in storing dried foods is mold. The risk is highest in a damp climate. So conditioning is very important, because it equalizes moisture so there are no damp spots where mold can get going. Conditioning allows excess moisture from some pieces to be distributed among and absorbed by drier ones.

After you finish the drying, put the food into a wide-rimmed, open-topped bowl for about a week. Give it a stir 2–3 times a day. Keep it covered with a screen or porous cloth fastened around the rim with a rubber band or string to keep out bugs. Then, if you wish, you can repack more tightly.

THE PASTEURIZATION OPTION: Some dryers heat up their dried foods once after they're done drying (and before storing) to "pasteurize" them. Other home dryers consider this step unnecessary and never do it. It's basically a final line of defense against bug problems. To pasteurize, heat the dried food before storing in a 175°F oven for 15 minutes, or in a 160°F oven for 30 minutes. Or else put in your freezer for 48 hours.

PREVENTING STICKING: Before bagging up sticky dried fruits, you can reduce sticking by shaking them in a bag of dusting material. Gen McManiman suggests dusting bananas with powdered oats, apples with cinnamon, pears with nutmeg, tomato slices with garlic powder or chili mix, and pumpkin pie leathers with pumpkin pie spice.

MORE TIPS ON STORING DRIED FOOD

1. Store in small batches because even one small still-moist piece can cause the whole container's contents to mold, and because dried foods are best if used within a short time after their container is opened.
2. If you live in a moist climate, put the dried food inside the jar, and screw the lid on tightly as soon as you've finished drying, so it can't accumulate moisture again.
3. The lid does not have to be a perfect-sealing canning-style lid; save your money. On the other hand, it's nice if the container is moisture-, bug-, and dust-proof. But the reality is that you can use almost anything for a while—and we do: even a paper bag, a recycled mayonnaise jar and lid, or a plastic box with a tight-fitting lid.
4. Don't store in glass jars or clear plastic bags. It's nice to easily check and see just what's going on in there, but where there's light, there's oxidation; and when there's oxidation, there's nutrient destruction. If you do use a glass jar, line it first with a brown paper bag. If you must use glass and clear plastic, be sure to store it in the dark. Or you can store in paper bags.
5. In a humid climate, if your plastic or paper bags aren't airtight, you could put them inside a larger glass or metal container and put a tight lid on that. The outer glass or metal will also protect against insects or rodents. *Dried food should never be stored in*

direct contact with metal! (Line containers with plastic or paper.)

6. Label jars and packages with the name of the food and date you dried it. An easy system is to just put a strip of masking tape on the container and write on that. Freezing and thawing doesn't hurt dried food.
7. Store out of direct light and in a dry, cool room. You can keep it dark enough by storing the jars inside a cardboard box or under a sheet of black plastic.
8. Check once or twice a week for the first several weeks, and occasionally after that. *If you see moisture beads inside the jar, the food should be dried some more!* Mold is the result of food that's too moist when stored or that is packaged so openly in such a humid environment that moisture is absorbed.
9. Dried food should stay in prime condition for at least 6 months and may last up to 5 years, but there will be slow but steady deterioration in the meantime.
10. If bugs get into your dried food, you can salvage it by removing them and then roasting the dried food at 300°F for 30 minutes. Repackage and store the food again in containers that don't allow air circulation or insect passage. It should be all right, but check again after a few weeks. If there are signs of bugs, give the food yet another heat treatment. Bugs are not poisonous, just visually unappealing.

Using Dried Food

You can eat dried foods straight or "rehydrate" ("refresh") them by soaking or cooking in water, broth, or fruit juice. The warmer the water, the quicker the food will soak it up. Don't add sugar or salt to the rehydrating fluid; they both hold back water absorption.

Eat dried fruits out of hand for snacks at home, on the trail, or in lunch boxes. Or use pieces of dried fruit in cookies, cakes, puddings, breads, etc. Reconstituted dried fruit makes nice stewed fruit or sauce served plain. Or add it to bread, gelatin, stuffing, homemade ice cream, milkshakes, or cooked cereal. Soak before cooking—6 hours or more.

Unlike fresh fruit, dried fruit needs little or no sugar. That's because the drying process changes the starch in the fruit to sugar. The dryness and the sugar content were the forces that combined to preserve it. A little lemon juice, though, usually improves the flavor.

Add dried vegetables to stews, soups, or sauces. Or make a basic soup mix by powdering them in a blender. Add herbs or spices and package for quick soup. Combine with dried milk for an instant cream soup mix. Use in meat pies and other main dishes or add to gelatin or vegetable salads.

⇒ **BASIC STEWED DRIED FRUIT** Pour 1 c. boiling water over 1 c. dried fruit. Add ¼ t. cinnamon, ¼ t. nutmeg, and a pinch of ginger. Let set until it softens to your taste. Tastes good sweetened with honey or mixed with yogurt.

⇒ **FRUIT GRANOLA** Chop dried fruit into small chunks; half raisins and half other fruit such as apples, apricots, or peaches is good. For every 2 c. chopped dried fruit, add 7 c. rolled grain (all one kind or a combo such as half oats and half wheat). Optional: peanuts, sunflower seeds, or other nuts and seeds. Stir together until well mixed.

⇒ **DRIED FRUIT AND RICE** Pre-soak 1½ c. brown rice. Then cook. Add lots of dried fruits, pumpkin pie-type spices to taste, perhaps nuts, and a pinch of salt. Serve with your choice of milk, butter, or honey. This is great warmed up with hot milk for a quick, good breakfast.

➲ **DRIED FRUIT JAM** Use dried fruit in any combination that suits you. Add extra sweetener if you like; $\frac{1}{2}$ c. dried apricots with $\frac{1}{4}$ c. dates, for example, is good. Make this in a blender and moisten with a fruit juice to enhance spreadability. One cup pineapple juice is about right in that apricot-date combo. It helps to soak the dried fruit overnight in the juice before blending. This dried fruit jam makes a nice syrup on pancakes and waffles too.

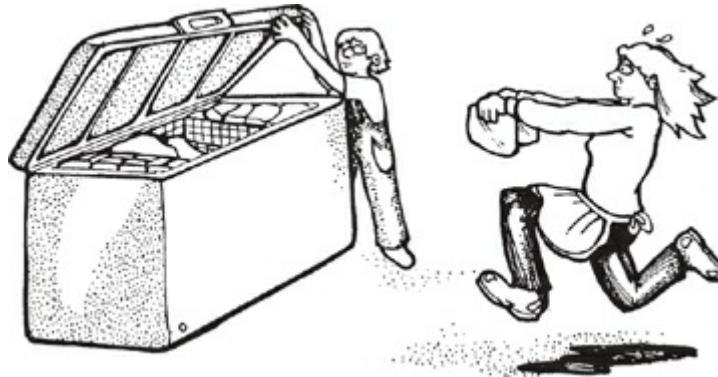

➲ **DRIED VEGETABLE SLICES AND DIP** Slices of dried carrot, cucumber, eggplant, and tomato are good with a dip.

➲ **INSTANT SPAGHETTI SAUCE** To a basic tomato puree, add dried onion, dried green pepper, dried basil, and oregano.

➲ **VEGETABLE POWDER** You can grind any thoroughly dried vegetables in a blender or in Gen's special powdering machine. Store in tightly sealed, small packages. To use, just add to boiling water. You can create your own formulas for instant soups or extra nutrition and flavoring for casseroles or stews.

FREEZING

Freezing is the most popular food preserving method. There is no risk of botulism. It's simpler and far faster than canning. And it retains more nutrients than any other form of food preservation. Freezing is a wonderful system for preserving meat.

The foods that freeze least well are the ones that you are accustomed to eating crisp: celery, lettuce, cucumbers, green onions, green peppers, and radishes. But even these can be frozen and used in cooked dishes. Food varieties have become very specialized; the fruits and vegetables that freeze best of all may now be distinct varieties developed especially for that quality. Check with gardening neighbors or your county extension agent.

After the home freezer was invented, people soon froze more than they canned, and they still do. However, you need a real freezer. You can't do serious food storage by freezing in that small space above the refrigerator. It isn't big enough, it isn't cold enough, and its temperature fluctuates too much for safe long-term storage. Upright or chest-type freezers will keep food in a good state for months or longer, though it will lose quality.

To sum up, freezing is great and most foods do wonderfully well in the freezer, even over long periods. But there is a big difference between food that has been in the freezer two weeks and food that has been in there a year!

Books: See *The Complete Book of Home Preserving* and *The Home Freezer and The Complete Book of Freezer Cookery*, both by Ann Seranne. The new *Ball Blue Book Guide to Home Canning, Freezing & Dehydration* is available from Alltrista, Direct Marketing, PO Box

2005, Muncie, IN 47305. But there's no substitute for experience. There's no way you can kill yourself eating frozen foods. So don't worry. Plunge in, start doing it—and you'll learn how as you go.

LOCKERS: A "locker" is a box-like space that you can rent in a public walk-in freezer. They are wonderfully cold. You can rent all the space you need. They're so cold that they're good for quick freezing both meat from hunting or butchering and a mountain of vegetable harvest that you will sooner or later move to your home freezer. They're good for holding a harvest overflow, and they're priceless if your power or freezer conks out and won't be operational again for a while. To find one, look in the Yellow Pages under "Lockers," "Frozen Food Locker Plants," or "Cold Storage." Lockers are inexpensive to rent. Get the size you need. You furnish your own pad-lock, and you can come and go as you please to add or remove food.

ONCE-A-MONTH COOKING: As the owner of a freezer, you have the option of this exciting new concept in food preparation! Once a month, in 1 or 2 hard-working days, cooks prepare 30 or more meals at a time, then package them in portions and freeze. The rest of the month, they just pull them out of the freezer, thaw, and serve. (Thaw in fridge 24–48 hours. Then bake, if not precooked—most of these are casseroles. Or microwave.) Once-a-month cooks say it helps them get the food budget under control, saves having to figure out what to fix for dinner every night, avoids excess visits to the grocery store, enables them to supply a meal on short notice with very little effort, and saves washing pots and pans every night. When a friend is sick, you can take her a meal from your freezer. And this system frees up a lot of time for things other than cooking.

Actually, not everybody who cooks this way makes 30 dinners at a time. Some cooks prefer to do it every 2 weeks and make 15 at a time, or to just double or triple the recipe every time they cook and put the surplus in the freezer. Some prefer to do 45 at a time! Learn once-a-month cooking with www.simplemom.com, the website of Deborah Taylor-Hough, author of *Frozen Assets Lite and Easy*. Or read *Once a Month Cooking* (also published as *Dinner's Ready*) by Mimi Wilson and Mary Beth Lagerborg.

Buying and Installing a Freezer

CONVENTIONAL OR RADICAL ALTERNATIVE? There are some amazing new appliances out there in the rapidly developing area of alternative energy products. Consider checking out the sources listed in [Chapter 1](#) that specialize in these, and see what they've got. When you buy these pioneering products, you finance people who are doing urgently needed research and help test their innovations. Even more energy-efficient versions of standard mass-market freezers are a good investment. They're likely to cost maybe 10 percent more up front, but you'll save money in the long run because a typical freezer will last for at least 20 years.

FROST OR FROST-FREE? Frost-free freezers use more energy and tend to dry out food. With the other kind, you'll have to defrost once a year.

CHEST OR UPRIGHT? The upright freezer takes up less floor space, is easier to see into and find stuff in, and you're less likely to lose stuff into the bottom until it is so old it no longer tastes good. In all other categories, the chest type is superior (and it is the most popular). The chest type is cheaper, won't need defrosting as often, and gives you more room for your money because you can pack it practically solid without everything falling out every

time you open the door. It's also more heat efficient and better at keeping the food at the needed steady cold temperature because the cold air doesn't fall out every time you open the door. We have the biggest chest type there is. It cost about \$250 [1974]. The freezer is a low-maintenance appliance. The guarantee probably won't be an issue for years.

SIZE? Chest freezers range in capacity from about 5 to as much as 28 cubic feet. Uprights can be just as small or even larger. On average, 1 cubic foot of freezer space will hold 35 pounds of frozen food. The size most often bought by families is the 16-cubic-foot capacity. The largest size freezers, 18 to 25 cubic feet, work well for large families that are doing major gardening, home butchering, and/or advance meal preparation. A family that uses its freezer a lot can make use of just about all the space they can get, as much as 7 cubic feet per family member. A bigger freezer can inspire you to do more food preserving, more baking and cooking ahead, and more shopping for bargains.

Some big families I know use 2 chest freezers. But I think one can do it for most families if you stagger the input. Vegetables and berries are frozen in season. Canning your fruit saves room. Wait to butcher until the weather is quite cold and there is increasing room in the freezer because the vegetables are being eaten up. On the other hand, if you have, say, two 10-cubic-foot freezers instead of one 20-cubic-foot one, you can use one for long-term storage and the other for frequently used items. The long-term foods will store better because the lid isn't going up and down all the time. And when you defrost, you can keep frozen goods in one while you defrost the other, and then switch and do the same thing to clean the other.

CORD AND PLUG: When you are setting up your freezer, put the cord and plug in a place that's as protected as possible from little gremlins. All they have to do is pull that plug to bring on a terrible disaster in the freezer. Since the first edition of this book came out, several people have written to tell me that you can buy a special attachment for a plug that makes it childproof. Sounds like a great thing.

WHERE TO PUT IT? It would be nice to have it close to your kitchen, but freezers generally aren't in the kitchen. That's because the cooler the location you put it, the less the freezer will have to run, which saves on electricity. On the other hand, don't ever put a freezer where the temperature goes below freezing. Oddly enough, they're built to cope with heat (up to about 110°F) but not to endure that much cold. So consider putting it on a back porch or in a basement, attached garage, or any relatively cool part of the house. Set it out of direct sunlight and in a well-ventilated space. A 50–65°F room is good. Don't put it near your wood stove or furnace, or in a humid area; that hastens frost accumulation.

NOTE: Figure out where your freezer will go before you buy! Check to make sure doors and turns are wide enough to get it in there. Allow for a 4-inch space between the back of the freezer and the wall (to vent condenser-coil heat).

IDEAL FREEZER TEMP: The ideal temperature at which to set your freezer is -5°F. You can double-check the freezer temperature with a mercury-type thermometer. Food will keep longer at lower temperatures, but your electric bill will be proportionately higher; 0°F will keep it long enough.

NOTE: Don't set it any higher than 0°F. Above that, food deteriorates much more quickly, even though it is still frozen.

Yes, I know that 32°F is the temperature below which things freeze, but though food stored even at 15–20°F seems solidly frozen, it just won't keep as well as food stored at 0°F

or below. Even at a few degrees above zero, the freezer life of your food is cut in half! Those low-temp-specialist microbes are really something. If your freezer or freezer compartment can't keep food at 10°F or below, try to use it up within 2 months.

Also consider that the top center of a chest-type freezer tends to be a few degrees warmer than the bottom. In an upright freezer, the storage area inside the door tends to be the warmest. Adjusting the freezer compartment of your refrigerator to store food at 0°F will tend to keep the refrigerator section underneath below 37°F (the ideal temperature for preserving nonfrozen foods).

So if you want to save on the electric bill, a better way than turning up the temperature is to keep the freezer at least 70–80 percent full. Keeping air cold requires more electricity than keeping food cold! Keep the freezer door shut except when you absolutely have to get in there, and make it fast when you do open it. That helps keep it cold. Be especially careful when the air is hot and humid. If your freezer is old, make sure it's staying well-sealed around the door. Gaps allow cold air to leak out and warm, moisture-carrying air to get in.

Milk Carton Tip. From Jan Grant, county extension agent, Seattle, WA: Fill up your extra freezer space with empty cardboard milk cartons full of water. Once they are frozen, they will help keep your food cold longer in case the electricity goes off. And you can use the block of ice when blanching vegetables for freezing: Put it in your chilling water. It's also an emergency water supply; just melt and drink.

Steps to Freezing Food

The four most important factors for success in freezing food are food quality to start with, speed in processing, airtight packaging, and temperature control.

1. FOOD QUALITY: Start with only high-quality, truly fresh-from-harvest food. You'll have best results if you choose young, tender vegetables. When I thin the carrots, I wait until I have some "baby" size—finger size, you can say. I pull those out and freeze them. That way I don't have to throw away any plants. I come back and get more later if the garden needs more thinning or my freezer needs them. Big carrots don't freeze well. They are better kept in the ground or in the root cellar, or sliced thin and dried. But those baby carrots can be frozen whole. The same goes for the baby beets. Beans for freezing should be no more than half grown, in the long, slender stage before they have gotten fat and tough with the beans inside too well developed. Full-grown vegetables are better off canned or stored in the root cellar. Lettuce, onions, cucumbers, and radishes don't freeze well.

2. PROCESS QUICKLY: Get food, especially vegetables, from the garden to the kitchen counter as rapidly as possible. If vegetables are sitting, they're losing both nutrition and flavor. If they must wait, store them in a cold place.

3. PREPARE FOOD: Wash the food thoroughly in cold water in a colander or sink filled with cold water. Scrub as needed with a medium-stiff bristled brush or a plastic or nylon-net scrubber. Lift the food out of the water when you're done to leave behind the grit that has settled to the bottom of the sink. If you want to freeze slices of vegetables such as broccoli, cut them before blanching, except for corn—cut it off the cob afterwards.

4. PRE-TREAT (BLANCH) VEGETABLES: Blanching destroys enzymes that cause food spoilage.

Don't blanch chopped onions, green peppers, sliced mushrooms, sliced zucchini, or fresh herbs. It also isn't necessary to blanch vegetables that are to be stored less than 3 months. For longer storage it's not a matter of life or death, but color and texture will turn out better if you blanch. At first there's no difference, but after 4 or 5 months, blanched foods are much nicer.

Non-Blanchers. Not everyone blanches before freezing. Ione Thompson of Colusa, CA, wrote me, "We do not care to blanch many of the vegetables we freeze, as they lose flavor and crispness. With peas and beans (also all fish) we clean them, put into plastic cartons, and cover with water. When frozen, take from carton, put in baggie, and return to freezer. We wrap corn and asparagus tightly in foil, then put in baggies or freezer paper and freeze." Indeed, many vegetables can be frozen without blanching, but their storage life won't be as long. Other than those named above, the best vegetables not to blanch are celery, corn in husks, cabbage, sugar snap peas, summer squash, and broccoli. To see what you prefer, run an experiment. Blanch some of your vegetable and don't blanch some. Label the packages and compare the results.

Equipment. You need a deep kettle that contains boiling water; a colander and/or big sieve (to hold vegetables to be blanched) that can be immersed in the kettle without having the rim or handles go under water; and 2 buckets or double sinks full of ice and water.

Blanch. Immerse the vegetables in hot water. Time the scalding starting from the moment the water returns to a boil. (The time needed to blanch a food is given under the entry for that food in this book.) Add 1 minute to the blanching time if you live 5,000 feet or more above sea level.

Chill after Blanching. Immediately after the blanching is completed, remove from the hot water. Sometimes I put larger vegetables directly into the kettle of water, as you do with corn on the cob. When they are blanched, I fish them out with 2 potato mashers, one held in each hand. Smaller vegetables are fished out with a sieve, which then holds them under cool running water from the sink faucet. The ideal procedure is to put the blanched vegetable into an ice bath or to cool in a colander under a stream of cool running water until you have its temperature down as low as possible. The immediate chilling reduces as much as possible the period of lukewarm temperature during which the bacteria quickly build their numbers. The thicker the vegetables, the harder it is to get them frozen (beets and whole carrots take longer than peas, for example), so you should have them cooled as much as possible before packaging. The only exception to chilling before freezing is if you're working with only a small amount that you can put in small packages for the freezer to cool.

Sample Blanching Procedure: Peas

- a. Put shelled peas in the colander and sink colander, peas and all, in the boiling water.
- b. Leave it there just long enough for the water to return to a boil. Then start counting. If it takes longer than 2 minutes for the water to boil again, you're trying to blanch too much at once. You can time the vegetable or do it by experience. When the peas change color, they're ready—"blanched."
- c. Lift out the colander full of peas and let it drip a moment. Immerse in a first bowl of ice water. Stir with your fingers to help it cool.
- d. In a minute or two move it to a second bowl of ice water.

e. When the peas are thoroughly chilled, drain, package and put in freezer. You'll have terrific-tasting peas using this system.

5. PRE-TREATMENTS FOR FRUITS: Fruit can be packed for freezing without a sweetener or a liquid. Fruits that will be eaten raw or used for pies or jams after thawing will be fine without a sweetener. Just slice or crush them in their own juice, or even freeze them whole.

Anti-Oxidant Treatment. To prevent discoloration of light-colored fruits and other deteriorating effects of oxidation, fruit can be briefly soaked in a solution of ascorbic or citric acid (or a combination of the two)—about $\frac{1}{2}$ t. per 1 qt. water. Or some lemon juice can be added to their water. You can buy the acid at any grocery or drugstore under a trade name.

Sugar and Syrup Packs. Fruits deteriorate in color, texture, and flavor less quickly if packed in a sugar or syrup pack than if frozen unsweetened.

Pectin Pack. Fruit is frozen in a syrup made by mixing powdered pectin, sugar, and water. Combine 1 package ($1\frac{3}{4}$ oz.) powdered pectin with 1 c. water. Boil 1 minute, stirring. Add $\frac{1}{2}$ c. sugar and stir until dissolved. Remove from heat. Add enough cold water to make a total of 2 c. syrup. Cool before using.

Dry Sugar Pack. Just mix sugar and fruit until the sugar dissolves in the fruit juices. Use 1 part sugar per 4 or 5 parts fruit, measured by weight. Or sprinkle $\frac{1}{2}$ c. sugar per 1 lb. fruit.

Honey Pack. Honey will work if your freezer faithfully stays at 0°F or below. If the temperature gets higher, the honey is likely to crystallize.

Syrup Pack. The fruit is prepared for freezing by immersing it in a sweetened syrup. Syrups may be called light, medium, or heavy, depending on how much sugar they contain. A light syrup is made by mixing 2 c. sugar with 4 c. water. A medium syrup is a mix of 3 c. sugar and 4 c. water. A heavy syrup is $4\frac{1}{4}$ c. sugar and 4 c. water.

6. PACKAGE: Use vapor-resistant or vapor-proof packaging materials. Package in such a way as to remove as much air as possible and seal the package airtight. Be sure to label the outside of the package with the date and name of what's inside! I like to package in plastic bags because it saves freezer space. Paper containers with only a thin layer of wax, and the thinner plastic bags and wraps, are not suitable containers.

Plastic Boxes. Best are plastic containers that are intended as freezer containers. You should be able to seal the cover airtight. You can use waxed cardboard cartons (cottage cheese, ice cream, or milk cartons) only with a polyethylene bag liner, because alone they are not moisture/vapor-resistant. If you put a plastic bag inside the plastic freezer boxes before you pour in fruit, the fruit keeps better and the outer plastic container lasts better. You can use regular zip-top plastic bags from the grocery store for this. Don't use hard plastic containers such as cottage cheese, yogurt, or margarine tubs at all—or at least only with an inside bag—because they tend to crack at low temperatures.

Jars. The best jars for freezing are widemouthed freezer jars with straight sides. The best shape for rigid glass or plastic containers is square, so they fit close together and don't waste freezer space. To pack food into a widemouthed container, allow $\frac{1}{2}$ inch headspace at the top for pints, 1 inch for quarts. If it's a narrow-mouthed container, leave $\frac{3}{4}$ inch headspace for pints, $1\frac{1}{2}$ inches for quarts. This is to allow for expansion of the liquid while

freezing. You can freeze in nonfreezer-proof jars if the contents will be relatively loose and dry rather than liquid.

Bags. The non-rigid containers that you can use are boilable plastic bags and plastic freezer bags. Boilable bags are constructed of heavy-duty, food-safe plastic that can handle both cold and heat. (If you are using boilable bags, you can blanch, cool, freeze, and later cook the vegetables, all right in the same bag.) Polyethylene film and bags are good for freezing. You can get them at grocery outlets. For freezing, it's best to use only plastic bags labeled "food safe." I bag all my vegetables. If the bags aren't sturdy, especially when holding peas and beans, I pack them into a larger, stronger plastic freezer bag. A chicken will fit into one big bag.

Freezer Wraps. We wrap other meats with butcher paper ("laminated paper" or "locker paper") fastened with freezer tape. Your butcher can tell you how to get such paper if your grocer can't. Or you can wrap in polyethylene or Vinylidene chloride film (Saran) sheets. Heavy-duty foil ("locker"- or "freezer"-grade) is another option, though I dislike putting aluminum next to food. Regular kitchen waxed paper is not enough protection for long-term freezer storage. When using a wrap, press it around the food to shut out as much air as possible. You want your package to be moisture/vapor-proof. The best wrap is the one that is most tightly sealed. To package food using rolled material, cut it to size, wrap around your food in about three layers, press to get out all the air, and seal with freezer tape.

Sealing Boilable Bags. Seal by placing the top of the bag on the small, heated sealing strip inside the bag sealer. Some bag sealers and bags are designed to use a continuous-roll bag that you custom-seal to whatever size bag the situation calls for. There are various brands of bag sealers, such as the Oster Automatic Bag Sealer, Dazey Seal-A-Meal, and Krupp vacuum sealer, all modestly priced. Or you can seal by filling the boilable bag, laying it on a heavily padded board, covering the bag with a damp cloth, and sealing the open edge using an electric iron at its low setting. This is more trouble than the regular bag sealer, but it works.

Foods Containing Free Liquid. For foods that are mushy or runny, you'd appreciate something sturdier than a plastic bag. You could line with a plastic bag a tin can, an odd-sized jar that can't be used for canning, or a jar with a chipped rim. (The bag also makes air space in the bottom of the jar that prevents the jar from breaking when the frozen liquid expands.) Pour in the liquid and close off at the top. Leave 1 inch headspace in glass jars, $\frac{1}{2}$ inch for plastic containers. Freeze it in the upright position; once frozen, it can go any which way. You can also freeze using freezer jars. In that case, pour the food in your jar, put on the lid, and screw the band down tightly. That is probably the best freezer container because it's an airtight, leakproof, moisture-proof, odor-proof container. Be sure and leave headspace at the top to allow for expansion during freezing.

Vacuum Sealing. Vacuum sealers for individual users are a recently developed product. You can buy them at Costco for \$250 or so.

NOTE: After you vacuum-seal food, it must be refrigerated and eaten soon—or kept frozen or canned. Otherwise, vacuum-sealed food can kill you from botulism, just as underprocessed canned food can! People see shrink-wrapped foods in the store that are keeping well and assume all the packager did was wrap them. But those foods were packaged and sealed and then heat-processed, much like canned foods!

7. **FREEZE:** Speed is important! Quick freezing minimizes ice-crystal formation and spoilage.

Secrets of Speed Freezing

1. Twenty-four hours before you're going to be doing a major freezing project, turn your freezer temperature to -10°F.
2. Small packages freeze faster than big ones.
3. You can freeze food most quickly by spreading it out on a tray and putting it in the freezer. When frozen, gather up the food and bag it for long-term storage. Not only is this style quick, but you can also freeze food loosely so that a little can be removed at a time rather than it all coming out in one big frozen hunk.
4. Put the packages of unfrozen food right next to the freezing plates or coils in the coldest part of the freezer. Or place unfrozen food against the freezer wall, and in a single layer across the top of your freezer, with space between packages. After they're frozen you can rearrange for long-term storage.
5. For big quantities, you can quick-freeze in a locker and then bring home to your freezer.
6. Once the food is all frozen, turn the freezer back to 0°F.

Freezing a Lot at Once. The bigger your freezer is, the more food it can handle freezing at once. But don't overwhelm it. The manufacturer's booklet that comes with the freezer will tell you the maximum amount that you can freeze at one time. If you have half a beef, perhaps it would be best to take it to a locker for quick-freezing first. The more unfrozen food you put into a freezer at once, the longer it will take the machine to get it frozen. Worse, having a bunch of warm food in there may raise the temperature of the frozen food already in there. It's more at risk than the fresh food, because frozen food whose temperature increases can quickly spoil. So be conservative in adding new food—in general no more than 2 to 3 pounds of food per cubic foot of freezer space. For example, a 16-cubic-foot freezer should not have more than 35 pounds of unfrozen food put into it in one 24-hour period of time.

FREEZER STORAGE TIMES FOR GOOD QUALITY

Fish and Meat

Fish

2 to 3 months

Oysters, crab, roe, lobster

4 to 6 months

Raw meat

8 to 12 months

Fried meat/poultry

1 to 3 months

Roast meat/poultry

2 to 4 months

Meat dishes, cooked/combo (stew, etc.)

3 to 6 months

Meat loaf

3 to 4 months
Meat, ground
3 to 4 months
Pork, cured
1 to 2 months
Pork, fresh
6 to 8 months
Poultry (chicken, turkey, etc.)
12 months

Dairy and Eggs

Butter
5 to 6 months
Cheese, hard or semi-hard
6 to 12 months
Cheese, soft
4 months
Cottage cheese
1 month
Eggs
12 months
Ice cream/sherbet
1 to 3 months
Milk
1 month

Baked Goods

Biscuits, baking powder breads, rolls
6 months
Cakes (angel, chiffon, sponge)
6 months
Cakes, shortening (chocolate, nut, spice, etc.)
6 months
Cheesecake
4 months
Cookies, baked
6 months
Cookies, unbaked (except meringue)
6 months
Cupcakes
6 months
Fruitcake
12 months
Muffins
6 to 12 months
Pastry crust, unbaked

6 to 8 weeks
Pie, baked pastry

2 to 3 months

Pie, chiffon

1 month

Pie, fruit or nut

3 to 4 months

Pie, mince

6 to 8 months

Waffles

1 to 2 months

Yeast breads, baked

6 months

Fruits

Fruits, citrus

12 months

Fruits, non-citrus

12 months

Vegetables

Onions, uncooked

3 to 6 months

Vegetables, cooked

1 month

Vegetables, uncooked (except onions)

12 months

Other Foods

Appetizers containing mayonnaise, sour cream, egg whites

3 to 4 weeks

Dips and spreads (no mayo, sour cream, or egg whites, but may contain cheese, cold cuts, fish, or egg yolk mixes)

1 year

Nuts

6 to 8 months

Pasta (macaroni, spaghetti, etc., cooked)

1 month

Soups, stews

6 months

It's best to use all frozen foods within a year, and most of them in less time. These recommended keeping times for frozen foods are based on quality loss. You could have a turkey in there for 14 years and, if it never defrosted, it would still be safe to eat, though not very tasty.

Using Your Freezer

LONG-TERM FOOD ARRANGEMENT: I try to arrange food in up-and-down columns so I always have something of everything on top. Meat takes up a lot of room, so it goes on one whole side, with the vegetables and fruits on the other. When I have only a little of something—like packages of butter, cream cheese, or bread—it goes into the baskets on top so it doesn't get lost down among the rest.

RECORDS: It's a good idea to keep an inventory taped to the outside of your freezer of what's in there. It should be a list of all the food inside and when you put in each item. That will help you plan meals and use food within its recommended storage period. Cross off items as you take them out.

DETERIORATION OF FROZEN FOODS: Each bag holds the amount we would use at one meal. That isn't always the same, though. As the year wears on, it takes larger portions of the frozen food to satisfy our hunger. Even when it still looks and tastes good, your frozen food is losing some food value and you have to eat more to get your hunger satisfied. Over the months, the frozen vegetables and fruits slowly but steadily lose taste, texture, and nutritional value. There is a big difference in the green beans, for some reason. What that means is that in the early spring, when cooking and serving, you have to serve—and eat—a bigger portion of those beans (or other frozen foods) in order to get the same amount of nutrients as you did when you first froze them in the fall. The "Freezer Storage Times for Good Quality" table gives guidelines on how long different kinds of foods will keep.

Deterioration of frozen foods can come from four sources: growth of low-temperature microbes; "freezer burn," which means dehydration and oxidation from air contact; ice crystals, which puncture cell walls, turning food into mush; and those ripen-then-rot enzymes doing their thing.

Microbes. Yes, some microbes are functional at even below-freezing temperatures, and they can reproduce even in the freezer, although very, very slowly. At that low temperature, mid-and high-temperature microbes can't grow at all, and even the low-temperature-specialist beasties can't grow very fast. They may double in number only every couple months instead of every few hours, as they would outside the freezer.

That growth of low-temperature bacteria is why food, even in the freezer—especially rich, moist foods like ice creams and gravies—will indeed slowly but eventually "spoil," although it takes 1–24 months depending on the food and the freezer. To keep low-temp bacteria under control, it really matters what temperature your freezer is set at and whether it remains constant or fluctuates up and down. To keep bacteria almost perfectly inactive, the food has to stay at 0°F or lower. Anything warmer, even for a while, is a marvelous window of opportunity for those cold specialists.

Freezer Burn. If your container isn't securely closed, the food will, over months, dehydrate and deteriorate. You can see freezer burn on the food; it will look kind of faded and dried.

Mushiness. Frozen water inside the food forms tiny ice crystals that can puncture cell walls. You know that has happened if, when the food thaws, the juices run out and the food seems mushy. But the faster the food freezes, the smaller the ice crystals will be; that helps preserve your food quality. Partial thawing and refreezing double the cell damage and diminish food quality that much more.

Enzyme Deterioration. If your vegetables aren't blanched or your large fruits aren't packed in syrup, the action of natural ripen-then-rot enzymes inside them will cause undesirable changes in color, flavor, and food value.

WHEN YOUR ELECTRICITY GOES OFF: When you have a freezer, there is always the nightmarish possibility of the power going off. For sure, sooner or later it will, or the freezer will break down. Plan what you will do when that happens. Locate a nearby freezer-locker plant or a place that sells dry ice. Your only other emergency option is to can or dry the food immediately as an alternate preservation method. The food would lose some, but certainly not all, of its quality in the processing.

1. If you know ahead of time about a possible or certain upcoming power loss, turn your freezer to the coldest setting. The colder it is to start with, the longer it will stay cold without electricity.
2. Keep the door closed!
3. Cover the freezer with blankets, except for the motor vent openings if there's a possibility the power might turn on again (that could overheat the motor if the vents are covered).
4. The more full your freezer is, the longer it can hold out without electricity. Food in a full freezer will stay frozen for about 48 hours without electricity, but food in a half-full freezer may keep only 24 hours; a quarter-full one, only 12.
5. If the power is likely to stay off longer than your freezer will stay frozen according to Step 4, wrap it in blankets and/or newspapers and move it to a locker. Or ...
6. If you know where you can buy dry ice *and if you can get it fairly soon after the power failure*, 25 pounds of it would keep a full 10-cubic-foot freezer below 32°F for 3 to 4 days. Fifty pounds would do the same for a 20-cubic-foot one. If the freezer is only half full, the ice will keep it below freezing only 2 or 3 days. But you have to get the dry ice in there as soon as possible, before the contents have started to thaw. Don't open the lid if you can help it, to avoid letting out the cold air.

NOTE: *When working with dry ice, don't put it directly on the packages. Lay a piece of heavy cardboard on top of the food packages. Put the dry ice on top of that. Wear gloves! Don't touch the dry ice with bare hands. After that, open the freezer door only to take out food or add more dry ice.*

WHEN POWER RETURNS: SAVE/Toss WHAT? Food that still contains ice crystals has not gotten warmer than 40°F. If there are no ice crystals left in the food, it is technically "defrosted."

Bread Products. Even if defrosted, these can be refrozen.

Cooked Foods. *Do not refreeze any dishes containing meats, fish, or poultry.*

Fish and Shellfish. *Never refreeze these* because they spoil very, very easily; also, they normally stink, so you can't use their smell as an indicator of dangerous spoilage.

Fruits and Fruit Juice. Even if defrosted, they can be refrozen (or canned or dried). There will be loss of quality. If fruits didn't thaw out completely and still have some ice crystals in them, they will refreeze without much loss of quality. Concentrated juices can be refrozen. They will lose quality, though, and may not reconstitute as well. Plain fruit juices will probably refreeze fine.

Ice Cream. *Do not use.*

Meat. *Do not refreeze cooked meats.* When my raw meat has thawed partly but not “defrosted,” I’ve refrozen it and then used it up as soon as possible thereafter. It looked and smelled fine, and I gave it a very thorough cooking to make sure. But any meat that thawed and didn’t look and smell fine, I gave to the animals. Spoiled meat looks and smells odd. “When in doubt, throw it out!” Technically speaking, if the meat has not heated above 45°F, it should still be fine.

Vegetables. If vegetables get even a little thawed out, they really go downhill fast—much faster than fruits. When this happens to me, I just throw them to the chickens or pigs. Or you can compost them. The experts agree: Don’t refreeze them.

DEFROSTING THE FREEZER: Our electricity has never been off long enough to matter. What invariably happens is that some child pulls the plug and it takes me a day to find out, although I try to maintain an unconscious habit of glancing at that light that indicates the freezer is on as I go by. This seems to be a spring phenomenon, so I haven’t yet had to set up a special time for cleaning out my freezer. When the accidental spring thaw comes, I just say “Praise the Lord” and very quickly finish emptying the freezer. Then I wash it clean, plug it back in, put back in what I dare, and threaten the children with horrible vague happenings if they ever do that again.

If I don’t defrost accidentally, then I defrost on purpose once a year. Ideally, you should defrost every time as much as $\frac{1}{2}$ inch of frost builds up over a lot of the inside of the freezer, and when frost starts to collect even on packages stored only a few hours. Frost buildup is a problem, but taking all that food out of its protective cold can be viewed as even worse. The ideal time to defrost is in early spring, when the freezer is getting toward its emptiest and before the new produce is ready in the garden. The frost has to be gotten rid of for several reasons. It acts as an insulator, preventing heat inside the freezer from getting removed by the condenser coils. The more frost you have, the less space you have. It also tends to absorb and hold foul odors. And the more frost you have, the more electricity the freezer must use to maintain its coldness.

Steps to Defrosting

1. Turn off the electricity.
2. Move the food to another freezer or to a well-insulated situation, wrapped in blankets and/or newspapers.
3. Scrape off what frost you can using a wooden or plastic (not metal!) scraper.
4. Place big pans of very hot water inside the freezer; then close the lid.
5. After the frost is all melted, scrub out the inside of the freezer with a mix of 3 T. baking soda per 1 qt. water.
6. Rinse.
7. Dry.
8. Turn electricity back on.
9. When the remaining dampness in the freezer has frozen, it’s ready for the food to be put back in.

Defrosting Food for Cooking

NOTE: Always defrost meat, fish, and poultry in the refrigerator, not out on the kitchen counter. These products can be defrosted in a microwave oven, but if you do this, the food must

be cooked immediately, because a microwave leaves hot spots in food. Do not microwave-defrost and then let stand for several hours before cooking. The USDA advises that cooked meats, vegetables, soups, ice cream and sherbet, frozen “dinners,” and meat, poultry, and fish dishes that have thawed and have been at room temperature longer than 2–3 hours are unsafe and should be thrown out.

The above warnings are given because when you freeze foods, you don't kill the beasties; you just put them to sleep. So it's important to thaw and cook the food in as fast a sequence as you can. Foods that have been frozen, especially vegetables, are subject to very fast deterioration once thawing has set in. For vegetables, I peel off the baggie and put the frozen hunk directly into a little boiling water. I serve as soon as it is thawed and hot. I drain the cooking liquid into the gravy or the pig bucket. Put a big glob of homemade butter on the vegetables and serve.

I thaw frying meat in the refrigerator on the morning I plan to use it. Frozen roasts and roasting meats, like ribs, are put into the oven still frozen. It takes about 1½ times the usual cooking time if the food starts out frozen. It takes a while to thaw a quart of frozen stuff like stew. I put it in a pan of lukewarm water and *very, very gradually* raise the water temperature as the contents of the jar start to liquefy. *Never plop a jar of frozen food directly into hot water. Glass containers are likely to crack if exposed to sharp changes in temperature.*

Improving Thawed-Out Stew. When I reheat a thawed-out stew, I usually add some fresh vegetables from the root cellar or garden to make it taste better.

Stir-Fried Frozen Veggies. Melt 1 T. butter per serving in a cast-iron frying pan. Add your frozen veggies. Stir-fry in hot pan until the water has evaporated and it's done enough.

Long-Stored Green Beans. When string beans are in really bad shape, I can make them most palatable by putting the icy hunk directly into a frying pan with a little bacon grease or a smear of oil. I stir them as they thaw, adding a few previously fried onion chunks or green spring onions out of the garden (the top-set onions are ready by March).

Long-Stored Meat. It will be dry and of poor flavor, but you can still get use out of it. Cook it well, and cook it in a soup or sauce to mask the off-flavor.

CANNING

A favorite neighbor of mine, Imogene, is about 60 years old. One of her arms is sort of paralyzed from a childhood case of polio, and she sees only well enough to read newspaper headlines. She lives on about 3 acres with her husband, who has been a total invalid with a bad heart condition for several years now, and with her widowed mother, who doesn't get around too actively due to arthritis. She was not blessed with children. Imogene milks goats and has a big garden. Of all the families I know, hers comes closest to living totally off their own produce.

But the important thing about Imogene is that she is the most cheerful, friendly, giving person I know—I'd even risk saying “in the whole world.” She's always got a big smile and a sincerely happy-to-see-you “Hello!” She loves company on any day but her precious Sabbath, which she withholds for rest and prayer, as she feels God wants her to. Seems like she's always calling me up wanting to give me something—a big sack of carrots and another of spuds or some such. I'd rather eat Imogene's vegetables than my own. Hers are raised with such love there just have to be more vitamins in them!

When the fruit is ripe in our orchard I can from morning to night using 2 big enamel water bath canners. It keeps me moving because as soon as I have loaded with fruit and juice the 8 jars that each canner will hold, it's time to take out the last batch and load in the new ones. That's because of the handling involved in getting the fruit ready—like washing, picking out the leaves, and pulling out the stems for cherries. When I can every day, even only 4 or 6 quarts, I have a lot of jars by summer's end. But many days I can more than that.

KEEPING THE HOUSE COOL: Most canning is done in summer. A lady wrote and asked me if it's possible to can on a wood stove. It sure is; I do. It's quite an experience to keep that fire roaring all the time on those hot summer days, because the big thing about safe canning is that *you can't let the water stop boiling for even one minute during your processing time. You have to watch it closely so the heat doesn't drop.*

One smart lady I know has her wood canning stove in the basement. I'm even more impressed with the ones who have a summer (canning) kitchen built outside, away from the house. If you have to can in the house, how can you cope with the extra heat? Especially if you are choosing to do without air conditioning anyway, which many fine people are doing as an eco-sound choice, even in the South. So if you are able, use a summer canning kitchen and do your summer cooking, especially canning, out there so you don't have to heat up the house. Basically all you need is a stove, even just a stove top, plus some counter space for working. Of course, it would be wonderful to have a screened-in outdoor kitchen equipped with water and electricity.

The Science of Canning

Drying and salting were the basic preservation methods until Nicholas Appert, a French baker, tried cooking food in tightly corked glass bottles in 1809. Napoleon had asked Appert for a system to preserve food for his far-flung troops. Appert continued his

experiments for 15 years. His basic system was to put food in a widemouthed glass bottle, close it with a cork stopper, and then heat in boiling water 5 hours or more. Some of his jars kept and some spoiled, but Appert's efforts proved that heat treatment of a sealed container could preserve the food inside. That was the beginning of canning.

The heat kills beasties that are invisible to the naked eye. But they're there, everywhere, always: in your water and air, on all the surfaces around you, on the food, and especially in the soil in which it grows. There are 3 types of invisible competitors for your food: molds, yeasts, and bacteria. They are present either as the adult form or as seed, or "spores." The spores are tiny, very tough particles that, when dry, float up into the air and travel thus. When they happen to land on something edible, their life cycle starts again.

You can clearly see when you've got a major crop of mold on something. Bacteria aren't visible in the same way. Like molds and yeasts, there are many different kinds of bacteria that could make a home in your food. Some bacteria thrive at a low temperature and are a problem in your freezer. Some are most comfortable in middle-range temps. For canners the important bacteria are the "thermophiles," which actually reproduce contentedly at a range of 130–150°F and whose spores can handle boiling awhile and still be okay. That's why you have to be so careful when canning.

Five basic factors are involved in safe canning: number of micro-organisms in food to start with, density of the pack, acidity of the food, canning temperature, and processing time.

1. NUMBER OF BEASTIES: The more beasties your food contains to start with, the more heat treatment it takes to eliminate them all. So start with fresh, unspoiled food. Remove any spots of decay. Wash food thoroughly in clean water. Chill freshly killed meats and poultry immediately after killing, and keep them chilled until canning.

2. DENSITY OF JAR CONTENTS: I know home canners who long to can in half quarts or gallons for the efficiency of it. But they don't, because it isn't safe. Heat during canning travels inward toward the center of the jar. The last place in the jar where the beasties die is in the center, because that's the last place to heat up. If the center doesn't get hot enough long enough, the contents will spoil. A factor in how long it takes to kill all the beasties in there is the nature of the jar contents. Pure fluid is the easiest to heat up and heat through, so juice is easy to can. A loosely packed food heats much faster than a jar whose contents are tightly packed, so green beans with liquid between them heat much faster and easier than a solid pack of squash. And a jar whose contents have a liquid cover heats through more quickly than one without, so that's why the liquid covering the food in your jar is there. The densest foods, and thus the slowest to heat, are corn, meat, and "dried" beans. Foods like apples and pears are loosely made and conduct heat easily and quickly through to the center.

3. ACIDITY OF THE FOOD: The more acid a food is, the less heating time is required to destroy bacteria. The pH is a way of measuring that acidity. The standard pH scale uses the number 7 to mean the neutral point. Foods with a pH smaller than 7 are more and more acidic as the pH number gets smaller; foods with a pH above 7 are more and more alkaline as pH gets larger. The "pH of Foods" table tells you the pH of some common foods; every food has some pH.

As you see, tomatoes are the lowest in acid of the high-acid foods, so they deserve special care. Pickles are high-acid because of all the vinegar in them. Salsas and taco

sauces need the same processing times as tomatoes. “Hotness” of a food doesn’t protect it from spoiling. Acid content is why fruit and other high-acid foods may be canned using a water bath, but vegetables and meat *must be pressure-canned* for safety.

4. CANNING TEMPERATURE: The standard canning instructions are that foods from tomatoes on up through plums can be processed at 212°F, but that foods from okra on down must be processed at 240°F—meaning in a pressure canner, which is the only way you can get them that hot. That temperature is required to kill the spores. The adult forms all die more easily.

CANNER'S PLANNER				
Food	Times/Week	Serving	Jars/Person	Jars/Family (4)
Meats, poultry, fish	4/week, 36 weeks	½ c.	36 pt.	144 pt.
Soups	2/week, 36 weeks	1 c.	18 qt.	72 qt.
Jams, jellies, preserves	6/week, 52 weeks	2 T.	40½ pt.	160½ pt.
Relishes	3/week, 52 weeks	1 T.	5 pt.	20 pt.
Greens, carrots, sweet potatoes, winter squash	4/week, 36 weeks	½ c.	18 qt.	72 qt.
Pickled vegetables	2/week, 52 weeks	2½T.	13 pt.	52 pt.
Citrus fruits/juices and tomatoes	7/week, 36 weeks	1 c.	63 qt.	252 qt.
All other fruits/veggies	14/week, 36 weeks	½ c.	76 qt.	304 qt.
Pickled fruits	2/week, 52 weeks	2½T.	13 qt.	52 qt.

5. LENGTH OF PROCESSING TIME: The higher the temperature, the shorter the time needed to kill those tough spores. For food with a pH of 7, for example, one test showed the spores could endure boiling for 330 minutes before they croaked. Boiling, of course, happens at 212°F. If the temperature was held at 220°, they could hold out only 100 minutes; at 230°, 33 minutes; at 240°, 11 minutes. A pressure canner is supposed to get up to 240°F. The rules allow it a little margin for error.

Old-timers used to can meats and low-acid vegetables using the water-bath method, boiling for as long as 6 straight hours, before pressure canners were invented that could achieve the higher temperatures. Because a lot of things can happen in 5 or 6 hours, including a temporary drop in temperature you don’t know about, to say nothing of the waste of fuel energy, that long-cooking method is no longer recommended for low-acid vegetables. On the other hand, water-bath canning is still very desirable for high-acid foods, because even in a water bath, their processing time can be faster than waiting for a pressure canner to heat up and then cool down again, and just as safe.

Whether you do “hot pack” or “raw pack,” meaning whether you put the food into the jars precooked and still hot or uncooked and still cold, affects your processing time. If hot pack is specified, it’s important to process that way, because the hot-pack precooking is figured into the processing time. Hot pack is also beneficial because the food shrinks, and you’ll get more into every jar. And the precook releases air, which helps your seal.

About Botulism

OF CANNING, BARGAINS, AND SAFETY: Canning is a bargain compared to buying store food. Being a frugal-minded person, in previous editions of this book I used to look for ways to make canning even cheaper. No more. I understand better now the risk of botulism. Over 700 people have died of botulism since folks started canning in this country. (In 1992 in the United States, 10,000 persons were killed by handguns, which puts that in some

perspective.) Last year [1976] in the United States, there were 20 reported incidents of botulism involving 30 persons and resulting in 7 deaths. One death from botulism is one too many, because they could all be prevented by following proper canning procedures. In this new edition I've painstakingly given you only the safest procedures, and the canning instructions scattered throughout the book have all been reviewed by true experts (which I am not) and either approved, changed so as to be approved, or dropped.

How BOTULISM GROWS: Botulism poisoning is caused by a certain kind of bacteria (*Clostridium botulinum*) that is practically everywhere in the soil. The food poisons specialists call the beastie "bot" for short. You're safest, and most likely correct, to assume that bot is present on your garden food too. The bacteria themselves are not poisonous. But it's a good idea to keep your baby out of the dirt because children under age 1 don't handle them as effectively as older people do. Bot won't grow in the refrigerator. When cooked, bot bacteria die easily, but their seed forms, called "spores," are extraordinarily resistant to heat. They aren't resistant to *high* acid and sugar, however; those inactivate the bot spores. (We're beginning to learn that botulism can survive in mildly acid products.) That's why high-acid foods, sweet preserves, and pickled foods can be canned using a boiling-water bath.

But if bot spores get a combination of insufficient heating, no air, low acid, and low sugar content, then they are in bot heaven. The area inside a sealed jar is a no-air place. And if it isn't jam or pickles or fruit, it's a low-acid food. In that case, you have to pressure-can. That extra heat is the only remaining line of defense. Bot spores can resist a lot of boiling, but they are reliably killed by the 240°F temperatures achieved by heating under pressure—"pressure canning."

"HIGH ACID" OR "LOW ACID"? Different foods naturally contain varying amounts of acid. As the acid strength increases, the temperature or time needed to kill the beasties decreases. High-acid foods can be processed more quickly than low-acid foods. High-acid foods can also be processed at a slightly lower temperature—merely the boiling point of 212°F—whereas low-acid foods must be processed at 240°F to be safe. And only inside a pressure canner can you get a sustained temperature that high. So low-acid foods such as beans and corn must be pressure-canned to destroy the spores of the bot bacteria. Spores are the most resistant seed form of the beasties. Unless you roast to death *all* the spores of the *bacillus botulinus* in low-acid foods, the remaining spores grow. As they grow they give off an invisible, tasteless, but powerful toxin (poison).

"BOT" TOXIN: This toxin is one of the most deadly poisons known on earth. If you merely touch a finger to it and touch that finger to your lips to taste, you could get enough to kill you. It is said that 16 ounces of bot toxin would be enough to kill the entire world's population. The toxin itself doesn't trumpet its presence. You can open the jar and it may look and smell fine. It is, however, destroyed by heat. That's why it is recommended that all low-acid home-canned foods be boiled 15 minutes with the lid on before tasting or serving.

The symptoms ordinarily appear within 18 to 36 hours of poisoning but have been known to take as long as 8 days to become evident. What are the symptoms? At first nausea and vomiting, later blurred vision, dry throat, and difficulty swallowing. Then comes progressive weakness that can paralyze the respiratory tract as well as the limbs. The poison does that because it affects the nervous system, breaking down communication between motor nerves and the muscles.

The botulism cases that I've heard about involved pickled beets, tomatoes (for which pressure canning has not in the past been recommended), spicy tomato products such as salsas and taco sauce (the problem being the false assumption that the "hotness" will preserve the food), mushrooms, olives, asparagus, beans, cabbage, carrots, and peppers. In rare cases, it has also happened with pressure-canned food.

Researchers are just now discovering that bot bacteria can survive in the presence of more acid than had previously been believed. Some standard canning directions used to say to simply bring pickled beets, for example, to a boil and then hot-pack them. Some people got bot poisoning from doing that. Now we know it's not safe to can pickled foods without a water-bath canning time. So therein lies the risk of using old recipes. Some cooks thought that because salsa was so hot, it could be canned without much processing. Again, now we know better because of a bot case. Spicy hot doesn't bother bot.

Now that I've practically scared you to death, let me revive you with success stories. Many's the family that cans 700 or more quarts a year, year after year, with great success. Florence Ward, Quilcene, WA, wrote me, "I have canned for over 50 years. When we lived on a dairy ranch for 17 years, I used to can around 600 quarts of fruit and meats each year. Pickles too. We had five children—all married long since. Fruit, such as peaches and apricots, cherries and pears—I've canned thousands of quarts of them."

Sandra Oddo, Hurley, NY, wrote me, "A year ago I got a pressure canner from Sears for \$24 (can 4 quarts, hold 8) and now I wouldn't be without it. It's too small for mass canning, but perfect for what's left of the lentil soup after we've had a ham—canned soup heats faster than frozen, too—and for food deliberately mass-cooked so there will be leftovers for pressure canning, which saves later work. It saves enormously on fuel. Would you believe that 45 minutes turns a 3-year-old rooster into a tender stew?"

From Maureen Darby, Leslie, AK: "The cost of the canner is easily offset by the fact that it requires far less fuel to operate than it would to can in boiling water. I even can fruit under pressure. I do have to watch it closely, but it's better than waiting to boil the quantity of water needed to cover the jars in a water bath. We don't own a freezer. The initial cost and the cost of the electricity to run them make them impractical—besides the constant worry of power shortage."

So be careful when you can. But bot poisoning is rare—an average 7–30 cases a year nationwide among about 100 million canners. It's rare because of all the careful home canners who read the rules that come with canning equipment and in good canning books, and follow them, and use pressure canners. Still, that's 7–30 too many sick people. Those safety rules are all very clearly stated here, too. Please, better safe than sorry. Follow them!

Canning Methods and Supplies

Get ready for your food preserving ahead of time, because when the harvest is on you'll be frantic. Good supply sources for home canners:

Cumberland General Store: 800-334-4640.

Gardener's Kitchen (old-fashioned no-phone lifestyle; great lids and prices); PO Box 322, Monument Beach, MA 02553.

Lehman's Non-Electric: 888-438-5346; www.lehmans.com.

Books

NOTE: Recent discoveries about canning safety mean that no canning recipe from an old book

(including older editions of this one!) can be fully trusted. Get your canning recipes from up-to-date sources. Until recently, all canning recipes were based on USDA research completed in 1942. In 1986 the USDA asked Pennsylvania State University to repeat that old research to double-check their results. By 1990 they were finished, and the news was out that there were numerous errors in the old research.

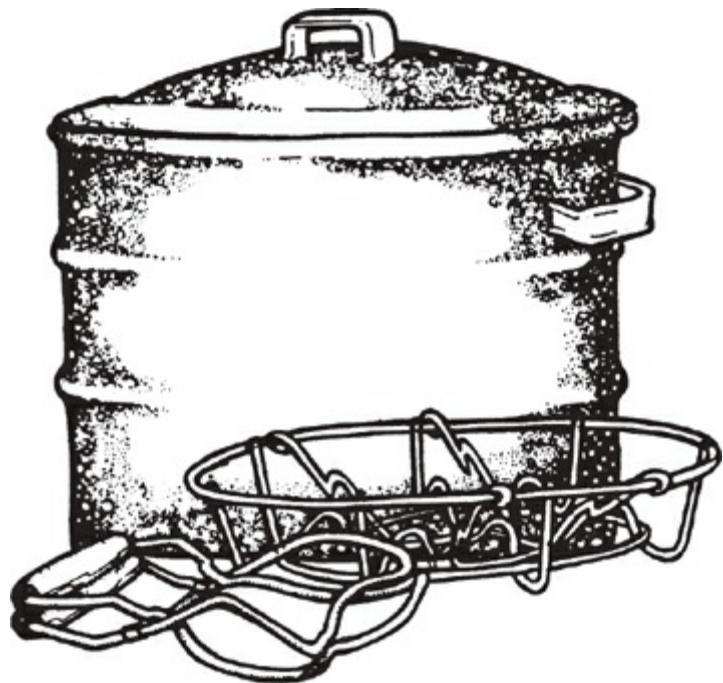

Current canning recipes are in recent books or university extension bulletins. For a free booklet, "Home Canning Made Pure and Simple," write Consumer Products Co., PO Box 2005, Muncie, IN 47307. This company now owns and markets both Ball and Kerr (another disgusting example of complete marketplace monopoly, the trend). For answers to food preservation questions, or to order the *Ball Blue Book Guide to Home Canning, Freezing and Dehydration* (\$6), call them at 800-240-3340; www.freshpreserving.com.

SUMMARY OF METHODS: Here's a basic summary of methods to illustrate what supplies you'll need. You'll either be doing water-bath canning or pressure canning—or both, depending on what foods you choose to can. The old-time "open-kettle method" is no longer recommended, even for jam making! Jams are now processed 5 minutes in a water bath. Paraffin is no longer recommended for sealing them because it isn't considered reliable enough—just use a regular jar lid!

Water-Bath Canning. James R. Coffey, Elkton, MD, wrote me that it's "known as cold packing in my area." Water-bath canning is only for fruits and high-acid tomatoes, *not for vegetables or meats*. Water-bath canning preserves food because the prolonged heat combined with the high-acid content of the food effectively kills botulism and other bacteria.

For water-bath canning you need jars, lids, rings, a canning kettle, a rack, and a jar lifter.

You put the prepared fruit in sterile, clean jars, covered with water or syrup. Then you put the lid and ring on and tighten. You lower the jar(s) into your kettle of boiling water. You need a perforated rack in the bottom of the pot for the jars to rest on. This ensures that they won't break if they sit on the bottom of the kettle itself. The water needs to be able to move freely around the outside of the jars. The kettle must be tall enough so that water will cover the jars by at least 1–2 inches at all times. During long boilings, have another kettle boiling nearby from which you can add water as necessary. Once the correct amount of time has gone by, remove the jars with a jar lifter. Set them on top of a towel or wooden board on your counter to cool. You start timing when the water comes to a boil again.

Pressure Canning. This method works to preserve low-acid foods such as vegetables and meats because low-acid foods have to be heated to at least 240°F in order to kill any botulism spores present that enjoy a low-acid environment, can live indefinitely through mere boiling, and thrive in the oxygen-free environment of a sealed jar.

To do pressure canning, you need jars, lids, rings, a pressure canner, a rack, and a jar lifter.

Follow the recipe for the food preparation. Put on the softened lids and rings. Set your canner on the heat with the lid off, with 1 to 2 inches of water in the bottom of it, to start heating. Make sure the rack is in there. Set the jars onto the rack in the pressure canner. Put the lid on. The water boiling in the canner will cause steam to escape from the vent on the lid of the canner. Once the steam release is constant, start timing and wait 10 minutes. By then all the air will have been removed from the inside of your canner. Shut the stopcock, or put your weight on. Watch the canner gauge. Wait until it shows the correct pressure has been reached (usually 10 lb. for low-acid foods and 5 lb. if you're canning high-acid foods, but a little more if you live at a high altitude—see “Altitude Adjustments for Pressure Canning” table later in this chapter). Now start timing your canning process.

Once the processing time is over, take the canner from the heat. Let it cool naturally and slowly. (The natural cooling time is part of the recipe!) When you’re pressure cooking, you can run water over the canner to cool it quickly, but don’t do that when pressure canning. The manual for your particular canner will tell you how to know when the canner is cooled. Once it is cooled, open the canner lid. Remove the jars using a jar lifter.

CANNING JARS

Getting Jars: If you plan to can, get your jars, lids, and screw bands ahead of time. You can buy new canning jars at big grocery outlets, but they’re not cheap. Nathan D. Justus, Fair Haven, NJ, wrote me, “For one dozen quart jars in my area, it costs approximately \$8, but I feel this is inexpensive, particularly since the jars can be reused many times, if they are treated with proper care.” It’s best to buy them by the case a year ahead of time, since stores sometimes run out at the peak of the season. Or look (or advertise) for used canning jars, usually a good bargain.

How Many? How many jars you need depends on how large your family is, how much of your preserving is by canning, and how many months a year of fresh garden produce you can grow. If you put up 100 quarts of green beans, your family could eat 2 quarts a week all year round; the same for corn or fruit. So you can figure out what you think you'll need. An average family of 4 in an average climate might want to can 300 quarts. Alice Flanigan, Blackstone, IL, wrote me of her neighbor with a family of 7 who cans 700 quarts a year.

You can also refer to the “Canner’s Planner,” the USDA’s attempt to take the guesswork out of planning for the coming year. In the Planner, the phrase “36 weeks” means that item is canned only for the out-of-season weeks of the year. The Meats category assumes you also have 10 other servings of meat, poultry, food-from-water, or eggs. A sizable old-time family with no meat preservation system other than canning, no modern refrigeration, and lots of animals on the farm canned as much as 400–500 quarts of meat per year. (Canning made it possible for them to have meat besides chicken in the summer months.) Any individual family will want some variation on this estimate based on their family’s personal preferences.

What Type Jars? The size jar you want depends on how much your family can eat at a meal. For my family, it works best to put up butters, jams, jellies, and taco sauce in half pints to minimize spoilage before that food gets used up. All stews, vegetables, and fruits go into quarts. (It is possible to can your family’s most loved high-acid fruit in half-gallon jars—but *only high-acid fruit*.) Pint jars are best for ketchups and vegetables, except string beans and tomatoes, which do well in quarts. You’ll have a choice of regular jars, widemouthed jars, can-or-freeze jars, and jelly glasses and jars.

If you wonder whether a jar is the right size for canning, test it with a screw band. If one of the three sizes will fit, it’s okay. The glass isn’t quite as heavy as in regular canning jars, but if you are careful that the food you put into the jars is hot or has hot water or juice poured over it before you put it in the hot canner, it won’t break.

NOTE: Don’t use antique canning jars, either the zinc-lidded jars or the old 2-piece glass-lid type, because their seals are not dependable, and replacement rings are getting impossible to find.

On the other hand, wonderful fancy jars are available from The Cook’s Garden (800-457-9703; www.cooksgarden.com) and other outlets. They offer stylish glass herb jars, hexagonal French jars, and imported German jars with the old-fashioned glass top, rubber ring, and small steel clips—all okay for canning homemade chutneys or jams.

Widemouthed Jars. The widemouthed jars are good for large whole fruits, such as peaches and pears, and for meat and pickles. They are easy to fill and clean because you can get your hand inside for thorough washing, but the lids are a little more expensive.

“63” Jars. The “63” jars (small size) are hard to fill, especially for hot-pack canning. Very liquid items like juices, or small fruits such as cherries, berries and apricots, go into them best.

PACKING HIGH-ACID FOODS FOR WATER-BATH CANNING

Apples: Hot-pack, cover with hot liquids.

Applesauce: Hot-pack.

Apricots: Wash, halve, take out pits. Pack in jars. Add liquid.

Berries (except strawberries/cranberries): Wash, stem, pack, add liquid.

Cherries: Can with pits, pack, cover with liquid.

Cranberries: Wash, stem, boil 3 minutes in heavy syrup, pack.

Currants: Wash, stem, pack, add liquid.

Figs: Cook 2 minutes, make syrup, cook 5 minutes in syrup, pack.

Fruit juices: Make your juices, pour into jars.

Nuts: Pack, oven-process at 225°F for 45 minutes.

Peaches: Peel, pack, add liquid.

Pears: Peel, pack, add liquid.

Plums: Pack, add liquid.

Preserves: Prepare according to your recipe, hot-pack, process at 180°F ("simmer").

Rhubarb: Cut in chunks, precook, hot-pack, add liquid if needed.

Strawberries: Stem, hot-pack, cover with hot juice.

Tomato juice: Hot-pack.

Tomatoes, whole: Scald, peel, core, quarter, heat. Hot-pack.

PACKING LOW-ACID FOODS FOR PRESSURE CANNING ONLY

Meats: Pack raw or precooked, salt 1 t. per qt. unless presalted in recipe (sausage, ham). Do not add liquids to meat packed raw. Pack loosely.

Fish: Pack raw, no liquid. Use only fresh, firm fish.

Vegetables

Asparagus: Hot-pack, add liquid.

Beans, snap (green or yellow): Snap, hot-pack.

Beans, lima: Shell, hot-pack loosely.

Beets: Wash, boil, skin, precook, hot-pack.

Broccoli: Hot-pack.

Brussels sprouts: Hot-pack.

Cabbage: Hot-pack.

Carrots: Hot-pack.

Cauliflower: Hot-pack.

Corn: Cut off cob, hot-pack loosely.

Greens: Wash, hot-pack loosely.

Hominy: Hot-pack loosely.

Mushrooms: Hot-pack loosely. (*Don't can wild ones.*)

Okra: Hot-pack.

Onions: Hot-pack.

Parsnips: Peel, chunk, hot-pack.

Peas: Shell, hot-pack.

Peppers, green: Cut out seed pod, hot-pack.

Peppers, pimentoes: Bake/boil, peel, remove seeds.

Potatoes, white: Peel, hot-pack.

Pumpkin: Peel, chunk, precook (don't mash), hot-pack.

Rutabagas: Peel, slice or cube, hot-pack.

Squash, winter: Peel, chunk, precook, hot-pack.

Sweet potatoes: Precook 20 minutes, peel, hot-pack.

Turnips: Peel, chunk, hot-pack.

Recycled Mayonnaise Jars. The cheapest way to get jars is to have everybody save their mayonnaise jars for you. I know that numerous other writers say this is awful. But I have the assurance of Jan Grant, King County extension agent and founder of the Master Food Preserver program, who carefully reviewed all the contents of this book, that there is no safety problem with these jars if all your other procedures are correctly followed. However, these quart and pint mayonnaise jars should be used for *only water bath—not pressure—canning* because they aren't as sturdy as regular home canning jars. And use them *only if you use a regular home canning-type Ball or Kerr lid set, not the store lid, with them.*

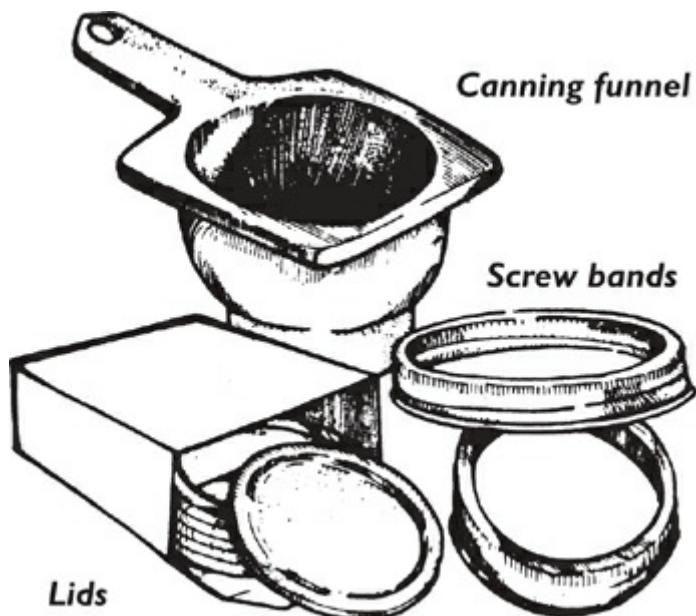

Avoiding Jar Breaks. Glass expands with heat and contracts with cold. If you pour

something hot into a cold jar, the inside might expand enough to crack the outside, and blooey—food all over your table and no jar. When working with glass jars, keep that in mind. But you already knew that, I'm sure.

LIDS: Brand-new metal jar lids are reasonably priced and are virtually your only expense when you're canning garden produce and already have the jars. So don't even consider reusing jar lids. They are made to work only once. Make sure the lids you buy will fit the jars you have. There are 3 standard lid sizes: "63" (which is small), "regular," and "widemouthed."

SCREW BANDS: These come in the same 3 sizes as the lids. Match the sizes! Screw bands, like jars and unlike lids, can be used over and over—unless they get bent. If a screw band is rusty or bent, it can prevent a safe seal. Throw away bent screw bands and use new ones.

About Reusing Lids and Screw Bands. Actually, you can reuse them *if you are canning only high-acid fruits*. That's because you never have to worry about botulism with high-acid fruits. As F.E. Pennington of Kelso, WA, wrote me, "Who cares how rusty the rings are? They never touch the product. And if you hold a bunch of lids together, you can detect any bent lids. They can be used same as new lids—that is, the Ball dome lids. Reusing does not work well with Kerr lids. I get at least a 90 percent seal."

UTENSILS FOR CANNING

Funnel. A widemouthed canning funnel is available from kitchen specialty stores and homestead mail-order outlets. If you don't have one, you'll wish you did, because you'll be always burning your fingers. They also prevent spilling, so the jar rim stays clean. They are especially necessary for hot-pack canning.

Soup Ladle. You can use a cup, but you're less likely to burn your fingers using a ladle if you're filling jars hot-pack style. F. E. Pennington says, "I find a funnel a nuisance. I ladle the fruit into the jar."

Slotted Spoons. Big spoons with long narrow holes inside are wonderful for lifting fruit out of a dip, and so on.

Canning Tongs. This tool is valuable for lifting lids and empty hot jars out of hot water.

Jar Brush. This is used for cleaning inside regular (narrow-topped) jars.

Hot Pads, Mitts, Heavy Potholders. Use so you don't burn your fingers.

Jar Lifter. You need this to get the hot jars out of the hot water. It closes around the jar and tightens as you lift. No risk of dropping hot jars with this! A funnel, jar lifter, kitchen tongs, lid lifter, and jar wrench are available as a set from The Cook's Garden (800-457-9703; www.cooksgarden.com).

TIN CANS: Seems like everybody knows somebody in Alaska who cans in real cans. (The rest of us are actually "jarring.") Lane Morgan says, "I have friends in Alaska who do subsistence fishing. They can lots and lots of salmon and they use commercial-style cans, not jars. I think they like the cans because they use the canner space more efficiently. I don't know how they put the lids on. They can their salmon with a teriyaki marinade and it really is sensational. Their other meats—mostly moose and bear—they freeze." People who can in metal fill the can, seal it, and then toss the can into boiling water and leave it there, boiling nonstop, for the designated number of hours. This method is the most common one used in commercial canning, but the equipment is not easily available to home canners. The cans are actually made of steel plated with tin or enameled on the inside. The can and lid are supplied as separate items, and you need a special can sealer. You can't reuse metal cans, and they're much more expensive than jars.

NOTE: When using metal cans, do not use procedures or processing times given here.

WATER-BATH CANNING KETTLE: These come in 22-to 26-quart sizes (which hold 4 or 6 quart jars at a time) and aren't expensive. The kettle is enamel and equipped with a jar-holding rack to keep jars on the bottom of the pan. Hardware and kitchen stores have them. But actually, any container large enough to hold jars covered with boiling water can serve as your water-bath canning kettle. You can make a big canner out of an old-fashioned copper washtub. Put it on 2 burners at once. It will hold 16 quarts at a time. You can get a stainless-steel canning-size kettle from Lehman's; 888-438-5346; www.lehmans.com. You can use a pressure canner as a water-bath canner if you don't fasten the cover down and are careful to leave the petcock wide open.

Steam Canners. Steam canner manufacturers have never done the very expensive testing necessary for USDA approval, so this cannot be an extension-recommended method. *However, if all you can in it is high-acid fruit, you may end up with spoiled fruit, but nothing that can kill you.* But you may safely use a steam canner in place of a water-bath canning kettle *only to can the most high-acid fruits*, because this method does not kill critters as dependably as a regular boiling-water bath. You especially can't use it in place of a pressure canner!

One model resembles an upside-down pot. There is a shallow bottom pan with a tray over that. Your jars of fruit go on the tray. Water goes in the pan. The tall, tightly fitting top covers the jars and holds in the steam from the heated water. *Don't let it boil dry.*

NOTE: A microwave oven cannot be used for canning because it doesn't heat evenly enough.

PRESSURE CANNER: These cost more than the other items on this list, but it's a one-time cost because they last a lifetime, and you absolutely must have one to can low-acid foods. A pressure cooker is not the same as a pressure canner. Incidentally, follow the manufacturer's instructions for proper washing and care of the pressure canner after using it. Be careful not to nick or chip its sealing edges.

NOTE: Pressure canners are potentially dangerous. Make sure a manual comes with yours. If you lose the manual, write to the manufacturer to get another one.

Dial Gauge vs. Weighted Gauge. When shopping in many outlets, you'll be asked to choose between a "weighted-gauge" and a "dial-gauge" canner. They are both safe, good canner types. The dial-gauge pressure canner is nice for high-altitude canners because it can fine-tune adjustments of pressure, even as little as $\frac{1}{2}$ lb. It's also quieter than the weighted-gauge style. But you have to take in the dial gauge every year to be tested for accuracy, and it must be watched to maintain pressure. Being more complex, it also has a few more parts to get lost.

NOTE: When the Penn State canning research was done, they discovered that in a dial-gauge canner, the ideal temperature of 238–240°F for killing bot was achieved not at 10 but at 10.5. So it is now recommended that every time you see a recipe that says "10 lb. pressure," you should actually use 11 lb. if you're using a dial-gauge pressure canner. On the other hand, the weighted gauge is manufactured to reach the 10.5 pressure even though set for 10. Based on that research, the weighted gauge is safer and preferable. In addition, its accuracy is guaranteed for the lifetime of the product.

The weighted-gauge style of canner, on the other hand, has an annoying, noisy nature and adjusts pressure by only 5 lb. at a time. On the good side, it's simple to use, has fewer parts, doesn't need to be tested every year because it cannot be made inaccurate unless the weight is damaged (very unlikely and hard to do!), and doesn't have to be constantly watched. But I prefer the weighted-gauge type. You can train yourself to recognize what its noises are saying, and it allows you freedom to do other things while canning. However, high-altitude canners who need added pressure may be wiser to choose the dial-gauge style.

James Coffey of Elkton, MD, a very serious home canner, wrote me, "I have 2 water-bath canners and 2 pressure canners. I prefer the dial gauge for most canning, but I use weighted gauge for tomatoes especially. I am a baker by profession and can at home as a hobby and to save on the food bill as well."

Sizes range from 7-qt. liquid capacity (holds only 4 pint jars for canning) up to the 22-qt. size, which holds 20 pint jars, and the 30-qt. size, which holds 19 pint or 14 quart jars. Lehman's also sells pressure canner parts such as knobs and gauges. Secondhand canners are a bargain and have been a blessing. But they can also be big trouble. Make sure yours comes with a little booklet about burns and explosions, unless it's identical to your other one or you can write to the manufacturer and get the right manual for it.

Gasket. Your old pressure canner needs a new gasket if steam persistently escapes around the rim and pressure fails to build up. An overage gasket either may get hard and slippery or may stretch and no longer fit easily and well.

Hard Water? If your area has water so hard that it leaves a mineral deposit on the outside of jars, add $\frac{1}{2}$ c. vinegar to each cannerful of water to prevent that.

Twelve Life-Saving Canning Rules

Canning low-acid food is the only preservation method that can be deadly, so with canning instructions you must follow the rules closely and not experiment. You will hear from people who insist that they canned food in less time or with methods that are not recommended and haven't died of it. Because so many factors enter into what makes food safe, with good luck you might be able to get away with it for a long time. But then again, that luck could run out at any time, and the unthinkable of botulism poisoning could

occur. These canning instructions are designed to always provide you such a wide margin of safety that poisoning is simply impossible. You follow the directions, and then you can be confident.

Learn and follow these rules absolutely!

1. Don't use jars larger than a quart. Home canning technology cannot guarantee that larger quantities will be sufficiently heated through for enough time. Rather, the food on the outside will overcook, while that on the inside won't get hot enough. Botulism spores can boil awhile and still be fine.
2. Use water-bath canning only for high-acid foods. High-acid varieties of tomatoes, fruits, rhubarb, sauerkraut, pickles, and jams/jellies are the only high-acid foods. All others (vegetables, meats, stews) must be canned using a pressure canner.
3. Use only modern canning recipes from reliable sources.
4. Never reuse jar lids. Used lids aren't reliable for sealing correctly. If a screw band is rusty or bent, it won't work right and should be discarded and replaced.
5. Don't use antique or "French"-type canning jars. They aren't as safe as the modern, regular (Ball, Kerr) type.
6. Check the jar rims carefully every year by running your finger over the top of the rim and checking for nicks. Even the tiniest nick makes a jar unusable for canning. A nicked jar rim won't seal reliably.
7. Raw pack is not safe for certain foods: beets, all kinds of greens (spinach, etc.), white potatoes, squash, okra, a tomato/okra combination, and stewed tomatoes!
8. You must allow the correct amount of space (headspace) between your food, together with the liquid that covers it, and the jar lid.
9. Don't begin counting the processing time until after the water with the jars in it comes to a good rolling boil if using the water bath method, or until after steam has vented for 10 minutes from your pressure canner.
10. Process the full recommended time. If canning on a wood stove, watch your fire carefully to make sure it stays hot. If your boil or your pressure fails at any point in the process, you must start over and reprocess for the entire recommended time.
11. Lift out each jar individually (not inside the rack) using a jar lifter; keep it upright and not tipped.
12. If a jar didn't seal, discard the lid, put on a new one, and reprocess. Or put the jar that didn't seal in the refrigerator and use the contents within a week or so.

General Canning Instructions

This section explains the canning process. First you prepare and pack the food; then you process it using either a water-bath method or a pressure-canning method; and then you cool the jars and store them. (And finally, if all goes well, you eat your good canned food!)

PREPARING AND PACKING

1. Run your finger around the rim of each jar to check for nicks. A nicked rim can't be depended on to seal properly.
2. Wash jars in hot soapy water till clean. If you can't get a jar clear-clean, don't use it to can. Get a head start on this part by getting the jars thoroughly clean after you

take food out of them, so they'll be all ready for the new year. Store them upside down or covered with old lids to keep out dust and the like over the winter. Then wash each jar before using it again, and rinse thoroughly.

3. Give jars a scalding rinse and turn upside down to drain on a clean folded cloth. A dishwasher is not a necessity, but if you have one, you'll find it a real help and time-saver when canning. You can use it to wash batches of canning (or freezing) jars and to keep them hot until needed. If you are doing a hot pack, keep the jars hot *so they won't break from the contact with hot food*. Never pour boiling water or hot food into a cool jar, and never place a cool jar directly into boiling water. You can keep jars hot by soaking in a big kettle of hot water until you're ready to remove and fill them.

NOTE: For food products that will be processed less than 15 minutes by either water-bath or pressure methods, it is recommended that you use a sterilized jar. A sterilized jar is one that has been boiled for 10 minutes.

4. If you are canning high-acid foods with the water bath method, now fill the water-bath canning kettle with water two-thirds full, and put it on to boil. You need a very big, hot burner or a very hot stove top to can with this method. If you have trouble with your water boiling down in a water-bath canner, keep an extra pan of water boiling on your stove and add boiling water from that to the canner.
5. Put a pan that holds about a gallon of water on to boil to make your canning liquid.
6. Follow your recipe for food preparation. You'll find canning instructions for specific vegetables and fruits under their entries in [Chapter 4](#) and [Chapter 6](#), respectively. You can add or omit salt in any canning recipe as it suits you; it will not affect the processing time except for brined pickles, where salt content is critical for safety!

The food to be canned should not have bruise spots or decay and should be as freshly gathered as possible. If you can manage 2 hours from garden to jar, you'll be a wonder and have the best-tasting canned food possible. Be especially careful not to let any dirt into the jar or food mixture, because bot bacteria live in soil. Thoroughly wash all food to be canned. The best results come from washing small batches at a time under running water, or in and out of several changes of water. Lift the vegetables out of the water so that any dirt gets left in the bottom of the pan. But don't soak the food, because then it loses vitamins and can get soggy. Scrub root vegetables especially well.

Here are more fruit-canning hints and options:

- To easily remove the skins of tomatoes and some fruit, drop them into boiling water for a minute or so, until the skins peel off freely.
- To prevent discoloration when peeling large, light fruits for canning, keep them in a brine (2 t. salt per quart of water, or 2 T. salt and 2 T. vinegar per gallon water). Remove the fruit within 15 minutes. Or you can not worry about darkening and just work fast, which is what I do; keeps down the salt intake.
- To prevent darkening and loss of vitamins, add ascorbic acid (a form of powdered vitamin C). Use $\frac{1}{2}$ t. powdered ascorbic acid per quart of fruit. Mix it in with the water/syrup that will cover the fruit in the jar.

For other fruit pre-treatments, see the “Freezing” and “Drying” sections on fruit pre-treatments.

7. Fill your clean jars with the fresh-cut food, leaving at least $\frac{1}{2}$ inch headspace (see Step 9). Food can be packed raw in the jars (called “raw pack”), or the food and its liquid can be preheated first and then ladled hot into hot jars (called “hot pack”). For packing instructions for the specific vegetable or fruit you’re canning, see its entry in [Chapter 4](#) or [Chapter 6](#). For a quick reference, see the tables “Packing High-Acid Foods for Water-Bath Canning” and “Packing Low-Acid Foods for Pressure Canning Only.” If packing halved large fruit, pack it with the inside down to get more in.

If you are canning juice, tomatoes, or something else that doesn’t need liquid added, skip the next step and go to Step 9.

8. Prepare canning liquid by adding sugar, honey, or a combination to hot water. Sugar helps fruit hold its shape, color, and flavor, but you don’t have to add it to safely preserve food. You may can food in plain water or use much less sugar than the usual recipe says. Or you can use a honey solution, can in fruit juice, or use no sweetening or water at all! Refer to the table “Standard Syrup Mixtures” for suggested combinations. See “Freezing” section for syrup recipes. Or you can add sugar directly to hot-packed juicy fruit. Use $\frac{1}{2}$ c. per quart of fruit, heat to simmering, and then pack.

For info on honey canning, see *You Can Can with Honey* by Nancy Cosper. Or use plain hot water. Sorghum, molasses, or brown sugar are other possible sweeteners but are less preferable because they tend to overwhelm the flavor of the fruit.

After mixing the ingredients for your syrup, heat and stir until in good solution.

STANDARD SYRUP MIXTURES (IN CUPS)

Sugar	Light Corn Syrup or Honey	Water or Fruit Juice*
Thin	2	0
Medium	1	1
Medium	0	1
Heavy	4	0
Heavy	0	4

*Any combination of water and juice (from the fruit you’re canning or from another kind) is OK.

9. If hot packing, pour liquid over the fruit in the jars. Leave enough headspace between the food and the jar lid. Too little headspace doesn’t allow the food inside room enough to expand when hot and boiling during processing. Too little headspace can result in liquid being forced out of the jar during processing, and a failure to seal. Usually your recipe says how much headspace to leave. But here are the guidelines that recipe writers follow:

Jellies, fruit syrups: $\frac{1}{4}$ inch headspace

Jams, preserves, pickles, relishes, syrups, juices: $\frac{1}{4}$ inch

Canned fruits: $\frac{1}{2}$ inch

All meats, poultry, fish, and low-acid vegetables (except limas): 1 inch

Lima beans: $1\frac{1}{4}$ inch (pints), $1\frac{1}{2}$ inch (quarts)

10. Release any air trapped in the jar by running a thin flat *plastic or wood (not metal)* utensil around the side of the jar. This will cause air bubbles to come to the surface. A

thin plastic spatula works perfectly for this. (Metal may crack or chip the jar.) Be especially careful to get the bubbles out if you have a product that has been in a blender. You do this because trapped air can emerge later and ruin the seal. Add more water if needed to maintain the proper headspace.

11. Wipe clean the rims of your jars before putting on lids. Use a wet cloth for syrupy contents, a dry cloth if there may be fat droplets.
12. Get your lids ready by heating them to simmering in a pan of water. Then remove from heat. Don't let them boil.
13. Put the flat metal lid on the jar, "composition" side next to the glass. Screw the metal band on over it. Screw down firmly by hand. Don't use a jar wrench for screwing down bands because lids must be loose enough so air can escape in the canner.

If you are water-bath canning, proceed by the following directions. If you are pressure canning, skip to "Pressure Canning Procedure," which follows "Water-Bath Canning Procedure."

WATER-BATH CANNING PROCEDURE

1. Load your jars into your rack. (You can load jars with the rack either inside or outside the canner, but when it's time to take them out, leave the rack inside the canner and take the jars out one by one to avoid accidents with boiling water.) If you loaded outside the canner, holding the rack by the two handles, lower it into your canning kettle. Adjust the water level so that it is at least 1 inch above the tops of the jar lids. Work quickly enough so that your jars are still quite hot from the hot liquid being poured in; otherwise, they may crack when they hit the boiling water. (Commercial jars, like mayonnaise jars, crack more easily than regular canning jars.)
2. When the water in the kettle returns to a cheerful boil (don't confuse the bubbles of air escaping from the inside of the jars with a boil), start timing and boil it the recommended processing time, being careful that it never drops below a boil, in which case you'll have to start your timing all over again. The "Processing Times for Water-Bath Canning" table shows how many minutes to boil various high-acid foods. If you live more than 1,000 feet above sea level, adjust the processing time as indicated in the "Altitude Adjustments for Water-Bath Canning" table.

PRESSURE CANNING PROCEDURE

This is the bot-safe method for canning low-acid foods: meats, poultry, fish, and vegetables (except rhubarb and tomatoes). Technically you can also pressure-can fruit, and some people do. But the canning times are so short that most people think a pressure canner is a pure nuisance to use for canning fruit, because fruit requires only about 8 minutes or less of pressure canning, and it gets frustrating to wait for the thing to heat up and then cool down so you can get on with the next batch. That's why we prefer to can fruit water-bath-style.

NOTE: If you have a dial-gauge canner, have the gauge tested every year before canning even one batch! Call your cooperative extension office to find out where to get this done. Even a brand new one must be tested before use, since shipping can make it inaccurate. When your canner lid is tested, you'll also get information about any recommended changes in time and pressure and procedure of canning.

1. Put wire basket in your pressure canner.
2. Follow instructions for your particular size and style of canner as to the amount of water to put in—probably enough to cover the bottom 1 to 3 inches deep, maybe 1 or 2 quarts. *Read the manual. Follow its instructions. You have to keep your mind on a pressure canner! They can be very dangerous!*
3. Put filled jars with tops screwed on into canner on the wire basket. (Setting jars directly on canner bottom will break them.)

4. Put lid on pressure canner and screw on until it is tightly closed.
5. Check petcock valves with a toothpick if you haven't used the canner lately, if you have that style.
6. Turn up the heat. *Watch* for the steam—when you hear it, start timing. *Watch for a steady flow of steam coming from the vent for 10 minutes.* This is air leaving the jars and canner. It's called "exhausting" or "venting" the canner. You want the air trapped in the canner to escape through the petcock or steam valve. If the canner isn't properly exhausted, the air will cause the reading on the gauge to be inaccurate, and your canning temperatures may be too low to be safe.
7. After the canner has exhausted for 10 minutes, close the vent or place the weight control over the steam valve.
8. Watch for the pressure gauge to reach the correct pressure for your altitude (see the "Altitude Adjustments for Pressure Canning" table). Then set your timer or look at the clock and begin the designated processing time, as shown in the "Processing Times for Pressure Canning" table. If you are processing food in jars of a half pint or smaller, use the time listed for pints.

9. Adjust your heat source so the gauge stays at your determined temperature. If it's showing a higher temp, turn down heat a little. If lower, turn up heat. If you have a gauge that has to be watched, turn it so you can keep an eye on it as you do your other work in the kitchen.

10. When the jars have been processed the correct amount of time, take the pressure canner off the heat (use dry potholders or heavy towels) and let it cool. Let the pressure go down of its own accord. Don't try to rush it. On the average it takes 45–60 minutes for the pressure to go down in a pressure canner.

11. *The steam and heat inside even a "cool" canner can be dangerous.* Wait until the pressure gauge has gone down to zero, or until steam isn't visible rushing out when the regulator is nudged (*with a pencil or long-handled fork, not your finger!*). You will hear a hissing sound whenever you nudge the regulator, but if you don't see steam, it's ready for you to remove the lid.

12. When you can see no more steam, first open the petcock or remove the weighted gauge (not with your fingers!). Open the petcock valve slowly. Let the canner cool further. Then unlock the canner lid. Slide lid across the top of the canner toward you, thus letting steam escape from the far side of the canner. Leave lid sitting loosely on

top of the canner for two more minutes. Remove canner lid. Take your jars out after 10 minutes. If you leave jars in the canner too long, they may not seal and they may overcook.

Cooling, Storing, and Using

1. For proper sealing, the jars must be removed from the water while still hot. Use your jar lifter to take out each jar *one by one*. You should use a jar lifter because it helps you keep them upright as they are moved from canner to cooling place. This is a dangerous time. Have the children out of the way of scalding hot drips. Don't wear shoes with slippery soles.
2. Set jars aside to seal on a surface warm enough that they won't crack because of a temperature contrast—a board, a cooling rack, or several layers of newspaper or towels—not a cold surface. *Turning jars upside down is no longer recommended, for jam or any other food.* Leave a couple inches between them for air to circulate. Don't cover them. *Don't tighten the lids.* That could break a seal which has already formed. Let them finish sealing on their own.
3. The beginning of the cooling causes a vacuum to develop inside the jar that sucks the lid down tight. You can often hear the pleasant “ping” popping sound as it seals. Test for the seal when the jar has cooled off. Most seal almost immediately, but some seal a little later on. The sealing takes place when airflow between the jar and the outside is cut off. The air inside the jar contracts because it is cooling, so you have a vacuum effect inside the jar, which pulls the lid downward and reinforces the seal.
You can sometimes tell whether or not the jar is sealed by looking at the lid. You can feel the seal too, the downward-to-the-center (concave) curve of the lid. Whether the lid moves when you press it down is also an indicator. If it stays down when pressed, the jar is sealed. But if the lid pops back up, it's not sealed. Some lids have a “safety button” in the center. When this button is flat, the jar is sealed. If it is popped up or later pops up, the jar is not sealed, or the seal has broken.
And you can hear it! If it is sealed, you'll hear the difference for sure if you tap it with a fork or spoon. A sealed lid makes a clear ringing sound when tapped with metal because of the tension on it. The only exception to this would be if the jar is too full and food is touching the lid. Then you can't know if it's sealed so must assume it is not, because it wouldn't make the canner's famous and beloved “ping.” If the lid is not sealed, the sound is lower-pitched and not musical or prolonged. After you've heard the difference a few times, you'll never mistake it. (However, hearing isn't as reliable as seeing and feeling the seal.)
If a jar does not promptly seal after processing, reprocess for the full canning time using a different lid, or leave off the lid, put jar in fridge, and use within a week. But reprocessed foods will be distinctly overcooked.
4. Let sealed jars cool undisturbed 18–24 hours. *Don't move them or tighten the rings any more because that can cause the seal to be broken.*
5. After at least 18 hours have passed, take off the rings (screwbands) so liquid under them won't cause rusting. Wipe any stickiness off the outside of the jars. Label them with type of food and date.
6. Store in a dry, cool, dark place. A root cellar or regular cellar is ideal. You have to store the food someplace where it can stay cool but can't possibly freeze. Freezing would break your jars as the water expands. In general, the cooler the storage, the

better the quality retention. Leaving at least $\frac{1}{2}$ inch headspace in the jar protects it from freezing to a certain extent but not entirely. That's why canned food should be stored together with root vegetables in your root cellar, if you have one. Otherwise it needs a cool, dark place such as a basement. The coolness helps hold down enzyme and microbe activity in stored food, and the dark helps protect the color. If you live in an earthquake-prone area, canned food arranged on shelves is very vulnerable to the slightest tremor. In that kind of area, store canning jars in boxes flat on the floor, with cardboard strips as cushions between the jars. When you run out of floor space, use strongly attached shelving with edging strips to prevent the jars from falling off.

7. When you open a jar, check for signs of spoiling. *Do not taste if you have any doubts. If you don't hear air rush in, that indicates it was not sealed; discard it. If the cap bulges upward or the food has a strange smell or look, don't taste it; discard it.* Some bacteria produce "flat-sour spoilage"—sour spoilage with no gas—in canned goods. Some cause gas formation, and you get a bulging lid. Spoilage can make food either more acid or more alkaline, depending on the beastie. Some, such as botulism bacteria, leave no sign of their presence at all—no taste or smell—but nevertheless make the food poisonous.

On the other hand, if the underside of your metal lid has turned dark, don't worry about it. The natural acids and salts in certain foods can interact with the metal and create those harmless brown or black deposits under the lid. They are not harmful to you.

8. *If in doubt, throw it out.* Don't throw it to the animals, because if there is really bot toxin in there, it would poison them. The USDA says, "Due to the risk of botulism, low-acid and tomato foods that are not canned according to ... USDA ... recommendations should be boiled before eating, even if you detect no signs of spoilage. Boil foods for 10 minutes at altitudes below 1,000 feet. Add an additional minute of boiling time for each additional 1,000 feet elevation. This is because bot toxin breaks down when heated. Boiling it covered gives you a higher temperature in the pan. If a canning procedure is not USDA-recommended, it says so in this book. If you followed the recommended processing times and all the rules, if your pressure canner was in good condition, and if the pressure gauge was accurate, your food is safe."

But I repeat, *if in doubt, don't taste it; don't try to salvage it by boiling; just throw it out.*

How Long Will Canned Food Keep?

Safety is one measure. Quality is another. As long as your seal lasts—which can be for years—canned food is safe to eat. But every year it sits on the shelf, you lose quality. You lose color, texture, taste, and nutritional value even though it's still safe to eat. With the passage of years, jars may lose their seal and the contents truly spoil, although they can last surprisingly long.

I think the best way to proceed is to plan so you eat up during the winter everything you canned the fall before. That way you can eat from your garden in the summer and from your garden via your various food-preservation systems, including canning, during the winter and have all your preserved food of the very best quality. If you manage correctly, you'll polish off the last jarful as the new garden is starting to produce.

May 18, 1976. I've been writing this book for 6 years now. I don't have a baby anymore. Sara just had her third birthday, and Luke is 4. Becca is ready for the first grade next fall, and Dolly will be 12 in a few weeks. Danny is a dignified young man of 8. This seventh edition has been a long time coming, longer than any of the others. This year and the year before, it seems like I've done everything but write. Last summer was my first attempt at a School of Country Living. Afterwards I had a lot of bills to pay.

I went back on the road with all 5 children and me living in the van and going from town to town all around the whole United States. Julaine was setting up appointments for me from Los Angeles, and we kept in close touch on the telephone. Darlene, Diann, Ivy, Kay, and the crew back at the Living Room Mimeographer in Kendrick were standing by to make and mail the books they hoped I'd create orders for. Mike was lonesome at home taking care of the big zoo of domesticated animals we had developed for the School and the stock cows that were to eat the grass crop. I didn't get on any big national shows because I wasn't that important, but Julaine could generally get local TV, radio, and newspaper interviews for me in the smaller towns, where big-star types didn't bother to go.

So I'd do about 5 cities a week, working all day. A typical day would be maybe 2 TV shows, 2 radio shows, and a newspaper interview. I'd get done about four o'clock and then in the evening drive a few hundred miles to the next town, with laundromat and grocery store stops as needed. We were so desperate for money to pay the bills I'd run up over everyone's dead body, trying to make my School go, that I just couldn't ask them for money back in Idaho. So I literally peddled my way. When I had a live show, I'd suggest that folks could meet me at the public library or a downtown park or some such, and I'd show them my books for sale and pictures of the School and pass out my free brochures. When I got low on both gas and cash and had no live interviews, I'd set out with a couple of books and knock on bookstore doors or pass out brochures to whoever was around until somebody bought one. I traded books for gas in gas stations, sold one to a stranger whom we asked for directions, and got a bath when somebody invited us home.

Many a morning I washed my hair in the sink of a TV station bathroom before the show. The plumbing plugged up in the van, and all through the Midwest we stunk worse than a load of upset skunks. And we practically died of asphyxiation from the fumes when I ignorantly mixed ammonia and lye trying to clean the toilet. Finally we completely quit using the thing, and it composted naturally and was done. I was grubbier and tireder as every day went on. "Sparkle, Shirley!" I'd remind myself as the lights came on. And in true show business style, I'd sparkle through the show as best I could and then drag myself

back to the parking lot.

But now the poor old van was getting sick. And without Mike, who had always changed my tires and oil and fixed engines for me, I was helpless. I barely made it through the Holland Tunnel, and the engine died at the intersection of Sixth Avenue and something-or-other street right in downtown Manhattan. I gave my next-to-last dollar to some fellows to push it out of the intersection onto the curb. Somebody stuck their head in the window and asked, "What are you going to do?"

"I'm going to sleep," I answered.

He looked dumbfounded. I was too tired to care. It was the middle of the night and I'd been fighting that engine all afternoon. It had taken me 3 jump starts with long waits between to get into New York City, where I had a show to do the next day. I crawled in the back and we went to sleep. In the middle of the night, somebody tried to crawl in a window of the van. When I raised myself up and stared at him, he looked more scared than I and ran away. I went back to sleep.

The next day there in New York City, we got to do the "To Tell the Truth" show, and that was a good respite. They fed us and bought us a room in a fine hotel. The children bounced on the beds and played in the bathtub and drove the hotel staff crazy. There was only one other show to do in New York, because nobody else had wanted me. That was a sort of blessing, for on the whole this trip was much busier than the one before had been.

ROOT CELLAR STORAGE

Root cellar storage keeps vegetables and fruits fresh (live!). And because of the cellar's coolness, they keep longer. It also protects your live foods, and jars of canned food, from freezing if you live in a cold zone.

Planning for this type of storage starts with planning your garden. You plant foods that store well in a cellar. Beets, late cabbage, carrots, celery, parsnips, potatoes, sweet potatoes, salsify, and turnips can be stored without canning, freezing, or drying in a root cellar. Carrots and potatoes in particular may stay crisp and nice until May. So you don't need to can late fall apples, onions, and big winter squash. To make it easier on the food preserver in the family and reduce dependence on electricity and the availability of jar lids, do fresh vegetable storage. If you want to do this, plant a larger portion of your garden with these kinds of foods.

My cellar is my favorite room in the house next to the kitchen. (Well, in wintertime I also love that big bed in our bedroom with all the thick quilts that I hate to rise from on cold mornings.) The walls are lined with shelves, on which rest the canned goods plus all our typical needs. I try to shop only once a month and buy things ahead as much as I can, so when we need something I can head for the cellar rather than the store.

On the floor are the pickle crocks, jugs of vinegar, cooking oil, honey and so on. On a wooden platform on the floor are cans of oatmeal, flour, and wheat. The deep freeze is in another part of the basement. But not everything can be kept in our basement because it doesn't have a dirt floor, and that's bad for vegetables. And in winter it's too hot for them once we have the furnace going.

MORE INFO: *Root Cellaring* by Mike and Nancy Bubel (1979) is a treasure of a book. It covers everything—how to store vegetables and fruits, recipes, etc.—but its strong point is its presentation of a multitude of various root cellar designs. There's a good article on this in *Backwoods Home Magazine*, Nov./Dec. 1992; www.backwoodshome.com. On the web, see www.postharvest.com.au for an Australian website with postharvest handling and storage info and links to other sites. And order “Postharvest Handling of Fruits & Vegetables,” free from ATTRA; or online at www.attra.ncat.org and search for postharvest. North Carolina State University offers a terrific series of fact sheets on postharvest cooling and handling of apples, strawberries, peppers, sweet corn, etc. Order print copies from 919-515-2861; Box 7603, Raleigh, NC 27695. Or read them online at www.ces.ncsu.edu/depts/hort/hil/post-index.html.

LIVE STORAGE GUIDELINES					
Food	Freeze Point	Place to Store	Temp.	Humidity	Time Stored
Dry beans/peas	N/A	Any cool, dry place	32–40°F	Dry	As long you want
Late cabbage	30.4°F	Pit, trench, outdoor cellar	Near 32°	Moist	Late fall and winter
Late celery	31.6°	Pit or trench; roots in soil in storage cellar	Near 32°	Moist	6 to 8 weeks
Endive	31.9°	Roots in soil in storage cellar	Near 32°	Moist	Late fall and winter
Onions	30.6°	Any cool, dry place	Near 32°	Dry	Through fall and winter
Parsnips	30.4°	Stay in garden, or in cellar	Near 32°	Moist	Through fall and winter
Peppers	30.7°	Unheated basement or room	45–50°	Moist	2 to 3 weeks
Potatoes	30.9°	Pit or storage cellar	35–40°	Moist	Through fall and winter
Pumpkins and squash	30.5°	Home cellar, basement	55°	Dry	Through fall and winter
Root crops	Various	Pit or cellar	Near 32°	Moist	Through fall and winter
Sweet potatoes	29.7°	Home cellar, basement	55–60°	Dry	Through fall and winter
Tomatoes (mature green)	31°	Home cellar, basement	55–70°	Dry	4 to 6 weeks
Apples	29°	Cellar	Near 32°	Moist	Through fall and winter
Grapefruit	29.8°	Cellar	Near 32°	Moist	4 to 6 weeks
Grapes	28.1°	Cellar	Near 32°	Moist	1 to 2 months
Oranges	30.5°	Cellar	Near 32°	Moist	4 to 6 weeks
Pears	29.2°	Cellar	Near 32°	Moist	3 months

Storage Places

You can store vegetables and fruits in an attic, unheated basement room, cellar, outdoor pit, etc. To figure out what food to store where, use a thermometer to learn temperatures. Any place that is dependably 32–60°F can be used to keep some kind of food; the temperature and humidity of each location determines which kind. A room 4 × 4 × 6 feet is large enough for most families. A room 6 × 7 × 7 feet will hold about 30 bushels of produce—5 bushels per month for 6 months. An 8 × 10 × 7-foot room will hold about 60 bushels of produce—10 bushels per month for 6 months.

A WARM ATTIC: In the fall, dry herbs, beans, walnuts, or hickory nuts here.

PANTRY OR UNHEATED ROOM: This is good for short-term storage of potatoes and long-term storage of onions, spices, vegetable oils, nuts, and commercially canned foods. Low storage temperatures extend the shelf life of dried foods such as dried beans, herbs, dried fruits and vegetables, coffee, flour, rice, pasta, and cereals. Be careful that the room doesn't get below freezing.

FOR ROOT VEGETABLES, CABBAGES, APPLES, PEARS: These need very cool, moist conditions. They store well without refrigeration in basements, cellars, outbuildings, and pits, but then you need cool outdoor air to provide the refrigeration. The kind of storage place you need depends much on your climate. Typical root cellar instructions assume outdoor temperatures during winter that average 30°F or lower. You can make do with a combination of cellar, attic, and outbuildings, but nicest of all is to have a "real" root cellar. A proper root cellar can be a little building sitting by itself or adjacent to another building, or it can be a real dirt cellar under an outbuilding. It should be near the house because you will be going there a lot in very cold weather and you don't want a long hike. **NOTE:** *Don't store live food in or near a garage, unless it is wrapped so that it will be fully protected from car emissions, which produce will absorb.*

HEATED HOUSE BASEMENT: A well-ventilated basement under a house with central heating generally is dry and has a temperature range of 50–60°F. It is fine for ripening tomatoes and for short-term storage of pumpkins, winter squash, potatoes, sweet potatoes, and onions.

Insulated Basement Storage Room. To store vegetables and fruits over winter in a basement that has a furnace, you would have to partition off a room and insulate it from the heat source. Build the room on the north or east side of the basement, if practicable, and don't have heating ducts or pipes running through it. You need at least one window for cooling and ventilating the room. Two or more windows are desirable, particularly if the room is divided for separate storage of fruits and vegetables. Shade the windows in a way that will prevent light from entering the room. Equip the room with shelves and removable slatted flooring. These keep vegetable and fruit containers off the floor and help circulation of air. The flooring also lets you use water or wet materials (such as dampened sawdust) on the floor to raise the humidity in the room. It's safest to store vegetables and fruits in wood crates or boxes rather than in bins, although my friend Imogene winters her carrots all in a big barrel and they do fine.

CELLAR UNDER HOUSE WITHOUT CENTRAL HEAT: Cellars under houses without central heat have long been used successfully for winter storage of fruits and vegetables in colder parts of the United States. These cellars usually have an outside entrance and a dirt floor. The door is a means of ventilating the cellar and regulating the temperature. Some cellars have no windows. If there is a window, it aids in ventilation and temperature control. If the cellar has separate compartments for vegetables and fruits, then you need at least two windows, one for each compartment. Shade the windows in a way that will prevent light from entering the cellar. Light causes potatoes to turn green and become bitter. Insulate the ceiling so cold air will not chill the house.

Out-of-House Storage

IN-GARDEN STORAGE: It is possible to leave some root crops, such as carrots, turnips, and parsnips, in the garden where they grew, for part or all of the winter. Parsnips, horseradish, and turnips actually get a better flavor after light freezing—between 28° to 34°F—because that cold causes their starch to change to sugar. After the ground begins to freeze in the late fall, cover the root crops with a foot or more of mulch—straw, hay, or dry leaves. Do not place mulch on warm soil, because doing so will cause vegetables to decay rapidly. Wait until the ground is cold. Root vegetables can be hard to dig out of the frozen ground, but will not be harmed unless the temperature around the roots gets down to 25°F or lower. Carrots are damaged at about 25°F, but parsnips can stand lower temperatures. But if rodents are a problem, it is wiser to store these in a buried closed container or in a rodent-proof indoor storage area. One gopher can chomp away a whole row of carrots.

Certain other cold-hardy crops such as beets, cabbage, Chinese cabbage, cauliflower, celery, endive, cos or romaine lettuce, kale, leeks, and onions can endure the early light frosts and can be stored in the garden for several weeks more under a heavy mulch. (See growing details in [Chapter 4](#).)

PITS: Foods that need a cold moist place (see “Live Storage Guidelines” table) can be stored outdoors. An advantage of pits is there’s no buildup of rot spores, as there may be after a

year or two in a cellar. But any outdoor storage has the disadvantage of sometimes being inconvenient or impossible to access, and rodents and other beasts may come to share. Pick a site that is well-drained so it doesn't collect water. You need lots of insulation to protect the food from frost and fluctuating temperatures. People use straw, hay, dry leaves, corn stalks, wood shavings, and plain dirt for insulation. (Dirt is best as a layer over other insulation.) Be sure your insulation isn't contaminated with chemicals or pesticides. Pits should be made in a different place every year because leftovers in used pits are contaminated.

Buried Can. One type of pit is made simply of a wooden barrel covered with several layers of straw and dirt. Or you can use an insulated wooden box or ice chest (but not a plastic "garbage" can!), buried in the ground. This makes a convenient and cheap storage place for your vegetables. Metal cans are most rodent-proof. The opening of the can should sit about 2 inches above ground level. Make sure the container hasn't held anything that would poison or give an off flavor to the food. *Never use drums or containers that might have held pesticides or other chemicals.* Make several holes in the bottom to allow drainage. Dig your hole deep enough so you have room for a layer of rocks in the bottom of it for drainage. Set the can on top of the rocks. The vegetables go into the can in layers with straw or other mulch between each layer. Cover the top of the can with a mound of insulating material that is at least 1 or 2 feet deep and that extends at least a foot on each side of the can.

Cone-Shaped Pits. Cone-shaped outdoor pits are often used for storing potatoes, celeriac, kohlrabi, rutabagas, winter radishes, carrots, beets, turnips, salsify, parsnips, and cabbage. They are sometimes used for storing winter apples and pears. The pit may be built on the ground or in a hole 6 to 8 inches deep in a well-drained location. Build the pit as follows:

1. Select a well-drained location.
2. Spread a layer of straw, leaves, or other bedding material on the ground at least 3 inches thick. Or dig a shallow hole 6–10 inches deep; this gives better frost protection (but increases the risk of water collection). Lay insulation in the bottom of the hole.
3. Stack the vegetables or fruits on the bedding in a cone-shaped pile up to 12 inches above ground level. Don't store apples and pears in vegetable pits, for they'll pick up odors.
4. Arrange them around a beanpole that will stick up through the top of the mound, high enough to be seen through snow cover, so you can find your food in winter.
5. Cover the vegetables or fruits with more bedding.
6. Cover the entire pile with 3 or 4 inches of soil.
7. Firm the soil with the back of a shovel to make the pit waterproof.
8. Dig a shallow drainage ditch around the pit.
9. Small pits containing only a few bushels of vegetables or fruits will get sufficient ventilation if you let the bedding material over the vegetables extend through the soil at the top of the pile. Cover the top of the pile with a board or piece of sheet metal to protect the stored food from rain; a stone will hold the cover in place. To ventilate large pits, place two or three boards or stakes up through the center of the pile of vegetables or fruits to form a flue. Cap the flue with two pieces of board nailed together at right angles.

Removing Pit-Stored Food. It's hard to get food from a pit in a frozen, snow-covered garden. *Once a pit is opened, its entire contents should be removed.* The vegetables that were in the pit will now keep only 1 or 2 more weeks. Though they look the same, pit-stored vegetables won't keep as long as freshly harvested ones. So you'll need to eat them up or shift them to another method of preservation. For this reason, it's better to construct several small pits rather than one large one. Put a small quantity of different vegetables in each pit. Then you can open only one small pit and get a variety of vegetables. When several kinds of vegetables are stored in the same pit, separate them with straw or leaves.

Root Cellars: Outdoor storage cellars may be attached to your house or located in your yard or under an outbuilding. But they should be convenient to your kitchen. Outdoor storage cellars can be constructed entirely or partly underground. Cellars constructed below ground stay at the best temperature longer and more uniformly than cellars that are above ground. The secret to a good root cellar is the combination of insulation where it contacts the air and a design that allows it to absorb warmth from the ground. That's why the more earth there is around your root cellar, the better it functions.

Water. It's important to dig a root cellar and not a well. Find out your water table level. Avoid a site that gets a lot of runoff from rain or spring thaws. Make the floor plan slope just a bit downward for drainage. If you have a water problem, ditch with drainage tile or gravel under it. Or if you end up with water 2 feet deep, make your floor out of planks over supports. You'll have plenty of humidity.

Outer Room. Some folks have an anteroom built outside the entrance to their cellar. That helps with insulation and provides a great place to store garden tools, empty canning jars, etc.

NOTE: Don't build using pressure-treated wood. The phenols used to treat it are dangerous poisons that will tend to vaporize into the air in your cellar.

Roof. Cover your roof with a waterproof material, and then put the dirt over that.

Underground Cellar. The walls and roof of an underground cellar must be strong to support the weight of earth over the roof. Stone and masonry block in combination with concrete can be used, but a cellar made of reinforced concrete is better. A typical underground cellar design has the whole structure, except the door, covered with soil. Wire screen over the outside ends of air intakes and ventilators keeps out birds and small animals. This kind of cellar can also serve as a storm cellar (or fallout shelter).

Partly Underground Cellar. This type of cellar is used in colder parts of the country. First you look for a small hill that you can dig into—or plan to haul dirt. This cellar has walls of masonry that are partly underground. Soil is banked around three walls, and one wall is left exposed. The exposed side has an insulated double door. If you have more than one storage compartment, an air inlet and a ventilator are needed for each one.

Bill Rogers lives in Wheatland, WY, one of the coldest places in the United States. He wrote me, "Your description of the double house, insulated, is great, but let's come back to the real ranch and mountain vegetable cellar. Most of us in the mountains have caves. We dig them in the mountainsides and it is extremely laborious, although not so laborious as you might think, going into rocky mountainsides—usually not blasting. Often your caves amount to no more than a slice into the hillside, walled up and roofed over. My own is inadequately insulated, but it became much more usable and dependable when I built a tool shed in front of the door—keeping it always sheltered and shaded. It never freezes, so I am inclined to believe I could not better my cave if I did insulate expensively."

More Types. Bill wrote me, "Some people in more level country shore up a huge mound of earth covering a specially constructed storehouse. An entranceway with a dead air space 3–4 inches thick between the inner and outer doors is really necessary in the way of insulating. This type of construction is necessary where the water table is relatively high throughout the year. Some people excavate a cellar and have done so since the days of the first pioneers. Two doors are necessary—one on the surface and one at the bottom of the steps. Ventilators are necessary for all types of vegetable cellars. Much more care is necessary in vegetable storing than most people realize. I lost my potatoes last winter due to the lack of air circulation through them. Cabbages keep fresh in bushel baskets, however! One of our garden problems is that in our short growing season everything ripens with a rush and you cannot use it—unless you can put the surplus in storage. Frost comes and everything will be lost unless you can move wheelbarrow loads into storage."

Mostly Above-Ground Cellars. Storing vegetables and fruits in outbuildings is practical only where the climate is consistently cold *but* the average temperature is not below freezing. Even in these climates, temperatures may drop to 0°F or below, and supplemental heat may be needed on very cold nights to keep your food from freezing. Thermostatically controlled heat can be used if the building is wired for electricity. Only a small amount of heat is necessary to prevent below-freezing temperatures in a building unless the cold outside is extraordinary. But you'll have to watch the storage temperature closely whenever low temperatures are predicted.

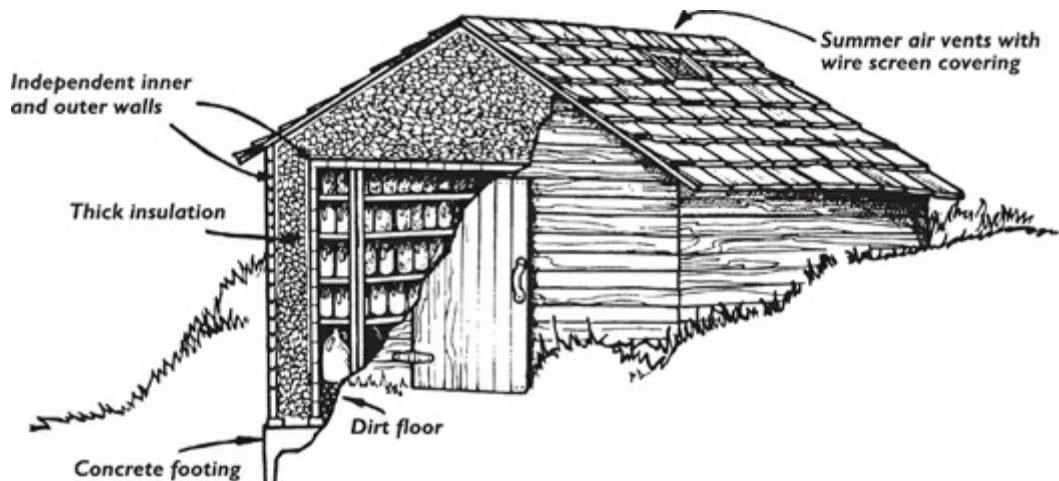

Storage outbuildings can be made of masonry or lumber, but they must be well insulated. Hollow-block walls, regardless of thickness, don't insulate much. Put vermiculite or some other dry granular material in the channels of hollow blocks as each layer of block is laid. If you use cinder blocks, scrub them on both sides with cement grout to make them less porous. Then paint them on the inside with aluminum paint; the paint serves as a moisture barrier. Lay tar paper between the ceiling and joists as a moisture barrier, and spread at least 12 inches of dry sawdust or other granular material in the attic above the ceiling.

A frame building can be built of 2 × 4-inch studding and rafters. Make walls tight by sheathing the inside and outside of the frame with matched lumber. Insulate the space between the walls with loose fill or mineral wool blanket. Put laminated kraft paper (with asphalt between layers), aluminum foil, or polyethylene between the insulation and inside walls as a moisture barrier. Put building paper over the outside sheathing before you lay shingles or siding to make the building tight. Paint the inside of the building with aluminum paint or whitewash. To ventilate above-ground storage buildings, you need intake and exhaust vents.

Imogene's Cellar Design. Here are her directions for building one like hers. The floor should be dirt, because root vegetables keep much better on a natural ground floor than they do on boards or concrete. The floor should be dug down at least a foot below natural ground level (more is better) so that you actually step down into your root cellar. This puts it below the level to which the ground generally freezes in winter.

Build your storage cellar as large or small as you like. It could be as small as 6 × 6 feet inside, but larger is nicer, especially if you have a large family. It will be mighty full in the fall and have lots of room in the spring. The walls are usually double and wooden and best set on a concrete footing. Build the concrete footing to go down a couple feet on the very outside to prevent rodents digging under. There are no windows, but the roof has summer air vents with a wire covering to keep out rodents. There should be at least two of these ceiling vents. They should be square, about 12 × 12 inches. After the freezing

weather comes, stuff them up. Most people keep their canned goods in the root cellar too, so they cover the wall space from floor to ceiling with wooden shelves for holding jars. The vegetables sit on the floor.

There is a space of 2 feet between the inner and outer walls all the way around, which is filled with a good insulation like wood chips or sawdust (free around here, since we are a land of sawmills). There can be a layer of plastic between the wood and insulation. If the outside boards are done tongue and groove, that makes it even better insulated. In your construction, it's also important to make the outer and inner walls as independent of each other as possible, because any connection between them will draw frost into your root cellar at that place. You have to connect them around the door, but you don't have to anywhere else, so don't. What you are building is a house inside a house, with insulation between the walls. The roof consists of a flat layer of boards (the inside house), 3 feet more of insulation, and then a gently sloped roof above that (the outside house) with a considerable overhanging eave. (That makes possible a good depth of insulation across the entire inside area of the cellar, except where your air vents go through in summer. They reach up through the insulation to the free air above.) The roof does not need to shed snow; snow is itself a good insulation. The door area should also be insulated by making two doors, one for the outside wall and one for the inside. You can add hanging blankets inside the door area for additional insulation.

Maintaining Your Storage

KEEP THE STORAGE SPACE CLEAN: Keep storage facilities for vegetables and fruits clean. *Get rid of vegetables and fruits that show signs of decay.* At least once a year, remove all containers from your storeroom. Then clean them and air them in the sun. Wash the walls and ceiling before you put back the containers.

HARVEST FOR LIVE STORAGE: Harvest during dry weather, not too soon after a rain, and let the surface of the product dry, since wet produce is much more susceptible to disease in storage. Handle food carefully to prevent skin cuts and bruises, which also invite decay. Containers should have smooth inner surfaces. Protruding wire staples in baskets and hampers, for example, damage food. Vegetables or fruits with skin breaks should go directly to the kitchen or another preservation system. Make sure there are no crushed, cut, or decaying foods mixed in with those to be stored. They'll cause their neighbors to soon decay also. Harvest in early morning, or let crops picked in daytime heat cool outdoors overnight before you store them. *Don't wash produce before storing.* Just leave the

garden dirt on; it helps them keep. Some commercial foods are waxed to reduce moisture loss and appeal to potential buyers. Home folks don't do that and have better food because of it.

Containers. Sturdy *food-quality* plastic cans with or without handles and with airtight lids are useful for holding grains, beans, flour, honey; making sausage; hauling produce and milk; and curing pickles and sauerkraut. You can reuse any plastic container from store-bought food. But don't make the mistake of putting food in regular plastic garbage cans or bags, because they may be made out of a kind of plastic that is very carcinogenic! It's safe to use a big enamel or stainless-steel kettle (enamel is cheaper, but it doesn't last as long because the enamel will chip). Crocks are romantic and healthy and unlikely to tip over, but a 20-gallon crock can be expensive.

Cans made for food storage are fine. Wooden bins are fine as long as the wood hasn't been "treated" in any way. Dried beans, peas, soybeans, and the like can be stored in airtight cans in your cellar. Squash, pumpkins, and onions need dry storage. Potatoes, late cabbage, cauliflower, and Chinese cabbage like cool and moderately moist conditions, so a wooden box or bin in the root cellar is okay for them. Carrots, endive, beets, parsnips, salsify, rutabagas, turnips, late celery, kohlrabi, and winter radishes need to be quite cool, 32–40°F. Storage in a wooden box under moist sand, or in wooden boxes containing sawdust, is best for them. Potatoes can go straight into the bins. That may be okay with carrots, etc., also. Try and see.

NOTE: Apples give off a gas that stimulates potatoes to sprout and shortens the keeping of other root veggies, so don't store fruits with veggies.

REGULATE THE TEMPERATURE: You will need at least 2 reliable thermometers to be able to carefully regulate storage temperature. Place one thermometer in the coldest part of your food storage place. Put the other one outdoors. Watch indoor and outdoor temperatures closely. You regulate the storage temperature by opening and closing doors, windows, or openings used as ventilators. In most regions, daily adjustment of ventilators is usually necessary to maintain desired storage temperatures. See the "Live Storage Guidelines" table for the freezing points and the best temperatures for long-term storage of your foods.

Outdoor temperatures well below 32°F are necessary to cool storage air to 32° and to maintain that temperature. Once cooled to 32°, the temperature will rise again from earth warmth if ventilators are closed, even though outdoor temperature is about 25°. Close ventilators tightly whenever the outdoor temperature is higher than the storage temperature. Be careful during subfreezing weather so that the stored food doesn't freeze. For example, in an insulated storage cellar partly above ground at Beltsville, MD, full ventilation both day and night was necessary to maintain a temperature of 32°F if outdoor temperatures ranged between 18° and 30° during the day and dipped to 10° at night. But if the minimum temperature at night was 8° for 5–6 hours and ventilators were still fully open, the storage temperature dropped to 30°—below freezing. During a night of high wind, even a minimum of 12° cooled the cellar to 30°.

For a more sophisticated postharvest storage system, consider buying a used, reconditioned cooler, freezer, or refrigeration system from Barr, Inc., "world's largest inventory": 888-661-0871; fax 920-231-1701; 1423 Planeview Dr., Oshkosh, WI 54904; info@barrinc.com; www.barrinc.com.

MAINTAIN NEEDED HUMIDITY/DRYNESS: Without enough moisture in the air, stored vegetables and

fruits may shrivel, lose quality, and eventually become unfit to eat. (See the “Live Storage Guidelines” table for specific humidity needs.) You can add moisture to storage air by sprinkling the floor, by placing large pans of water under fresh-air intake vents, by covering the floor with wet materials such as damp straw or sawdust or by any combination of those. Humidity of 95 percent is almost rainfall and is difficult to achieve indoors. Humidity of 90–95 percent is very moist and good for storage of potatoes and other root crops. Too much humidity encourages mold and other decay critters. (Excessive humidity is present when water droplets form on the surface of the food.) A humidity of 60–75 percent is dry and good for storage of pumpkins and winter squash.

Testing for Dampness. But pumpkins, squash, and onions need a very dry but not cold place for their best storage. So they don’t belong in your basement or root cellar at all if it’s damp. To find out if your basement is damp, test for condensation by placing a small mirror against the wall. Should droplets or fog appear on the mirror after a few hours, it means that condensation is the cause of dampness. Ventilation fans might help but aren’t worth it. Store those particular foods upstairs.

You can install a humidity gauge in your cellar. Delta Trak sells a “Hygro Thermometer,” which is about the size of a deck of cards, battery operated, with a digital display of temp and humidity and recording of daily min./max. of each: 800-962-6776; PO Box 398, Pleasanton, CA 94566; www.deltatrak.com. Or do this simple test for condensation in your basement. Spectrum Technologies sells humidity monitors: 800-248-8873; 12360 S. Industrial Dr. East, Plainfield, IL 60585; www.specmeters.com.

Regularly Check the Stored Food

This old-fashioned way of food preserving is going to require a real adjustment in your attitude if you’re used to thinking of preserved foods as a near absolute—putting the cans or jars on the shelf and the packages in the freezer, and forgetting about them until needed. It isn’t so with storage of fresh vegetables and fruits, nor is it so with dried, salted, sugared, spiced, or alcoholed foods. These items require upkeep—regular, faithful attention all the while you have them.

ROOT CELLAR CHECKLIST

1. Tour your root cellar at least once a week, carefully looking for problems. You’ll be in a race with decay all winter long, just as you were in a race to preserve nature’s abundance from your garden and orchard all summer long.
2. Be ready to make a switch from this method of preserving to another if it looks like you’re going to lose some food. That means if there’s a problem, you salvage what is possible and can, dry, pickle, freeze, or quickly eat it. You also want to remove any and all spoiling vegetables or fruits because the rot spreads to others if you let it go.
3. Green tomatoes and apples: If they have begun to spoil, check them every day or two. Remove bad apples and tomatoes. Take tomatoes that have turned red for kitchen use. If the apples start going in quantity, make a lot of pies or applesauce or freeze apple slices in syrup for pies.
4. Check crock pickles for excessive scum (or mold) on top. If they have it, pour off the brine, boil it, add another cup of vinegar and an extra handful of salt, and then pour it back onto the pickles.
5. Check dried fruits and vegetables for signs of mold. If you have mold, heat in your

oven and then repackage.

6. Check grains and grain products for insect infestation. (See [Chapter 3](#).)
7. Check for mold or bugs in your home-dried fruits. If bugs are present, put the food in a small cheesecloth bag and dip into boiling water for 6 seconds. Dry again and then store in something bug-proof. Or freeze for a few days.
8. Jams and jellies may develop surface mold. If one does, throw it out.
9. If a squash or pumpkin has developed a soft spot, cut out that spot and give to the animals. Cook up the rest to use, can, or freeze.

If you are interested in storing large quantities of food for a very long time (like years), make some Mormon friends. They have made a complete study of this and have lots of practice too. I am blessed with a Mormon mother-in-law who is a dear and precious mother to me and has guided me to a lot of learning. They'd rather be called "Latter-Day Saints," but you probably already knew that.

I think the biggest single principle of cellar-type storage is that you should put away more than you expect to need in order to allow for losses during storage. The thing that makes root-cellар storage really pay off is owning a pig or chickens, so you can recycle the food that doesn't keep into bacon and eggs. By late March, seven-eighths of your winter squash either will have been brought up to the kitchen for cooking or will have spoiled or be near enough spoiled so that you have fed it to the animals. In other words, if you let all your squash set on the shelves all winter long in whatever condition it was (and that would hasten spoilage of the remainder), only seven-eighths of it or less will make it to March. If you do end up with good food left over, you can share it with your neighbors (or the animals).

When you have made your major weekly inspection, sorting out what's bad and should be fed to the pigs and chickens (which is good for them) and setting aside what needs to be cooked up next week for the family, then stop a moment. Admire your shelves covered with home-canned food, your deep freeze full of vegetables and meat, the boxes of apples in the garage, the crocks of pickles and boxes of root vegetables covering your cellar floor, and the cabbage waiting in trenches outside in the garden. Feel good about what your family accomplished and secure about the future, and give thanks to your Good Lord for it.

SUGARING—AND FRUIT PRESERVATION

Sugar, salt, and alcohol were the original "chemical" preservatives. At sugar concentrations of 50–60 percent, sugar's preserving action begins to work. Above 70 percent, nothing grows. Because 15 percent salt and 70 percent sugar don't appeal to human taste, in the old days the former brine and the latter syrup were diluted before use. Pickles were removed from the brine for a day and soaked in several changes of clear water. Syrups were diluted with water to taste.

My favorite food "preserved in sugar" is pure honey, which will keep literally forever. You can make any jam into a self-preserving recipe by altering the amount of sugar used to the required 70 percent. But it's healthier to dry fruit, make fruit leather, or can fruit for a winter sweet, because those are naturally sweet without adding the empty calories of sugar.

In colonial America, dried pumpkin, maple sugar, and honey were used as sweetening agents. My mother bought plain old white sugar in 25-or 50-lb. bags and then transferred it to a bin in the kitchen. There was a bin for flour, too. They didn't go to town too often

from the ranch. It was a long day's proposition, so when they did, the car really came home loaded. The sugar lasted a long time. Mama didn't often make desserts, though when she did they were delicious. Fudge and divinity at Christmas time was her candy repertoire. Oven-baked custard, apple pie, or oatmeal cookies were her everyday desserts.

I've got a real sweet tooth, and I practically ruined my teeth with candy bars and pop once I got away from Mama. Now I'm a mother too and fighting the same battle. I prefer using honey, and I can make a 5-gal. can last all winter.

There are four kinds of sugar. Fructose is found in fruits and honey. Glucose is also found in fruits and in the blood; it's the sugar they give in hospitals. Lactose is a kind of sugar found in milk; the whey from cheese making is rich in it and will sweeten your bread. If you boil down the whey, you get a more concentrated lactose syrup. Sucrose comes from sugar cane and sugar beets.

Fruit is a wonderful natural sugar. In summer when the fruit starts, the children and I quit cooking breakfasts. We just get up in the morning and head for the orchard. Who needs any other start to the day when there are trees loaded with heavenly ripe cherries waiting to be eaten? It's fun to gather 'round the tree, big ones handing down fruit to the smaller ones, Mother pulling down low-hanging branches for smaller children to hang onto and strip. That's the easy part. Then we've got to put up the winter's supply.

SUGAR ALTERNATIVES

Honey. Some people substitute honey for sugar in food preservation recipes. This doesn't reduce the sugar content of preserved foods because 2 types of sugar—fructose and glucose—are the major components of honey. Honey can be substituted for sugar in canned and frozen fruits. The flavor of honey is sweeter than that of granulated sugar, so it is advisable to use less honey than the amount of sugar specified in the recipe. In jelly recipes without added pectin, honey can replace up to one-half of the granulated sugar. With added pectin, honey can replace up to one-fourth of the sugar. Be sure to use light, mild-flavored honey if you don't want noticeable flavor changes in your preserved food.

Corn Syrup. Light corn syrup can replace up to half the amount of sugar in syrups for canned fruits. Be sure to use light corn syrup. Dark corn syrup, sorghum, and molasses are a problem to use because their flavor overpowers the fruit flavor and may darken the fruit. On the other hand, if that's what you have, it won't win a county-fair prize, but it's good food.

Artificial Sweeteners. This stuff isn't good for you, but diabetics and desperate dieters may resort to it sometimes. You'll generally get better flavor if you can or freeze without any sweetener than if you use saccharin or aspartame (Nutrasweet or Equal). Saccharin may become slightly bitter when heated or frozen. Aspartame should not be used in canning because it breaks down when heated, but it can be added to food to be frozen. The best way is to add either of these just before eating the preserved food. If you do add them, it is better to undersweeten the fruit than to overdo it.

Fruit Juice and Juice Products

The quickest and easiest way I know to keep working men and women happy in hot weather is to keep gallon jars of cool liquid in the refrigerator and a plastic gallon jar of ice cubes in the freezer compartment. I make lots of tea (wild strawberry leaf is Mike's favorite, and wild mint is mine). I sweeten the tea with honey, chill it, and serve it plain or with ice cubes for a special treat. I also keep some of our spring water chilled in the

refrigerator in summer for drinks. And the children enjoy the juices canned up from the previous summer's fruit crop, thinned with cold water.

Way back when this book was first getting made, I had hopes of finding a young woman to come and work with me in return for room and board. I advertised. The first answer was somebody's sister, whose sister I think was more enthused than she was. She called me up long-distance from Michigan, and when I told her we worked about a 12-hour day in the summer, she decided she wasn't interested. Then an Oregon woman drove all the way here to look us over. She stayed an hour, declared, "Your place is just like my mother-in-law's," and left. By the next summer I was getting some real solid inquiries, but by then Mike and I had decided not to take on any extras. But it's really not so bad around here in the summer—12-hour days and all. Part of what makes it tolerable is having good things to drink.

JUICE EXTRACTOR AND BOTTLING EQUIPMENT: You don't need special equipment to make fruit juices. Cider, grape juice and other juices in quantity are fairly easily extracted with the aid of a fruit press or a Mehu-Maija, which is the brand name of a very fine Finnish steam process juice extractor. Or you can buy a juicer. A juicer or fruit press makes juice without cooking the fruit. *The Juicing Book*, steamers, a press for juicing citrus fruits without heating, a juice extractor for other fruits and veggies, a food strainer/sauce maker, etc., are available from Back to Basics: 866-290-1851. You make juice in the steamer, simmer for 40 to 70 minutes (still in the steamer), and then empty the hot juice directly into soda pop or wine bottles, or half-gallon or gallon cider jugs.

JELLY-BAG JUICE EXTRACTION: Cook the fruit (some berries can simply be mashed) and put it through anything from a cloth to a colander (good for liquids like tomato juice with some seeds). A modern one can be a fine-mesh nylon bag suspended somehow for juice to drip

through. Prop the bag/sieve up in a pan and go do something else while it drops, or use a rotary colander and rub the pulp around with your wooden pestle. If you are using a cloth, make it a sturdy one. You can “wring” out the juice, or pin the cloth to the sides of the colander with clothespins and let it drop. A first treatment often yields juice with pulp floating in it. If you want clear juice for jelly making or a beverage, give the juice a second straining through a clean cloth, or let it set overnight and pour off the top. You can often get extra juice from berries by taking the pulp of your first squeezing and putting it back on the stove with some water. Boil 5 minutes and then squeeze again.

Crushing Fruit. When directions call for crushing the fruit, you can use a wire potato masher, pastry fork, or slotted spoon for soft fruits. Firm fruits can be crushed with a food chopper. A colander, food press, or strainer will give you a puree. Don’t use galvanized ware in direct contact with fruit or fruit juices because the acid in fruit forms poisonous salts with the zinc. Metallic off-flavors may result from the use of iron utensils, chipped enamelware, or tinware that is not well-tinned.

NECTARS: Juices like apricot, berry, melon, peach, pear, and plum are categorized as the ones that make “nectars.” They are best thinned with water or added to other juices.

MIXED JUICES: Home-grown fruits vary widely in sweetness and flavor. Fully ripe fruits are best for making fruit juices. Use your judgment as to the thinning and sweetening desirable for your own juice. Berries, sweet cherries, apples, melons, pineapples, peaches, and apricots have relatively sweet juice. Cranberries, plums, currants, rhubarb, sour cherries and tart grapes have tart juice. The tart juices can be drunk sweetened and make fine additions to other juices or ginger ale. The amount needed to dilute sour cherry, plum, grape, and berry juices is generally one-third to one-half; you can use water or a bland juice or ginger ale to dilute. The “citrus” juices are orange, lemon, lime, and grapefruit. These are generally thinned with water and sweetened, and are often combined with other juices.

Preserving Juices

Your juices, once extracted, can be easily canned (water-bath time is 5 or 10 minutes), frozen, drunk on the spot, or made into syrup or frozen concentrate to be diluted later.

FREEZING JUICE: Freezing liquids isn’t hard. Put a plastic baggie into a pint or quart jar or tin can you’ve saved. Pour in the fluid and fold the baggie over the top of the fluid. The air space at the bottom of the baggie protects jars from breaking. If it is a widemouthed jar or if you don’t fill it near the neck, you can freeze liquids in glass without a baggie. When the juice is thawed out again, it will probably be more diluted near the top and oversweet near the bottom. Just stir it up.

Although you can freeze juice in almost anything, you’ll have a better-tasting long-term product if you manage to make it something you can seal. If you freeze in a canning jar, leave plenty of headspace:

Widemouthed pint jar

½ inch headspace

Narrow-mouthed pint jar

¾ inch headspace

Widemouthed quart jar

1 inch headspace

Narrow-mouthed quart jar

1½ inches headspace

Homemade Frozen Juice Concentrate. Many recipes assume you have frozen fruit juice concentrates, since there are so many fun things you can do with them. To make a homemade frozen juice concentrate just like the store-bought kind, you need only a large, narrow-necked container, such as a gallon jug, and a freezer.

Pour your juice into the container. Food-grade plastic works well. If you aren't using plastic, be sure to fill no more than three-fourths full so you won't risk breaking the jug when the liquid expands in freezing. Cap and freeze. After it is all frozen, remove the cap and turn the jug upside down. Suspend it by the "shoulders" over a lower container, such as a widemouthed gallon jar, so the drips won't make a mess and because the drips are the good part. Don't try to rush the draining process with heat. That would mess up the process because the ice melts, runs down, and dilutes the juice concentrate.

The reason it works is because the juicier bits melt before the plain water crystals do. When the drips running off are no longer sweet and colored, take away the jug. Finish melting the ice. Throw out the ice water. Now repeat your freezing and dripping procedure 2 more times (3 total). You now have a fine concentrate. Store it in the freezer.

CANNING JUICE: Heat high-acid fruit juices—from apricots, berries, red cherries, red grapes, peaches, plums, and rhubarb—to 190°F to inactivate enzymes and deepen color. If you do it in the top of a double boiler, you'll get a fresher fruit flavor. Don't let the temperature reach the boiling point. Once it has reached 190°F, cool it quickly to keep the fresh flavor. If you have a choice, don't heat apple, light-colored cherry, light grape, or citrus juices. Heat destroys vitamin C. Store in freshly sterilized bottles. (Sterilize by boiling, covered with water, for 20 minutes.) Cap with cork-lined metal caps and turn upside down for 5 minutes. Leave bottles in a dark place. If you haven't one, put the jars in paper bags or cardboard cartons. To hold flavor, color, and vitamins, have a storage place that doesn't get above 70°F.

Old-Time Sealing Wax for Bottle Corking. Use 1 lb. resin, 2 oz. beeswax, and 1½ oz. tallow. Warm and combine. First cover cork using a brush, and push it into the bottle. Then dip the entire corked end of the bottle into the melted wax.

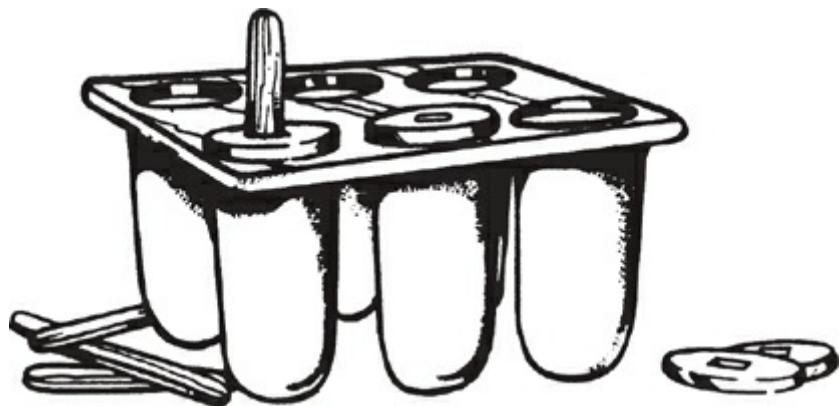

Summer Ices, Frozen Fruits

An "ice" is a frozen beverage. A "frappe" is a dessert ice that is basically a fruit sauce frozen only to a coarse mushy stage. A "sherbet" can be a water ice with a little dissolved gelatin or beaten egg white added. (For milk-based sherbets, see [Chapter 10](#).) And then there are popsicles. Actually, you can use any popsicle recipe to make a frappe and vice versa. To make a frappe, just eat it out of a bowl before it is frozen clear solid. If you get a dessert ice frozen too hard to serve, let it thaw again until it has the consistency of thick mush. Then serve. Feel free to change the sweetening type and amount to suit your preference. You don't have to have a crank freezer for any of these, although if you do, then by all means use it.

An electric ice shaver turns ice cubes into soft, fluffy snow. You can pour flavoring over it to make snow cones, slushes, etc. Shavers are available from Back to Basics for \$29.95 (866-290-1851). They also sell lime, raspberry, grape, kiwi, etc., flavor concentrates (powdered—add water and sweetener, or liquid), dispenser bottles, ice molds, and recipe booklet.

HOMEMADE POPSICLES: These are cheap, easy, and even more fun for the children than going to the store. Children like strong, sweet juices like grape and cranberry for popsicles—but when kids are hot, anything will do. My little ones enjoy goat's milk popsicles. Popsicle making is a nice way to use leftover juices from canned fruit, too.

Of Handles and Molds. You can use wooden sticks for handles and sturdy small bowls or cans for containers—work up a collection. Or buy popsicle molds; Tupperware and Back to Basics carry them. If you have a big family or lots of small friends, I recommend getting at least 2 molds so you can have one freezing while they are consuming the other. You can even make parfait popsicles by freezing a layer of one color and then a layer of another color. My plastic holders soon got lost or fell apart, but then we substituted sticks in a bowl or can and were fine. Fill the molds not quite full, insert your holder, and freeze.

Unmolding. Don't let the gremlins pull the holders until you're sure the center of the popsicle is solidly frozen and you have loosened the sides by running hot water over the back of the mold. Otherwise they might pull out the holder prematurely, leaving a hole that it won't freeze back into. You don't have to unmold all the popsicles at once. Just loosen as many as you need. Refill the emptied units and return to the freezer.

➲ **BASIC FRUIT POPSICLES** Puree 1 c. any kind of fruit or a mixture of fruit and mix with 1 c. water. Pour into your ice cube tray. When they are starting to freeze, add a wooden stick or toothpick to each section.

➲ **PUDDING POPSICLES** Susan Staley was in Germany when she sent me this recipe. She said, "If your children love the Fudgsicle-type popsicle, you can easily make them. Just make up a batch of pudding and freeze it in your popsicle molds. They're delicious and you can make different kinds besides chocolate. Butterscotch is very good. In fact, any flavor of pudding your children love hot, they're bound to like cold in hot summer weather."

➲ **ANY FRUIT ICE** You could juice pomegranates or barberries or red currants, or cook and strain quinces, or grate pineapple, or boil and pulp apples or rhubarb—whatever you have. Sweeten to taste, add lemon juice if the flavor needs it, and freeze.

➲ **GINGER ALE ICE** Combine $\frac{3}{4}$ c. sugar and 2 c. water. Heat and boil 5 minutes. Cool. Add 1 c. orange juice, $\frac{1}{2}$ c. lemon juice, and 2 bottles ginger ale. Freeze.

➲ **ROOT BEER ICE** Combine 1 bottle root beer, 1 T. lemon juice, 1 T. brown sugar, and a few grains salt. Freeze.

➲ **STRAWBERRY OR RASPBERRY ICE** Remove the green stem end from fruit, enough to make 3 or 4 cups. Pour $\frac{1}{2}$ c. honey over the fruit. Mash the mixture with a potato masher until you have it pulped as finely and mixed as well as you can. (If you like, strain out the seeds.) Add 1 c. water and the juice of 1 lemon. Freeze, stirring occasionally. This is a delicious summer dessert and my favorite ice to make.

➲ **FROZEN FRUITS** Strawberries, raspberries, fresh peaches, or crushed pineapple (as well as canned fruits, especially pears and peaches in syrup) can be frozen. Mash the fruit, add sweetening to taste, and let stand until a syrup is formed. Then use your crank freezer or freeze in trays, stirring occasionally. It can be served in slices or dished up casually. Good with whipped cream on top.

Jams and Jellies

Jams and jellies preserve easily because the sugar itself acts as a preservative. Jam is fruit boiled thick with sugar. Most jam recipes call for a 2:1 ratio of sugar to fruit by weight or volume. Some jam recipes that are really trying to hold down the sugar content call for a 1:1 ratio. Jelly generally has a 1:1 ratio, 1 c. juice to 1 c. sugar. Jelly making depends on having proper amounts of fruits, pectin, acid, and sugar. Jellying is a chemical change based on the presence of pectin and acid.

JAM/JELLY RECIPES: Canning books always have jam and jelly recipes. You can get free ones with any package of commercial pectin that you buy or from your extension agent, and you'll find lots here and there in this book. You can personalize recipes with your own flavors and spices, but stay close to the recipe for the essential pectin/sugar/acid proportions.

PECTIN: Pectin is the key to jelly. It's a natural substance in some fruits, especially underripe ones, that "jells" when heated and combined with acid from the fruit and sugar. Apples are usually rich in pectin. Natural ripening causes the pectin to break down. So if your fruit is overripe, your jelly will never get firm no matter how long you boil it. Peaches, strawberries, and cherries don't have much pectin. You can combine pectin-rich fruits with pectin-poor fruits, use commercially prepared pectin, or make your own.

No-Sugar Pectin. Pomona Universal Pectin sells low-methoxyl pectin. That's a pectin which jells fruit without using sugar in the recipe. In this way, jams, jellies, and fruit

spreads can be made without sugar or long boiling times: 413-772-6816; PO Box 1083, Greenfield, MA 01302. For more ideas, see *Canning and Preserving without Sugar* by Norma M. MacRae. Her recipes for canned fruits and jams use honey, frozen juice concentrate, canned juice, date sugar, and dried fruits for sweetening. But keep in mind that *every time you reduce the sugar, you're reducing the time the jam or jelly can be safely kept out of the freezer before mold grows on it.*

Homemade Pectin From Apples. To make this, use skins and cores of cut-up apples or whole apples, or apple pulp. Boil 2 lb. apples with 4 c. water for about 45 minutes. Extract the juice through a cloth or jelly bag without using pressure. Boil the resulting juice 15 minutes and can it if you won't be using it right away. Use a cup of this apple pectin per 1 c. pectin-weak fruit juice. When making jellies using this combination of apple pectin juice and other fruit juice, $\frac{3}{4}$ c. sugar per 1 c. liquid is usually correct.

Old-Time Test for Pectin. Here's a way to tell whether you have enough pectin present for good jelling: Into a glass container put 1 T. juice; with this mix 1 T. alcohol. If you have enough pectin, the fruit juice will turn into a jellylike mass that you can gather up with a spoon. If not enough pectin is present, it won't jell when you add the alcohol, and that tells you to add some more pectin.

Modern Test (Jelmeter). Or you can buy a modern pectin tester from Lehman's, Box 41, Kidron, OH 44636, and have perfect jelly every time. It's called a Jelmeter. In 60 seconds it tells exactly how much sugar must be added to your juice and whether or not pectin is needed. Comes with instructions and 50 recipes.

Short of Pectin? Add sour apples, crab apples, currants, lemons, cranberries, sour plums, loganberries, or green gooseberries. Ripe apples, blackberries, oranges, grapefruit, sour cherries, and grapes have a sort of average pectin content. Fruits that don't jell well on their own because of low pectin content are apricots, peaches, pears, strawberries, and raspberries.

ALTITUDE AFFECTS JELLY MAKING: Martha Mohan, who lives over 6,000 feet up near Hotchkiss, CO, wrote me, "To make jelly from wild berries at altitudes over 6,000 feet, I have found that the wild berries should be boiled at least 3 times and preferably 4 times as long. At 6,500 feet I cook all jellies 3 times as long as cooking charts show, until it sheets off the spoon. An old-timer, a lady we know, who lives at 8,300 feet elevation, told me this and it works for me. These jellies are really worth the extra effort and are great with any wild meat."

ACID CONTENT: You must have enough acid content to jell. Taste the juice for tartness. If it isn't very tart, add lemon juice for extra acid.

JELLY MAKING, OLD-TIME DIRECTIONS: To make jelly, the fruit has to be cooked; cooking brings out the pectin in the right form for jelly making. Only with commercial pectin can you jell uncooked fruit. To jell with natural pectin, the fruit is generally cleaned, cooked, mashed, and put through a jelly bag or two to get the juice that is the jelly base. If you squeeze the bag you will get pulp too, which is okay unless you want a clear jelly—in that case, don't squeeze the bag.

JELLY MAKING WITHOUT ADDED PECTIN: These are USDA instructions. Use only firm fruits naturally high in pectin. Select a mixture of about $\frac{3}{4}$ ripe and $\frac{1}{4}$ underripe fruit. One

pound of fruit should yield at least 1 c. clear juice. Do not use commercially canned or frozen fruit juices because their pectin content is too low. Using peels and cores adds pectin to the juice during cooking of the fruit and increases jelly firmness.

Wash all fruits thoroughly before cooking. Cut firm, larger fruits into small pieces. Crush soft fruits or berries. Add water to fruits as needed. Put fruit and water into a large saucepan and bring to a boil. Simmer, stirring occasionally, for the amount of time listed or until the fruit is soft.

When fruit is tender, press lightly through a colander. Then let juice drip through a double layer of cheesecloth or a jelly bag. Excessive pressing or squeezing of cooked fruit will cause cloudy jelly.

Using no more than 6 to 8 c. extracted fruit juice at a time, measure and combine the proper quantities of juice, sugar, and lemon juice and heat to boiling. Stir until the sugar is dissolved. Boil over high heat, stirring frequently, until the jelling point is reached. Here are some recipes.

⇒ **APPLE JELLY** Add 1 c. water per 1 lb. fruit. Simmer 20 to 25 minutes before extracting juice. To each 1 c. strained juice add $\frac{3}{4}$ c. sugar. Optional: add 1½ t. lemon juice. If you start with 4 c. juice, your jelly yield will be 4 to 5 half pints.

⇒ **BLACKBERRY JELLY** Add 0– $\frac{1}{4}$ c. water per 1 lb. fruit. Simmer 5 to 10 minutes before extracting juice. To each 1 c. strained juice, add $\frac{3}{4}$ t 1 c. sugar. From 4 c. juice, your jelly yield will be 7 to 8 half pints.

⇒ **CRABAPPLE JELLY** Add 1 c. water per 1 lb. fruit. Simmer 20 to 25 minutes before extracting juice. To each 1 c. strained juice, add 1 c. sugar. Jelly yield from 4 c. juice will be 4 to 5 half pints.

⇒ **GRAPE JELLY** Add 0– $\frac{1}{4}$ c. water per 1 lb. fruit. Simmer 5 to 10 minutes before extracting juice. For each 1 c. strained juice, add $\frac{3}{4}$ to 1 c. sugar. Jelly yield from 4 c. juice will be 8 to 9 half pints.

⇒ **PLUM JELLY** Add $\frac{1}{2}$ c. water per 1 lb. fruit. Simmer 15 to 20 minutes before extracting juice. To each 1 c. strained juice, add $\frac{3}{4}$ c. sugar. Jelly yield from 4 c. juice will be 8 to 9 half pints.

⇒ **NO-SUGAR JELLY** To 1 c. fruit juice, take 1 to 2 T. unflavored gelatin that has been dissolved in 1 to 2 T. cold water. (Stir the gelatin into the cold water until well dissolved. Let stand a few minutes.) Now add hot juice steadily and stir well. Set aside to cool in your refrigerator. Because there is no extra sugar in this kind of jelly, it won't keep without refrigeration and you must use it up within two weeks.

⇒ **HONEY-FRUIT JELLY** Combine 2 c. high-or medium-pectin fruit juice, $\frac{1}{2}$ c. mild-flavored honey, and 2 t. lemon juice. Bring to a boil and stir in all at once 2 T. powdered pectin. Let boil 10 minutes and pour into your jelly glasses. For low-pectin fruit juices, use 4 t. lemon juice and 3 T. powdered pectin. If you want to use homemade pectin, substitute 2 c. homemade pectin for both the lemon juice and powdered pectin.

MICROWAVE JAMS AND JELLIES: Use only recipes developed specifically for the microwave (see your librarian). And consider that recipes developed for one microwave may not work in another because of differences in power output between the ovens.

TESTING JELLY DONENESS

Temperature Test. Use a jelly or candy thermometer. Boil to a temperature of 220°F at sea level, 218°F at 1,000 feet, 216°F at 2,000 feet, 214°F at 3,000 feet, 212°F at 4,000 feet, 211°F at 5,000 feet, 209°F at 6,000 feet, 207°F at 7000 feet, and 205°F at 8,000 feet of altitude.

Sheet or Spoon Test. To see if the jelly is ready for canning, dip a cool metal spoon into the boiling jelly mixture. Raise the spoon about 12 inches above the pan (out of the steam). Turn the spoon so liquid runs off the side. The jelly is done when the syrup forms 2 drops that flow together and sheet or hang off the edge of the spoon.

If your jam or jelly doesn't jell, here's a tip. Thin jam or jelly is often caused by lack of pectin, or too much or too little acid. The best way to fix it is add gelatin. Just pour the non-jelled stuff back into the pan. Heat to boiling. Shake a package of gelatin out over the top and then stir it in until all dissolved. One envelope (1 T.) gelatin thickens 4 c. runny jelly or jam. Now pour it into jars. To can, put on lids and process in boiling-water bath 10 minutes.

WHEN JELLY IS DONE: Remove it from the heat and quickly skim off foam. Using a widemouthed funnel, ladle the jelly into sterile jars, leaving $\frac{1}{4}$ inch headspace. Adjust lids and freeze or can.

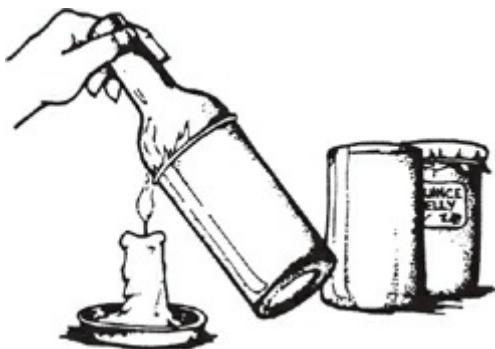

Freezing. If you use commercial pectin you can freeze your jams and jellies. Use plastic freezer containers. Good instructions for both canned and frozen jams and jellies come with each package of Sure-Jell or Jam and Jelly Pectin. Frozen uncooked jam keeps that delicious fresh fruit flavor but will be softer than cooked jams.

Canning. Pour hot into sterile half-pint or pint canning jars, leaving $\frac{1}{4}$ inch headspace. To sterilize empty jars, put them open side up on a rack in a boiling-water canner. Fill the canner and jars with hot (not boiling) water to 1 inch above top of jars. Boil jars 10 minutes. Remove and drain hot sterilized jars one at a time and fill with food. Food residue should be removed from each jar's sealing edge with a clean, damp paper towel. New 2-piece canning lids prepared according to manufacturer's directions should be put on.

After screw bands are tightened, process jars in a boiling-water canner. Fill canner half-full with water and preheat to 180°F. Load sealed jars into the canner rack and lower with handles, or load one jar at a time with jar lifter onto rack in canner. Add water until you have a level of 1 inch above jars. Cover. When water is boiling vigorously, lower heat to maintain a gentle boil. Process all jellies and jams in half-pint or pint jars for 5 minutes if you live at 1–1,000 feet; for 10 minutes at 1,001–6,000 feet; or for 15 minutes above 6,000 feet. After the processing time is over, remove jars from the canner with a jar lifter and place on a towel or rack. Do not retighten screw bands. Air-cool jars 12 to 24 hours. Remove screw bands and check lid seals. Jelly and jam are best if consumed within a year.

NOTE: Here a few jam/jelly precautions. Don't put a jam or jelly into a quart jar; it won't jell. Don't double a recipe. Open-kettle canning is no longer recommended for jams and jellies; they need at least a 5-minute water bath. Paraffin sealing is no longer recommended because it's not reliable enough, and the contents are more likely to mold.

MAKING A WINE BOTTLE INTO A JELLY GLASS: Old-timers made narrow-necked wine bottles into preserve holders by tying strings soaked in kerosene around the shoulders. Then they set the strings on fire. That cracked the necks so they could be knocked off and the edges filed smooth. The bottles were washed and sterilized, the hot jam poured in—and then the bottles were sealed with paraffin. You let your jelly set up (jell) and cool clear down first, before you added the paraffin.

SEALING JELLY WITH PARAFFIN: Doing this enables you to use odds and ends of jars other than regular canning jars, thus stretching your jar supply. You simply pour a $\frac{1}{4}$ - to $\frac{1}{2}$ -inch layer of melted paraffin onto the top of the jelly after the jelly has cooled enough to set up. And you can wash these little disks of paraffin as you use the jelly, toss them in a box, and melt them down again the next year for reuse.

The USDA, however, now recommends canning with a 5-minute processing time instead of sealing with paraffin, because research has shown that paraffin-sealed jams and jellies—especially low-sugar ones—are more likely to mold.

JAMS WITHOUT ADDED PECTIN: For best flavor, use fully ripened fruit. Wash and rinse all fruits thoroughly before cooking. Do not soak. Remove stems, skins, and pits from fruit; cut into pieces and crush. For berries, remove stems and blossoms, and crush. Seedy berries may be put through a sieve or food mill. Measure crushed fruit into large saucepan.

➲ **BASIC JAM** Pour 3 c. sugar over 4 c. fruit or berries prepared as above. Boil about 10 minutes (or until it has boiled down by a fourth). Test for jelling by dropping 2 or 3 drops in a saucer of cool water. If it feels jelled, put it in jars. If not, keep on boiling until the mixture is thick enough to spread. To pack in jars, pour hot jam into hot, sterilized jars. Wipe the edge of the jar clean and put on a hot lid and ring. Screw down tightly. Check next day to make sure it has sealed.

➲ **APRICOT JAM** Use 4–4 $\frac{1}{2}$ c. crushed fruit, 4 c. sugar, and 2 T. lemon juice. Jam yield is 5 to 6 half pints.

➲ **BERRY JAM** Use 4 c. crushed fruit, 4 c. sugar, and no lemon juice. Yield is 3 to 4 half pints.

➲ **PEACH JAM** Use 5 $\frac{1}{2}$ to 6 c. crushed fruit, 4–5 c. sugar, and 2 T. lemon juice. Yield is 6 to 7 half pints.

JELLIES AND JAMS WITH ADDED PECTIN: Fresh fruits and juices, as well as some commercially canned or frozen fruit juices, may be used with commercially prepared powdered or liquid pectins. The order of combining ingredients depends on the type of pectin used. Complete directions for a variety of fruits are provided with packaged pectin. Jelly or jam made with added pectin requires less cooking, generally gives a larger yield, and has more natural fruit flavor. In addition, using added pectin eliminates the need to test for doneness. The following recipes are usually available with packaged pectins.

Jellies. Apple, crabapple, blackberry, boysenberry, dewberry, currant, elderberry, grape, mayhaw, mint, peach, plum, black or red raspberry, loganberry, rhubarb, and strawberry.

Jams. Apricot, blackberry, boysenberry, dewberry, loganberry, red raspberry, youngberry, blueberry, cherry, currant, fig, gooseberry, grape, orange marmalade, peach, pear, plum, rhubarb, strawberry, and spiced tomato.

NOTE: Buy new packaged pectin each year because old pectin may not jell well.

PACKAGED-PECTIN RECIPES

➲ **GRAPE-PLUM PECTIN JELLY** You'll need 3½ lb. ripe plums, 3 lb. ripe Concord grapes, 1 c. water, ½ t. butter or margarine (optional ingredient to reduce foaming), 8½ c. sugar, and 1 box (1 ⅓ oz.) powdered pectin. Wash and pit plums. Do not peel. Thoroughly crush plums and grapes, one layer at a time, in a pan. Add water. Bring to a boil, cover, and simmer 10 minutes. Strain juice through a jelly bag or double layer of cheesecloth. Measure sugar and set aside. Combine 6½ c. juice with butter and pectin in a large pan. Bring to a hard boil over heat, stirring constantly. Add the sugar and return to a full rolling boil. Boil hard for 1 minute, stirring constantly. Remove from heat, skim off foam, and quickly pour into sterile half-pint jars, leaving ¼ inch headspace. Adjust lids and process. Yield will be about 10 half pints.

➲ **PEAR-APPLE PECTIN JAM** You'll need 2 c. peeled and crushed fully ripe pears, 1 c. peeled and finely chopped apple, ¼ t. ground cinnamon, 6½ c. sugar, ½ c. bottled lemon juice, and 6 oz. liquid pectin. Wash, peel, and core pears. Crush well and measure 2 c. into a large pan. Wash, peel, core, and finely chop 1 c. apples. Add apple to pears and stir in cinnamon. Thoroughly mix sugar and lemon juice into fruits and bring to a boil over high heat, stirring constantly. Immediately stir in pectin. Bring to a full rolling boil; boil 1 minute, stirring constantly. Remove from heat, quickly skim off foam, and pour into sterile half-pint jars, leaving ¼ inch headspace. Adjust lids and process the jars as above. Yield will be about 7 to 8 half pints.

➲ **STRAWBERRY-RHUBARB PECTIN JELLY** You'll need 1½ lb. red stalks of rhubarb, 1½ qt. ripe strawberries, ½ t. butter or margarine (optional to reduce foaming), 6 c. sugar, and 6 oz. liquid pectin. Wash and cut the rhubarb into 1-inch pieces and blend or grind. Wash, stem, and crush strawberries, one layer at a time, in a large saucepan and simmer 10 minutes. Strain juice with a jelly bag or double layer of cheesecloth. Combine and mix 3½ c. juice and sugar. Add butter if desired. Bring to a boil over high heat, stirring constantly. Immediately stir in pectin. Bring to a full rolling boil; boil hard 1 minute, stirring constantly. Remove from heat and quickly skim off foam. Pour into sterile half-pint jars, leaving ¼ inch headspace. Adjust lids and process as above. Yield will be about 7 half pints.

Syrups

Homemade syrups can be beverage-based syrups or sweet pancake-type syrups meant to be used straight and poured over another food.

BEVERAGE-BASED SYRUPS: These are handy for making drinks on camping trips and at picnics. They keep well in the refrigerator, and a little syrup poured into a glass three-quarters full of cold water or soda water and ice makes an easy, quick drink the children can fix for themselves. Just about any fruit juice can be made into a syrup—cherry, raspberry, and the like. Add ice, if possible, when serving. Dilute with ginger ale or various clear bubbles for variety. You can store unsealed syrup in bottles or a fruit jar. Store in a cool, dark place.

➲ **PLAIN SUGAR SYRUP ("SIMPLE SYRUP")** Boil 2 c. sugar with 2 c. water for 5 minutes. Chill and store in a covered jar. Or water-bath process this for 15 minutes, and then it can be stored on the shelf for the long term. This was popular with Great-Grandmother for sweetening summer drinks, because the sugar was already in solution and she didn't have trouble with sugar settling in the bottom of the glass.

➲ **STANDARD FRUIT SYRUP RECIPE MEANT TO BE SEALED** Wash currants, black or red raspberries, blueberries, grapes, elderberries, and so forth. Simmer in water to cover until soft. Drain juice and strain it. For every 2 c. juice, add 1½ c. sugar. Boil 15 minutes. Skim and pour into sterilized bottles. Bottle hot and seal or cork, making sure the bottles are airtight. Tie plastic or foil over the top, wrap around the top with sticky tape, or tip the tops of the bottles into sealing wax. Because syrups may ferment after being open for 2 or 3 days, use small bottles.

➲ **STRAWBERRY SYRUP** Take ripe strawberries, crush in a cloth, and press out the juice. For each 2 c. strawberry juice, add 2 c. Plain Sugar Syrup (recipe above). Boil gently for 15 minutes. Bottle.

➲ **RASPBERRY SYRUP** First extract the juice from the raspberries. (See "Fruit Juice and Juice Products.") Measure the juice, pour it into a pan, and bring to a boil. For each 1 c. juice, add 1 lb. sugar, bring to boil again, and let boil for 1 minute. Skim off the scum. Pour into sterile bottles and seal. Optional: Add some whisky to the syrup.

➲ **PLUM SYRUP** Cook 3 lb. plums and 3 lb. sugar with a little water for 20 minutes, stirring often. Drain without squeezing. Measure your syrup. For each 2 cups, add ½ t. almond flavoring. (Optional: Add whisky or brandy, from ½ t. up to 1 qt.) Use the leftover plum pulp to make a fruit pie or butter.

➲ **LEMON SYRUP** Put 1 c. water and 1 qt. sugar into a pan. Simmer, stirring constantly, for 3

minutes. Skim if needed. Add 1 c. lemon juice and 1 T. grated lemon rind, and simmer another 2 minutes. Pour into sterile bottle and seal.

PANCAKE SYRUPS: Homemade syrup was one of the delights of my childhood. Usually it was chokecherry syrup poured over pancakes. Sometimes it was honey syrup, for we allowed bees on the place and the bee man repaid us in honey, more honey than we knew what to do with.

The first money I ever made was peddling buckets of chokecherries in our local metropolis—Livingston, Montana. I rode my pony, Shorty Bill, laden with empty buckets a couple of miles on up the mountain from our home to a little canyon where the chokecherry bushes were thick. I worked hard all day picking berries and filling those metal buckets. Rode home, tired but satisfied, with the fruit of my labors. The next day was Mama's day to drive the 30 miles into town to do a few weeks' shopping. She took me and my buckets of chokecherries. I went from door to door, knocking on doors, offering my chokecherries for sale. I think I charged about a dollar a bucket. Those housewives were really pleased to see buckets of chokecherries like the ones they had picked when they were little—something that wasn't sold in stores.

The old-time syrups were used not only on hot breads like biscuits and pancakes and on ice cream but also on puddings and pound cakes, as flavorings in sauces and sherbets, and as beverage bases. One or two spoonfuls of a fruit syrup in a glass of cold water with shaved ice makes a nice summer beverage. Most of the recipes below call for white sugar, but you can substitute honey. The trouble with using honey is that it has such a distinctive flavor of its own that if you use it in everything, you get tired of honey's flavor pretty soon.

➲ **BASIC FRUIT SYRUP** Fruits vary in natural sweetness or tartness, chokecherries probably being at one extreme and dark sweet cherries probably the other. So the amount of sugar to add involves your judgment. But in general, get the juice from the strawberries, raspberries, currants, grapes, or what you want as directed for fruit juices. After the juice is brought to a boil, add sweetening and boil down to the density you want. Then can.

➲ **WHOLE FRUIT SYRUP** Wash, core, and pit the fruit; peel if you think the peels wouldn't make it through the blender or wire-mesh strainer or wouldn't be nice. Now blend or force through a wire strainer. For every 1 c. mashed fruit, add ¼ c. water, 2 t. lemon juice, and ½ c. honey. Boil together 5 minutes, stirring constantly. Now take your syrup off the stove. Skim off the foam. Pour into hot jars and seal or cool for serving.

➲ **QUICK BERRY SYRUP** If you haven't time for all the boiling down, do this. For each 4 c. berry juice, stir in 2 c. sugar and 2 c. light corn syrup. If it is strawberry or raspberry juice, add 2 T. lemon juice (the others don't need it). Boil. Skim if needed. To can it, process 10 minutes for pints or quarts.

➲ **RESOURCEFUL WOMAN'S SYRUP** Take any leftover fruit syrup or juice. Sweeten as needed and boil down until it is syrup-like.

➲ **PHONY MAPLE SYRUP** Boil 1 c. dark brown sugar with ½ c. water for 5 minutes. Add ¼ t. maple flavoring and 2 T. butter. Serve warm.

➲ **CREAM AND SUGAR SYRUP** Mix in a pan ½ c. cream, 1 c. brown sugar, and ½ c. dark corn syrup. Bring to a boil and serve warm.

Fruit Sauces

If you have a batch of fruit that is going bad, and you want to get it put up the quickest, easiest, cheapest way possible—sauce it! Applesauce isn't the only member of this family. You can sauce cherries, peaches, rhubarb, cranberries, etc. Berries make fine special sauces to go on desserts. Apricots and even prunes can be made into a sauce. The sauces aren't meant to be supersweet. Sweeten to taste. The right amount of sweetness depends on you—and on the fruit.

➲ **BASIC SAUCE** Prepare your fruit (*peel, core, or whatever is appropriate*). Add it to boiling water (*a third part or less of your fruit amount*). Cover and simmer gently until tender. Remove from heat. Put the fruit through a strainer to make a smooth sauce, or use as is. Add sweetening and mix well. Always use a wooden spoon to stir and a really heavy (*non-aluminum*) pan to cook it in.

➲ **BASIC FRESH, RAW-FRUIT SAUCE** Crush fruits such as peaches, raspberries or strawberries. Sweeten to taste and serve over ice cream, pudding, or cake.

CANNING A HIGH-ACID SAUCE: Follow Basic Sauce recipe (above). Return to a boil again. Have jars ready. Boil some lids in a pan of water. Using a widemouthed funnel, quickly pour the very hot sauce into the jar. Put on the first lid and then the screw one. Now give it 15 minutes of hard boiling in a water bath. Lift out, tighten, and set aside to cool.

FREEZING A FRUIT PUREE OR SAUCE: If needed, cook or steam your fruit in water until soft. Then mash or press through a colander or strainer, or blend. Add sweetening and/or lemon juice to taste. Heat to boiling; then cool as rapidly as possible. Pack into freezer containers. Leave headspace for expansion from freezing.

Other Sauces

Great-Grandmother was strong on sauces. She made her own and made lots of different kinds. Her “pudding” (really a steamed bread) was always served with a sauce. The calf's-foot jelly also usually had a sauce. I like coffee jelly with a simple brown-sugar-dissolved-in-rich-cream sauce. Sauces generally run in three types—sauces for fruit, meat, and pudding. My sauces for fruit generally are based on whipped cream. To go with meat at table, it's usually a homemade fruit ketchup for me. The other kind I make a lot is a barbecue sauce, which to me means some form of tomatoes, plus molasses, a dash of vinegar, and some chopped onion, which I mix together and pour over the meat when it's about one-third to one-half done. Barbecued meat is a favorite with the children. (Anything sweet is a favorite with the children.)

➲ **FRUIT AND CREAM SAUCE** Whip 1 c. cream and sweeten with about $\frac{1}{4}$ c. honey. Put the whipped cream on your pudding or shortcake and then pour a spoonful of fruit on top.

Fruit Butters

A “butter” is a thick, smooth sauce made by straining fruit or vegetables. You can use a butter just like a jam, to spread on pancakes or bread, but it doesn't have nearly as much sugar in it. Just cook up the food with enough sweetening to suit you, add any other seasoning you want, can it, and you're done. Personally I think the tarter fruits make better butters. Peach or sweet cherry butter turns out almost too sweet. But apple and apple cider butter made with a tart variety of apple is good, and apple-plum butter is our all time family favorite (recipe under “Apple” in [Chapter 6](#)).

We first started making apple-plum butter at our first home in Juliaetta, 4 miles down the road from here. The nearest thing that place had to an orchard was a big walnut tree in the front yard—so when fruit season came, I scavenged up and down the highways and byways. This region is unusual in that everywhere, throughout the years, pioneers and others have stopped to lunch or picnic and have left apple cores and plum pits. The volunteer apple and plum trees generally have a smaller fruit, but they are loaded almost every year and free for the picking. So the children and I would drive down the road with a back seat full of cardboard boxes and then go home and make apple-plum butter, one-third plum to two-thirds apple.

MAKING A BUTTER: It basically takes long cooking over very mild stove-top heat. You have to watch it closely and stir very frequently. For fruits, cook in an enamel or stainless-steel pan and use a wooden spoon to stir. Cook on low heat slowly for a long time. If you are very busy, cook it in the oven instead, in a covered kettle at a temperature of 300–350°F. Then you don't have to stir it, and it doesn't burn on the bottom. If your sauce doesn't get smooth enough to suit you, put it through a rotary colander after cooking. Season your finished butter with cinnamon, cloves, nutmeg, allspice, or whatever you like.

FOLEY MILL OR ROTARY COLANDER: This is a cone-shaped colander with a wooden mallet to help work the stuff through. You fill it with goop and then turn the wooden mallet, rolling it around the sides of the colander. Don't just stomp with the mallet—that gets you nowhere.

CANNING A FRUIT BUTTER: Have the butter boiling on the stove and proceed by my directions under “Canning” in this chapter. Use the times under “Applesauce” in [Chapter 6](#). Be careful, because the thick sauce is hard to heat clear through.

FREEZING: Just pour into a container, cool, and put in the freezer. Can or freeze butters in half pints or pints because a butter that isn't heavily sweetened will mold in a couple weeks, even if refrigerated, unless you can depend on your family to eat it up faster than that.

Candy

I don't eat much candy now because it gets in my cavities and reminds me dramatically that sweets feed bacteria that dissolve teeth. But, lest the art be lost forever, here's how to make it. We have candy on Halloween, Thanksgiving, Christmas, Easter, and birthdays. After supper and homemade, if possible. I'm not thrifty, either, when it comes to all that store candy that comes home with children on Halloween and Christmas. The next day, what's left over gets given away, thrown away, or put away for the next special occasion.

CANDIES WITHOUT WHITE SUGAR

➲ **VIRGINIA'S QUICK GOOD HONEY BARS** Grind raisins until you have a cupful. You can finish the grinding with a piece of bread ($\frac{1}{2}$ slice). It gets the last of the raisins out of the grinder and doesn't hurt the candy a bit. Combine with $\frac{1}{2}$ c. peanut butter, $\frac{1}{2}$ c. powdered milk, $\frac{1}{2}$ t. flavoring (coconut, vanilla, etc., as you wish), and 2 T. honey. Mix. Then knead with your hands. Make into a log shape. Chill and then slice. (Chilling makes it easier to slice.) If you want it sweeter, work in some powdered sugar. Nuts, coconut, and the like can be added. Kids can make it and the ingredients are very flexible. Try substituting some of your other home-dried fruits for the raisins.

➲ **RAISIN-NUT BARS** Grind together 2 c. raisins and 1 c. nuts (whatever kind you like). Mix the raisins/nut mass with $\frac{1}{4}$ c. honey. Press into a $\frac{1}{2}$ in. sheet. Cover and put a weight on top for a day and a night.

➲ **JUDITH'S GOOD QUICK HONEY BARS** I got this recipe as part of a beautiful letter. Mix 2 c. powdered milk, 1 c. peanut butter, and 1 c. honey (or molasses). Roll in nuts. Roll into balls and chill. Good with some corn syrup or cocoa mixed in too.

➲ **BUTTERSCOTCH SYRUP** Mix $1\frac{1}{2}$ T. butter and 1 c. brown sugar in pan. Cook and stir over medium heat until sugar is melted, but not dark. Add 1 c. boiling water and 1 more c. brown sugar. Bring to boiling point, stirring constantly. Cook until sugar is melted (about 10 minutes). Remove from heat and stir in $\frac{1}{2}$ t. vanilla. For a thicker sauce, add a little more cornstarch. From Judy Hines.

OLD-FASHIONED SWEETS: For horehound candy, see "horehound" in the Herbs and Flavorings Chapter.

➲ **CARAMEL** The old-timers used homemade caramel for coloring and for flavoring. It keeps indefinitely. To make it just put sugar in a pan and melt it slowly. Cook until the color is dark brown. But don't scorch! Now add as much boiling water as the amount of sugar you started out with. Slowly continue cooking until you have a thick syrup. Pour it into a jar and put a lid on it.

➲ **CREAM CARAMELS** You'll need 4 c. white sugar, 4 c. of quite thick cream, 1 c. light corn syrup, a pinch of salt, and 1 c. chopped walnuts. Remember to stir all the time you boil. Put the sugar, 1 c. of the cream, the corn syrup, and salt into a pan. Bring to a good boil. Add another 1 c. of cream and bring to a good boil again. Do this twice more until all the cream is used. Then boil to the soft ball stage. It will be quite thick. Add the chopped walnuts. Beat at once until thick. Pour onto buttered platters. It will make 2 platters.

➲ **KISSES** Beat 2 egg whites stiff. Add a pinch of salt, $\frac{1}{2}$ c. powdered sugar, and $\frac{1}{2}$ t. vanilla. Drop from a teaspoon onto a lightly oiled cookie sheet. Bake in a 300°F oven about 30 minutes until firm and dry. Variation: Add $\frac{1}{4}$ c. coconut, or 1 square chocolate, melted and mixed in.

⇒ **PECAN MACAROONS** (Almond ones are actually the more traditional.) Beat 1 egg white stiff. Gradually beat in $\frac{1}{3}$ c. pecan nut meats (chopped fine). Drop mixture by teaspoonfuls on a buttered baking parchment. Or try it on a plain buttered sheet. Make smooth rounds of your drops. Sift powdered sugar over the top. Bake at about 350°F until light brown.

⇒ **TRUE MACAROONS FROM SCRATCH** Blanch $\frac{1}{2}$ lb almonds and pound them to a paste in a mortar, or put through a grinder, set on fine, several times, or blend. Add $\frac{1}{2}$ lb. powdered sugar and 2 stiffly beaten egg whites. Work it all together. Form balls about the size of a whole nutmeg. Bake at 250°F until light brown.

⇒ **PHONY MARZIPAN** Make a dough with $\frac{1}{2}$ c. butter, $\frac{1}{4}$ c. sugar, 1 t. vanilla, and $1\frac{1}{4}$ c. flour. Divide into parts. Color each with food coloring. Shape dough pieces into fruit shapes or whatever. Roll in colored sugar. Bake at 350°F.

⇒ **PRALINES** Combine 2 c. powdered sugar, 1 c. maple syrup, and $\frac{1}{2}$ c. cream. Boil to soft ball stage. Remove from heat. Beat until creamy. Add 2 c. chopped nuts. Pour into a buttered pan. Cut into squares.

⇒ **ENGLISH TOFFEE** Combine 1 c. sugar, $\frac{3}{4}$ c. dark corn syrup, $\frac{3}{4}$ c. cream, and a pinch of salt in a heavy pan and cook until sugar is dissolved. Cook until a firm ball forms in cold water (244°F). Add $1\frac{1}{2}$ T. butter and $\frac{1}{2}$ t. vanilla. Pour in a thin layer on a greased slab. While still warm, mark into squares. Wrap each square in waxed paper when cold.

⇒ **PEANUT BRITTLE** Make this only when the weather is dry. In a heavy pan, stir together 3 c. sugar, 1 cup light corn syrup, and $\frac{1}{2}$ c. water. Cook over medium heat, stirring constantly, until sugar has dissolved and it comes to a boil. Continue cooking, without stirring, until temperature is 280°F (or until it makes threads that are hard but not brittle). Stir 3 c. salted peanuts in gradually. Cook, stirring often, and watching temp closely until it reaches 300°F. Remove from heat. Add 2 t. soda. Stir in gently but quickly, as it bubbles over pan. At once, pour candy onto 2 large buttered cookie sheets. Tilt pans and press with the backs of 2 spoons to spread candy. Keep spreading until the brittle is no more than 1 peanut deep. When the candy has finished cooling, break it into pieces and store. If kept in airtight tins or jars, it will keep just about forever.

⇒ **HOT FUDGE SAUCE** Mix 1 c. sugar, 1 c. water, 1 T. cornstarch, 2 T. cocoa, 2 T. butter, and $\frac{1}{2}$ t. vanilla and cook over medium heat in a heavy pan until thick. Stir constantly (it will stick). When cool, store in a jar in a cool place. To reheat, place jar in hot water until it is heated. If you want it thicker, add just bit more cornstarch. From Judy Hines.

TAFFY: As candies go, I like taffy. It's sticky. You put it in your mouth and roll it around and around and it gradually dissolves. In the in-many-ways-wonderful Old Days, entertainment consisted of getting together and making something: a barn, a quilt, or candy! "You didn't tell me," wrote a reader, "that it takes all day to make taffy! But we managed it and we had fun." Now you know.

Mixing and Cooking. Mix your ingredients and then cook them, stirring frequently, to the hard ball stage (250–266°F).

Candy-Making Temperatures. Candy making involves the chemistry of how heat affects sugar. That's why sometimes a recipe gives a temperature that you must heat the mixture to, or says something like "soft ball" stage. The ball/crack stages have corresponding temperatures, so you could substitute taking the candy's temperature for identifying the "stage." To take the temperature you could use a candy thermometer from the kitchen

supply store. (Check its accuracy by heating it in water. When the water boils, it should say 212°F.) Or cook the candy in an electric fryer-cooker. You should combine ingredients before you plug it in. Then set its dial to the temperature you're aiming for. When its light goes out, the candy is at the right temperature.

Or use the old-fashioned way. Every once in a while hold up your spoon and watch how the syrup drips from it. At first, it just drops off like any liquid. Then it drops more slowly. Next, there is a little thread between the drops. This is called the thread stage. Now put some cold water in a cup, and drop about $\frac{1}{4}$ t. of the syrup in there. Work it, under water, with the tips of your fingers into a ball. If the ball is soft, you have the soft ball stage. The taffy isn't ready yet. By the time you are done with your first test for hard ball, try testing again because by now it may be! When the taffy can be pushed together into a hard ball that clicks when you take it out and rap it against the edge of the cup, you're at the hard ball stage.

THE CANDY STAGES

Type of Candy

Temperature

Reaction in Cold Water

Fudge/Fondant/Penocha

234–241°F

Soft ball (feels soft)

Divinity/Caramels

242–248°F

Firm ball (feels firm)

Taffy

250–266°F

Hard ball (clicks on cup)

Butterscotch/English toffee

270–290°F

Soft crack

Brittle candy

300–310°F

Hard crack

Caramelized Sugar

310–338°F

Caramel stage

Color and Flavoring. Once the taffy is at the hard ball stage, if you want to add flavoring or color, now's the time, while the candy is still in the pot. For peppermint striped candy, divide the candy and color one part red, one green, and the rest white. (Pull each color separately.) Flavor taffy for candy canes with peppermint extract from the store, or from your peppermint patch. Delicate flavorings such as peppermint or lemon juice should be added at the very end, just as the taffy is taken from the heat. Now pour the candy out into a generously buttered pan or platter.

Cooling the Taffy. Don't cool your taffy too fast by putting it out in the cold or into the refrigerator. The outside edges would set up while the inside would still be too hot to work. Stir occasionally as the taffy cools in order to get the outside edge to the center and keep the cooling throughout the whole mass as even as possible. But don't stir any more than

necessary to accomplish that or the taffy will “sugar” (get sugar granules). As the taffy hardens, you “stir” merely to lift the outside edges and bring them to the center. It’s the same motion as kneading bread.

Pulling. Start pulling as soon as the taffy is cool enough so it won’t burn your hands. Pulling has to be done quickly. Once the taffy sets, it is hard to do much with it. If some gets hard in the pan before anyone has a chance to start pulling it, the case is hopeless. Get ready by washing your hands. Then butter them. (Some people prefer to dip their hands into cornstarch because you don’t then have such a buttery final product). Take the taffy from the outside of the pan first, since there it is the coolest. If you are having a jolly old-fashioned taffy pull for family, friends, and kids, divide the taffy up into several gobs. A pair of two people take a gob between them. Pull the gob out into a long strand and then fold it back into a single gob again. Pull out and fold back over and over again. As you pull, the taffy gets lighter in color because more air is getting in it.

You stop pulling when it’s hard to make the taffy stick back together again after pulling it. Or when it is cracking as you start to pull it out. Or when it is just too hard to pull. If the temperature is 100°F or above, your taffy may never get brittle. When you’re done pulling, have ready a tabletop sprinkled with powdered sugar. Lay the taffy down and arrange it in the final shape you want, maybe a twisted rope, or figure eights, or whatever. Or make a basket by winding strands around the bottom or outside of a cup or bowl. (Butter the cup or bowl on the outside before you start.) Put a handle on your basket and let cool. When it is cool you can easily remove it from the mold. And eat some ...

⇒ **STRIPED CANDY** Divide the taffy into several sections and color them differently. Make each color into long strands. Put together the strands of various colors—braided or as you like—until your stick is as thick as you want. Lightly rolling the new “rope” on a firm surface makes it stick together well. Then cut lengths with a scissors or knife.

Using a Taffy Hook. The old-fashioned taffy hook made it possible for one person to make taffy. It was a large iron hook screwed into the wall. When you’re ready to use it, slather the hook with butter. Pull the candy by hand just enough to fit over the hook with ends long enough to be grabbed in each hand and pulled. Then slap together the ends of the taffy. Remove the “old” middle from the hook. Put the “new” middle on it, and pull it again. Do this over and over until the candy is done.

⇒ **NUTTY TAFFY** Add chopped nuts to the taffy by putting them in the bottom of the buttered pan and pouring the taffy over them. Cool and pull as usual.

⇒ **PURE HONEY TAFFY** Heat 2 c. honey to boiling. Add a pinch of baking soda, 1 T. butter, 1 T. lemon juice, and a few grains of salt. Boil to hard ball stage. Pour into buttered pan. Cool. Pull.

⇒ **SALTWATER TAFFY** Mix 1 c. sugar, 3 T. cornstarch, and a few grains of salt. Add ½ c. water and ⅔ c. honey. Cook to the hard ball stage. Pour into buttered pan. Cool. Pull.

⇒ **VINEGAR TAFFY** Combine 1 c. sugar, ⅛ t. cream of tartar, 2 T. butter, ½ c. vinegar, and a few grains of salt. Boil to hard ball stage. Cool. Pull.

⇒ **MOLASSES TAFFY** Combine 1 c. white sugar, 1 c. brown sugar, 2 c. light molasses, and ¾ c. water in a pan. Cook to hard ball stage. Pour into buttered pan. Cool. Pull.

⇒ **TAFFY WITH CREAM** Combine 1 c. sugar, ½ c. light brown sugar, 1 c. molasses, ¾ c. corn syrup, ½ c. cream, and ½ c. water. Boil to the hard ball stage. Remove from heat. Add a pinch each of salt and soda, ¼ c., butter and ½ t. vanilla. Beat this all up well and pour into

buttered pan. Cool. Pull.

MARSHMALLOWS: Marshmallows and marshmallow cream, of a sort, can be made at home. Before store gelatin existed, marshmallows were a confectioners' specialty made with gum acacia (gum arabic). Avoid making them on damp, rainy days. Dust them with cornstarch or powdered sugar when cut. Homemade won't turn out like store ones, and they don't keep well. They'll dry out too fast unless you wrap and freeze them. Aplets and cotlets turn out the best of these.

⇒ **PLAIN MARSHMALLOWS** Dissolve 1 T. gelatin in $\frac{1}{4}$ c. cold water and set aside. Combine 1 c. sugar and $\frac{1}{2}$ c. hot water and boil to the soft ball stage. Add the softened gelatin, a dash of salt, and 1 t. vanilla to the syrup. Beat until stiff (takes about 10 minutes). An electric mixer or blender is a must for this job. Pour into a buttered pan. Refrigerate overnight before cutting up. When cold cut into squares. Roll them in powdered sugar, or a mixture of powdered sugar and cornstarch, if you want to hold down the sweetness. Wrap in plastic or they'll dry hard by the next day. Variation: Soak 1 T. gelatin in $\frac{1}{4}$ c. cold water. Dissolve in the top of a double boiler over hot water and add to 1 c. warmed honey. Beat until light and fluffy. Pour into oiled pan. Let sit 24–48 hours. Toast 1 lb. grated coconut and roll to make it fine. Spread the coconut out and roll the marshmallow on to coat it. Cut marshmallows into squares with a knife dipped into cold water. Now roll each piece again in the coconut.

⇒ **PASTEL MARSHMALLOWS** Combine 1 (3 oz.) package of Jello, any flavor, 1 c. sugar, and $\frac{2}{3}$ c. boiling water. Put it on the stove and simmer, stirring, until it's clear and well dissolved. Then add 3 T. light corn syrup. Refrigerate 30 minutes. Beat until it's thick and stiff. Takes about 7 minutes with an electric beater. Put into buttered pan or drop by spoonfuls on waxed paper. Refrigerate overnight before cutting up.

⇒ **MARSHMALLOW CREME** Cook 1 c. light corn syrup with 2 T. water until firm ball stage. Pour slowly over 1 beaten egg white. Beat well. Soak 1 t. gelatin in a little water. Then add 1 t. vanilla, $\frac{1}{2}$ t. salt, and the dissolved gelatin to the corn syrup/egg white mixture. Beat until shiny and thick. From Judy Hines, whom I met in the Dairy Queen in Ottawa, Kansas! Great topping for cocoa!

Ketchups

A "ketchup" is a fruit or vegetable pulped and preserved with some combination of salt, vinegar, spices, and sugar. Just which of those and how many can vary a lot. It can be made out of tomatoes, grapes, cucumbers, peaches—lots of things. Tomato ketchup is the best known and most popular version of this type of sauce. To make a ketchup, the food consistency is the key. It's a cooked, strained fruit or vegetable that is highly spiced to make a smooth, thick sauce. Don't worry about color. Homemade ketchups won't turn out like the commercial ones, but color isn't everything. The spices can be varied to your taste; add or subtract as you please.

APPLE, PLUM, OR GRAPE KETCHUP: Start with 1 qt. applesauce. Or for grape sauce, cook grapes in an enamel kettle slowly until soft (about 25 minutes). Then put through colander to get the grape puree. Cook plums and colander them for plum sauce. Combine 1 qt. of any of those sauces with 1 t. ginger, 1 t. cinnamon, 1 t. cloves, 2 c. vinegar, 1 t. pepper, 1 t. mustard, 1 t. onion juice, and 2 t. salt. Simmer slowly until thick. Pack into pint jars. Adjust lids. Process in boiling-water canner 15 minutes. If you like sweet sauce, add brown sugar or molasses to taste.

APPLE KETCHUP: Peel and quarter a dozen round, tart apples. Stew until soft in as little water as possible. Sieve them. For every quart of sieved apple, add ½ c. sugar, 1 t. pepper, 1 t. cloves, 1 t. mustard, 2 t. cinnamon, 2 medium-sized onions chopped very fine, 1 T. salt, and 2 c. vinegar. For some reason I'm having a hard time concentrating this morning. Dolly is playing the piano. She had a little sleighing accident day before yesterday and still isn't able to walk. We tried to get her to the doctor yesterday, but it is the first week in January, with unusually heavy snows. After struggling about an hour we gave up and decided to wait until today. I'll try again this afternoon. The pickup is all chained up (no heater in the beast), and then Dolly and I will try to get to Troy and our wonderful Dr. Drury. Maybe by then the sun will have melted some of the snow and black ice off the highway. Looking out my living room window right now, I see the highway where it runs along the other side of the canyon, and it is still snow-covered.

The worst is getting off our personal mountainside and down to the highway. Worse still is trying to get home again up our mountainside. About a week ago Mike and I were driving in, and we literally started to slide off the cliff. It's a good 200 feet to the bottom. I chickened out first, opened the car door, and said, "Mike, I'm leaving." He lasted about 10 seconds more, and then left too. The car hung there until the next day. He got our crawler tractor (a Cat with tracks instead of wheels) going and recovered the vehicle.

In a way I enjoy the snow. It reminds me of winters when I was a little girl. On the sheep ranch in Montana, we were really on top of the world. The lowest point on the ranch was 6,000 feet. The buildings were located at that point. If I rode my horse on up to a high point, I could easily see 75 miles on a clear day, and days were mostly clear in summer. ("Oh, give me a home where the buffalo roam, and the deer and the antelope play, where seldom is heard a discouraging word and the skies are not cloudy all day.")

So today I have all five of them home instead of the usual four. I'm trying to keep them usefully occupied. Danny and Dolly are working in arithmetic workbooks. Becca is working in a pre-primary reading workbook. Luke is in the basement playing with the pumpkins, and Sara is discovering she can crawl under chairs. When I was a little girl, I spent a lot of time studying at home with my parents—usually January and February. When I did go to school, I rode horseback the 2 miles each way.

It wasn't really a "one-room" school, for it had a cloak-room in front and a teacherage in the back. The teacher slept and cooked there when the snow got too deep for her to drive back and forth from the ranch where she lived with her husband, in the Shields River Valley below, between Clyde Park and Wilsall. Our creek, school, and community were all called Bracket Creek. That is home in my heart, though long gone in the world of reality. On cold days like today, Mrs. Carroll would fix us some hot canned soup on top of the potbellied wood stove that heated the classroom to complement the cold lunches we brought from home.

Everybody rode horseback to school. Some rode 5 miles each way. You can make fast time when you have a good horse and when you're used to it. There was a little barn behind the schoolhouse where the animals waited patiently for school to be out, and then the merry race to the crossroads began. I always lost. I rode a not-so-young half-Shetland gelding called Shorty Bill.

He was my closest friend. I would go out to the field to get that horse after breakfast—a little kid running with bridle in hand. He would run across the field to meet me. We'd go down to the big red barn with its vast mow full of hay and its underparts full of a complicated wonderland of stalls, pens, grain, and harness rooms, where Shorty would have his breakfast of rolled oats, and I'd saddle him up.

On summer days, when the business at hand wasn't serious, I would often ride him with

no saddle or bridle. I could pull myself up by a handful of his mane. (It got sparser and sparser at the point where I grabbed.) I'd push on his neck to show him the direction I wanted him to go, kick him to make him go, and slide to the side to tell him I wanted to stop. In summer there was hard work to do on horseback, though, and Shorty had no part of that. That was for the 5 big horses we had, the largest being a great big pink-eyed Appaloosa that could pick his way down a cliffside with 200 lb. of pack rattling on his back like there was nothing to it.

Once every week we had to take the Appaloosa and the other horses, all loaded with food and general supplies, up to the sheep camp to help move it. We'd take down the tent and sack up the pots and pans and sleeping bag and gun. Then the horses would carry it all to the new grazing site. The ride was generally miserable. Big biting horseflies drove everybody crazy, man and beast. They are the meanest fly in the world, I think, with a bite so hard it leaves a bloody mark. If they happen to get your horse in a tender place, you've suddenly got a very insecure seat.

Well, that ought to be enough digression to get my head organized. Digressions are easier and more fun to write than the rest of this.

Spiced Fruit

Spiced fruit doesn't have to be canned or frozen. The real old-time recipes don't spoil—they just get spicier and spicier. In small amounts they are very tasty—like the spiced crab apples that you can get in the store, only much more spicy. This is not a method of preserving a staple food, just a holiday goodie.

If your fruit does show signs of fermentation, pour off the liquid, boil it awhile, and then pour back over the fruit. Branded fruit has an alcohol content, but spiced fruit doesn't. For a milder version, you can cut back on sugar, vinegar, and spices and then can the results. The real thing can be left in a bowl with a plate on top all winter. I've done it. Whenever you want some, just fork it out. Don't be bothered by floating mold or scum. Your fruit is below the level of the fluid's surface. Rinse the fruit before serving, in case any top glop came along as you fished it out (like when you make crock pickles).

BASIC SPICED FRUIT: Use 7 lb. fruit, 4 lb. sugar, 2 to 4 c. vinegar, and 1 T. each of cinnamon, cloves, and allspice. Pare peaches and pears. Prick plums and tomatoes with a needle in several places to help the preservatives get inside. Boil the fruit in the syrup 5 minutes. Remove fruit and boil the syrup until it has thickened some. Put the fruit in jars and pour the boiling syrup over it. You can spice blackberries, currants, gooseberries, peaches, pears, plums, tomatoes, cherries, crab apples, watermelon rind, pieces of almost-green cantaloupe, apricots, nectarines, prunes, quinces, citron, and so on. Let your spiced fruit stand at least several weeks before using it.

HONEY SUBSTITUTION: My spiced fruit recipes all use sugar. But in the Middle East, fruit is preserved in a syrup made of honey and vinegar, and I'm sure you could convert any sugar recipe and do the same thing.

Becca (short for Rebecca) just crawled down from my lap to go hold a bunny. Santa brought her two little half-pounders for Christmas. They make great pets. Fearless now, they hop all over the place. Makes January a little livelier for the at-home folks. Luke, his silver pistol, and his little toy crawler tractor are now all in my lap (replacing Becca). And on we go to branded fruit.

Brandied Fruit

Foods preserved in alcohol are "brandied." Wines and foods containing over 14 percent alcohol by volume are self-preserving. Wines and foods with a weaker concentration of alcohol can become sour and vinegary. Brandied food should be kept cool and airtight. Burying it deep in the ground works well. The trouble with preserving food by brandying is that it will give you a hangover. I'd hate to have to get drunk to eat.

Incidentally, many people hold very strong opinions for or against the use of alcohol. Some of my best friends wouldn't let the stuff in their homes in the form of tutti-frutti or anything else. I have sympathy with that point of view. I don't see any excuse for debauching, because it is invariably damaging to something. So for me the most significant thing about brandied fruit, for better or for worse, is that it has an alcohol content. It makes a heady dessert—and not one that children can have very much of—so you don't need much for a winter's supply. Tutti-frutti is the most common and versatile sort, because you can eat it straight, use it for an ice cream or general dessert topping, or make a sort of fruit cake out of it (actually better than eating it straight).

Incidentally, baking or boiling evaporate most, but not all, of the alcohol in any recipe. Despite the cooking, 10–15 percent of the alcohol will remain. You can indeed get intoxicated from fruit cake—if you eat enough of it.

➲ **EARLEN'S TUTTI-FRUTTI** You can start with $1\frac{1}{2}$ c. fruit and $1\frac{1}{2}$ c. sugar. For your first mixture, half-drained crushed pineapple and half-drained chopped canned peaches are good, along with 6 chopped maraschino cherries. (Peaches brandy best, and after them cherries.) A package of dry yeast stirred in helps to get the fermentation off to a quick start. Stir it several times the first day. At least every 2 weeks after that, add 1 more c. sugar and 1 more c. fruit. Alternate your fruit so you don't end up with all the same thing. Don't put it in the refrigerator, but don't have it too near the heat either.

Once you get it going, you can give a cup of "starter" to friends, who can soon work up their own supply of tutti-frutti from it. The mixture is at its best after 4 weeks have passed. You can take out fruit to use as needed, but try not to let what's left get below 1 cup. To have more, just add more fruit and sugar ahead of schedule. You can use fresh, canned, or frozen fruits such as Bing cherries, raspberries, blueberries, apples, pears, or fruit cocktail as well as the first ones I mentioned. But if pears and fruit cocktail are used, treat them gently so they don't become too mushy. Don't use bananas.

Be sure to keep the fruit under the liquid. You can use a weighted saucer to hold it down. Fruit exposed to air will darken in color and taste too fermented.

⇒ **OLD-TIME TUTTI-FRUTTI** *The first recipe I gave you is quite common around the country now and implies some city-type living with the maraschino cherries and pineapple. Here's a way to make tutti-frutti from your own garden and orchard, a sack of sugar, and a cup of brandy.*

Start this at the beginning of the fruit season. Strawberries are probably the first fruits you'll have and are great for this purpose. You can start in a jar and transfer to a crock as your supply grows. I'd suggest keeping it in the coolest place you can find during the summer. As the season goes on, add cherries, apricots, plums, nectarines, and peaches. Avoid apples, pears, melons, and blackberries.

Into the jar put 1 c. very good brandy, rum, or cognac, 1 c. sugar, and 1 c. fruit. Stir and let rest. Don't refrigerate. Cover to keep the dust out but don't seal. As each new fruit comes along, add it and more sugar, at the rate of 1 c. sugar per 1 c. fruit. You don't need more brandy. Cut large fruit into small pieces and stir well at each addition. Take out pits and seeds where appropriate.

If you figure 3 months for it to mature, it will be about ready by Christmas time. Serve over plain pudding, cake, or ice cream. Or make a fruit cake or a holiday fruit bread with it.

⇒ **ALMOST-INSTANT BRANDIED FRUIT** *Use canned fruit. Apricots, peaches, pears, and so on are all right. Save the juice from the fruit and boil it down to half the original amount. Add 1 part brandy to 2 parts of your boiled-down syrup and pour that over the fruit. Let it rest at least 24 hours before serving to let the fruit absorb the flavor.*

⇒ **RUM-BRANDIED FRUIT** *You can also make brandied fruit using rum. Mix 2 c. well-drained fruit with 2 c. sugar. Cover well with rum. It takes about 1½ cups. Just as in the other recipes, you then can add more fruit and sugar every week or two to keep it going.*

⇒ **TUTTI-FRUTTI ICE CREAM** *Softens store-bought vanilla ice cream or make your own. At the very end, add tutti-frutti and refreeze or freeze.*

⇒ **TUTTI-FRUTTI FRUITCAKE** *Mash ½ c. butter together with 1 c. sugar until well mixed. Add 4 eggs, 3 c. flour, 2 t. soda, 1 t. cloves, 1 t. allspice, 2 c. your brandied fruit of any sort, 1½ c. applesauce, 1 c. raisins, and 1 c. nuts. This bakes best in an angel food-type pan because it is very moist—a buttered 9-inch tube pan would be right. It takes a long time to bake—70 or 80 minutes or more in a moderate oven (350°F).*

⇒ **COMBINATION SPICING AND BRANDYING OF PEACHES** *Peel about 4 lb. peaches. Dissolve 4 lb. sugar in 3 c. water. To spice with cloves alone, insert 2 whole cloves in each peach. To spice with cinnamon and cloves, put 1 T. stick cinnamon and 1 T. of whole cloves into a spice bag and boil with the syrup. Put in the fruit a little at a time and boil each 5 minutes. When done, remove the fruit to jars and boil the syrup about 10 minutes, or until thick. Pour syrup over the fruit to fill the jar two-thirds full and then finish filling with brandy. Remove the spice bag when syrup suits your taste test for spiciness.*

⇒ **RUMMED BLACKBERRY JUICE** *Steam 4½ qt. blackberries until the juice starts to flow. Strain in a cheesecloth bag until you get all the juice you can. Add the juice of 3 lemons and 4 oranges to the blackberry juice. Bring to a boil what you have left of the blackberries with 6 c. water; strain again and add that to your juice. Add 2 c. sugar. Now bring juice just to a boil and add 2 c. rum. Can or bottle it. (You could substitute brandy.)*

⇒ **BRANDIED CHERRIES** *Boil 5 c. sugar with 2 c. water for 12 minutes, or until you have a*

clear syrup. Pour that syrup over 5 lb. cherries (the small sour kind) and let stand overnight. Drain off the syrup and boil it again. Add cherries and boil about 5 more minutes. Take out cherries with a skimmer (the kind with holes in it to let the juice drain away) and put the cherries into canning jars. Boil the syrup down 15 more minutes. It should be getting pretty thick. Add 2 c. brandy. Remove from heat. Pour over cherries and seal.

⇒ **BURIED BRANDIED PEACHES** I think the very best brandied fruit of all is made by this recipe. I found it in an antique book, and Mike and I tried it out of curiosity. I imagine it would work with any fruit, although we used peaches. This recipe needs no brandy, only fruit and sugar. Choose fine, ripe, very sweet peaches. They must not have bad spots. Peel them. Cover with whole peaches the bottom of something you can bury. Pour in enough sugar to cover them. Add more peaches and then more sugar in the same manner, until you are out of peaches or room in your container. Cover very tightly, but not absolutely airtight, and bury in the ground for 4 months or more. We put ours about 3 feet down, which made the top of it about 2 feet down. Mark the spot so you'll know where to dig it up.

I was really afraid dirt would get into it, but not one speck did. We put it down in peach season, just outside the back door, and dug it up for Thanksgiving (which isn't a full 4 months). The floating top layer, the part that was out of the liquid, was discolored and yucky-looking from oxidation. We threw that away. What was left was brandied peaches of a quality the likes of which I'd never seen before. The peaches' color was perfectly preserved; they looked just as they had the day we put them in.

But they darkened very fast when exposed to air; within 24 hours we could see and taste the difference as they commenced to deteriorate. Apparently exposure to air was causing the trouble. If I had it to do over, I'd reseal them in smaller jars as soon as we dug them up and just open them as needed, so there would be as little exposure to air before serving as possible. You absolutely must keep any brandied (or spiced) fruit below the liquid and out of the air, but this stuff was even affected by the exposure of the liquid to the air.

I think the temperature control also helped make it good. I imagine if you sealed a crock of tutti-frutti and buried it the same way for 3 months, it would do as well, because the temperature underground is evenly cool but not too cold—especially early in the season, when above ground it's hot. Brandied fruit made from scratch needs a cool temperature, since you don't have the help of the preservatives that are in store-bought foods.

Chutney

Chutney is a fruit or vegetable mixture, flavored with spices, and cooked with sweetening and vinegar until it has a thick, jam-like texture. You can use slightly overripe fruits and vegetables for this. Possible vegetable ingredients for a chutney are beets, carrots, eggplant, onions, peppers, pumpkins, rutabagas, squash, tomatoes, or turnips. Fruit ingredients (fresh or dried) could be apples, bananas, berries, citrus fruits, cranberries, plums, lemons, mangoes, peaches, pears, or rhubarb. Typical herbs and spices in a chutney are allspice, bay leaves, cayenne, chili, cinnamon, cloves, coriander, cumin, garlic, ginger, horseradish, juniper, mustard seed, paprika, and/or peppercorns. Some sugar is usually added: white, brown, or molasses. (Most chutneys are dark colored.)

⇒ **BASIC CHUTNEY** Combine 1½ c. sugar, ¾ c. wine or cider vinegar, ½ c. chopped onions, ½ c. raisins, quartered and thinly sliced lemon, 2 T. minced fresh ginger root, 1 t. black mustard seed, 1 t. salt, ½ t. cardamom, and ½ t. red chile pepper flakes in a big pan. Heat to boiling. Add 2 lb. peeled and chunked fruit (peaches, mangoes, or pears are good in this recipe) or vegetable from list above to the pickling sauce. Cook, stirring often, until the food is

tender but not mushy.

➲ **GREEN TOMATO CHUTNEY** Put $\frac{1}{2}$ lb. finely chopped onion in a pan with $\frac{1}{4}$ c. vinegar. Cook on low heat until soft. Add 2 lb. green tomatoes, $\frac{1}{2}$ lb. peeled, chopped apples, $\frac{3}{4}$ c. vinegar, $\frac{1}{2}$ lb. sugar, $\frac{1}{2}$ t. salt, and 1 t. of a pickling spice mixture (in a spice bag). Cook until the tomatoes and apples are soft. Boil until thick.

➲ **TOMATO-RAISIN CHUTNEY** Peel and cut 8 lb. tomatoes. Combine with 4 lb. sugar, 4 c. vinegar, 2 oz. salt, 4 oz. ginger, and 2 lb. raisins. Cook until thick. Pour into hot jars and seal. Optional: Add red pepper and/or garlic.

➲ **PLUM CHUTNEY** Chop $\frac{1}{2}$ lb. onions. Cook on low heat in 2 T. vinegar. Remove the pits from 2 lb. plums. Simmer them in 2 c. vinegar with 1 t. ground ginger, 1 t. cloves, and $\frac{1}{2}$ t. dry mustard. Stir in $\frac{1}{4}$ lb. sugar until dissolved. Boil until thick.

➲ **CHUTNEY FLAVORED PEACHES** Use chutney to flavor other foods! For example, spoon 1 T. chutney into the center of each canned peach half. Bake the chutney-filled peach halves at 350°F, 10–15 minutes. Serve hot.

February 1975. Dolly had hurt her knee, went to the doctor, and got a crutch. I thought then she'd soon be fine. I had no idea that the next morning she would be unable to walk on the remaining good leg. Subsequently, both arms went bad, then neck and back. It all turned out happily in the end, but the end was much longer in coming than I had expected. She's much, much better now than she was in the middle of January, when there were days when she could not use her hands even to turn the pages of a book or to feed herself. In fact, she seems very nearly well again.

The doctors predict she is almost certain to suffer another, worse attack within a relatively short time. But that's doctor thinking for you. As far as I'm concerned, it's over and done. Dolly is well now, and she's going to stay well. I'm going to take such good care of her that the old bug, whatever it is, doesn't have a chance. And this isn't the first time my opinion parted company with the doctor's and I won. There's too much at stake here for me to agree with something like that. God will guide my hand in nursing her, and He's the greatest Physician of them all. [She never did have an attack of arthritis again. Dolly's nearly 30 now, married, with children of her own.]

When people have the creative urge, you just have to get out of their way and let them go. I used to write poetry, and maybe that's just as useless a product as a cookie or cake decoration—and maybe more so because it isn't even edible. I tried to sell my poems by mail once. Out of a mailing of several hundred, 2 dear people responded—more to keep my morale up, I think, than for the sake of the poems.

When Mike was a student in the big city, I used to take my poems down to a street corner in Greenwich Village (along with a baby or two), put on a great big sandwich board that said "Poems for Sale" on each side and sell copies for 25 to 50 cents apiece. (Mike priced them for me.) I barely made enough to pay my bus fare and buy lunch, but it was really beautiful just standing there sharing my work all day with people who came to read my notebooks and pick out one or two poems that would really go home and live with them and become a part of their lives. That was the only thing I've ever missed about New York—selling poems. I never was one to write in an ivory tower. I needed people to react to what I was writing. Their reactions provided a sonar for me as I swam through the literary waters, guiding me to a better and better result—better because it meant more to them. Though I've always written something or other, it's best when there is a real human

being on the receiving end who can laugh and care and learn something they really want to know.

PRESERVING WITH VINEGAR, SALT, AND FAT

Pickles

The “Cucumber” section in [Chapter 4](#) has lots of information on crock and canned cucumber pickles. But you can actually pickle just about anything using different combinations of salt, sugar, vinegar, and spices. Cured meats like ham, bacon, and corned beef are made using salt and sugar, with the addition of saltpeter (makes foods red and helps preserve them). Dill pickles use salt and vinegar, leaving out the sweetness. Spiced fruits leave out the salt and put in sugar, vinegar, and spices. Krauts and salted-down vegetables are vegetables and salt only. (See “Cabbage” in [Chapter 4](#).) These ingredients aren’t there just for flavoring. Salt, vinegar, and (under certain circumstances) sugar are the original chemical preservatives.

There is a nearly infinite number of different ways to pickle different foods, depending on your choice of picklers, how strong they are, which vegetables you choose to pickle, and just how you go about it. There are some great books on pickling in your library or bookstore.

Vinegar

Vinegar is high-acid and thus is the basis for another sort of natural “chemical” food preservation. I’ve never managed to make it—not for lack of trying, and not because it can’t be done. A dear old lady in Juliaetta named Mrs. Eggers took my recipe and made wonderful vinegar from it, absolutely the best wine-type vinegar I ever tasted. And she ended up with a “mother” (a thick substance that vinegar-making critters live in) that was like a colored firm-but-clear gelatin, just like you’re supposed to. She even gave me the mother after she got done making vinegar. I brought it home and tried to make vinegar out of it: still no luck. For the time being, I’ve given up.

My last attempted batches were in the living room. One was a jar of mixed grape and peach wine. One was a big crock of malt stuff that I hoped would become malt vinegar. And, oh yes, there was also a yet larger crock of rotting apple peels and cores on the way to becoming cider vinegar. They all smelled so bad it got to be a social problem. Like the

day Dolly's music teacher got a funny look on his face and gave a very short lesson (the piano was in the same room, and I never explained about the crocks). One fine day soon after that, Dolly was sitting on top of the (unused) stove, playing, and she fell off *splat* right into the biggest crock of all. She gave out an anguished cry—half embarrassment and half pain. By the time we got her fished out of there, all 3 containers were either spilled or contaminated, so I called it quits for the time being. So I'm going to tell you how Mrs. Eggers makes vinegar.

To get the right cultures (and home boiling gear), check the Yellow Pages under "Beer Homebrewing Equipment & Supplies" or "Winemaking Equipment & Supplies." Or get a list of suppliers from The American Homebrewers Association, Box 1679, Boulder, CO 80306; www.homebrewersassociation.org. Or ...

Alternative Beverage, www.ebrew.com; 704-527-2337.

Beer & Winemaking Supplies offers hard-to-find mead vinegar cultures: 413-586-0150; 154 King St., Northampton, MA 01060; www.beer-winemaking.com.

How to MAKE VINEGAR: Making vinegar is a two-step fermentation. First, one kind of organism turns the sugar into alcohol. Then another takes over and turns the alcohol into acetic acid. Acetic acid is the textbook name for vinegar, only what we put on the Swiss chard at dinnertime isn't nearly as strong as what they use in the laboratory. Adding yeast makes the alcohol stage get going faster. Adding the mother helps the acid formation from the alcohol, because it adds the right kind of organism for that change. If you don't use either yeast or acid, eventually the right kind of critters will just fall in from the air. Mrs. Eggers did it that way.

A lady who read what I had written before this wrote me, "When I was a child some 50 years ago, the apples were ground in an old outside cider mill; then the juice was pressed out with a wooden press, yielding 50-gallon barrels. They were wooden barrels with wooden lids. A large cloth was tied over the top of the barrel and the lid propped open to let in air. The barrels were stored in the smokehouse to ferment all summer. The smokehouse was made of hewn oak logs, with a solid door and one cat hole large enough for the family cat to enter to catch all the mice that might enter. It had no windows and a dirt floor. It was always cool and damp even on the hottest day. An old iron pot was in the middle of the building where a fire was built to cure the ham and sausage in winter. The fire was always smothered to a smoke and Daddy watched it very closely."

"Before cold weather the vinegar was stored in big barrels that lay on their side with a large stopper in a hole in the top side. We sold gallons of vinegar to everyone in the community year-round. The barrels were never used for anything but vinegar and were washed with fresh well water each year, removing the mother, and refilled with fresh apple cider. All the kraut and salt pickles were made in the same building. There was an attic above the smokehouse with a ladder to climb. We stored apples and Keiffer pears and jars of canned fruit and vegetables in the attic. Daddy always brought a small barrel of salt fish for the smokehouse every winter, and we had a leg of dried beef."

You want to know how they make "cider vinegar" nowadays? Commercial cider

vinegar starts with apple wastes (peels and cores), which is really not bad. You can do the same thing. The cider company presses the apple wastes to get out the juice. It adds water and sugar, heats it to cause fermentation, and then rapidly oxidizes it to produce the acetic acid content. The vinegar is diluted and labeled and takes less than 48 hours from apple core to finished product.

Well, back to how you can make vinegar like Mrs. Eggers ...

WHAT'S IN VINEGAR: You can't use store-bought vinegar to hurry your vinegar making, because if you add vinegar in the first step, while you are making wine, the vinegar will tend to mess up or stop that reaction. Adding it to the second stage, when you want the wine to turn to acetic acid, will do you no good because the store vinegar is all pasteurized so the needed beasties in it are dead. You can use unpasteurized homemade vinegar for that purpose, however.

Starter Foods. Vinegar flavors and acidities vary according to the kind of juice you start with. You can make vinegar from any fruit juices, even from the leftovers from your fruit canning—the peelings and corings of peaches, pears, apples, grape hulls, and whole cherries. Mrs. Eggers made hers from apple peels and cores. *Cider vinegar* means you started with apple juice (cider) or some apple product like peels and cores. *White vinegar* starts out from grain. *Malt vinegar* is made from barley. You can make vinegar from any homemade wine but not from cheap store-bought wines, because those contain preservatives that would prevent the second-step fermentation you need. Some expensive imported wines can be used because they don't contain preservatives.

FERMENTATION STAGE 1: MAKE ALCOHOL: This is identical to the process involved in wine making except that to make vinegar it isn't necessary to have perfect fruit, and for vinegar you won't want as much sweetening, although you could add sugar or molasses to beef it up. Or anything sweet—leftover sweetened tea, leftover canned fruit juices, jellies, sugar-bowl rinsings.

Container and Cloth. Put your starters in a crock, wooden or stainless steel container, or glass jar. *Never ferment in aluminum or chipped enamel containers.* Leave from a half to a fourth of your crock space empty for later additions—you can add more makings every day for a while, adding a little more water each time—and general bubbling up. Cover with a clean cloth and tie it firmly around the neck of your container with a string to keep bugs from falling in and dying. That crock is going to be sitting there a long time, and if you aren't careful the contents will get dirty. Wash and replace the cloth once a week. Set the crock in a warm place—80°F is a good temperature. It will work at a cooler temperature, but the cooler the temperature, the longer it takes.

Bubbles. During the first fermentation stage, it bubbles. As long as that stage is going on, you'll be able to see the bubbles coming up if you hold a match over the surface. If it won't bubble for you, or if you want to hurry it up, or if you want to be sure the right kind of microbes move in, add 1 T. yeast to get it working. While it's bubbling, it's "working." When it gets done bubbling, it's ready for the second stage.

FERMENTATION STAGE 2: ALCOHOL TO ACID: When the sugar-to-alcohol (primary) fermentation is totally completed, you're ready for the secondary fermentation, which changes the alcohol to acetic acid. Vinegar is a dilute, household-use solution of acetic acid.

Transfer. Siphon, dip, or strain the liquid from your fermentation crock to a (dark-

colored) glass, enamel, wood, stainless steel, or pottery container, *leaving behind the sediment*. A wide-topped container is helpful because acetic bacteria need oxygen to do their work. Fill no more than three-quarters full. Use a cloth cover, same as before. While it's working, store your becoming-vinegar container in faint light (sunlight holds the change back) and warmth.

Getting the Vinegar Beasties. Now I know why Mrs. Eggers could make vinegar and I couldn't. She caught the acetic bacteria, without which you can't make vinegar. They're carried both through the air in general and on the feet of vinegar flies! But you're always at risk of getting your crock infected by one of the bacteria and molds floating in the air that do *not* change sugar to alcohol or alcohol to acetic acid. In that case you could end up with a disgusting mess, which is what happened to me—unless you start Stage 2 with a fairly high-alcohol solution, which would protect it from just about everything except the acetic bacteria. But it's easiest, quickest, and surest if you can start by putting some mother in there.

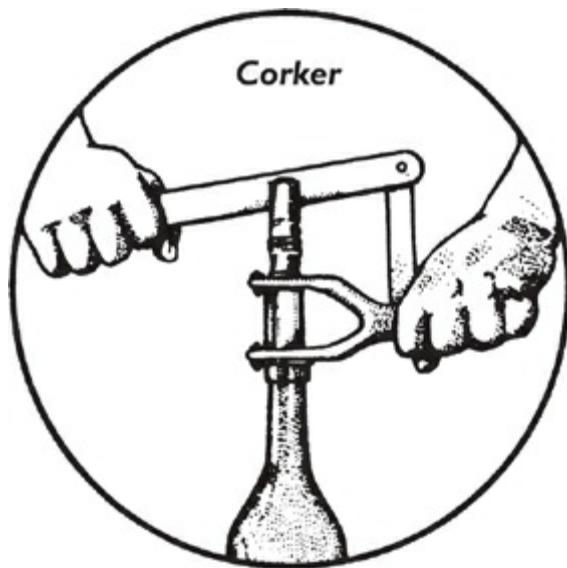

Mother. This thick, clear, jellylike amber substance is made by the kind of beasties that make vinegar, and they live in it. If you've got some to add to your crock when you're ready to get Stage 2 going, you'll soon have the nicest vinegar you ever tasted. If you don't have it, you may be able to buy it from a health food store or a winemaker's supply house. Using mother can make a big difference in time as well as taste. If you don't have any mother to add, it could take as long as 6 months to complete your first batch of vinegar, because you must wait for the right kind of beastie to be brought by the vinegar flies.

When that does happen, the crock surface will gradually start to show a thin graying film floating on top. This is your mother getting started. Don't disturb it. It's important that the mother stay on top until its work is done. It will settle to the bottom of your crock, heavy and thick, later on. Taste occasionally to see how sour your vinegar-to-be is becoming.

How Long? The length of Stage 2 can vary greatly. It depends on whether you have some "mother" or have to wait till you catch some vinegar microbes, and on the temperature during the fermentation. In general, at 75–90°F cider should turn to vinegar within 4 months, but it can happen in as little as a few weeks or take as long as 6 months.

Care of Mother. Don't lose your mother now that you've got her! Strain it off. To store, just put it in a jar, cover with vinegar, and put a (non-metal!) cover on the bottle. Or keep a batch going continuously.

BOTTLING: Strain off the vinegar and put it away safely. Strain the vinegar out of your crock until it's "clean" enough to suit you; 3 layers of cheesecloth are about right. If the vinegar is sufficiently strong (made from full-strength hard cider), you can bottle in sterile bottles, seal, and store as is. If the vinegar was made from incompletely fermented cider, pasteurize it before bottling to avoid the possibility of it making more bubbles and blowing the bottle. When capping any container of vinegar, *don't use plain metal lids, because vinegar corrodes metals!* So seal with a cork, a cork-lined cap, or some such.

From the time of sealing, the vinegar will gradually grow more mellow and more distinct in flavor, although you can use it immediately if you want. This homemade vinegar can be used as a "starter" for your next batch. But it will keep best if you pasteurize it.

Pasteurizing (or Not). If you pasteurize your vinegar, it can't be used as a starter. If you don't want to pasteurize the vinegar, strain it through a wet, doubled cheesecloth before bottling and then store in a cool dry place.

But pasteurization will keep your vinegar from clouding due to formation of mother. Put the bottles or jugs of vinegar into a pan filled with cold water. Heat the water gradually. Be sure the bottles are loosely corked or unsealed while pasteurizing. Then heat until the vinegar is about 145°F and hold it at that temperature about 30 minutes. Then cool it.

➲ **PIONEER CIDER VINEGAR** Put 1 gal. good sweet natural cider and 1 qt. molasses into a crockery or glass container. Cover the top with cloth and set it in the sun. Cover it when it rains. When it stops bubbling, add some mother if you can. In a month or so it should be good strong vinegar. You can dilute it if it is stronger than you want.

➲ **CIDER-SEDIMENT VINEGAR** Lois Rumrill, Forks of Salmon, CA, described her vinegar-making system for us: "When we make cider, I let it set in jugs for at least 24 hours and siphon the clear juice off the top of each jug, which leaves 1-1½ inches of sediment. [Lois doesn't mention the time for Stage 1; I'm sure it was in there.] I then pour the sediment into glass gallon jars, add mother to each, cover with cheesecloth and a cocked lid, and let it go to work. Lo and behold! In almost a month ... vinegar! I remove the mother (to another gallon jar containing vinegar), siphon the vinegar into ketchup bottles, and pasteurize: I pour the vinegar into a large pan, turn on heat, heat vinegar to 170°F, and hold at that temp for 10 minutes. Pour it into hot jars, seal, and store. Or sometimes I don't pasteurize—just let the bottles of vinegar keep forming mother. When I use those unprocessed bottles of vinegar, I just put the mother into that gallon jar with the rest of my mother. My vinegar tastes so very much better than store-boughten."

➲ **FRUIT-HARVEST LEAVINGS VINEGAR** When you are processing a bunch of apples, peaches, pears, grapes, or cherries, wash them thoroughly before preparing for use and save the peelings, hulls, cores, or seeds as appropriate. Place these in a crock. Sweeten well. Add enough water to cover them. You can sweeten with honey, molasses, or sugar. Let stand several days, keeping the top covered with a cloth. You can add fresh peelings now and then. The scum (mother) on top will gradually thicken. When the vinegar tastes right, strain and

bottle. Another method is to let your peelings, water, and sweetening stand several days; then strain and let the resulting juice stand until you have table vinegar.

➲ **PURE CIDER VINEGAR** Sylvia Nelson, Hillsdale, WY, wrote me, "I've made both malt and apple cider vinegar. The trick to making good cider vinegar is to start with cider, not apple parts. I sweetened it somewhat (white sugar does fine), added a few grains of yeast (I'm impatient), put a cloth over the jug, and left it in a warm place until done. The more sugar, the stronger the vinegar."

➲ **WINE VINEGAR** You can make your own wine vinegar by starting with homemade grape or dark berry juice. Dilute; sweeten and mix, if desired, with a lighter juice such as peach. Keep in a warm place, covered. First it will ferment. You'll see the bubbles of carbon dioxide rising poetically as it works. Then it will go flat and your vinegar making will begin; that takes much longer and is less dramatic. You don't have to have mother to start. It speeds things, but unless you live in the frozen north, mother is all around us. In the South you may end up with father, aunt, and uncle too.

➲ **APPLE COMBO VINEGAR** Combine a fruit juice with a tart apple juice. Pear is good. If you don't have a juicer, it will be easiest for you to just wash and mash the fruit by stomping with your kraut stomper. Then let it work until you like the vinegar flavor. Strain and store in glass in a cool dark place.

USE OF VINEGAR: It has a multitude of uses. In general, wine vinegar makes the best salad dressings, while apple cider vinegar is used to make pickles and ketchups—and an old-time beverage, "shrub."

Strength of Homemade Vinegar. Commercialized vinegars have a standardized acid content; they are diluted to a predetermined strength and then pasteurized and bottled. Homemade ones vary in strength. A plain hard cider with no sweetening added will develop about 6 percent alcohol, which in turn will become about 6 percent acetic acid, which is a good strength for kitchen use. If you start out with sweetened liquid, your vinegar will be stronger. Take that into consideration when you are cooking or pickling with it. Or dilute to the strength you want with distilled water. To strengthen the vinegar, let it freeze on top. Then take the ice off the top, since only the water portion freezes.

Shrub. The base for the beverage called shrub is a vinegar-fruit mix. To serve, dilute it to taste with water or ginger ale. Great-Grandmother liked it served hot for coughs and colds in winter and as a chilled beverage in summer. When bottled, it will keep for years.

➲ **BLACK Currant, RASPBERRY, OR BLACKBERRY SHRUB** Wash 2 lb. berries. Remove stalks and stems. Put into a crockery bowl and crush very thoroughly with a potato masher or pestle. Pour over the fruit mush 2 c. white vinegar and let stand for 5 days, stirring every day. Strain through a cloth. Measure the resulting juice and for every 2 c., add 1 lb. sugar. Boil very gently for 10 minutes, removing any scum. Strain again. Pour into bottles, cork, and seal with paraffin. (Stores that handle beverage-making supplies carry corks. The grocery store has paraffin.)

➲ **RASPBERRY OR STRAWBERRY SHRUB** Add enough vinegar to cover 1 gal. red raspberries or strawberries. Let them stand 24 hours, scald, and then strain. Measure the juice. Add 1 lb. sugar per 2 c. juice. Boil 20 minutes and bottle.

➲ **SPICED RASPBERRY SHRUB** Put your raspberries in a crock or jar. Cover with cider vinegar. Mash. Let stand overnight. Strain. For every 2 c. juice, add 2 c. sugar, 1 cinnamon stick, and 6 whole cloves. Boil 10 minutes. Bottle and seal while hot.

➲ **CLASSIC SWITCHEL** Switchel is an old-time vinegar, molasses, and ginger-flavored beverage. Mix together 1 qt. water, ½ c. cider vinegar, 1¼ c. sugar, ½ c. molasses, and 1 T. gingerroot (freshly grated if possible). Bring to a slow boil and keep there for 15 minutes. Then cool. Add 3 qt. previously boiled and cooled water. Chill and serve.

Salting

Salting is another method of food preservation. A 5 percent salt solution reduces bacterial activity, 10 percent stops most of it, and 15 percent stops anything. See “Cabbage” in [Chapter 4](#) for instructions on making sauerkraut, a basic salted, fermented food whose formula can be applied to other vegetables (corn, green beans, turnips). Carrots, beets, and turnips keep well if peeled, shredded, and salted. They also do well in a root cellar. String beans and corn cannot be stored in a root cellar, but they salt well. Peas and onions do not salt well, but peas dry well and well-cured onions store well if put away on a shelf where they won’t freeze. Peppers, green beans, and asparagus salt well but need to go into a brine rather than be put down in dry salt. For more information, see *Making Sauerkraut and Pickled Vegetables at Home: The Original Lactic Acid Fermentation Method* by Annelies Schoeneck.

NOTE: Never use galvanized containers for pickling—acid or salt works on zinc and makes a poison.

DRY-SALTING VEGETABLES: Any root vegetable should be peeled and then sliced or chunked. Corn should be cut off the cob and string beans snapped into sections. Use a glass, crockery, or wood container to store the food—nothing made of metal, unless it’s stainless steel. You’ll need about 1 lb. salt for every 4 lb. vegetables.

Put a layer of salt on the bottom of your container, then a layer of vegetable, then salt, and so on until it is full. You can add more at later dates as your crop in the garden is ready for harvest. When you have as much vegetable in there as you want (don’t go clear up to the brim), pour a final layer of salt. Lay a plate on top, weighted down with a boiled stone, a jar full of water, or some such. Lay a cloth over the whole thing to keep flies from dying in it.

Let rest 2 weeks, changing the cloth weekly. The salt will draw the natural juices out of the vegetables and create a brine. When you need food, take some out and replace the plate. You must keep your vegetables out of contact with the air. Add more water as it evaporates to make sure that the water level is always higher than the vegetables.

Brine Salting Vegetables. With peppers, green beans, and asparagus, lay vegetables whole in your crock. Pour over a brine of $3\frac{1}{2}$ lb. salt per 1 gal. water. Then follow the rest of the dry-salting instructions above. You can salt down in canning jars too. For example, pack green beans down in jars between layers of salt and then close up the jars.

SERVING: Any salted vegetable must be freshened by soaking overnight in several changes of water and then promptly cooked. A vegetable that has been preserved in salt will spoil amazingly fast once the salt is rinsed off, so you must be very efficient in getting it from your brine crock, through the freshening waters and the cooking, to the table.

Larding

Another old-time method of food preservation is “larding.” The French call larded bird meat a “comfit.” Julia Child’s *The Art of French Cooking* has a chapter on this process, using goose fat. The fat seals the air out. August Bartelle, San Diego, CA, remembers: “After slaughtering a hog, the fat was rendered into lard. Those cuts of the hog that were not cured for smoking or made into sausage, like the shoulder, were fried. While still hot, these slices of pork steak were preserved through the winter by larding. In a large crock, layer on layer of the fried steaks was covered with hot lard. This meat was then used through the winter by scraping the lard off each layer. The amount necessary for a meal was removed and reheated. The used lard was reused in pies or other baking or cooking and ultimately for soap.”

F. E. Pennington, Kelso, WA, wrote me about her pioneer childhood: “I was raised on a stump ranch in western Washington. We grew what we ate and ate what we grew. If we didn’t grow it, we didn’t eat. We let nothing go to waste. Once Daddy killed a fat bear and larded it in its own grease. We ground the meat up and cooked it in balls, then packed it in a 4-gal. stone crock which was set in the spring. The spring was as cold as ice water where it emerged from the hillside. It worked.”

NOTE: If you try this, make sure the food is stored under refrigeration, because there could be a botulism problem in that air-free, low-acid environment. The old-timers larded only in winter and stored it outdoors, where it was really cold.

February 1, 1974. I have to write up the “Butters” section, the “Beekeeping” section, the introduction to this chapter, the “Fruits (Apple to Pomegranate)” section, and the middle of the “Dairy” chapter—and then I’m done with this [first edition of] the book.

If you think that because I’ve written a book and I’m a Christian and I don’t use white sugar (not to imply equality among these various qualities), I never had my troubles, let me tell you different. You don’t know the half of it. But I’ve had my miracles too. And that’s the important thing. And just making it—just having gotten one foot in front of the other and kept moving all day long no matter how heavy the foot and the heart felt—can be miracle enough in some situations.

Being this near to finishing the first draft of the book seems a miracle. A year and a half ago I made up my mind not to take it up again. My husband’s preferred choice with regard to the book from the very start has been that I refund the money on all those early

orders I took. I would have, only I never had the money again.

Then we came to one of those great marital shake-ups that have to happen once every 5 years or so, I guess, and I got thoroughly shook up and swore off everything except what could make me a better housekeeper, wife, and mother. Not a bad decision. I did need strengthening in those directions. So I swore off the book and regarded it as a selfish desire and any further involvement with it on my part as in the nature of being tempted into sin. For one full year, I never touched the manuscript. For most of that year, I didn't think about it much because I was busy just trying to get the housekeeping in my head done and become somebody that God and I could be satisfied with.

But around last August, thoughts of the book started coming to me again—first, in terms of responsibility to the people whose money I had taken and spent, to whom I had promised so much by sending them, first of all, that ambitious table of contents. I had already sent parts of the book in three separate mailings to them all, and most of them were willing to consider that good enough, but a few were still holding me to that original table of contents. I'd left them all hanging now, without any further word, for a year. I've always been an almost painfully responsible person and, although I've had my fantasies of disappearing in the Underground or becoming a waitress in Tahiti, I don't expect it will ever happen. So I started to try to plan how to refund the money and get a letter out to everybody explaining why I had given up. But I just couldn't seem to get that done, even though it meant typing only one stencil and mimeographing it and mailing it out.

And the notion of finishing the book kept cropping up in my head more and more often, no matter how hard I tried to put it down. I regarded that oft-upcropping thought with almost tearful frustration: We had less money than ever; Mike had been laid off from the part-time job he had been working at in addition to his full-time one. I had less time than ever because when I started the book, I had 2 children, but I now have 5. How could I buy paper with no money? How could I get the mimeographing done since I no longer had access to the machine at Mike's office I'd been borrowing (because I had broken it)? How could I pay for postage?

But the urge to write again just got worse and worse, even though just getting through the chores I had seemed to take all my strength. I'm not a lazy or puny person. (I had my fifth baby, Sara, on a Thursday morning, left the hospital Friday evening, and went home and commenced to catch up on the dishes and laundry.) But it seemed like I was at my limit, and being nagged by the urge to write seemed to make me even more tired. (That's a curious thing, because once I actually started writing, the sensation of weariness gradually left.)

But was the desire just mine? In my one year of experience with God's way of leading me, a thought that nags me, patiently, relentlessly—the "do this, do this, do this"—is one way God has of showing me His will. And that's the way the thought of finishing the book came to me, more and more.

One day I literally broke down. Kneeling on my living room floor, crying out with lifted hands, I said, "Okay, Lord. I submit. This seems to be Your will. I can't see the way it's possible, but if it's Your will, I know You have a way through for me if I just go ahead and trust You."

The next day, secretly, I went back to work on the book. I constantly sought for God's leading with regard to the project and followed it explicitly. I had no hope outside His Power to accomplish miracles. I worked on it during daytime hours, while my husband was at his job. I did the displaced housework in the evenings: scrubbing floors and ironing shirts, usually until 11:00 at night. God gave me the strength. That was His first miracle for me. I was able to accomplish twice as much work as before.

When, weeks later, I finally felt it was time to tell Mike, he was good about it. That was a second miracle: Over the years past, Mike had grown to hate with almost a passion everything relating to the book and my work on it, but ever since then he's been very patient.

* Researchers at Washington State U. discovered that the acid content of tomatoes ranged this much and depended on the climate where they were grown as well as on their variety and ripeness.

INTRODUCTION

Domestic animals are basically human-created, symbiotic species. Most have been companions to people, caring for and being cared for, for literally millennia. For example, all but about 2 percent of the chicken varieties now sold in North America are breeds whose characteristics have been affected by careful selection by human breeders. Wild chickens, though they still run about in the jungles of Southeast Asia, are scarcely available for purchase elsewhere and would be impractical to own. The chicken as it now exists is dependent on its keeper to survive.

But in return for the responsibility you take for domestic animals' care, feeding,

housing, and doctoring, your animals eat your garden waste, kitchen surplus, and the field plants that humans can't eat, like grass and brush; and they turn it into high-quality protein foods for your diet (eggs, milk, meat). They also contribute manure to renew your pasture, field, and garden soil, and they devour insects. They can be used as pack animals; they can provide transportation, pulling power, and by-products such as wool, feathers, hides, and horns. Truly, they are benevolently symbiotic species that have been carefully evolved by fine farmers throughout the world over thousands of years to be the best possible companions, economic and social, to food growers. They are *not* imprisoned wild animals! Most would quickly become extinct if not cared for by people.

My humble friend Stephen Scott (who makes a living growing pork, chicken, and organic vegetables for mail-order and his local farmers' market) has a wonderful way of putting things. He wrote me, "What raising pigs is all about, aside from the meat, is getting back to our roots as providers in a way that is much more important than just working at a job to put food on the table. I believe that the act of raising and caring for our own animals makes us more human."

RESOURCES

Books: There's info about raising animals for meat in *Raising Your Own Meat for Pennies a Day* by Will Graves (1983); *Raising Animals for Fun and Profit* by the editors of *Countryside* (1984); *Barnyard in Your Backyard*, Gail Damerow, editor; and *Small-Scale Livestock Farming: A Grass-based Approach for Health, Sustainability and Profit* (1999) by Carol Ekarius (last two from Storey Books, address in [Chapter 1](#)). *Organic Livestock Handbook*, Anne Macey, editor, is a project of Canadian Organic Growers Inc. (www.cog.ca).

MAGAZINES: *Ranch and Rural Living* is a monthly about sheep, goats, and cattle: \$25/yr; free sample; 325-655-4434; PO Box 2678, San Angelo, TX 76902; www.ranchmagazine.com. The *High Plains Journal* covers the livestock scene, too: 800-452-7171; fax 316-227-7173; PO Box 760, Dodge City, KS 67801; journal@hpj.com; www.hpj.com.

MAIL-ORDER SUPPLIERS OF LIVESTOCK EQUIPMENT

Brower Equipment for Poultry, Livestock, Pets: Highway 16 W., PO Box 2000, Houghton, IA 52631; 319-469-4402; 800-533-1791; fax 319-469-4402; sales@hawkeyesteel.com; www.browerequip.com. Free catalog of equipment for poultry, pigs, and cattle; mousetraps; high-tech incubators.

Jeffers Livestock sells vaccines, cattle and goat supplies, fencing systems: 800-533-3377; www.jefferslivestock.com.

Klubertanz's Equipment specializes in welded wire and hex mesh, 1 × 2 in. spacing and smaller, and supplies for small animals. Free catalog: 1165 Hwy. 73, Edgerton, WI 53534; 800-237-3899; fax 608-884-7509; www.klubertanz.com.

Modern Farm sells farm and ranch supplies. Free catalog: 800-443-4934 or 307-587-5946; 205 N Stephanie, Ste. D, Henderson, NV 89074; customerservice@codymercantile.com; www.modfarm.com.

Premier1Supplies offers goat/sheep supplies, fencing, clippers: 800-282-6631; fax 800-346-7992; 2031 300th St., Washington, IA 52353; www.premier1supplies.com.

Sheepman Supply Company provides a wide range of supplies to sheep, goat, cow, horse, llama, alpaca, and horse farmers, including shearing gear, health care products, books, and videos. Free catalog: 800-331-9122; 301-662-4197; fax 301-662-0361; PO

Box A, Frederick, MD 21702; info@sheepman.com; www.sheepman.com.

LEARNING LIVESTOCK CARE: 4-H, your extension service, and agricultural college classes are all resources. All the counties of western Washington state have a program that produces “WSU Extension Livestock Advisers” after training in animal care, “from how to feed a llama to how to eliminate goat horns.” Although “master gardeners” are everywhere, right now that is the only livestock master program in the country; I hope others will soon start up elsewhere. For info, contact the program founder and guiding light: Mike Hackett, Skagit County Cooperative Extension; 360-428-4270; 11768 Westar Ln., Ste. A, Burlington, WA 98233; hackett@wsu.edu; <http://skagit.wsu.edu>.

Heifer Project International is a charitable worldwide organization that provides a female animal to a poor family in return for their gift of a female offspring to another family to pass on the help: 800-422-0474; 1 World Ave., Little Rock, AR 72202; www.heifer.org. They seek donations in rich countries and donate animals in poor ones.

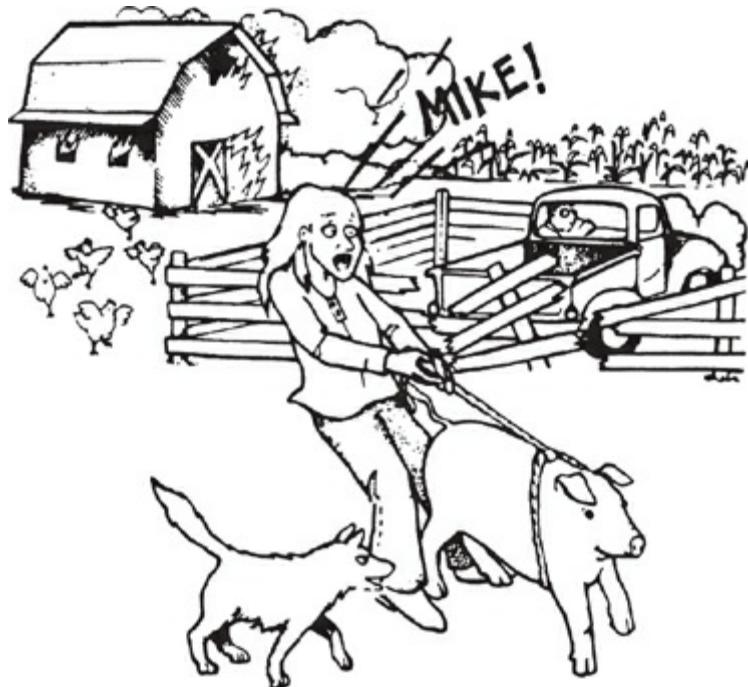

Considerations About Keeping Animals

Home-grown meat and eggs will always taste better and probably be healthier for you. They may even be cheaper to produce than store-bought eggs. You may hope to sell surplus animals for a profit as meat, breeders, or pets. Or you may just want to keep the animals as food sources for your family, as pets, for their beauty, or to show at judged poultry events as a hobby—or any combination of those.

RESPONSIBILITY: A basic question to ask about raising any livestock is whether you can afford the space, time, nuisance, and expense of adding them to your family. They may not be permitted by your local zoning. They may cause odors and noise and attract flies, mice, and rats. You won’t be able to take vacations unless you can arrange caretaking. No matter why you want to keep poultry or any other livestock, start small enough so that you can try out your management ideas without too much stress on either you or the animals, which will be dependent on your expertise, faithfulness, and ability to provide for them.

One of your most important responsibilities is simply being around your animals. You won’t be able to leave home without considering their needs. You can limit the responsibility and tied-downness of animal keeping by just raising a spring crop: buy a flock of young ones in the spring, raise them to butchering weight, transfer them to the deep freeze, and you’re done for the year. Your schedule may determine whether you choose a small egg flock of hens to raise year-round, or have a big meat-chicken production operation for just a few months a year—or do both. You can stay away from most egg flocks for a few days and they’ll be fine, but a bunch of meat birds requires daily tending.

Carol Caple, Neosho, MO, wrote me, “It really boosted my ego to read that someone else has troubles from time to time and that some other woman has had to chase escaped livestock while her husband was at work in his clean, air-conditioned office. People (me included) thought we had done something wrong when our one and only goat died of pneumonia. I now realize that nature takes its course and things like that happen.”

Your Animals' 4 Basic Rights

1. Treatment when injured or diseased.
2. Freedom from extreme physical discomfort.
3. Sufficient and nourishing food and water.
4. Care that minimizes fear and stress.

ANIMAL PSYCHOLOGY: Animals are different, but they're all heavily endowed with instinct and subject to habit. You have to work with their instincts and instill good habits in them. Once your animals have gotten their routine established, you must patiently subject yourself to their rules. Take time to listen to them and learn what their noises, expressions, and behaviors communicate. They listen to you. They may not understand all your words, but they'll understand some, and your voice's tone, facial expression, and body motions will communicate eloquently to them whether you're pleased, angry, insistent, or indifferent. Rule them like you do children: you must have a history of 8 or 10 true kindnesses before you will have earned the privilege of a moment's needed educational discipline. When you come to see them, bring a treat. When you get an animal someplace you want it to go—the stanchion, pen, or pickup truck—reward with a treat. Animals you've handled since they were young will be more friendly and less fearful than those bought as adults.

ZONING: Before investing in any farm animals, small or large, check your local zoning ordinances. Animals make smells and noises and occasionally escape from custody, and the very ones you love may be regarded by your close neighbors as unbearable nuisances. Chickens and turkeys, in particular, smell because of the high concentration of ammonia in their droppings. So choose where to live with your farm family in mind, or choose your farm family keeping in mind where you live. I have had the experience of being visited by the town police officer and told I must either get rid of my animals (goats) or move (I moved).

CHOOSING YOUR ANIMALS: You'll be concerned with the hardiness of the varieties you buy, suitability for your situation, and length of time to slaughter. For example, broiler chickens go into the deep freeze after 8 weeks at about 4 pounds each; ducks go into the freezer after 8 weeks at 7 pounds each. Turkeys will weigh more at slaughter (15–20 lb.)

but must be cared for longer (5 months) and fed more, and they're not quite as hardy. Some animals can forage better than others and thus cost less to feed. For birds destined for a commercial meat market, white-feathered breeds are preferred because their pinfeathers (small, immature feathers that tend to remain in the flesh) are white and don't show up. Every situation has individual angles you'll want to consider. You may want just one kind of animal, or you may want an assortment.

Shawn Trumble, Ionia, MI, wrote, "When I first bought your book, we were living in a little apartment in town. The landlord wouldn't even let us plant a few tomato plants. Now we have 3 acres (not enough!), a big garden, the start of a small orchard, 30 or so assorted hens, a pig, 4 assorted Jerseys including a cow we milk, a veal calf (good use for extra milk!), a few geese, and a turkey! The kids raise and sell broiler chickens in the summer and have a waiting list of people for the next batch. We also sell eggs. So we raise our own beef, pork, poultry, dairy products, eggs, fruit, and vegetables!"

ANIMAL ECONOMICS: A lot of people who raise animals end up complaining that it costs them more to home-grow eggs and meat than to buy them from the store. They generally qualify that by adding that the meat tastes much better, and they usually believe home-grown is healthier. But cheap is desirable, too, and sometimes is necessary. With good management it's possible to home-grow at a profit. To raise any animals, your basic expenses will be the animals (or their parents), their feed, their housing, and the equipment you need to raise them, such as feed and water troughs and a brooder lamp. Some things you can buy used at a bargain. Most housing and equipment can be used over and over again so that it becomes a minimal expense.

Farming is the only industry in which you buy retail and sell wholesale. It's hard to make a profit, although the organic market has been growing and becoming more competitive. If you can afford only a small piece of land that won't run enough animals to support your family in a commercial operation, and yet you want to be a full-time farmer, there are two other ways to do it. One is raising organic meat; you get paid much more for the carcasses than you would otherwise (so you can make it with fewer animals). The other is raising registered animals. But both of these are somewhat risky, like all farming, and both depend a lot on your ability to sell yourself and your animals. It's also important to get into, and along with, the groups that promote these special products and breeds.

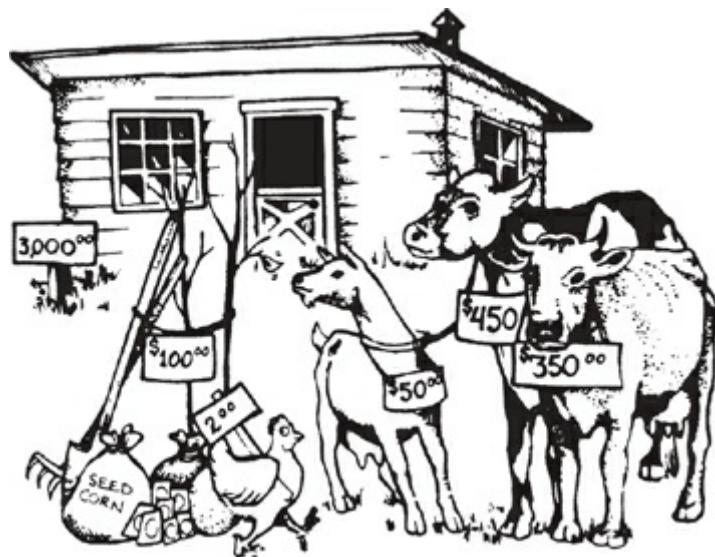

STEP-BY-STEP BREAKING TO LEAD

Any mammal that is trained to wear a halter and act appropriately on the other end of a lead rope is easier to live with than a halter-ignorant one.

1. Start as young as possible. Younger ones are easier to handle and easier to train. Be patient and gentle.
2. Start by getting up to and putting a halter on the animal's head.
3. Next, just tie up the animal for a couple hours to an immovable object. This gets them used to the idea that they can't get away and accustoms them to the feel of the halter. Tie up the animal with just a foot length between its head and the fence, or whatever it's tied to, so it can't get its legs tangled in the rope. If possible, tie it to a fence rather than an isolated post so it can't wind itself

around it. Have a sharp knife handy so that if something goes wrong, you can cut the animal loose.

4. Repeat every day until this lesson is learned. Don't leave it alone at first. It might fight and choke itself. Grooming it while it stands there helps reassure and gentle it.
5. Take the animal into a small, totally enclosed space like a pen or corral (to keep it from escaping; an animal that has gotten away once will be twice as hard to train the next time). Practice leading it counter-clockwise around and around. Don't tie the lead rope around your arm or body so there's no risk of being dragged. Keep the animal's head up and bent a little toward you. Practice about half an hour. Stop the practice for six hours or so. Then practice another 30 minutes. (Same-day practices really help!) Practice every day until it gets easy.
6. For a difficult large animal, it may help to first tie the animal to the back of a vehicle (a "leading gate"), which is then moved to lead the animal. Or tie the trainee firmly to another animal that already knows what it's all about, and lead them both in that way.
7. For your first out-of-corral leading, let your animal get a little thirsty, and then lead it to water.

You'll have a vastly different approach to raising animals depending on whether you want to make money on them. If you have a few animals to help provide healthy food for your family, you'll know them well and be friends with them. But to profit from livestock, you have to operate like a business and view the animals more impersonally. Know what's possible: for instance, a calf can grow 100 pounds of meat for you in only 3 months (more meat quicker than any other animal), but it takes 10 years to develop a herd of 30 cows, even if you start with 3 beef cows with calves. On the other hand, one bred sow can have 700 descendants in three years. But also consider rabbits ... and chickens ...

Then set goals. Try to continually increase the quantity or quality of your product and have better cost control. Keep track of all you spend and earn, and regularly reconsider the project according to those numbers.

NOTE: P. Wells of Smallholder, the English homesteaders' magazine, wrote me: "Tell people

to check local laws. There are several new guidelines on selling, processing, and producing foodstuffs, eggs, and dairy produce." That applies equally to readers in any country—or U.S. state, for that matter.

THE AUCTION RING: Cull cows generally go to the auction ring; some good cows do too. The Lewiston auction ring handles hundreds of animals every time it's in session: cows, pigs, sheep, and sometimes others. It's a sight to see. I was there once when they brought a Charolais bull through. Charolais is one of the new beef breeds, off-white and very big—a bull can be over 3,000 lb. This was a big bull, and he had horns and was in a horrible mood. It really had us nervous for a while because he was charging everybody in sight and they couldn't even get into the ring to open the gate to let him out. Finally a brave man dodged out into one side of the ring and let the bull charge him (he got away) while another person just managed to get the gate open at least partway before the bull saw him and charged him too.

TRAVELING WITH ANIMALS: You need to be prepared to travel with your animals. Even if the person you buy it from agrees to deliver the animal, 2 days later you may need to take it to the vet, or you may be mad enough at it to want to take it back to the previous owner. A half-ton pickup can hold any smaller animal, including a small cow like a Jersey. (It can hold a bigger cow, but it's a real struggle.) You'd have to bend a big Shorthorn cow pretty near to an S-shape to get it in. A $\frac{3}{4}$ -ton pickup bed will hold any cow or bull easily. You'll need stock racks, of course, to haul cows. You can make your own. A 1-ton truck can transport 3 big cows plus 1 or more calves tucked in around the sides.

You can transport a goat in the back of a pickup most comfortably by tying a rope to each side of its collar and fastening the ends to each side of the pickup. That holds it in the pickup so it cannot jump over the side. Or you can tie it to the middle, right behind the cab, on a very short lead. You can tie the legs of a calf or goat and put it in a car trunk with the door a little open, but I don't care much for that method. If you can spread out a big sheet of plastic so your upholstery is perfectly protected, you can move one or more goats, small pigs, or sheep in the back of a car. (Just don't try to eat anything in the front seat during a trip with goats, or you'll have goats in your lap.) You can bring a newborn calf or smallish pig home in a gunnysack tied around its body that leaves its head outside the sack.

I once traveled 60 miles in a small car with 5 goats, 3 young children, and myself very largely expectant. The humans and goats made it fine, but it took the car a while to recover.

Genetics

There are distinct genetic lines of poultry (and other animals) that go by the same name and yet have inherited differences, some of which are beneficial and some of which can be a problem. That's why it is helpful to always buy stock from a breeder you trust. Genes matter. They define what your animal's ancestors were and what your animal is capable of becoming—what its strong points and weaknesses will be.

For example, the modern hen lays about 7 times as many eggs per year as does a wild hen. This achievement is, above all, the result of farmers' careful and continual selection of her predecessors for many generations. You can decide what characteristics you want your poultry to have and then obtain birds with those traits. If you decide to become a breeder yourself, remember that good breeders ruthlessly eliminate stock that doesn't meet their standards.

OF PEDIGREED ANIMALS: A pedigreed, or registered, animal is one with known genetic characteristics. Its parents, grandparents, and so on have been recorded. When it is bred to another animal with known characteristics, you know what sort of offspring you are going to get. There is a long, valuable tradition of exhibiting the best breeding animals at the annual local county fair. So that's a good place to go to study the breeds.

If you decide to raise registered animals, you will pay a sizable price for your start of breeding stock. To start with, you just breed and build up the numbers of your herd. You don't eat any of the offspring. The registered stock is much too valuable financially to be wasted on your dinner table. You'll have to raise some cheaper animals for your family's food. And you can't sell your registered animals through the regular outlets—like a stockyard for cows on regular sale days. You'll have to wait for a special sale of registered animals, and you might have to truck your animals quite a way to get there. Or you sell them through ads in specialty magazines. To sell pricey registered animals, each animal must be carefully and thoroughly halter-broken and in tiptop condition. And it's almost a must to take your best ones around to all the stock shows you've got the time and money to go to, because the more ribbons they win, the higher the prices you can charge for them or their offspring.

You'll also join your state and national associations for your particular breed of registered animal. You'll get a monthly publication, and part of your dues will be applied to the cost of the advertising that keeps up the national, or even international, image of your breed. These associations also usually put out a directory of members and sometimes a handbook on caring for their breed; many sponsor an annual convention or meeting. Many have affiliated state groups that meet more frequently. If you happen into a breed whose central organization has troubles, one that isn't really meeting the competition in the national advertising market, you may have trouble getting the top price for your animals. To locate the society for any particular breed, look in the *Encyclopedia of Associations* at your local library.

Who will you sell to? To people who think that a registered animal is so much better than they are willing to pay the higher price. And to people like you who hope to make money selling registered animals and are trying to get their own start of breeding stock. And to parents of 4H'ers and FFA teenagers looking for an animal that might win a prize at the county fair. (They'll favor breeds that have recently been winning.) And to people who have money and think of owning registered animals as an upper-class thing. And to large-scale livestock raisers who want to introduce particular characteristics into their herds. (For example, a dairy owner may buy a purebred big meat-type bull (or artificially inseminate with its semen) so the bull calves will sell at the higher prices that beef with

those characteristics brings.) And to commercial operations that want to start with the best or upgrade the stock they have. And to plain folks who want a guarantee of no bad genes in the offspring.

BAD GENES: We had a problem once with a herd of purebred cows that every so often produced a naturally sterile heifer. (Now I know why they were cheap and the owner was getting out of the business!) We have a heifer out here now that was born without a tail and missing the last couple of humps of her backbone. Otherwise she's fine, but we won't use her for a brood cow, since the trait might pass on. I had a 4-titted nanny goat once (they should have 2: cows have 4) who had 4-titted nanny kids. I wouldn't keep her offspring for breeding either, since they might pass it on. Some people say never to mate 2 animals that have the same fault, but that's not good enough. If an animal has a serious fault, don't let it mate at all. You don't want that trait to continue.

ARTIFICIAL INSEMINATION: In some cases, you can make more money selling semen from your animal than selling the animal itself. That's because it's cheaper to buy as many females as you can afford and artificially inseminate (A-I) them than to buy a champion male. You do that by buying frozen semen from the champion male of your breed. But even the semen may be very pricey. This method is sometimes used by cow breeders. You probably can take an A-I course somewhere in your area to find out how to do it. Check with your local extension agent or 4H leader.

If you set out to buy a registered animal, keep in mind that you're being exposed to an expert at person-to-person salesmanship. And be alert to the possibility that the animal is being misrepresented. Owners have claimed that their animals were bred when they weren't, and that they gave more milk than they really did. At such a high price, it pays to be very, very careful. Remember also that the owner is selling his or her own culls. An owner of registered animals is trying all the time to improve the characteristics of the herd: how much milk the animal gives if it's a dairy herd, how fast the calf gains weight if it's a beef herd. The animals offered for sale are the ones that don't meet the breeder's standards. You can't buy the best ones, unless you're prepared to pay fantastic prices.

A final summing up and advice from Carolyn Christman, program coordinator of the American Livestock Breeds Conservancy: "You can choose purebred animals or animals of unknown breeding. An advantage of purebred animals is predictability: you know exactly what the offspring will be when they grow up. If you choose purebred, you can then choose registered animals. Registered animals cost more. This cost is worthwhile if you are at all interested in the sale of breeding stock or in the development of a breeding herd. If you are making this kind of investment, shop around and find reputable breeders from which to start your herd. An auction can offer a bargain, but because things happen so fast, you can't do very careful buying. Don't assume that because an animal is stated to be a particular breed, it is. Look at the papers and make sure that they match the animal (check brands or tattoos if possible) before you pay extra for that registration! And make sure that the registry is a legitimate outfit. In short, do your homework!"

Heritage Breeds and Exotics

These aren't the same thing.

HERITAGE LIVESTOCK BREEDS: These are old-time livestock breeds. Some are still popular, but many are quite rare and some have vanished forever. Back in the old days they were regular farm livestock, an essential part of rural life and agriculture. Years ago there were far more breeds of the 9 basic livestock species (asses, cattle, chickens, ducks, horses,

geese, sheep, swine, and turkeys) worldwide than there are now. Back then, every area of the earth where people lived was a distinct eco-niche in which those humans and their specifically adapted animal breeds sustained each other. Modern times and agribusiness (mass) production of a very limited number of the most profitable breeds have caused the extinction or near-extinction of most of those other old-time domestic species. The mass-market producers tend to choose just one or a very few breeds and let the others approach or cross the line to extinction.

The preservation of these heritage livestock breeds happens on family farms that have a use for or an interest in such critters as pigs that thrive on pasture rather than in confinement (such as the Tamworth breed); poultry that will set and hatch their eggs; and a cow that is small in size and moderate in milk production (the Jersey). The Florida Cracker cow is adapted to the hot, humid climate of the Deep South. The horned, spotted Jacob sheep is a good survivor.

Commercial agriculture has zillions of the one breed most suited to agribusiness' mass production: Holstein for the dairy industry, Leghorns for the chicken industry, etc. But homestead-type folks keep the others going. The old-time breeds of livestock are worthwhile for their genetic uniqueness as well as their historic value. For example, someday there might be a disease in pigs equivalent to the hybrid corn blight. Rare breeds also may produce lovely colored wool, unusual cheeses, astonishing feathers, etc. And heritage breeds are typically better suited than industrial ones for the free-range, chemical-free homestead family's needs.

Carolyn Christman of the ALBC again sums it up: "These animals have better forage efficiency on pasture, maternal abilities, disposition, longevity, parasite and disease resistance, and general health. Their animal services—such as brush clearing, pest and waste control, production of manure, and grazing to improve pasture—are also quite valuable on the homestead farm."

I hate to spoil the fun, but I can't end this without sourly adding that some less common species have been left behind for good reasons, and the ALBC says only the good things about heritage livestock. Do your homework so you aren't disappointed.

NOTE: Before shopping for livestock, know exactly what you want your animals to be able to do in your particular eco-niche, or what market you are aiming their production toward. Then choose the most suitable species.

By the way, the American Livestock Breeds Conservancy works to protect nearly 100 endangered breeds of American livestock and poultry from extinction. They take a periodic census of all varieties of domesticated livestock in the United States. They name those at risk of extinction and encourage people to buy and breed them. If you join (\$35/yr), you get a bimonthly newsletter, annual breeders directory, and access to a long list of reports and publications on rare and endangered livestock: ALBC; 919-542-5704; Box 477, Pittsboro, NC 27312; albc@albc-usa.org; www.albc-usa.org. Their newsletter contains classified ads for heritage breeds as well as a calendar of events like these:

United Suffolk Sheep Association: PO Box 995, Ottumwa, IA 52501; 641-684-5291; www.u-s-s-a.org.

Exotics: An exotic breed is one that is either newly created, a once-wild native (such as buffalo!), or recently imported and new to the United States. For instance, have you considered raising butterflies? Contact 877-485-2458, www.butterflyrelease.com for more info. The Asclepias Seed Co. provides milkweed planting seed for nurturing monarch butterflies and larvae: 308-284-8404; 218 Prospector Dr., Ogallala, NE 69153; www.buymilkweed.com.

You'll find listings of many rarer breeds of livestock at www.ansi.okstate.edu/breeds. Their scarcity, the media interest in them, and speculators' hopes for profit make for risky business. The exotic market has on occasion seen speculators making large profits—and the unaware taking large losses. The beefalo (a cow-buffalo cross) was once the center of bidding excitement, as were a relatively useless rabbit variety called the Belgian hare and later the ostrich. It's safest to pay a price for an animal based on its potential to produce meat, work, hide, fur, or feathers rather than its potential as a breeder (rather than speculating, that is, that since you were willing to pay a mint for an animal, that means you'll be able to sell its many offspring for a mint each too). That get-rich scenario runs into trouble when there are no more well-heeled speculators available to buy your animals—or when the media interest shifts to some other unfamiliar creature.

Nevertheless, there are good profit possibilities in raising exotics, so I'm not trying to totally talk you out of it; I just want to instill a healthy caution. Do consider raising breeds such as buffalo, ratites (ostriches, emus, and rheas), caribou, elk, antelope, water buffalo, red or fallow deer, cattalo (another buffalo-cow hybrid), and South American humpless camels ("camelids") such as llamas, alpacas, guanacos, and vicunas. You can sell to restaurants that want unusual meats on their menu and to people who want the meat or an unusual pet. You can sell exotic fibers (such as camelid wool). You can sell the animals for packing (the camelids, www.packllama.org), or performing draft work (river buffalo). In South America, guinea pigs (raised on a diet of corncobs, grass, alfalfa, and lettuce) are butchered when they are 6 months to a year old. Their meat is an Andean

special treat: "cuy."

Exotics include breeds such as yak (International Yak Ass'n; www.iyak.org). Also, there are now miniature breeds of cows, horses, goats, pigs, etc. Miniature horses, for example, stand 19 to 38 in. high. They're too small to be ridden, even by children, but they can pull a cart. (Available from 520-682-8009; fax 520-616-7022.)

Humpless Camels. For expert advice on the medical problems of South American camelids, especially guanacos and vicunas, contact Dr. William L. Franklin: wlf@omnitelcom.com.

Llamas are said to be useful as livestock guardians. Doesn't make sense to me that one could handle a bear, cougar, pack of wolves, or coyotes. (I recommend you get one or more Great Pyrenees dogs for this.)

Here are lots more camelid info resources:

Alpaca Discussion List is for alpaca owners and those interested in them. The mailing list serves 700+ persons and is moderated by John L. Pinkowski:

Deer/Elk/Reindeer Farming. Deer and elk farming is big business in New Zealand, which exports, and in the former West Germany, which consumes venison second only to beef and imports more than 25,000 tons per year [1989] and produces at least the same amount within the country. Commercial venison production is doing well in the United States too. The first deer farm ever in this country was the Lucky Star Ranch in Chaumont, NY. An extension bulletin says Lucky Star Ranch raises 3,000 deer on 1,500 fenced acres and has done well with its own USDA-inspected slaughter and processing plant on the premises. Owner Joseph von Kerckerinck, founder of the North American Deer Farmers Association, sells fresh and frozen venison cuts directly to consumers by mail, but most deer and elk ranchers make arrangements with a cattle slaughterhouse to do that work.

Von Kerckerinck wrote me that the big start-up expense for raising deer or elk is a fence between 6 feet 3 inches and 8 feet high, which is a necessity. He says if you are raising fallow deer, you can keep 4 deer per acre; wherever you can pasture 1 cow, you can keep 6 to 7 fallow deer. Coyotes and domestic dogs are a problem for deer ranchers, but there are ways to make your pastures predator-proof. And for meat that may sell at \$5-\$10 per lb., the risks may well be worth it. He sells a videotape on the subject: 315-649-5519; Lucky Star Ranch, 13240 Lucky Star Rd., Chaumont, NY 13622. Or contact North American Elk Breeders Association, 402-756-3355; www.naelk.org.

The H & A Ranch offers bison bulls, bred bison cows, elk bulls, and bred elk cows: 888-886-5671; 411 Redbud Lake Rd., Lexington, TN 38351; dlaudry@pchnet.com; www.autryfarms.com. For more info, order the *Bison Breeder's Handbook* and *The Buffalo Producer's Guide to Marketing and Management* from the National Bison Ass'n: 303-292-2833; fax 303-659-3739; 8690 Wolff Ct. #200; Westminster, CO 80031; www.bisoncentral.com. ATTRA's article on "Bison Production" is at www.attra.ncat.org/attra-pub/bison.html.

Want to raise reindeer? Ray Donohue is Corresponding Secretary for the Reindeer Owners and Breeders Ass'n: 507-726-6996; roba-info@reindeer.ws; www.reindeer.ws.

Ostrich. Ostrich hides make good boots, and ostrich meat is plentiful and good, but these birds can live for as long as 70 years and will keep producing beautiful plumes all their lives. You can't determine the sex of ostrich chicks until they're at least 8 weeks old. Ostrich chicks are liable to have nutritional problems and pneumonia unless kept well fed, warm, and dry. An ostrich hen can lay as many as 30 to 50 eggs a year, but not all the eggs will hatch. Abuse or teasing stresses the birds. They should not be left alone with

small children, for they don't understand the strength of their peck. Their big bills snatch up a wristwatch, glove, ring, or buttons in an instant. Their strong forward kick protects against coyotes or stray dogs. Young ones can be crowded, but adults need space—½ to 1 acre per adult pair of ostriches. Fence height depends on age; for adults you need a 5-foot fence. Ostriches don't fly or jump, but they will lean into a fence. As long as it doesn't fall over and they don't fall over it, it will hold them.

Dale Coody offers a 36-pg manual, *Ostriches: Your Great Opportunity*, for \$12.50 and a video for \$59.95 from his 4-C Ostrich Farm: 580-353-3078; Rt. 1, PO Box 71A, Lawton, OK 73501. He also sells ostrich-scaled incubators and brooders. A subscription to *Emu Today & Tomorrow*—\$25/yr for 12 issues—is available from phone/fax 580-628-2011; 11950 W. Highland Ave., Blackwell, OK 74631; www.emutoday.com.

MORE EXOTIC INFO

Animal Finders' Guide is "The Magazine Devoted to Animal Lovers," covering current animal issues, reader letters, classified ads, 18 issues/yr, \$30, \$2.50 for sample copy: PO Box 99, Prairie Creek, IN 47869; 812-898-2678; www.animalfindersguide.com.

Heart of America Game Breeders' Assn., annual dues \$10, offers twelve 8-pg newsletters with free ads for members and a Breeders' Directory listing about 475 members in 27 states: Terry Smith, 14000 W. 215th St., Bucyrus, KS 66013; www.gbwf.org/hoagba.

Rare Breeds Journal, "The Digest of the World of Alternative Livestock, Wildlife, Animals and Pets," offers an exotic market review, a global connection to the exotic animal industry for \$25/yr.; Box 66, Crawford, NE 69339; 308-665-1431; fax 308-665-1931; rarebreed@bbc.net; www.rarebreedsjournal.com.

Predators

When you raise animals, especially small stock like poultry and rabbits or vulnerable stock like sheep and goats with kids, you're likely to soon find out if something's out there that likes to kill and eat—or merely kill—your kind of animals. The predators may be wild animals like hawks, owls, mink, skunk, raccoon, coyote, foxes, weasels, and ferrets, or they may be domestic dogs. Dogs are much worse than coyotes. While coyotes kill only to eat, dogs may kill a whole flock of sheep.

IDENTIFYING PREDATORS: Your first problem is to identify the problem animal. Each variety of predator has a characteristic modus operandi, and if you discuss the details of what happened with old-timers in the neighborhood, they'll give you good advice. Mammals will take small stock of all ages and can be a big problem if you live far from town. Rats usually kill only very young or very small poultry, but they can wipe out a hatch of chicks or ducklings in one night and can consume or ruin a lot of feed. Hawks hunt by day; owls, weasels, raccoons, and foxes hunt by night. A weasel may suck the blood or take only the head of even a mature small animal. The predators may be domestic animals gone wild, like uncared-for cats; or they may turn out to be domestic animals that should be under better control—possibly even your own pet.

Since knowing what you're dealing with is important in planning a defense, check out *Tracking and the Art of Seeing: How to Read Animal Tracks and Signs* by Paul Rezendes, a good book that covers 46 mammals.

PREDATOR-PROOFING: If the problem is your own pet, you must train it not to kill livestock, physically control it by fencing in or tying up, or destroy it—or you give up on that type

of livestock and get something too big for it to kill—like a draft horse! You can predator-proof confined small animals by housing them in well-built quarters that predators can't squeeze or dig into. You can protect against night predators by confining your animals in predator-proof quarters at least at night. Covering the top of your birds' or bunnies' outdoor runs keeps out both flying predators and disease-carrying wild birds. Some counties trap wild predators as a public service.

Rats can be a problem. Keeping feed grains in rodent-proof containers helps. Both rats and mice are attracted by poultry feed. It's best to keep feed in covered metal containers like metal garbage cans. Keeping a mousing cat, trapping, or putting out poison grain are more combative approaches.

To protect animals in a herd, get a guard dog (918-967-4871; C&C Farms, Rt. 3, Box 6815, Stigler, OK 74462). Read ATTRA's article "Predator Control for Sustainable & Organic Livestock Production." It's free from 800-346-9140 or downloadable at www.attra.ncat.org.

FIRE ANTS: An especially ugly and growing problem is fire ant predation. These newcomers to North America are gradually spreading through the southern United States. They are expected to spread eventually to western Texas, most of California, and through the Oregon and Washington coasts. Fire ants sting like a bee with a formic acid poison, are very aggressive, and will swarm over unmoving victims, possibly giving a fatal number of stings. They eat meat as readily as vegetable products. They attack anything alive and are most able to destroy young, slow, or otherwise vulnerable animals. So they can kill setting hens, baby chicks, and mother and baby rabbits. They've been known to attack calves, starting with their eyes. (They're hard on wild animals too.) They basically eat everything from their victim but the skin and bones. Boiling water kills them.

CHICKENS AND PREDATORS: Make sure your chick area is safe from predators: dogs, cats, rats, weasels. Rats and weasels have been known to squeeze through 1-inch chicken wire. If you're covering holes with wire mesh, the holes should be no more than $\frac{1}{2}$ inch in diameter. Baby chicks can easily be squeezed to death by a carelessly tight grip. And, like other animal babies, they do best with a schedule that allows a lot of rest and a minimum of stress.

The facilities you plan for your poultry will reflect your judgment about what risks you care to take—as well as what existing housing there is, what you can afford, and what the individual species' needs are. Living any life requires balancing the joy of freedom against the wisdom of precaution. Chickens love to roam, but then they're more likely to get run over, carried off by a hawk, killed by somebody's dog (maybe even your own), or afflicted by parasites. You may have to lose a few to find out just what the perils and limits to practical freedom are in your particular environment. You also have to consider the neighbors, because free-roaming chickens do not observe property lines.

Dogs: Dogs often are allowed to run loose at night, and sometimes they form packs that will chase and even bring down fairly large animals. If you see this happen or catch an offender in your trap, you have legal recourse and should use it, because it is never right for someone else's animal to hassle or destroy your property—which includes your animals. A Havahart trap will capture, without injuring, 4-footed night prowlers, including somebody's pet. You can order one from Rocky Top (865-882-8867; www.rockytopgen.com).

After the capture or identification, the next step is to tell the animal's owner what happened. The owner should agree to control the pet in the future and offer to repay your

losses. You bill him/her a just amount, the owner pays, and it's done. If the owner will not cooperate, or if you do not know the owner, call the local animal control officer. Of course, if your animal causes damage to your neighbor, then you also have to do the right thing. It works both ways!

Dynah Geissal, homesteader and country-topics writer, suggests, "If at all possible, raise your dogs in contact with your livestock. You certainly don't want to have to worry about your own dogs harming your animals. Unless you know for certain that your neighbor's dog is good with livestock, do not allow it near your animals. Call or visit your neighbor immediately and make it clear that you will not tolerate their dogs on your property. Every livestock owner understands this.

"The trouble usually comes from people who think they can let their dogs run loose because they live in the country.

"The best defense against feral dogs and coyotes is a dog of your own. I'm talking about a farm dog, not a dog that spends its time in the house. It should be a dog that willingly and naturally protects your livestock. With a good dog on guard, a predator will usually look for easier pickings. (I have a Great Pyrenees and they are tops.) A gun is a last, but sometimes necessary, resort."

BARNs AND FENCES

Do a bunch of thinking before you start building. The design needs to be just right for the purposes it will serve.

Building a Barn

Homestead writer Don Fallick said, "Truthfully, most livestock need little protection from the elements, except for the wind and direct sunlight. They will need more feed in cold weather, though, if poorly sheltered. Of the many considerations involved in planning a barn, two of the most important, and most often neglected by novices, are animal control and manure handling. If you design your barn right, your animals will go just where you want them to, with very little effort on your part. Do it 'wrong' and you'll be fighting your livestock several times every day. This can range from inconvenient, with goats, to hilarious, with chickens. With cattle and horses, which are bigger than you, it can be downright dangerous." Wise words!

MORE INFO: For building animal shelters, I recommend *Building Small Barns, Sheds and Shelters* by Monte Burch, *Practical Pole Building Construction* by Leigh Seddon, and *Build It Better Yourself* (Rodale Press, 1977). Ashland Barns offers 100+ barn plans ... stables, garages, workshops, homes, country styled. Also, weather vanes and signs: 10150 Wheeler Rd., Central Point, OR 97502; ashlandbarns4U@yahoo.com; www.ashlandbarns.com.

SITING: Where will you build your barn? You want a place where water won't be running into it and where there's good drainage. Allow for unusually heavy rains. Make it strong enough to withstand the amount of snowfall you typically—and might atypically—get. Make it able to stay dry even when all that snow is melting in an off-season warm wind. Site where it will be easy to bring water and power to it. Don: "I know people who've been milking cows for 30 years in a barn with neither electricity nor running water. It can be done, and done well. But there will be times when you really wish for good, strong light or plenty of running water."

BUILDING MATERIALS: My friend Stephen Scott and I are firm believers in recycling where possible. He said, "Many times you will be able to pick up building materials where you work. A lot of people won't bother with 5-foot 2 × 4s or ones of any length that are sawn. Talk to the people who work in the shipping and receiving areas. Many times junk lumber will be thrown back in trucks or rail cars. Usually people will save some of it for you for the price of a cup of coffee. If this is not your situation, you can buy new lumber as a last resort. Think about places in your area where you may be able to get some construction material for free."

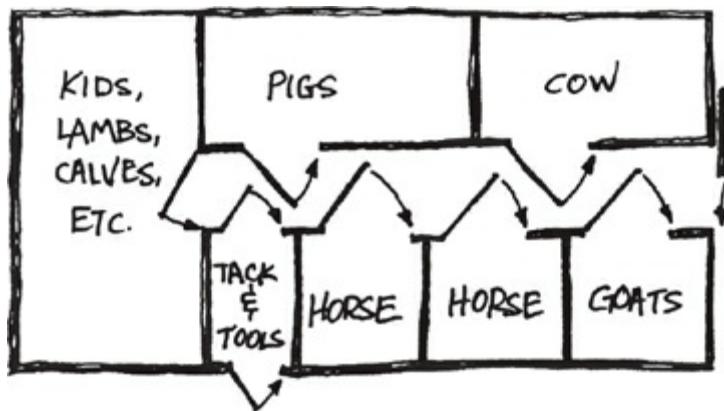

FLOORING MATERIALS: Your barn will likely have a concrete, wood, or dirt floor. Each has pros and cons.

Concrete. Don: "Horse stables should *not* have concrete floors, even though this would make manure handling much easier. Impervious concrete keeps the urine trapped in the bedding and can cause hoof problems, even if the bedding is changed daily. One solution to this problem is to use sand for the floor. The sand soaks up the urine in the top inch or so, which can be shoveled out and replaced as needed, like cat litter. Eventually, it all needs to be removed and replaced, though, and this can be a very big job."

Wood. Don: "A more traditional solution is to make floors of wood, 3 or 4 inches thick. This allows for raking as well as shoveling of the bedding, which is placed on top of the wooden floor. The problem with wooden floors is that they, too, eventually need to be replaced, which can be quite expensive."

Dirt. Don: "The cheapest solution, and the least satisfactory from the standpoint of hygiene, is bedding directly on an earthen floor. The earth gets compacted by the horse walking on it and becomes as hard as concrete. It turns to mud where the horse has scraped away bedding material, which horses all do. It catches pitchfork tines and shovels nearly as much as wood, and needs to be removed periodically like sand, but must be broken up with a pick before it can be shoveled out. It makes for very heavy compost, which can be a real pain if you are handling manure without benefit of a tractor. But it's literally dirt-cheap, and horses like it. Whichever method you decide to use, plan your barn so the flooring is easy to replace and level with the rest of the barn."

DESIGN: Don: "If you are going to keep several kinds of stock in the same barn, it is not necessary to design a special room just for each species. The same room that serves as a lambing pen in the spring can be used for raising goat kids or foals. The important feature of a properly designed barn is that every room opens onto a common hall, with doors or gates big enough to completely block the hall when opened outward. This makes it easy to separate species by driving the whole herd down the hall and simply opening and closing gates to make each critter go where it's supposed to go. Then you can separate animals by species, even separate kids and calves from their mothers, without having to drag them or entice them with grain or treats.

"For example, suppose you have a horse, a cow, and a few goats. The dominant animal, usually the horse, will go into the barn first, followed, perhaps, by the goats and the cow. You open the door to the horse stall so it blocks the hall, and beyond it, you open the gate to the goat pen. Then you open the main barn door at the end of the hall, and all the animals enter in order. Close the barn door before the cow enters. The horse will go right into its stall. Close the horse stall door, and the goats have nowhere else to go but into their pen. You can open the cow pen gate and the main barn door and drive the cow right into its stall."

For Goats. Don: "The same principle applies when building a milk parlor for goats. To eliminate the hassle of trying to get only 1 goat at a time into the parlor, build it with 2 doors—one for the goats to enter the parlor by and another for them to leave by. These work best if they are goat-sized, in which case you'll need another, larger door for you. The entrance door opens in while the exit door opens out, and both lock from the inside. With a setup like this, it's easy to train the goats to come into the parlor one at a time and leave after they've been milked, especially if you feed them grain while milking and "free choice" hay afterward. The principle remains the same: allow the animal nowhere to go but where you want it to go, and you won't have to 'convince' it every time."

For Horses. Don: "Horses present special problems for the barn builder. They're as big and heavy as cattle, they kick things, and they frequently 'crib,' or chew on wood. Any horse barn or stall simply must be built of pieces of lumber no smaller than 2×8 , as high as the horse can kick. All boards used as dividers should be screwed to their posts, not because nails won't hold (they will) but because this makes it easier to remove and replace the pieces of the old boards after the horse breaks them. Stall walls should be planned with large, long-span horizontal boards to minimize the number of nails and screws, for two reasons: horses will crib around the nails and may hurt their tongues, lips, and teeth; and long boards are more flexible and therefore more durable around horses than short boards. Replacing bedding for even one entirely confined horse every day can quickly become a real chore if the barn is not arranged to make this easy. If you design a door from the stable directly to the yard, the bedding can be forked out of the stable and out of the barn in one operation."

"Some people who have never kept horses might think it would be cheaper to run horizontal stringers at the top and bottom of the wall, and maybe even in the center, than screw vertical boards to the stringers. This is false economy, because it places the bottoms of the vertical boards where they are subject to rotting from the wet bedding. And you dare not use pressure-treated lumber in a stall, where the horse may be inclined to crib on it. It also places the center stringer right where a horse that is inclined to crib can best reach it."

For Cattle: Loafing Sheds. Don: "In many parts of the country, including the mountains

of Colorado and the upper Midwest, it's quite common for cattle to sleep in three-sided, concrete-floored 'loafing sheds' and enter a barn only to be milked. The manure is scraped out by a tractor with a blade on the front or back; it is pushed into piles to compost or loaded directly into manure spreaders. In the milk parlor, the cow stalls are arranged so any manure or urine released during milking can be hosed easily into a manure channel and then out of the barn. I have even seen horses kept in loafing sheds quite successfully. Sheep are rarely kept in anything more substantial, except around lambing season. Goats and pigs need more protection although, in warmer climates, goats too can sleep in a loafing shed."

Design for Feed Handling. Don: "After handling of the stock themselves, the most important aspect of a barn to the animal keeper is ease of handling feed and manure. In the Midwest, most barns are built with an earthen ramp leading up to the hay mow, usually in the center of the barn. This makes it easy to back a truck up to the haymow and unload hay and other feeds, which can be pitched down to the animals on the lower story as needed. Often feeders are arranged so grain can also be fed directly from the hay mow. Similar patterns of barns can be found all over the country."

Feed Storage. Store hay up off the ground and with a roof, tarp, or plastic sheet to cover it. Openly available grain feeds attract rats and mice and can result in foundering. Most barns are designed with a separate room for feed storage. Inside that, make your storage containers or areas as rodent-proof as possible. Good possibilities are *food-grade* plastic cans or buckets, or metal drums that have never held poisons. And they must all have lids! Lacking a true lid, you can make do with a piece of flat, sturdy wood held down with a big rock.

You can also protect your stored livestock feed by making the habitat uninviting for rodents. Carefully clean up any spilled feed. Piles of lumber and junk are favorite nesting places for rodents, so try to keep those cleaned up and off the ground. Similarly, if your chicken houses, etc., are constructed up above the ground, you'll eliminate the dark, moist, sheltered spaces under them that rats enjoy. And a couple of big, tough mouser/ratter cats will help too. You can also set traps.

Design for Manure Handling. Every animal creates manure, and all their manure has to be dealt with regularly. How will you get the manure out? If you're working by hand, plan for a downhill run from the barn to the compost pile. Don: "It's okay to carry it uphill to the garden. Composted manure is *much* lighter than fresh, wet manure. Your best manure-handling system depends on the species of livestock, your method, and your intended use of it. Cattle produce copious amounts of manure, which is sloppy and must be shoveled, hosed, or scraped away frequently. Horses produce drier manure but equally large amounts of urine, which must also be frequently dealt with. Goats and sheep produce small amounts of very dirty dry manure, which can be left to accumulate for a long time if they have sufficient clean bedding to sleep on. Pigs are very clean animals and will not drop manure in their bed area if there is room for them to walk 12 feet away from it upon arising."

See "Manure" in [Chapter 2](#) for more!

Fencing

A basic fencing principle is to get it right the first time. Be sure and put the fence exactly on the line if you and your neighbors (talk to them first!) agree on where that is. They may even be willing to share costs or labor. Otherwise, put the fence at least a foot inside your boundary to save a legal hassle. Find out if there are any county restrictions on fences, such as setback rules or height limits. Make the fence strong enough. If animals get

the idea that they can go through a fence, they're that much harder to keep in. In fact, once they've tested a fence and won, they're likely to ram their way through a fence that otherwise would have held them. Another basic principle is that the type of fence has to be tailored for the type of animal.

Don wrote me, "Fences can be used to fence animals in or out, to cross-fence pasture, to define spaces, for ornamental purposes, or even to use up rocks in a field. Construction of fences depends on their purpose and on the materials available. Common materials are barbed wire, woven wire, welded wire, electric wire, rails, slabs, milled lumber, stone, and combinations thereof. The overwhelming factor in deciding what type of stock fencing to build is the type of livestock to be fenced in or out. Cattle require very strong fences. Deer and goats need high fences; pigs and sheep, very tight ones. The old-timer's adage about building all fences 'horse-high, bull-strong, and pig-tight' applies only if you don't know what you're going to be keeping behind it, or if you have an unlimited source of labor and materials. It's far cheaper to build a 4-foot tall, 4-strand barbed wire fence for horses, a 4-foot high, 3-strand fence for cattle, a solid wood fence for goats, and a pen of welded "hog panels" for pigs, for example, than to try to build one fence that will do for all of them."

Here's the rebuttal from William F. McCamman, president of New Zealand Fence Systems, a guy who sells fencing for a living. He makes a good point and wants you to always have the best (though he isn't giving any away). "That paragraph advocates building a fence for only the animals you know you will have rather than the full range you might expect. It is very expensive and laborious to raise a fence height later. A dime saved now might well cost a dollar later. Using barbed wire for horses is very short-term economy until the veterinary bills start accumulating. Fence designs vary due to topography, animal characteristics, pressure on the animal, consequences of failure, and the owner's mental satisfaction."

FENCING BOOKS: For specific info on fencing for chickens, turkeys, goats, pigs, etc., see this book's sections about those animals. The latest and possibly greatest fencing book is *Fences for Pasture and Garden* by Gail Damerow (Garden Way, 1992), especially useful for goat people. Or see John Vivian's *Building Fences from Wood, Stone, Metal, and Living Plants* for complete how-to on every imaginable type of fence and hundreds of drawings and photos; *Build It Better Yourself*, edited by W. H. Hylton; G. A. Martin's *Fences, Gates and Bridges*; S. Schuler's *How to Build Fences, Gates; Walls, Fences, Gates and Walls* by Chamberlin and Pollock; *How to Build Fences and Gates* by D. W. Vandervort; *How to Plan and Build Fences and Gates*, edited by J. Barrett and D. Rutherford; *Fences and Gates, Walkways, Walls and Drives* by E. A. Proulx; and J. Russell's *Walks, Walls and Fences*. Pennsylvania State U., College of Agriculture, Cooperative Extension Service, University Park, PA 16802, offers *Smooth-Wire Tension Fencing—Design and Construction* by Mark Mummert, et al., which gives info on design and building of New Zealand-type fencing. The Small Ruminant Page at www.sheepandgoat.com/fencing.htm contains many links to publications on fencing, as well as to many fencing vendors.

FENCING PRODUCTS AND SPECIALISTS

Gallagher Electronic Limited: PO Box 5324, Frankton, Hamilton, New Zealand. For those New Zealand fences; 03-9308-7722; www.gallagher.com.au. They also have distributors in other countries; www.gallagherams.com.

Kencove Farm Fence, 344 Kendall Rd., Blairsville, PA 15717; 724-459-8991; 800-536-2683; www.kencove.com; farmfence@kencove.com; farmfence@kencove.com.

MaxFlex Fence Systems: U.S. Rt. 219, Linside, WV 24951; 800-356-5458; fax 305-753-

4827; www.maxflex.com.

Parmak Precision Electrical Fencing Products: 2000 Forest Ave., Kansas City, MO 64108; 800-662-1038; www.parmakusa.com.

Premier Fencing: 319-653-7622; 800-282-6631; 2031-300th St., Washington, IA 52353; www.premier1fence.com.

Southwest Power Fence & Livestock Equipment specializes in electric fence systems and solar-powered automatic gate technology: 800-221-0178; 830-438-4600; fax 830-438-4604; 26321 Hwy. 281 N., San Antonio, TX 78260; www.swpowerfence.com.

West Virginia Fence Corp.: U.S. Rt. 219, Lindsdale, WV 24951; 800-356-5458; www.maxflex.com.

Waterford Corp.: 404 N. Link Ln., Fort Collins, CO 80524; www.waterfordcorp.com.

Wellscroft Farm, New England electric fencing specialist; c/o David Kennard, 167 Sunset Hill-Chesham, Harrisville, NH 03450; 603-827-3464; www.wellscroft.com.

ABOUT ELECTRIC FENCES: Don: “If you have 15 or 20 acres of rich grass per cow, almost any kind of fence will do for cattle, as long as it’s stout and strong, 4 feet high, and visible to the cattle.” (Note: Don lives in the eastern Washington desert. Lane Morgan, who lives in the rainy Pacific Northwest coastal zone, says, “We have an acre per cow. That’s plenty around here.”) Don: “Most ranchers who keep cattle have found that electric fences work best. Cattle quickly learn to respect the fence, especially if rags are tied to it every 10 feet, so they can see it. Cattle don’t have very good eyesight, but after a few shocks, they’ll learn to avoid the area. It’s not a good idea to depend entirely on the live wire, though. If the juice is off for some reason, or a cow or bull breaks the wire, there will be nothing to restrain your animals from going wherever they please. It’s amazing how much damage even 1 cow can do in a very short time. Three or four strands of barbed wire strung with the electric wire can prevent a lot of grief. Use wooden posts set 8 feet apart, with the electric strand set about 3½ feet high, between the top 2 strands of barbed wire. Many ranchers build 2 fences—an electric fence set about 2 feet inside a stout barbed-wire fence. There are different kinds of electric fences and fence chargers, even solar-powered ones that require no electric hookup.

“‘New Zealand’ fence chargers seem to be getting more popular. They give a stronger shock than the traditional kind—too strong, some folks believe. I’ve never heard of one killing a cow, but I have seen one kill a mule deer. My personal feelings are that anything that can kill a large deer is not safe to have around dogs or children.” Lane Morgan adds, “New Zealand fencing has been very big around here in recent years, especially for horses, but lately I’ve been hearing about some problems. This is a windy area, and it turns out the tape shreds in the wind and shorts the fence. The shorts are very difficult to locate since the tape may still look intact.”

For specific instructions on building and testing an electric fence, see [Chapter 11](#).

WIRE FENCING—BARBED AND WOVEN: Don: “If you are not going to use electricity, you’ll do your cows a favor by using 9-gauge woven wire fencing. Cows sometimes develop the habit of scratching themselves on fence posts, and barbed wire can tear up their udders. It has even been known to entangle and kill horses. Woven fence with 12-inch wide rectangles is fine for cattle and horses but *not* for goats or sheep. They’ll get their heads stuck in the fence. Sheep are so dumb they may not think of pulling their heads back out, and they can starve to death! Goats will chew on the wire until it breaks and pokes holes in their cheeks. The experts recommend 6-inch mesh for goats and sheep.”

Posts: Don: "Posts of cattle fence absolutely must be the strongest you can afford. If you are using metal posts, use only the heavy-duty kind. They can be driven into most soils with a driver made by cutting the end off a truck drive shaft. The hollow shaft fits over the post, to be lifted up and slammed down repeatedly until the post is driven. Round wooden posts are not generally suitable for cattle. They are usually made from small-diameter trees, which have a high percentage of the soft heartwood. Use splits or other hard posts. Quartered sections of old telephone poles make adequate fence posts, though they have to be replaced after a few years."

"Just how long such posts will last depends mostly on how moist the ground is. In fairly dry soil, an untreated softwood post may last 3 to 5 years. The strongest wooden posts are triangular sections split from large diameter trees. Osage orange, black locust, catalpa, northern white cedar and red cedar will all last 20 years or more in average soil. In general, the softer the wood, the shorter the time it will last. Pressure-treated wooden fence posts, available in lumber yards or farm supply stores, cost about as much as metal posts but don't last as long. They look nicer, though."

Making Fence Posts. A "wedge" is a piece of metal shaped like an ax blade, flat on top—like a single-bladed ax head with no handle. Wedges are sharpened a little bit but not too much, because they tend to get stuck if they're too sharp. You need at least 2 wedges to make fence posts ("splitting rails"). Cedar is the most popular wood to make wedges from because it is wonderfully easy to split and is slow to rot. Cedar is a nice wood in general; it has a good smell and a pretty appearance.

Pick a point on the side of the pole, up toward the "top." Try to make that point a natural crack if there is one; there usually is in old wood. Tap the wedge in. Then drive it in with a sledgehammer as far as it will go. Take a second wedge and start driving it in where your pole still isn't split apart farther down the line. That will loosen up the first wedge and put it at the farthest point of the split from the second wedge (you're working your way from the top down). Keep going this way until you've finished splitting it.

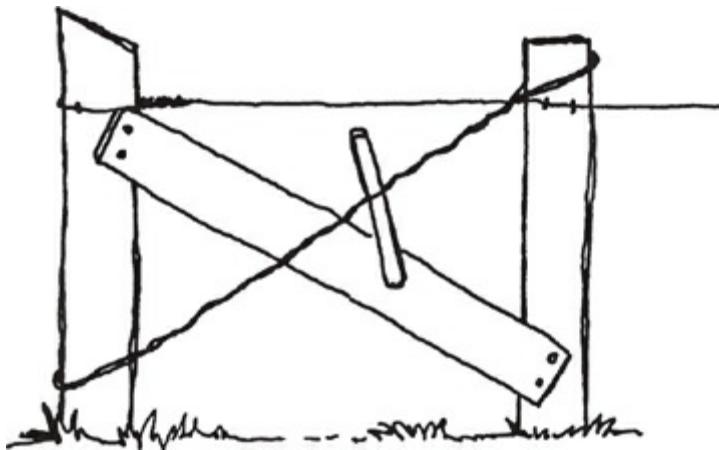

Another way to get fence posts is to start by felling the tree; long, straight pines are good. You want regular posts to be about 3 or 4 inches across, so that's what the diameter of your tree should be, because trees other than cedars don't split well. After felling, cut them across to be the length you want. For uprights, the length should be how high you want your fence to be plus how deep you want it to go in the ground. Corner posts need to be really husky: more than 4 inches in diameter is good. The poles to lay lengthwise can be longer.

Now you want to skin your pole. You smooth off all the knots and then strip away the bark. A flat-headed shovel is a good bark stripper. Hardwood doesn't need a preservative treatment, but softwood does. That's to keep bugs from lunching on it until your fence collapses in a heap of dust. So soak those poles for 2 months in a vat of used motor oil, and they'll last longer than you will. If you haven't got that kind of time, soak them in a mixture of pentachlorophenol and oil for a couple of days. If you have neither the time nor the money, use red fir, cedar, or black pine because they are the most rot-resistant. You'd get 15 years out of an untreated cedar post around here—less in a more southern or wetter climate. It also depends on soil acidities, and that gets complex.

STRETCHING WIRE: Back to Don: "Wires can be stretched tight with a ratchet fence stretcher, available at farm and ranch supply stores, or even by tying or chaining them to a tractor or pickup truck. The idea is to grab onto the wire several inches before it reaches the corner post, so there will be enough slack wire to wrap around the post and twist around

the tightened wire. Then go back and staple the wire loosely at each intermediate post. This supports the wire while allowing for future stretching and retightening.

"Woven wire fences can be stretched the same way, but you may need to use a couple of fence stretchers together. One way is to wrap the end of the fence around a board or short post and then pull the post with fence stretchers, tractor, etc. After stapling the fence to the corner post, the horizontal wires of the excess fence can be cut free with pliers and wrapped around the post and themselves. Fence pliers are very handy for dealing with wire fencing, but very heavy wire cutters and a couple of claw hammers make an adequate substitute."

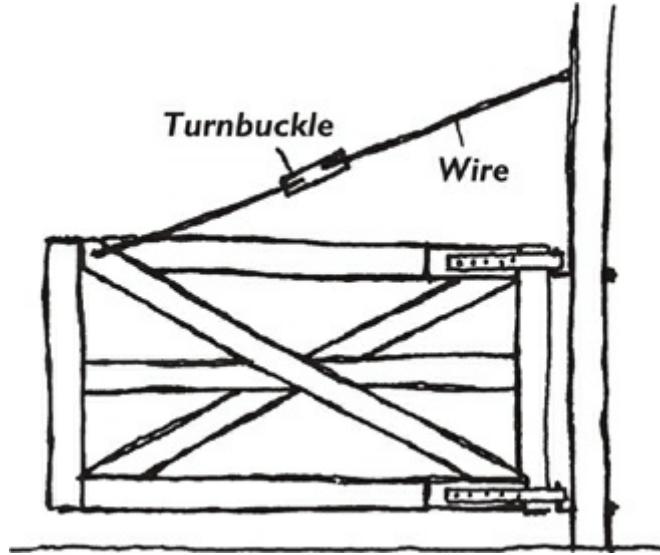

Bracing and Corner Posts. Don: "Wire fences for horses and goats need wooden rails at the top, or the animals will break them down and just walk over them. And any kind of wire fence needs special bracing at the corner posts. These should be the stoutest posts you can get. Used railroad ties in good condition make good corner posts. They are treated against rot and can be purchased for \$5–10. Stout as they are, they still need bracing. One way to do this is to brace the corner post on the diagonal, with a short post notched into the top of the corner post. The other end of the brace can rest on a flat rock on the ground. A variation of this, which I think is stronger, is to place the first line post 4 to 6 feet away from the corner post and notch the bottom of the diagonal brace into the line post near the ground. A double strand of wire is then wrapped around the top of the line post and the bottom of the corner post. A stick is thrust between the two strands, twisted tight, and secured. Protect the tops of corner posts from rain and snow by tacking sheet metal flashing over the ends, or at least cut them at an angle, so water will run off."

Wire Fence Upkeep. Don: "Since cattle like to rub against fence posts, the posts must be checked regularly and replaced when needed. A broken post can be jerked out of the ground by tying or chaining it to a horizontal post, which can then be used as a lever. Sagging wires can be tightened temporarily by crimping them into a zigzag with the claws of a hammer. Two framing hammers can be used to permanently tighten a strand of barbed wire. Hook the claws of one hammer over the line at one of the barbs, and use the handle as a lever to pull the wire tight, just like pulling a nail. While holding the wire tight with one hammer, use the other to pull the free end around the post and wrap it around the tightened strand."

GATES: Don: "The simplest gate for a wire fence is one made as a freestanding panel of wire, secured to the gateposts with removable loops of wire. The gate can be stretched to a reasonable degree by making it just a bit too short to reach. The bottom of the gate endpost can still be hooked in the bottom wire loop by leaning the endpost at an angle. The top of the endpost can be pried toward the gatepost with a short stick and attached to

the gatepost with a short length of wire. Even the shortest wooden gate is too heavy for normal hinges. The best kind of hinge for wooden gates is the kind that has a single metal loop on the gate and an L-shaped hinge pin that screws into the wooden gatepost. It'll last forever, and you can easily compensate for sagging gates by lifting the gate off and screwing the pins in or out. Metal gates are light and strong, last forever, are readily available in many sizes, and cost plenty. You get what you pay for."

WOODEN FENCES: Don: "Nothing beats wooden fences for keeping horses or goats. For horses, you need three or four 2×6 rails, equally spaced, with the top of the top rail 4 to 5 feet high, depending on the height of the horse. The top rail should be capped by a 2×8 rail laid horizontally, for strength. The horses *will* lean on it. Posts should be 8 inches in diameter or 6×6 square stock, every 8 feet. If you're going to spend this kind of money on a wooden fence, it's silly not to buy pressure-treated posts and top rails. They'll have to weather for a year before you can paint them, though."

"That's the ideal fence for horses, but few horse owners can afford that kind of expense. Peeled poles 3 to 6 inches in diameter will do fine for fence rails, if they are inspected often. Lumber mills sometimes sell 'slabs' (the outside portion of the tree, with the bark still on) really cheap. They look 'rustic' and may be plenty strong. Watch for thin spots, though. Trees work really well as fence posts. Nail the rails to the inside side of the post or tree with 20d nylon-coated sinker nails."

STONE WALLS: Don: "Much of rural New England is divided up into picturesque fields surrounded by stone walls. The walls, for the most part, began simply as something to do with the stones that constantly surfaced in the fields. The farmers had to haul them to the edge of the fields anyway, and building walls there served as a boundary and used up the rocks without having to cart them further. If you are cursed with such a field, you might adopt the same plan for dealing with the stones. I can't honestly recommend any other good reason for building stone fences."

For more on stone fences, see "Fencing" in [Chapter 8](#).

FEED

You'll either buy your animal feed or grow it. You can feed animals with live food that's growing in the field, such as pasture, or feed them from stored food such as hay and grain.

About Forage Crops

You can grow forage crops to feed animals in northern zones where you can't grow many fruits and vegetables. In practice, that means it's natural to eat a diet largely based on milk and meat (which your animals manufacture from the grass they eat) in the cold-climate places, where you can't grow enough vegetable-type foods to keep you going. Cheat grass, which grows on rocky hillsides (and is thus useless for vegetable gardening), is that sort of forage crop; there are much better ones. But cows can eat cheat grass in the spring and get fat. (Goats get abscesses from it, though.)

A reader named Tom asked me if any special feed or type of pasture was necessary for animals. The feed question is really complex. I've tackled it in the section on each animal in this book. For the most chemical-free food possible, the best economy, and a good feeling of self-reliance and the adventure of it all, it's nice if you can raise as much of your own animal feed as possible (as long as you have unpolluted ground on which to do so). The old-timers raised food for their livestock as well as their kitchen, and so can you, although some feed companies do their dangdest to discourage you from doing so, for obvious reasons. Animals raised on home-grown feed typically gain weight a little more slowly and give fewer eggs and less milk. This doesn't mean you're an abusive owner. It means you aren't pushing production to the max as a factory farmer would. The value you gain in self-sufficiency, reduction in cost, and healthiness of your product can more than outweigh that extra production.

For more info on forage crops, see Richard Langer's *Grow It!* (1973) and D. A. Miller's *Forage Crops* (1984).

VEGETABLE FEEDS: The old-timers extended the forage season in pasture by planting special crops that the animals would harvest themselves in the fall, when the grass started dying back, or that the farmers could feed to confined animals during the winter. In fact, the following foods, together with hay, were generally used where grain is now used in animals' winter diet: sugar and mangle beets (the mangle, or "mangle wurzel," also known as the "stock beet," is a very large, nourishing beet), marrowstem kale, thousand-headed kale, turnip, rutabaga, carrot, forage radish, Swiss chard, Jerusalem artichoke, comfrey, beets, kohlrabi, and parsnips. These should be fed in combination with hay.

If root vegetables are to be your animals' basic winter feed, plan to supply about 40 lb. per day to a milking cow, 3–4 lb. per day to a sheep. But the best diet is a combination of various vegetables and hay, since too much of one thing in the vegetable line, especially beets, can be bad for animals—even make them sick. Horses winter better on carrots than on beets, and most animals do better on turnips, carrots, etc., than on beets. You can feed root vegetables whole to pigs (though they like them best cut and cooked), but you should cut them into pieces (or even grate or pulp them) for other animals. Fresh beets tend to cause diarrhea, so store your crop at least 4 weeks before feeding and then ease into this diet. Never feed moldy or partly decayed roots!

ABOUT RUMINANTS: Of the common domestic animals, the cow, sheep, and goat are "ruminants." A ruminant is specially adapted to eat much food quickly and then go elsewhere to digest it. And it is an animal inside an animal, because it digests food in a private fermentation vat where microscopic beasties transform the food so that the ruminant can digest the cellulose. Every ruminant is alive because it's in lifelong symbiosis with the tiny digesters in its rumen.

Pasture

Ruminants are capable of being nourished by grasses, leaves, etc. Pasture is a perennial

grass crop, probably the most important use for grass. Tree crops and pasture are the two most underrated and overlooked ways to use land. Yet, compared to urban development and tilled soil, they are the two that are most protective of the soil and the environment. They both prevent erosion and enrich the soil.

Livestock growing on grass is a beautiful example of sustainable agriculture. The grass nourishes the animals. The parts of their feed that they can't use are excreted in a form that actually nourishes the grass, which uses the livestock's manure to help make more forage—and so on, year after year.

In the fall in more northern climates, the grass dies back and, during the months of winter, hay has to be fed. When spring comes, the grass grows again, the hay-feeding season ends, and the grazers can feast on that green stuff and get fat. But every pasture is different, and some are worse than others. Making a good pasture from a bad one or even from bare ground takes some effort. And it takes good management to maintain a proper animal/grass balance in order to avoid overgrazing and thus causing holes in that protective grass cover.

GRASS MAGAZINES & BOOKS: Here's the competition to factory farming techniques! *Graze* is a monthly publication with articles from and about graziers on pastured dairy, beef, sheep, hogs, and poultry. Subscription is \$30/yr; \$54 for 2 yrs. Free sample: 608-455-3311; fax 608-455-2402: PO Box 48, Belleville, WI 53508; graze@grazeonline.com; www.grazeonline.com. Another magazine focused on pasturing is *The Stockman Grass Farmer*, a monthly devoted to the art and science of turning grass into cash. It costs \$32/yr; \$50 for 2 yrs. To subscribe, or for a free sample, contact: 800-748-9808; PO Box 2300, Ridgeland, MS 39158; www.stockmangrassfarmer.com. They also sell great books with titles like *Pa\$ture Profit\$ with Stocker Cattle*; *Grass Farmers*; *Quality Pasture: How to Create It, Manage It, and Profit from It*; and *Paddock Shift: Changing Views on Grassland Farming*. Those are all by Allan Nation, founder (1975) and guiding hand at *The Stockman Grass Farmer*.

Other good grass books are Rebecca Lewis's *Making Pastures Produce* (Rodale Press, 1980); *Grass Productivity*, by Andre Voison (1988); *Why Grassfed Is Best!* by Jo Robinson (866-453-8489 or 253-759-2318; www.eatwild.com/); and *Holistic Resource Management*, by Alan Savory. David Schafer's new book, *Just the Greatest Life*, is available from him at 760 SW 55th Ave., Jamesport, MO 64648; 660-684-6035; info@featherman.net; www.featherman.net. (He also sells natural beef, lamb, chicken, and pork.)

American Farmland Trust provides info on grass-based farming systems plus many links at www.farmland.org. The American Forage and Grassland Council offers info at 800-944-2342; www.afgc.org. Another website with extensive info on raising animals on pasture is www.eatwild.com. Their site includes a state-by-state directory of pasture-based farms so you can buy meat, eggs, butter, or cheese from pastured animals just a pleasant country drive away! ATTRA's look at "Nutrient Cycling in Pastures" is at www.attra.ncat.org/attra-pub/nutrientcycling.html.

SEEDING PASTURE: If there's nothing left out there but brush and weeds, plow it up and replant to a good pasture mix of grains, grasses, and legumes. If there's something there but not enough, or if your land is hilly, don't plow it up to plant; just add new growth. To do that, plant in early spring, when the most bare ground is exposed. Go over it with a shallow-set disk and then broadcast seed, use a no-till drill, or just toss the seed out there in the spring, when raindrops have already softened the ground and future rain will

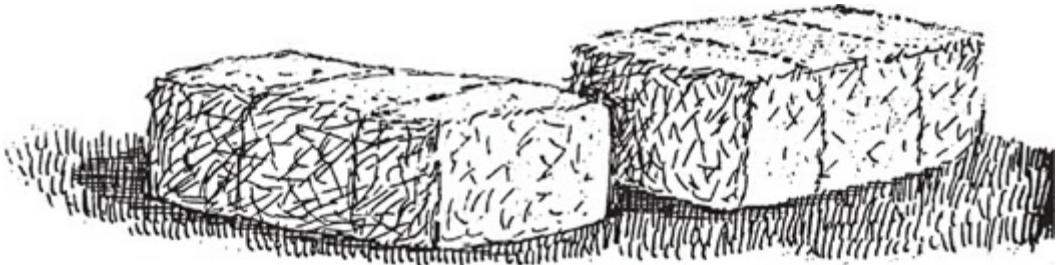

splash soil over the seed to cover it.

Pasture Seed Mixes. The most nourishing pasture should include legumes (clover, alfalfa, lespedeza) because grasses don't provide as much protein and sugars for the animals. Pasture needs a soil pH of 6.5–7.0 and some nitrogen to thrive. Usually folks plant a mixture: a few grasses, a few legumes. Usually a few kinds of weeds are in there too, and that can be a good thing, since the more kinds of plants in your pasture, as long as they aren't poisonous, the better balanced in vitamins and minerals your animals' diet will be. It is possible to seed in some additional desirable plants for a pasture without actually tearing up and reseeding the entire thing.

Choose very hardy plants that are well suited to your area's soil and climate conditions. Drive around and look for a beautiful pasture. Then ask the owner what's in it. It'll probably have some grasses and some legumes (clovers). Bird's foot trefoil is a good combo livestock pasture plant and ground cover because animals can graze it to the bottom, but it always comes back. Good legumes are vetch, sainfoin, peas, trefoil, alfalfa, and the clovers—red clover, white Dutch clover, yellow sweet clover, and subterranean clover (or "subclover"). Legumes, of course, build up the soil at the same time as they provide protein-rich food for the animals. Some farmers rotate periodically between grass and legumes, plowing up grass and planting legumes every 3 to 5 years for a hay crop or green manure, and then returning to a grass mix meant for years of pasturing. But Luane prefers a closely managed permanent pasture for economy and topsoil retention.

OF WATER AND PASTURE: This last spring we planted 50 acres to a combination of peas and oats. We mixed the pea and oat seed and planted it together. We were raising the mixture to be winter feed for the cows and chickens. Well, there was a terrible drought, and most of it never germinated. In August we were having to feed our cows hay to keep them alive because there was no grass. It literally didn't rain one drop all summer. The price of hay shot up from the normal \$45 per ton to \$80 and more per ton. When the rains came at last, in the fall, the field finally turned green. The seed hadn't died; it had just waited. But December is no time to make hay. You have to get your forage planted before the good spring rains have stopped coming and hope there will be enough summer rains to finish the job. Or irrigate.

HARVESTING PASTURE: Grass needs to be mowed occasionally for best health, but your grass-eating animals will accomplish that without any effort on your part. They'll also fertilize the pasture for you. Ideal pasture harvesting is done consciously and carefully: it's a planned, intensive grazing that maximizes your crop's forage-producing ability. Grass is the cheapest feed for animals that can live on it. Making the most of your grass as feed can mean the difference between an operation that goes broke and one that makes a profit. Expert grass farmers use controlled rotational grazing, which means they have their grassland divided into smaller paddocks of as little as 1½–3 acres, usually by electric fencing. Stock growers using rotational grazing keep a close eye on the grass height and frequently change their stock from one paddock to another as often as every day. (This also reduces or eliminates having to search for lost animals.) An experienced animal owner can pretty much look at the grass in a paddock and know how long and how well it's going to feed the animals. Move the animals after the grass is eaten but before it is overgrazed and its comeback ability is damaged.

NOTE: Pasture plants are most nourishing for the animal when they're fresh and green. That means spring pasture—or pasture that hasn't been grazed for a while, has gotten water, and has had a chance to renew itself.

Regular shifting of animals plus a relatively short grazing period maximizes the ability of grass to come back and make more. Grass needs to be left alone to grow for at least a month after having been grazed down. This is time enough for the root system to recover its health and be able to store enough food to be able to grow back quickly from yet another livestock feeding. Grass with healthy roots grows, on the average, $\frac{1}{8}$ inch per day. But if you let the animals keep it too short, the roots lose their recovery ability and can't manage that maximum rate of growth any more. As a stock grower, that costs you money because then your land is no longer producing the maximum amount of forage, and your animals can put on only as much weight as the amount of food they can get.

The number of animals has to be suited to the amount of grass. In a drought, you'll have to sell some grass eaters, because your pasture won't be able to feed as many as usual.

Another way to get the most from your pasture grass is to use more than one tier of grass eaters: use animals that clip it closer to follow animals that eat just the top. But don't let the grass get eaten down so close that its ability to recover is harmed. A third method is to keep the animals out foraging in the pasture as late in the year as possible before resorting to hay feeding. It might surprise you how long the grass and animals can keep each other going.

Pasturing Green Hay. Alfalfa is even better pasture for cows than grass if you can spare it for them. But don't start animals on alfalfa if they aren't used to it; they'll bloat. Wet alfalfa is the most dangerous of all! We've got that situation now: a whole field of wet—soaking wet for 3 weeks—alfalfa with a layer of bleached hay on top of it. My husband Mike says we'll just give up and turn the animals in there. But they aren't used to alfalfa—to say nothing of wet alfalfa. So first we must wait until it dries off. And then we'll let them in there for an hour, and for a couple of hours the next day, and so on until they get used to it. And we'll buy hay from somebody who had better luck with this winter's feed. If very many people had the kind of weather we did in haying time, the price of hay will be up this fall!

Hay

"Hay" means a harvest of grasses (carbonaceous hay) or legumes—such as alfalfa, clover, or peas. Hay is dried plant food, preserved to serve as a winter food supply for herbivores.

WINTER FEEDING: To winter an animal, you'll need a certain amount of food stored: the kind of food that's right for each animal, or a combination of such foods, and enough of it. For grass-eaters, "winter" means the number of days that the ground is covered with snow or that, for some other reason, there is no grass. But a summer drought may dry up all the grass and have you feeding hay in summer too, long before the snow comes. Or your pasture may be too small to supply enough grass for the number of animals you have. In that case, you'll have to supplement with hay even in summer.

HAY PLANTS: Plants are grown specifically to be cut and dried for hay. Red and white clover and timothy (both brought over by pioneers from Europe) were old-time hay crops. Those are still valuable, but now there are other good hay species. The best hay is green, with leaves on the stems. This green, leafy hay is great feed for any herbivore. Just what you grow (or buy) for hay depends ... Here are some possibilities.

Legume Hay. Best-quality legume hay is 12–14 percent protein. Possible plants to grow for legume hay are alfalfa, clover, lespedeza, peas, and vetch. The pioneers planted hay by scattering hay chaff as well as barn and haymow sweepings. Now you plant it by buying seed. You plant red clover or sweet clover at 10 lb. per acre. Weight per bushel of both is 60 lb. Ladino clover and white clover are planted at 2 lb. per acre but also weigh 60 lb. per bushel. But the most popular legume hay of all is alfalfa.

You don't need a big farm to grow good, high-protein alfalfa hay for your animals' winter feed. You can grow clover or alfalfa in your yard, as a garden rotation, or on a couple of spare acres. Just cut and dry well, and store under cover.

Plant alfalfa at 15 lb. per acre; weight per bushel is 60 lb. Here's my friend Stephen Scott on growing alfalfa for part of his pigs' feed: "If you plant a legume, you will be providing your pigs with protein. Protein supplements are the most expensive part of your balanced ration, so if you plant some legumes, you can eliminate the supplements. Alfalfa is a legume—capable of fixing nitrogen from the air. Nitrogen is the critical building block for the production of proteins."

"I have an Esmay seeder that I picked up from a rummage sale for 25 bucks. It is a push-type seed planter. It has an aluminum frame, two plastic wheels, and a little hopper for the seeds. You can get one from most seed catalogues, but they are quite expensive there. If you plant a very big garden it may well be worth the price, as it works well on almost all types of garden seeds."

"I plant alfalfa in early May, after I have worked the ground well. I plant it in rows about 10 inches apart. When it starts to come up, I go between the rows with my old high-wheel cultivator. Alfalfa grows slowly; it would be overwhelmed by the weeds if I didn't cultivate. Just for good measure I go through the patch a few times a year as needed and pull weeds in the rows. If weeds are not a problem in your fence, you can broadcast the alfalfa seed and rake it in with a garden rake. You will need about $\frac{1}{2}$ lb. seed per 1,000 square feet. You can buy small amounts of legume seeds from garden seed catalogs, but you can save money by buying the seed from places that sell whole bags of it to farmers. Usually they will have an open bag from which they will be glad to sell you a couple of pounds. The very best alfalfa seed goes for about 4 bucks a pound from a farm seed store; it will be about twice as much from the seed catalogs."

"I plant alfalfa in the field that the pigs will not be in during the year that I plant it. That is the case because the alfalfa plant will not be established and ready to provide much protein in the first year. It gets itself started and mainly grows the root system that it will need in order to provide grazing in the next year. If you have only 1 field, then alfalfa will not work for you [as a rotation forage crop for pigs]. But you can still harvest to feed to animals."

GRASS HAY: "Carbonaceous" hay means grass—not legume—hay. Native grasses provide good pasture but ordinarily do not grow luxuriantly enough to make good hay for winter feed. They also tend to be low in protein compared to legume hays. The best carbonaceous hay plants are probably bluegrass, oats, sudan grass, timothy—and any grass grain. If fed to animals, these hays always need a grain supplement.

Grain Stubble. You can cut (or pasture) the straw stubble that is left after grain crops are

harvested. It can be part of your winter feed for big animals. The straw provides roughage, which they need, but you'll have to supplement it with better feed because straw doesn't have protein, which they also need. If the grain is harvested with the seed heads on, and before the straw is all bleached out, it's a different situation.

Oat and Pea Hay. This is a mixed legume and grass (including grain!) hay. For winter hay we use part alfalfa and part oat and pea hay. We plant a mixture of oat and pea seed and then cut it for hay when it's grown up. It's very nourishing for the animals, and I like it because it has grain right in there for the cows and chickens. This year the chickens got in there and scratched around for their own grain all winter long and did fine. I didn't feed them this winter except for that, and they're giving me 15 eggs a day now, plus the ones being set on. Harvest mixed oats and peas just as the oats start to turn. If you wait longer, the oats will be too ripe and won't make good hay. Peas and oats are good protein, and the pea vines and oat straw are good roughage.

MAKING HAY: There isn't anything complicated to it: you make hay while the sun shines. Hay is just dried grass or other green leafy stuff that is food for animals. But it's really vital to have, because with hay you can keep your cows, goats, sheep, rabbits, horses—and chickens, too, if the hay contains some grain heads—alive through the winter. And the animals will be making milk, meat, and eggs for you during the time when vegetables and fruit don't grow. You can cut any grass for hay; in time of terrible drought, I've seen farmers get out and mow every open field an owner would give them permission to mow, trying to get something together to keep the animals alive through the winter.

Mike and a neighbor may hay all summer. Mike has a baler and Doug has a mower. They get our hay and Doug's, and then put up hay on shares all up and down the valley for people who don't, or can't, do it for themselves. When the hay has grown high enough again, it's time for the second cutting, and they go through all the fields making hay again.

So we've usually had plenty of hay for ourselves, some to sell, and some to trade. With the cost of machinery and everything else nowadays, you just can't afford to own everything yourself for one farm. So neighbors here trade machinery and labor, too. And they don't make a big deal out of what they're going to get out of it. It's more like a giving contest: "I can do more for you than you can do for me." It's a good game that works to the benefit of everybody, but it really baffles some people. They have notions of capital and labor and how they're supposed to be at each other's throats.

I've seen people come out here and be given a job more out of charity than because they were needed and then turn around and act vicious because they thought they got paid 2 dollars less than they should have been. Then they wonder why they couldn't find another job. The bush telegraph is almost as inexorable as credit companies' files for carrying ratings on people's characters. City people are used to anonymity, but that doesn't exist in the country. You are what you are, and everybody knows what you are—for better or for worse.

The important thing with hay making is not to let the hay get rained on. Cut the grass when it is tall, rich-looking, and green, before the stalks have turned real tough, and when no rain is expected. For the very best hay (the kind you can feed your cows and need no grain supplement at all), grow it on a well-manured field, cut legumes when they are beginning to blossom, and cure it as fast as possible.

Mowing. When you know there's a lengthy spell of hot, dry weather coming up and your hay crop is tall enough to be worth cutting, you come through with a scythe (see "Mowing" in [Chapter 3](#) for details) for small amounts of hay or a tractor-driven mower for

a big field. Or you can mow hay with a horse-drawn mower. To scythe hay, the old-timers had a special kind of cradle that put the hay in a windrow, which is a long pile of hay for drying. Their scythe was a steel blade mounted on a crooked stick. (Frequently sharpen the blade—that razor edge is important! And get rid of stones in the field so they don't ruin the blade.) In general, to put up more than an acre of hay, you'll be glad for a tractor-driven mower and a rake.

Here at Kendrick, Idaho, on unirrigated land, 2 hay crops is a good year. On irrigated land here in the river valley with plenty of good hot sunshine, I've seen an enterprising farmer down the Potlatch River harvest as many as 5 cuttings of hay off a single field. In irrigated country in California, where they grow hay year-round, they can get 10 crops. It takes both moisture and heat to make hay.

Raking. The cut plants are then left lying right where they have fallen. Or the cut hay can be gathered using a horse-drawn dump rake, which then dumps it in a windrow. Or it can be forked by hand up into piles or rows by hand to dry. It cures in the sunshine until nearly dry. Then you come back and, by hand or by machine-pulled equipment, rake the hay into windrows.

Drying in the Field. You let the hay lie in the sun for a few days until it has dried out (it doesn't have to be all bone-dry). You probably haven't got it safely dry yet if you twist a wisp of hay and it feels tough, if you break a stem and it feels tough, if you break a stem and there is evidence of moisture, or if you can scrape the epidermis off a stem with your fingernail. It is probably cured enough when the hay is acting sort of brittle, and there's no wetness when you twist a stem, and the epidermis doesn't peel off the stem when you scrape it with your fingernail. Then gather it up and get it under cover.

From the time you cut it until the time you can get it under cover, you pray that it won't rain. If it rains all the time, you can't harvest hay. You want rain when the stuff is growing, but when you are ready to harvest, you want sunshine. If you have good hot sunshine, you should be able to get your hay cut and out of the field in 4 days. Then it can rain again, and you'll be glad because that gets your next crop started growing. If you're rich and can afford a swather, you can harvest hay even more quickly. You could swath on a Monday and, if it's hot, you could bale on Wednesday.

The reason I'm moved to make these remarks is because this summer it has rained practically 3 weeks in a row (we normally have hot, dry summers), and our first hay cutting is ruined. If hay is cut and then lies on the ground in the rain (and you can't finish harvesting if it is wet), the rain washes out the color and a significant amount of food value. You'll have to wait again for it to dry out, and it'll take longer this time because it's lying in a mass on the ground. Instead of being nice and green, it then looks yellow like straw. Such hay is called "bleached," and it's no good. Even so, you've got to get it up off the field so the grass can grow back again. If you left it lying there, it would act like a mulch and stifle the plants underneath. So now we've got that bleached hay to get rid of—whenever it dries out enough so we can get into the field and work.

Moving Hay: The old-timers, after raking hay into windrows and curing it, loaded it with a pitchfork from the windrow into a wagon—literally “pitched” it up there—for moving to an outdoor haystack or indoor storage in the barn's haymow. Then they pitched the hay from the wagon into a big net that hung from a rope on the end of a derrick. Then they turned the derrick around and pitched it from the net into the haymow.

Baling. Baled hay is so much less work to move than loose hay. For a large field, you must consider hiring somebody with a baler to come and bale it. A baler picks up the cured hay from the windrows, presses it into a rectangular block, and ties the block firmly together

with wire or twine. Those bales then are dropped in the field. You'll have to come back to pick them up, load them onto something, haul them somewhere, and stack them there. There's a newer type of hay baler that rolls the hay into huge, heavy, round bales that are like mini-haystacks in themselves, each weighing about a ton. The stacks can be left in the field and used as feed right where they lie.

Hay Hooks. These are invaluable at haying time if you're working with 50-100-lb. bales. I've used them on untold hundreds, ever since I was a little girl. You'll soon get the knack of slipping that hook into the bale and lifting the bale wherever you want it, bracing the other end of the bale against your body.

STORING HAY: Gather up your dried loose or baled hay and pile it to make an outdoor haystack, or move it to the haymow of your barn. But be sure it's dry.

Of Damp Hay and Fire. Another reason for wanting your hay dry before you bring it in is that damp hay has a little trick of setting itself (and your barn) on fire by spontaneous combustion in a composting heat-up. Hay has this tendency if it is piled up in storage incompletely cured—that is, too wet. I know it doesn't make any sense that damp hay is more likely to catch on fire than dry hay, but it's true—heavy, leafy legume hays are more likely to do that to you than is grass hay. Stacked hay (or unthreshed grain) makes heat in its early stages of curing.

To get an idea of how hot your stored hay is, push a 4-foot wooden stake deep into the stack but still reachable from outside. Leave for a while. Then suddenly pull it out and feel the inner end of it. That will give you a sense of the temperature.

Bale Storage. For bales out in the open, use sturdy plastic or tarp; tie it firmly down so it doesn't blow away. Unprotected hay is likely to mold. To get the bales off the ground, stack them on crisscrossed boards to allow some air circulation under the bales.

Making a Haystack. Haul the hay from your field to the place where you're going to build your stack. Now create a haystack that is at least 12 feet tall, with a diameter at the base of around 14 feet or more. The general shape is round at the base and as conical as possible at the top. The idea is to build a pile so dense and so conical in shape that although the outer layer will probably be ruined by weathering, from a few inches on in, the hay will stay green and delicious for your livestock.

FEEDING HAY: The best hay for horses is what's left over after you've fed the other animals, like cows and goats and rabbits. That's because horses can get by with almost anything, but the others can't. Horses even like timothy hay. But don't give them moldy hay; that gives them a condition called "heavey horse." Milk cows won't hold up so well on grass hay, and goats and rabbits need good green alfalfa. Hay gives cows 2 important foodstuffs, protein and roughage. Protein feeds them, and there's lots of protein in alfalfa and pea hays (not so much in clover hay). And they need roughage, provided by the grasses or stalks, to make their systems work right. Alfalfa hay is good hay because it has both. If you're feeding a low-protein hay like clover or grass, then you need to supplement that feed with grain to supply the needed protein.

Silage

Crops for forage (livestock feed) are preserved by either drying (hay) or ensiling (silage). I'll take a time-out here to tell how you can salvage a crop that will never get dry by making it into silage. There are parts of the country where during many years, grains never get dry enough in the field for normal curing. There are occasional years in other areas where that happens too. If it does, the grain can't be saved for people food, but it

can be salvaged for livestock feed by a natural fermentation (and preservation) process called “ensiling.” Grain silage is a sort of hay-based sauerkraut. It will smell awful and be a disgusting brown color. And your animals will love it and survive the winter on it.

MAKING SILAGE: Start with any moist green plants: grains, grasses, legumes, hay mixtures ... But not too moist. To reach the ideal dampness for a non-corn silage, wait to harvest until the leaves and stems are wilted and limp-looking. You can make it from any or all parts of the plant—including the roots, if you want to take the trouble to pull them out. To make good silage, the green stuff must be well compacted and stored in a dark, confined, airtight container. Under those circumstances, it undergoes fermentation, creating organic acids that preserve the silage as long as the container is airtight.

Chop. To speed the compacting and fermenting, chop or grind the plants. Inch-long sections are ideal. You’re making salad for animals.

Moisture. If the chop is too dry, you need to add water to produce the bacterial fermentation. But usually the plants are plenty moist, unless they’ve been harvested after a frost. If corn is let dry on the cob, right on the plant, and then the whole thing is dried, pulled up, bundled, and made into silage, it will need moisture. Chop the corn, mix it with some water (and possibly also stock-grade molasses), and then let it ferment.

Too much moisture is also a problem. Too much water can cause a partial failure of the preserving process, yielding bad-smelling, poor-quality silage. At worst, there must be a hole in the bottom of the sack or a drain in the bottom of the silo to allow excess liquid to run out. For good silage, the greens or grains need to be damp but not submerged in liquid. If you drain, then close the hole to keep out air.

Airtight Storage. To make small-scale silage, pour that chop into plastic sacks, packed in as tightly as possible. For large-scale silage, you put the chop into a giant plastic bag that looks like a huge sausage casing or into a special building made of hollow tile, concrete blocks, or reinforced concrete, or into a glass-lined steel cylinder called a “silo.” To make large-scale silage without the special building, you can use a trench or pit in the ground called a “pit silo.” Simply bulldoze a ditch, put the silage in there, and pack it down as tight as possible. If there’s no cover, the top foot will spoil. It helps to cover any silage pile with plastic.

The fermentation process that preserves this feed will occur only if all the oxygen is used up by the fermentation process and no more oxygen can get in. So when packing,

avoid air pockets and pack as tightly as possible. The silage will pack tighter if you pack a large amount over several days, giving each layer time to wilt and settle before you add another one. If air gets in, an equivalent amount of the silage will be spoiled. (You can still use spoiled silage as organic manure.)

CAUTION: *The gases that accumulate in a silo can be fatal to breathe. Operate the blower for a few minutes to remove them before entering the silo.*

FEEDING SILAGE: Silage that contains grain is a more nourishing feed than silage that doesn't. Supplement a silage diet with some form of protein (a dairy product, good alfalfa hay, commercial protein concentrate, or some such), because that's one thing silage is comparatively short on.

Of Grain and Grain Sprouts as Food. All the grains are good food for both human and beast, although some need to be husked or ground for better digestibility. Baby poultry need small cracked grain at first, like what you could make in your blender, but they can manage larger grains within a few weeks. A livestock feed of half wheat and half corn is great. All the grains will sprout. The best of the old-time farmers regularly fed some sprouted grain to all their livestock in wintertime. Do that and you won't need to use "all-vitamins-included" commercial feeds! (See [Chapter 2](#) for more on sprouting.)

Animal Feeds You Buy

For every animal you are feeding, you can go one of three routes:

- Go to a feed store and buy pre-mixed rations.
- Go to a feed store and buy foods that you have them mix, or mix yourself, to the formula of your personal choice.
- Raise your own feeds for your animals, making your own choices about what to grow and what proportions to feed it in.

FEED MILL FEEDS: The good thing about these feeds is that they are assembled according to formulas devised by expert animal nutritionists, and all feed elements the animals could possibly need are present in ample amount. The bad news is that although people doctors and, yes, animal doctors too must write a prescription if they want to administer drugs, feed mills have no similar restrictions. Thus animal feed companies can put into the feed whatever antibiotics or other drugs they choose, in whatever amount they choose. There is no supervision of what they put in. They have a huge loophole, and they use it.

Because animal antibiotics and people antibiotics are exactly the same drugs, this is a serious problem. Every factory farm that is feeding antibiotic-laced feeds year in and year out is potentially breeding yet another antibiotic-resistant supermicrobe. These bugs then can sicken humans, for all too many human diseases have started by crossing over from animals (most recently, the AIDS virus), and this potential will always be there. Low-level, permanent antibiotic drugs are most commonly used (as of 1993) in the feeds for poultry and for feed-lot cattle (not cows/calves on grass). Drugs are used not only because they keep the cows well but also very much because animals on an antibiotic diet grow faster and larger. That side effect makes feeding antibiotics profitable to the grower.

But I think that antibiotics should *never* be given to animals as a routine lifelong or long-term dietary supplement. Instead the animals should be raised with such a nourishing diet and healthy environment that they are able to naturally resist disease. And farmers should do without the extra growth caused by the antibiotics. If such an animal actually does get sick, it could be treated; if there is a risk of transmission of the illness to the herd, the animal could be briefly given a preventive treatment. But that's it.

Just recently [1993] a U.S. senator introduced a bill calling for regulation of the feed mills' practice of adding drugs to animal feeds. It didn't pass. He'll try again. This is much-needed legislation. I hope he receives more support next time!

FEEDS GROUND TO ORDER: With these, you buy the feed ingredients you want and have them mixed and ground to order. This way you can include what you want—and omit what you don't want. Shawn Trumble of Ionia, MI, wrote me, "We try to stay as far away from chemicals as possible. The feed store can never understand why we have our feed ground with no antibiotics or other strange stuff in it! We do, however, vaccinate for everything we can. We figure we're money ahead!"

Growers who are striving to produce certified organic meats are now looking for organic livestock feed suppliers. They need grains that are organically grown in their feed mixes with no antibiotics, growth promoters, or hormones of any type. ATTRA's list of such feed suppliers is at www.attra.ncat.org/attra-pub/livestock_feed.html. For example ...

Buckwheat Growers have a farmer-owned cooperative that grinds and mixes alternative grains as feed for livestock: 218-631-9212; 206 Aldrich Ave., PO Box 492, Wadena, MN 56482; www.buckwheatgrowers.com.

Modesto Milling: 209-523-9167; PO Box A, Empire, CA 95319; www.modestomilling.com.

Organic Feeds.com: 800-767-4537; 570-374-8148; fax 570-374-2007; info@kreamerfeed.com; www.organicfeeds.com.

Organic Unlimited is a NOFA-NJ certified feed mill: 610-593-2995; fax 610-593-2155; PO Box 238, Atglen, PA 19310; www.organicunlimited.com.

Petaluma Poultry Processors: 800-556-6789; 2700 Lakeville Hwy., PO Box 7368, Petaluma, CA 94955; www.petalumapoultry.com

Valley Ranchers: 800-354-4503; 5611 Peck Rd., Arcadia, CA 91006-5851; www.chinovalleyranchers.com.

Willow Brook Feeds, 707-795-7190; PO Box 750818, Petaluma, CA 94999.

ANIMAL DOCTORING

Ask neighbors or your vet what diseases are prevalent in your area so you can take preventive measures or be on the lookout for the ailments. Keep your animals well by providing good living conditions, giving whatever immunization shots are needed in your area, and checking on them daily.

SOURCES OF MAIL-ORDER MEDICINES AND SUPPLIES

Jeffers Vet Supply: 334-793-6257; 800-533-3377; Box 100, Dothan, AL 36302; www.jefferspet.com.

Nasco Farm and Ranch offers general equipment, including dairy and A-I supplies: 920-563-2446; 800-558-9595; fax 920-563-8296; 901 Janesville Ave., Ft. Atkinson, WI 53538; www.enasco.com.

Omaha Vaccine Co. offers everything for pets (dogs, cats, birds), and for horses and large animals (not just vaccines); 800-367-4444; fax 800-242-9447; 11143 Mockingbird Dr., Omaha, NE 68137-2332; www.omahavaccine.com.

PBS Animal Health offers thousands of products for pets, livestock, and horses at

everyday low prices. Free catalog: 800-321-0235; fax 330-830-2762; 2780 Richville Dr. SE, Massillon, OH 44646; www.pbsanimalhealth.com.

Spalding Laboratories sells beneficial insects for fly control! Call or write for fly or flea control catalog: 888-880-1579; fax 866-738-9632; 760 Printz Rd., Arroyo Grande, CA 93420; www.Spalding-Labs.com.

UPCO sells pet supplies of all kinds and wormers for some farm animals. Free 200-pg catalog: orders 800-254-8726; fax 816-233-9696; inquiries 816-233-8800; PO Box 969 (3705 Pear St.), St. Joseph, MO 64502; sales@upco.com; www.upco.com.

Valley Vet Supply offers wormers, calving supplies, sheep and pet supplies. Your choice of the 72-pg free Equine (horse), Pet, or Farm and Ranch catalogs: 785-562-2484; 800-419-9524; PO Box 504, Marysville, KS 66508; 1118 Pony Express Hwy (East Hwy 36); www.valleyvet.com.

Wiggins & Associates offer 3,000+ items of international vet and animal care supplies: 503-667-0716; fax 503-667-4701; 800-600-0716; 503 SW Victoria Court, Gresham, OR 97080-9265; webmaster@wigginsinc.com; www.wigginsinc.com.

HOME VETTING Books: Most books about livestock have a vetting section. *Animal Husbandry and Veterinary Care* by Guy Lockwood, DVM, and *The Merck Veterinary Manual* by Merck and Co. (1986), are especially useful. *Handbook of Livestock Management Technic* by Battaglia and Mayrose (1981) covers procedures, not diseases, and is very professional, but usable by an amateur. Rural Bookstores carries *Cattle Lameness & Hoof Care* by Roger Blowey; *Horse Foot Care* by Doug Butler; *How to Be Your Own Veterinarian (Sometimes)* by Ruth B. James, DVM; *The Lame Horse* by James R. Rooney, DVM, etc.: 319-362-3027; fax 931-268-5884; ruralheritage.com. *Keeping Livestock Healthy* (revised/updated 4th edition) by N. Bruce Haynes, DVM, focuses on prevention and covers nutrition, housing, and care, plus livestock disease and treatment (Storey Books, address in [Chapter 1](#)).

The Complete Herbal Handbook for Farm and Stable by Juliette de Bairacli Levy pioneered herbal veterinary medicine. First published in 1952, now a classic in its field, it has been revised, updated, and enlarged. The American Holistic Veterinary Medical Ass'n does "holistic veterinary medicine, acupuncture, chiropractic, herbal medicine, homeopathy, nutritional therapy & other complementary or alternative modalities." The website contains listings of manufacturers, practitioners, publications, suppliers, links, treatments, etc., none guaranteed: 410-569-0795; fax 410-569-2346; 57 Kensington Pkwy., Abingdon, MD 21009; www.ahvma.org; or www.altvetmed.org.

Common Home Vetting Procedures

The most important is the daily lookover you give your animals. You get to know who they are and how they are. Then your observation and gut instinct will tell you when something isn't right.

GIVING SHOTS: Practically everybody who's any sort of a farmer gives their own shots. It is cheaper and more convenient. You can buy vaccines in bulk from vet suppliers that specialize in mail-order business to farmers. But it's better to buy from your own vet or vet supply center because of all the free advice you'll get with your purchase and the promptness with which you can get it home. Another disadvantage of mail-ordering vaccines is that there's no way to know in advance for sure who is going to be sick with what. You can also get needles, antibiotics, and immunizers from your vet or supplier.

Combiotic is a veterinary antibiotic that will store in your refrigerator and is a good thing to have on hand, and it keeps for a few years anyway. Sick animals that need an

antibiotic get shots—usually one a day for 3 days, or more if necessary— $2\frac{1}{2}$ to 3 cc. for a baby calf. Penicillin and its descendants are very precious stuff for man, beast, and even insect. (There's a variety of Terramycin in an edible powder that's for bees.) Boil your needles between uses. Plastic needles can be boiled too.

Filling the Needle. Peel off the little foil cover in the middle of the metal cap on the medicine bottle. That exposes a rubber area. Just force the needle point right through the middle of the rubber into the bottle. (Turn the bottle upside down.) Force the air out of your needle before you put it in the bottle by pushing the plunger clear down. Fill your needle with as much as you need, measuring by the calibrations on the body of the needle as you pull back on the plunger. (If you accidentally pull it all the way out, you have to start over.) Pull the needle back out of the bottle. Look at it to make sure that you don't have air in it. Squeeze a drop out of the end to make sure. Air inside a cow is unhealthy.

Bobbi McCollum, a Pietown, NM, nurse, wrote me, "When you pull medicine out of the bottle, do this first—draw plunger back to where you want to fill and inject an equal quantity of air into the bottle whose medicine you're removing. If you don't, you create a vacuum in the bottle. I assisted in a surgery of glass removal from a nurse who had had a bottle shatter in her face for just this reason."

Fill your needles on the site. Don't let children carry them with bare tips. I've had the experience of falling with a needle in my coat pocket. It rammed right into my innards. I was lucky it wasn't an eye. So get your animal ready first; then get the needle.

Sticking. Cows don't like shots any more than you do, and they have a lot more fight. Lock their head in a stanchion with the lure of some grain. Hobble or tie at least one hind foot very securely. With goats you can have someone sitting on the head and someone on the behind; same for a calf. If your cow isn't gentle and won't come into a stanchion, you need the kind of squeeze chute used for loading cows (a tight corridor that can be locked off in front of and behind the animal so it can't go anywhere). Or you will have to rope and tie it, unless you're so expert that you can give a shot practically on the run. (The needle is liable to bend or break out.)

Find a bulge of pure muscle in the front shoulder or rear thigh. Don't stick into a bone. Aim that needle right in the middle of the muscle. You won't have to jab as hard as you think—the needles are really sharp. The hard thing is to get the plunger pushed carefully all the way down and the needle removed if the animal is carrying on like crazy. But it may stay calm. Lane Morgan says, "I've never had trouble giving shots to cows or horses. When I was a kid the vet taught me to punch the horse 3 times on the chosen muscle and jab in the needle on the third punch. Usually it takes me several more punches to get up my nerve. Maybe the punch is a local anesthetic because they usually don't even twitch. With cows I do the same (in a stanchion), and it has worked so far."

NOTE: Don't let a needle break off at the neck. If you do, you'll have to get the needle out of the cow to prevent it from bleeding through the hole in the needle.

FEEDING A PILL: Cow pills seem huge. Here are the basics for giving pills to calf, cow, goat, or horse. For a calf, have somebody help you hold it. For a cow or goat, put it in the stanchion. A good horse should just stand there and accept anything, but you may need help. Push your fingers into the mouth, up at the corner where there are no teeth, and the animal will open up the teeth part. (You open a horse's mouth to put the bit in the same way if it won't just do it for you.)

Put one arm firmly around the neck and, with the hand you've got in its mouth, just push that big bolus pill right down the animal's throat hole as fast as you can. Don't worry about choking it. You won't. Don't worry about making it uncomfortable. If the animal is

sick enough to need the pill, a moment's discomfort is unimportant. When you think the pill is shoved down far enough, pull your hand out and with both hands try to hold the animal's mouth shut.

Bolus Gun. From Lane Morgan: "In my wimpy opinion, you'd have to be nuts or desperate to give a cow a pill without a bolus gun. You stick the pill in the slot at the end of the plunger and then push it down the beast's throat. Use the nose holder to keep her head pointed up until the pill is swallowed. We've had 3 milk cows. Two have been Holstein/Hereford crosses—bigger and not as docile as our one sweet little Jersey. I could dose them myself with the bolus gun and nose holder. Without it I wouldn't want to try. If you have two people, you can substitute someone's fingers for the nose twitch."

Down or Out? Now the animal will try to get the pill up and spit it out. One of 3 things will happen. It will either swallow the pill. Or it will burp it up, chew a moment, swallow half of it back down (that's why you're holding the mouth shut), and spit out the other half when you finally let the mouth open. Or it will spit the whole thing out. If it spits out half or all, you simply have to start again and try to poke it down farther this time, over and over, until you finally get that pill down your animal. The usual beginner's problem is not poking it far enough down. That's one of the reasons that a bolus gun is so helpful.

ELECTROLYTE DOSING: Lane Morgan says: "If you're raising a lot of calves, especially bought calves, I think it's worth it to buy the rig for dosing them with fluids. It has a bottle that you fill with your electrolyte solution or whatever and hang from something high. That's attached to a hose that you put down the critter's throat. The hose has a clamp so you can release the fluid when the time is right. All the parts are easy to sterilize and reuse. Of course, you could make your own. The point is to have something that works with minimum struggle and maximum cleanliness. I brought a far-gone scouring calf back from the brink with one of these, so I'm a believer. One saved animal will more than pay for it."

BODY TEMPERATURE: *Use a vet thermometer with a string or clip, or tie a string on a drugstore thermometer if you don't want to go in after it, because they tend to get sucked in!* You put the thermometer up the animal's rectum, just like you do with a baby. A vet thermometer comes with an attachment so you don't lose it into the animal. Or use a baby thermometer with your version of the attachment.

The usual rectal temperature of a goat is 101–102°F. For a calf it's 98–102.5°F; for a cow it's 101.5°F, but can range from 100.4–102.8°F. normally. Sheep temp is 100.9–103.8°F. A pig's is 101.6–103.6°F. Rabbits are normally 102.5°F. The normal body temperature of any baby poultry is 102–106°F. For any adult poultry in the daytime it's 107.5°F!

Managing Livestock Reproduction

DEFINITIONS

Freshen: To give birth and start milk production

Gestation: Pregnancy

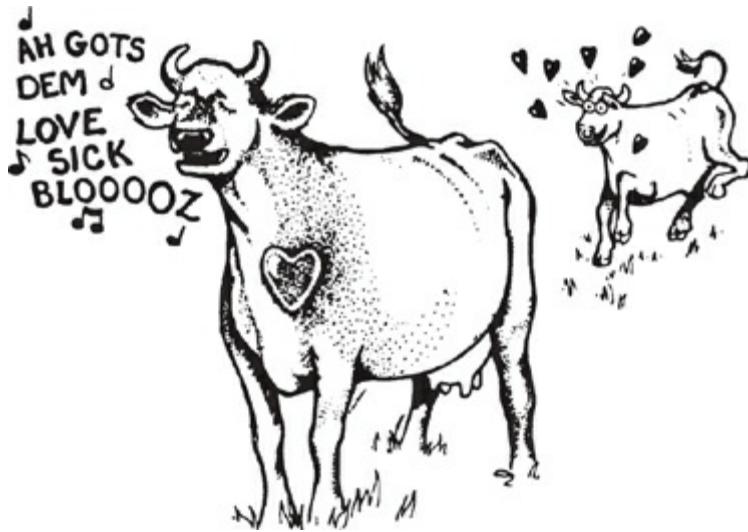

In heat, in season: When the female is ovulating and will stand still to receive the male and get bred

Service (v.): To breed an animal; to get her pregnant

Settled: Pregnant and out of heat

Spring: When the lips of the vulva swell, a sure sign that the birthing is coming

Udder: Her "breast" milk bag

HEAT PERIODS: A mare (female horse) stays in heat for 2–11 days, usually around 6, and comes in about every 22 days. She will be in heat again in 3–15 days after giving birth to a colt. A sow comes in heat again 1–8 weeks after pigging (which means to have a litter of babies). A ewe (female sheep) comes in heat for about 35 hours every 16 days. A lady dog will stay in heat for 9 days, more or less, and a cat can stay in even longer. After a large animal is bred and out of heat, she is said to be “settled.” She won’t feel that good again for a long time.

ARTIFICIAL INSEMINATION (A-I): A-I enables you to breed a cow when you can’t manage or don’t want to provide a bull. Instead, the cow is given bull semen through a metal tube while she is in a chute. Ask around to find somebody in the A-I trade in your area. Or ask the nearest vet; he or she will know for sure. Or take a course and learn to do it yourself!

GESTATION PERIOD: A “gestation period” means how long an animal is pregnant before giving birth. People take about 9 months. These periods vary somewhat, but in general, a cow will calve 285 days from her date of service, a goat will kid 151 days after, a mare will foal 336 to 340 days after, a sow will pig 112 to 113 days after, a ewe will lamb 150 to 152 days after, a dog has her litter 60 days after, and a cat has hers 64 days after. In other words, a mare bred on September 4 would be due to foal on August 7 of the next year. A sow bred on September 4 would be due to pig on December 25.

HELPING WITH BIRTHING: This is a delicate matter where experience means a lot. If you pull a baby, such as a calf, out too fast, it can turn the womb inside out, which is very serious and requires vet treatment to keep the cow from dying. It’s best if nature can take its course unaided. However, sometimes help is needed.

The moment when the baby’s head and shoulders push out is the time when tears are most likely. If you are pulling to help the baby come out, *pull only very gradually* to prevent or minimize tearing. And don’t get involved too early, before cervical dilation is complete, because that can cause tearing too. Don’t pull on both protruding legs at once. Pull first on one, then the other. This allows the shoulders and hips to move out one at a time instead of both at once, making the baby less wide, so it will come out more easily. A calf that is coming out backward, rear end first, may be a hard delivery.

CARE OF NEWBORN’S NAVEL: For the offspring of large mammals such as pigs, goats, sheep, and cows, the baby gets its navel cord coated inside and out after birth with iodine. There’ll be a few inches of cord hanging under the animal’s abdomen. An infection from germs that entered through the navel is prevented by grasping the baby firmly while it is lying on its

side and dipping that end of the cord inside a bottle of iodine. Then tip the bottle up against the baby's tummy so that some of the iodine runs up into the center of the cord. For best protection, this should be done within minutes after birth. To be safest, do it again 2 days later.

VACCINATIONS: This depends on the kind of animal and what diseases you have in your area. Ask a livestock-raising neighbor or a local vet. We give all our calves immunity shots. Much as I hate to stick a needle in anything (I really have to pray hard to get the courage), it's better than seeing them sick.

Once I didn't practice immunization of my children. After almost losing a child to whooping cough, I've totally changed my mind on that issue, and now my babies get shots against diphtheria, tetanus, and whooping cough (the famous DPTs); the oral medicine against polio; and the 3-in-1 against hard measles, German measles, and mumps just as soon as the doctor allows.

Now it makes me so upset to see advice in otherwise sensible and useful books and newsletters telling women that immunization is more risky than the disease. That's totally false! And it makes me furious to read that for whooping cough, you're supposed to give a "decoction of garlic and thyme" and "apply clay poultices on the back of the neck, wheat bran-climbing ivy poultices on the solar plexus," etc. What baloney! Absolute, total baloney! I know these writers never had a child with whooping cough, or they'd have offered more realistic advice. How irresponsible of them to presume to give advice that's not based on experience to trusting young mothers faced with the true risk of their child getting a desperately serious disease.

What you do for whooping cough is give up peace of mind and sleep. Your child of any age—infants can get this!—will have a literally life-threatening coughing attack, desperately battling to dislodge the constant dangerous buildup of the most thick, copious, ugly masses of phlegm you can imagine, every 8 to 18 minutes, day and night, for the next couple *months*—and longer. The child can drink light liquids like 7-Up. There won't be much other eating going on because the constant battle with phlegm predisposes to vomiting, though you have to try to get food down. But milk curdles the phlegm and makes it worse. You have to be present for every coughing attack to get the child sitting up and leaning slightly forward so the exhausted victim can get the phlegm out of their mouth. Literally scoop and pull the long strings of phlegm out of the child's mouth with your fingers if the child is choking on them and is unable to get them out without help.

There is no medical treatment for whooping cough, even in these modern medical-wonder times, although perhaps intravenous feeding could help. Once the child has the disease, all you can do is practice unending vigilance and tender nursing until the next spring, when it will finally completely go away. You'll need somebody to bring you whatever you need because you'll have to stay constantly at home with the sick child until the disease has run its course. You cannot possibly leave even for a moment. It's extremely contagious, so you'll have to practice quarantine. If a medical person knows your child has whooping cough, they will insist that the child be hospitalized, even though they have no treatment. With luck and faithful nursing, in or out of the hospital, your child will live. But not all do. The younger they are when they get it, the more risky it is for them.

Nor is measles a routine, harmless disease in the way that chicken pox is. Measles can have horrible results: brain damage, deafness, blindness, etc. Mumps can result in permanent male sterility. German measles can result in a dead or brain-damaged baby if you're pregnant at the time. When I was young, polio was the mysterious scourge of the summer season, and I personally knew people who died or were heartbreakingly crippled

from it. I can't imagine why anybody would invite these illnesses upon their child and themselves for the sake of avoiding the so-called "risks" of immunization, which are something like 1 in a million. Nursing my 14-month-old baby Danny through whooping cough was one of the most terrifying, exhausting—and instructive!—experiences I ever went through.

The technology of immunization is not witchcraft. If this book could be long enough and you took time to get the lab tech training and could afford the lab equipment, you could be told how to make and administer vaccines. Pasteur invented the process way back in the 1800s and began saving lives right away, vaccinating against rabies and the scourge of smallpox.

Well, back to animal immunizations. Around here newborn calves get 2 cc. of vitamin A and D solution and 2 cc. of Bose (the immunizer against white muscle disease) as soon as possible after they are born. At 3 months they each get 5 cc. of black leg vaccine.

TEACHING BOTTLE DRINKING: To give a bottle to a resistant kid or calf or other young mammal who doesn't know what it's supposed to do: Force its mouth open. Put in the nipple. Hold its body to prevent it from backing away from you. Once the nipple is in, hold your hand around the sides and bottom of its mouth to prevent it from spitting it out. Once it gets some swallows of good milk, it'll get the idea. Kid goats are easier to bottle-break than calves.

Castration and Dehorning

REASONS FOR CASTRATION: Castration is worth considering with sheep, pigs, or goats and almost unthinkable with calves and horses unless you specifically want to use a male for breeding. There are good reasons for castrating.

Aggression. The following section focuses on cows, but the same principles apply to other large species. (And if you think human males aren't aggressive, just read a history book—or the newspaper. Or study anthropology. One study of bones from a dig found that those of females had 25 percent more fractures than those of males. The conclusion was that the prehistoric ladies had suffered those injuries at the hands of their not-so-gentle men. Thank God we're more civilized now.)

Bulls have very reckless, aggressive instincts and the size to easily do harm. But even ram sheep and buck goats have hurt people. The male is said to be willing to risk itself at the slightest provocation. I got a letter only a couple of weeks ago from a friend homesteading in Mexico whose 8-year-old boy was run down by a Charolais bull that escaped from his pen. The boy's leg was broken. The list of animal owners who've been harmed, even killed, by uncut (not castrated) male animals is tragically long.

Bulls with horns are even more dangerous. Horns and testicles are no joke when your bull calves are in the alfalfa and you are trying to chase them out before they bloat themselves to death. The next thing you know they are taking the whole thing wrong and have decided to charge you.

The reason the word "steer"—the term for a castrated bull—has become practically synonymous with "beef" is because extra bulls are so hard to manage. Bulls, with horns or without, can be dangerous. They are more aggressive than cows, more likely to attack if they think they have been provoked. Bull calves grow big enough to become dangerous well before the age of butchering. Nature meant the bull to protect the herd from predators as well as to compete with other bulls for dominance in breeding.

Don't think that because milk cows are so gentle, milk-breed bulls will also be gentle. In fact, it is just the opposite. For some reason, the bulls with the worst disposition of all are

those of the dairy breeds.

Premature Breeding. A bull calf (or a male of another species) is ready to breed well before he is ready to butcher. If bull calves would only mature to butchering size before they mature in sexual capability and aggressive instincts, this problem wouldn't exist. Unfortunately, when they are less than half-grown, they think and act like any full-grown bull. So if you have a lot of young bulls around, you are liable to get 5-month-old heifers bred.

If a heifer (a young female cow) gets bred too young, she is bound to have trouble in calving, possibly meaning a choice between her life and that of the calf, or even a dead calf. Even if she calves successfully, she may not be able to make much milk, and her full growth may be stunted by the premature calving. The same is true of other species.

Fence Busting. Cows are very strong and can go through fences if they want to badly enough. A bull—even a very young one—is a big, husky animal. They quickly reach sexual maturity, and the first time they smell a cow in heat it doesn't matter whether they've ever been near a cow before. The fact that there is a fence between the bull and the cow in heat is no more important to the bull than if it was 2 garden stakes with a string between them. He will be inclined to just walk through, over, or under the fence, scarcely showing bewilderment at why that thing happens to be there just then.

Control of Herd Genetics. Genetically speaking, you have a lot more control over what's happening in your herd if you are breeding only from known sires at known times. If you have a Jersey bull calf and your neighbor has registered Herefords, and your bull calf goes through the fence and breeds some of his cows, he is going to be just furious! And that is bound to happen if you are keeping bull calves anywhere but locked up in your barn or in a real tough corral. He would owe you the same consideration if your situations were reversed. Cattle ranchers, as a matter of routine, make steers out of all their bull calves except the few they mean to raise and keep or sell as breeding sires.

How to Castrate: So you see, the alternative is worse than a brief surgery at a young age for male calves and young males of other species in which these problems are possible.

Age When Castrated. On big ranches, the calves get cut and branded and have their shots all at once when they are moved. The February calves go to spring pasture in April (more or less depending on where you live), and that's when they are handled. The fall calves are done when the animals are brought back to their winter feeding place. So the typical age is 6 to 8 weeks on a calf. It is important to do the castrating after the animal is well established but before it is too old. Don't castrate too late. I've heard of people who had 5 or 6 big yearling calves bleed to death because they were too old when it was done. A year is way too old.

Nowadays there are several different ways to castrate.

With the Knife. Castration by the knife is a technology that has been around a few thousand years. It is a bloody and disgusting business and the most traumatic for the animal. Cowmen did it at branding time. They branded, gave shots, and steered, and so got all that stuff over with at one time. The first time you do it, get help from somebody who has done it before. If there isn't anybody to help, I'll give the best directions I can.

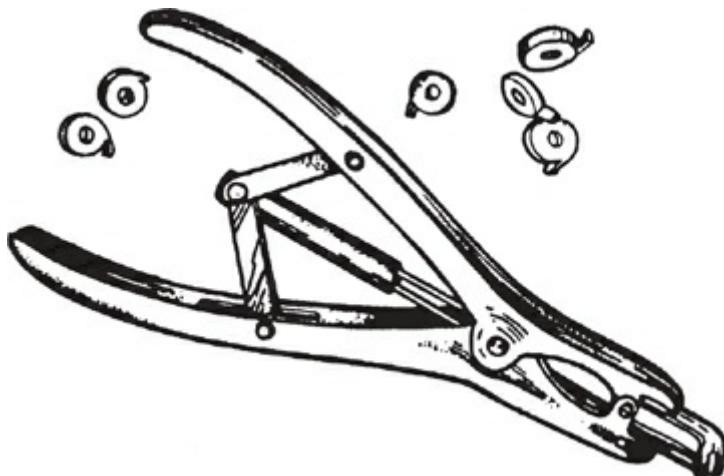

You have to first throw the animal, of course, and tie its legs and have plenty of help with sitting on it to hold it still. Slit the scrotum right down the middle belly line. There are about three layers of tissue, one of which is pretty hard to get through. Have your knife razor-sharp. Now put your hand around the outside of the scrotum so you squeeze the testicles clear out. There's a cord attached to each one. You cut that away and it's done. Have the gear ready to give a shot of Combiotic or some other animal antibiotic. Some

Blood Stop helps, too; it's a purple powder available from your vet.

➲ **ROCKY MOUNTAIN OYSTERS** Save those round balls in a bucket. Then you can be like the old-time cowboys and have them next morning for breakfast with eggs. In country talk, they're called "Rocky Mountain oysters." To cook them, just bread and fry like oysters. Store in the deep freeze like any other meat while you're working up your nerve.

Docking Tool. The docking tool is, if anything, an even bloodier business than the knife, but it is also very fast and efficient. The tool is a round circle with sharp blades around the inside. You put it up over the scrotum and squeeze. The blades close in a pincerlike action and take the whole thing right off. You have to use it on a young calf because an older one will bleed too much. This tool is sold by Sears, Montgomery Ward, Ranchrite, and so on. It also dehorns. It's the quickest way to do it, but they bleed the worst. Don't use it on a very big calf—one over 250 lb. He'd bleed to death.

Elastrator (Emasculator). You buy this from a veterinarian or vet supply house. Ask advice on using it when you buy it. It's used for docking sheep's tails as well as for castrating various animals. It's a better method for a beginner—maybe better for everyone. It's simple, there is not a drop of blood, and the animals don't seem to suffer excessively. The elastrator is a special tool that holds open a tough rubber band. You pull the testicles through the held-open rubber band. Put that tough rubber band around the base of the animal's scrotum, right where the scrotum joins the abdomen. Then you release the band and it remains on the calf, choking off the blood supply to his testicles. Elastrate a bull calf when it's about 1 week old. Don't wait.

Yet even this system is not perfect. This last year both we and a neighbor had calf trouble using the elastrator. I don't know if the manufacturer tried to make the band out of some new rubber that wasn't as good, or what. So watch for infection. Eventually the testicles (or tail) drop off for lack of blood.

DEHORNING: I always used to just let my goats that were going to grow horns go ahead and grow them. I reasoned that a fine set of horns is a glorious sight and that because of our predator problems, the goats needed their horns for self-defense. We had goats come home with blood on their horns and spots of blood on their heads—and it wasn't from fighting each other! And no goats were missing. That's absolute proof that the predators got the worst of it! Mike says when goats are attacked by coyotes, they get in a circle with the kids in the middle and their horns facing out.

On the other hand, if you want to show goats at the fair, if your goats will be playing with small children, or if you have a buck you intend to keep, there are arguments for dehorning. My children never have been hurt by a goat, but I've been lucky. Cows of both

sexes can be much more dangerous than goats. Naturally hornless animals are called "polled." A lot of the breeds now have polled strains. So the easy alternative to dehorning is to buy "muley" goats or "polled" animals. Otherwise, you can burn, nip, or saw off horns. Burning is the easiest method.

Age at Dehorning. If you're going to dehorn, it's much, much better to do it when the animal is 3 days old rather than later on, when the horns are big. You can dehorn a baby goat using a caustic paste or a burning treatment. Goats with horns that have already started to grow are dehorned by nipping. Baby muley goats have straight hair around their horn buttons; don't do anything to them. A baby that is going to grow horns will have curly hair there.

Dehorning by Burning. You can buy a special tool for this, the "bell-shaped dehorner," or use any make-do iron rod as long as the base is equivalent to the size of the horn. Commercial hot irons for this purpose come in a set of sizes to be matched to the horn. You can use this method on any young animal as long as their horn is shorter than $\frac{3}{4}$ inch. Calves can be dehorned this way up to 4 months of age.

Heat the electric dehorner as instructed. Heat the rod dehorner in a fire, branding-iron style, until it is really hot. Then press the hot end to the horn button. You have to have an extremely solid hold on the young animal so it can't wiggle. Having it in a stanchion that holds its head tightly is best. Hold the heated dehorner over horn, button, and horn base. Keep it there until you see a circle of copper-colored skin become visible around the horn's base. It takes only about 10 to 20 seconds. You'll smell the burning skin and hair. Do this once for each horn, and you're done forever with the problem. You can turn the animal loose right away.

Dehorning by Caustic. Caustic comes in sticks and in a paste. The sticks are easier to use. Caustic is a problem either way because it eats indiscriminately wherever it lands. A kid goat with caustic on can't be allowed out in the rain because if the caustic runs into its eyes, it could go blind. If you're going to use caustic, you have to do it on a very young goat, like 3 days old, before the horn has started to grow out. And you've got to do it right, or what you end up with is ugly, deformed horns—but horns anyway. To apply caustic:

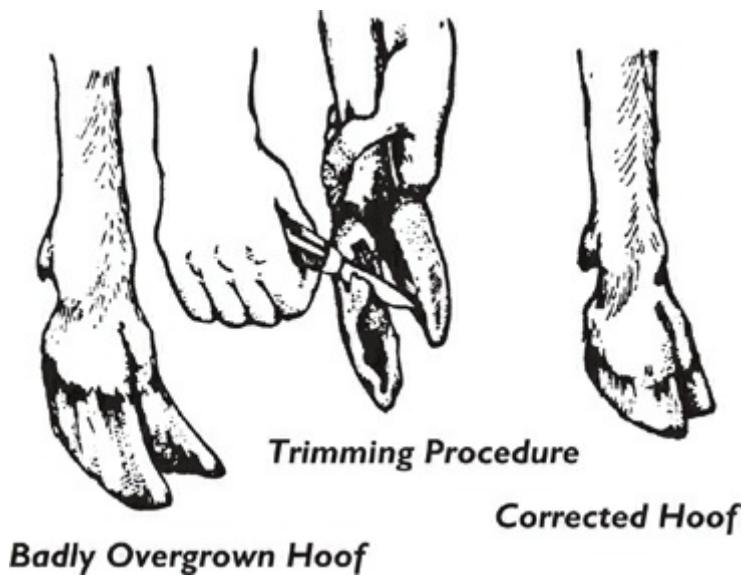

1. Have your Vaseline and dehorning stick handy.
2. Restraine your animal. A miniature stanchion works well, or use a box with just space for the head to stick out.
3. Trim off hair from around horn buttons as completely as possible.
4. Cut off the horn button's tip using a sharp knife. This ensures that the chemical can get to the tissue that builds horn. If the horn button hasn't yet grown out through the skin, you'll have to cut the skin that's over the horn button with a knife to allow the chemical to get at the horn.
5. Lay Vaseline around the skin near the base of the horn button to protect that area from the caustic. It helps to stick adhesive on the button to protect it. Take adhesive off the button after you get the Vaseline in place. The Vaseline is to protect the animal's skin and eyes.
6. Dampen a caustic stick. Then apply using leather gloves or with stick enclosed in a paper towel. (Don't get it on your skin. It really eats.) Put caustic on exactly as the directions tell you. It's important to get on exactly the right amount. Too little results in a stub horn. Too much overflows the Vaseline. If using paste, apply to the thickness of a dime. Apply stick caustic to horn button with circular motion. Also apply to area

right around the horn. Rub the stick on the horn button until you see blood.

7. You're going to have to figure out something for the next several hours until the caustic dries so the animal doesn't spread that stuff around itself or get it on its mother. You could have somebody sit and hold it for that time. Or keep it in the very confining cage you used for restraint.
8. You've got to go through this every day until you're sure you've won. If the horns get ahead of the paste, forget it. Go on to "Nipping."

Nipping. Young goat horns can be cut with nippers. You can get proper dehorning nippers affordably. *Pruning shears won't work.* Get some Blood Stop from your vet too. The animal will struggle, scream, and bleed. Have help to sit on it while you're nipping. Make sure the edge of the nippers is almost even with the skull. Put the nippers carefully where you want them and then do it quickly and firmly.

Sawing. Big, old horns have to be taken off by sawing with a meat saw. It's a hard job. You need at least three men to do a goat—two sitting on the goat and one sawing. They bleed like the dickens, but Blood Stop will lessen the blood. The hole in the horn goes right down to the nostrils. You can look down there and see them breathe. But Blood Stop seals it up in a hurry. Shake the powder on the horn right where you have cut. The wound will seal in a hurry. If you have a goat who is making itself dangerous with horns, this treatment will solve that.

FOOT PROBLEMS

Hoof Trimming. Some animals grow more toenail than others. You may be able to get away with no trimming, but sometimes regular trimming is the only way to keep hooves from getting so long in front that the animal can't walk normally. An overlong hoof can even split, and infection can get into the crack. Before you trim hooves, watch somebody with experience while they do it.

A horse will let you pick up its foot (usually) and work on it to trim or shoe it. A horse's hoof is first trimmed and then filed with a horse's hoof rasp. A cow is harder to trim. She won't pick up her foot for you as a horse will. Won't. Period. If she's a sedate and friendly animal, she will allow you to do her hoof trimming while she's lying down. Second best is to trim her hooves while she's standing on them. You need a special cow hoof trimmer to do that. Put her into a stanchion so her head is held still, and have her stand on a clean board so you can see what you're doing. (The only other way is to put her in a squeeze chute or rig a body sling under her belly and raise her off the floor.) See [Chapter 10](#) for

how to trim goat hooves.

NOTE: Trim hooves a bit at a time. If you cut too short, you will temporarily, or even permanently, lame an animal! Don't draw blood! If hoof color is getting pink—or if it's feeling soft—you're getting close to blood and must quit!

Foot Rot. If your cow gets swollen feet and acts as if she has pain in her legs, the cause is probably foot rot. "Foot rot" means any bacterial or fungus infection (swelling, redness, etc.) in the soft tissue between a clovenhooved animal's toes or in the hoofhead. It's a misery for the animal, makes it lame, will reduce milk production in a milker, and will cripple a draft animal.

It can happen anytime and under any conditions, but it usually happens when animals stand in muddy or wet ground. They're also more likely to get it if standing on frozen ground, in gravel, or on other ground types that raise the possibility of a cut on the foot where an infection can start. To prevent foot rot in stabled animals, keep bedding and pen clean and dry. Hoof trimming also protects their feet. If you have a case, it's best if you can notice and treat it soon. Not every lameness is from foot rot. The animal may have a puncture wound or hoof abscess instead. Carefully cleaning the hoof so you can clearly see what is actually going on there is the necessary first step. Cows with foot rot can be treated with injected antibiotic and/or a dipping of the foot into copper sulfate.

Barbara Stone from Stites, ID, has a wonderful "Glenn's grandpa" who has been around cows all his life and has passed on this remedy through her. "Foot rot can happen to just about any animal with hooves. This is quite painful to the animal. The symptoms are limping and sometimes holding the foot up off the ground. Either rope or stanchion the animal before beginning the treatment. Using a stick or a horse-hoof pick, clean off all the manure, rocks, and whatever else is in the area between the toes. Pick up the foot and just stick it in a pail of used motor oil. Leave it in there for a few minutes or as long as the animal will allow you to have it there. Sometimes it is not too easy. This treatment should be done once a day for as long as needed. Usually it won't take more than 2 or 3 times. Try to keep the animal in a floored place that is not too wet or full of manure so the hoof can dry off. If nothing else, lock it in the barn."

Digestive Ailments

BLOAT: See Foundering.

CONSTIPATION: Sometimes an animal becomes plugged and cannot have a bowel movement. To check on a cow's digestion, a vet listens at the hollow behind the ribs. One vet said that when a cow's gut is working right, it sounds "like a spring storm." Give mineral oil for constipation. Contact your vet to find out the proper dosage for the specific animal.

FOUNDERING: Foundering happens to ruminants (cows, goats, sheep) and horses. It's serious indigestion—quite often fatal. Not too long ago I accidentally left both the door to the grain room in the barn and the outer people door of the barn open. My enterprising milk cow, Buttercup, went in that people door, walked down the corridor into the grain room, and there nearly polished off a 50-lb. bag of chopped barley. Needless to say, she promptly foundered.

She was a big cow and used to grain in lesser quantities, which is what saved her life. But when I found her she was suffering terrible diarrhea and looking very, very sick. Foundering affects cows in one of two ways—diarrhea or bloat. Diarrhea is better. We got her to the vet right away, and he dosed her and sent her home with follow-up pills for us to give her. She took the pills nicely for 2 days. The third day she was feeling better than

we realized. When Mike tried to give her the pill, she turned her head suddenly and firmly pressed him between her head and the stanchion, breaking three of his ribs. We pronounced her well enough. She never did get that last pill.

But that wasn't the end of the troubles from Buttercup's foundering. She got so dehydrated from her diarrhea that she dried up. I had to abruptly wean her little calf. After more time, her milk did come back a little but was still way down from where it had been. I sold her and used the money to buy a fresh cow.

Cause of Foundering. Foundering and hardware sickness are the 2 most common large animal ailments I've seen. Both are due to human carelessness rather than to germs. Animals depend on our good management; they have no natural judgment about what to eat, how much, or when. They will eat as much of the richest feed they can find, as fast as they can gulp it down.

Foundering is caused by a sudden, great change in diet from less rich to more rich food. In other words, if I started Buttercup on a cup of grain a day and gradually worked her up, she could digest big quantities without harmful effect (although probably still not 50 lb. of grain per meal). When we had an alfalfa field and kept the cows pastured in it from the very earliest spring day, they got fat on alfalfa and thrived. They were there when the first little starts of alfalfa came on slowly in the early spring, and they ate them. As more alfalfa plants grew, the cows got accustomed to their feed getting richer every day. That's why, when the alfalfa was waist-high and chock-full of food value, the cows could eat a bellyful of it as often as they wanted and be fine.

When alfalfa is cut and dried in the sun, it turns into hay and no longer has a potential bloating effect. Green alfalfa is the dangerous kind. If those same cows had been pastured in the field next to the alfalfa, on plain old grass, or on dry baled hay, and a child came to tell me they were through the fence into the hay (the green alfalfa), I would run, knowing time was precious and hoping they hadn't already been in there long enough to eat themselves to death!

Bloat can also be caused by grazing on frosted or wet, lush, spring pastures. If you buy an animal, ask how much grain and what green feed it has been eating. Drill it into your children that animals may slurp up grain like crazy, but grain in amounts the animal isn't used to can kill. Prevention is by far the best cure.

We've had all our bloat cases from over-graining. We had a nice 5-month-old billy kid. Company came to visit the farm. The children thought it would be nice to give grain to the little goat. Unbeknownst to me, they gave it a terrible quantity. That goat was not accustomed to grain in its diet at all. That evening it could not stand up. The following morning it was dead. You'll find "Tips to Avoid Bloat" at www.dairyherd.com/nutr73.htm.

Symptoms of Foundering. Foundering kills all sizes of animal. Bloat can take a 3,000-lb. bull just as easily as it did my billy kid. It kills quickly. You have to identify and treat it fast. You're usually certain of the diagnosis because you know when your animal was overfed. They usually founder from eating either grain or unaccustomed green alfalfa in the field—or other rich green food when they are used to hay.

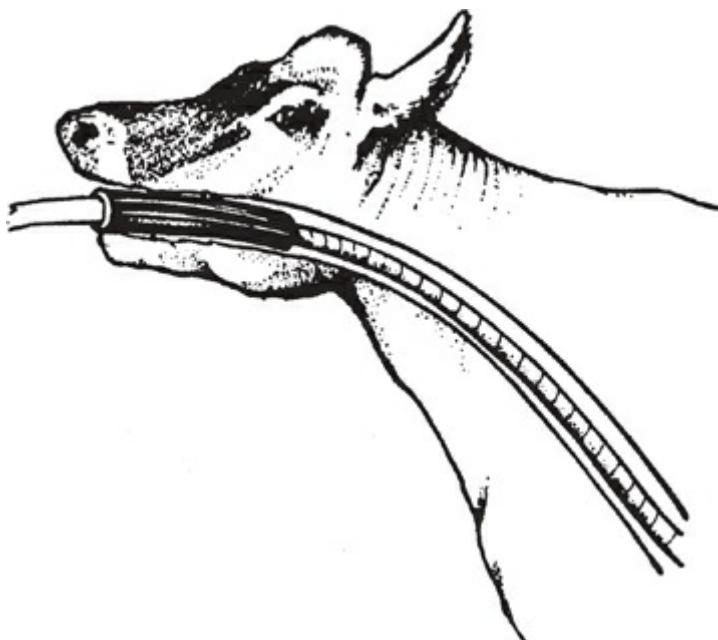

The worst foundering is a "bloat." The animal's sides swell up and up. At first it belches quantities of gas. If it is still swelled up but stops passing gas, the disease is turning fatal. You know what really happens in a bloat? All that rich food ferments inside there and makes gas. The problem is how to get the gas out before there is so much that it squeezes the animal's lungs and causes suffocation.

Step-by-Step Treatment for Foundering

1. For any mild bloat keep the animal moving, and don't let it lie down. That helps it

belch, which is what's needed.

2. If the animal belly continues to swell (especially on the left side) instead of getting smaller, get the front feet higher than the rest of the body, such as in a loading chute. Again, that's to help it belch. Or use some other system to get the front feet 6 inches higher than the back ones. Keep it standing.
3. Raising the front feet works even better if you force the animal's mouth to stay open by tying a length of hose with a rope threaded through it into the animal's mouth, over its tongue, and from side to side at the rear of the mouth, like a bit. This helps belching too.

4. If the animal isn't belching effectively yet, you'll have to resort to a stomach tube ("hosing"). Barbara Stone, Stites, ID, wrote me, "Here is the method to use in 'letting the cow down,' letting the gas out of its stomach. First, get a piece of garden hose approximately 4–5 feet long. If possible, use a $\frac{3}{4}$ -inch rubber hose rather than plastic hose. Next get a piece of 1½-2-inch black plastic pipe, the kind used for irrigation. Make sure both pieces are thoroughly cleaned. If the hose is the hard plastic kind, take a bucket of boiling water to the area where you are working. Take the garden hose and put it in the pail of water, let it set for a few minutes, and then drain completely. Take the end of the hose and carefully cut off all the rough edges. It may hurt the animal if left sharp."

"Place the black pipe in the mouth and carefully put the garden hose through it down the throat. The black pipe in the cow's mouth prevents the animal from chewing on the hose, so you can get it down. How far down you go depends on the size of the animal; on a cow you may have to go 3–4 feet before hitting the air pocket. When you hit it, they will immediately start burping and belching. Keep the pipe out of line of your face, or it will just about knock you off your feet. Keep the hose in the stomach until all the gas is out. By putting the hose to your ear, you can hear if there is any more left. Take the hose out. The animal should be on its feet in just a few minutes. If not, work with it until you can get it up. If the cow has her head lying flat on the ground, try to get her on her knees; otherwise it doesn't go in the right places. Sometimes if the animal is in the barn or is up on its feet, you can use the same method, but hold the head back slightly so the hose will slip down easily. This works

on calves as well as cows.

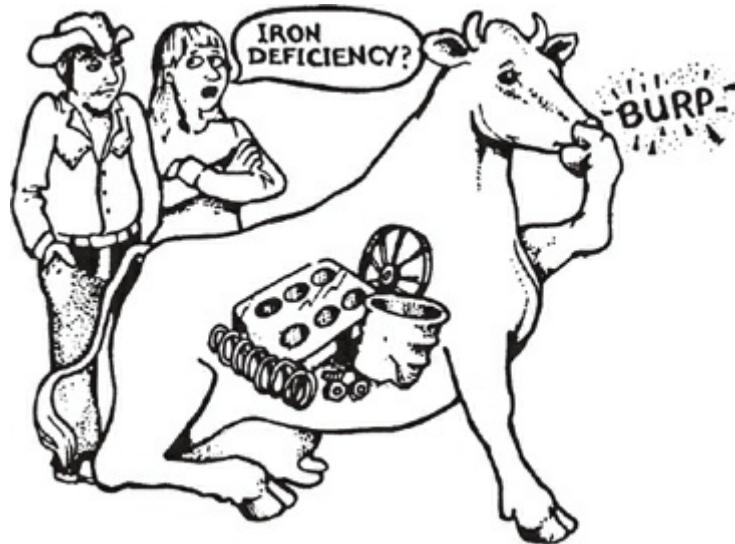

"If you don't have a hose handy, you can use a regular rope. Stanchion the animal and take the rope in both hands, placing it sideways in the mouth over the teeth. Put this as far back in the mouth as possible. This makes the animal chew and gag and start belching. Continue this until the gas is out. But as in the other method, stay out of the line of fire. Don't put the rope down the throat."

5. Give mineral oil (or salad oil) or turpentine. For a cow-sized animal, give 1 pt. to 1 qt. oil or 2 oz. turpentine mixed with 2 c. cold water. The oil or turpentine acts to reduce foaming in the animal's stomach and so helps the gas escape through belching.
6. If the animal is down and you can't get it up, its legs are extended, and it's gasping for breath, there isn't time to call a vet. Bloat kills when it causes the animal to suffocate. You have to try "sticking," since once it cannot rise, it will soon die. For this very last resort, you stick a pocket knife in the gut to let out gas. Stick the knife into the *left* side exactly equidistant between the animal's last rib, and hipbone, and loin area of the backbone. That's right behind the rib cage, below the spine, in that swayback spot where it sort of caves in naturally. Have the knife point pointing forward toward the right front knee of the animal. It isn't good enough to just get a blade in there. You need to then turn the blade to make space for gas to come out. (Get your eyes out of the way of the gas, digestive juices, and food that may blow out!) Turn the blade or follow it with a small tube that will hold the cut open and allow the gas to escape. Keep the tube in place until no more gas is coming out.
7. If you stuck the animal and saved its life, great. But now it's at risk for peritonitis because of your non-antiseptic sticking. So check with your vet about further treatment.
8. For a recovering foundering case, it's best to give grass hay rather than alfalfa hay for the next few days. And no grain!

HARDWARE SICKNESS: That's what the old-timers call what happens when your cow eats a piece of metal. Our vet tells me that he gets around 200 cases a year. Cows, unlike goats, aren't picky about what they eat. They munch mechanically along, and if there is a nail in or near the food, it goes down too. I had a neighbor whose cow ate baling wire. That's bad. She eventually had to be operated on by the vet. But cows can survive eating nails, bolts, and even hinges if you know how to help them. The old-timers came up with a remedy for hardware sickness that's still used. Of course, prevention is the best remedy of all, so check your feeding places, keep your eyes open when you're walking around in your pasture, and pick up any small, loose metal pieces you see. Once in a great while, a goat gets hardware sickness too.

Symptoms. The animal stops eating. It gets a miserable look in its eyes and will stop going out to browse with the herd. It just lies around by the barn being reluctant (but not unable) to get up. There is no fever.

Treatment. The old-timers went to town, bought a magnet, and forced the animal to swallow it. If the metal has not progressed beyond the big stomach region, this will save your cow. The magnet grabs the metal and pulls it to the bottom of the cow's stomach. It doesn't ever pass out. She has a magnet and metal inside for the rest of her life. But the important thing is that she doesn't die. When she starts eating again, you can relax and feel safe. Veterinary suppliers sell small, very heavy, smooth, oval-shaped magnets for this very purpose.

Getting to a vet will make treatment easier. In the first place, a vet can make a surer diagnosis than you can. First take the cow's temperature. The above symptoms with no fever may lead you to suspect hardware sickness. But the animal doctor will have a metal detector. Doc can put the earphones on and run the rod around under her belly. If it screeches, Doc knows for sure that it is hardware sickness and also knows the location of the metal. If it goes untreated for too long, the metal can tear up her insides. The vet will probably give her a dose of medicine to stimulate her bowels, since hardware sickness makes them stop moving. It will make her have diarrhea for a couple days, but in this sickness that's a good thing. Then the vet will make her swallow the magnet. And Doc may give her a shot of antibiotic and send some home with you to give to her for 2 more consecutive days.

Our vet tells me that they have to operate on only about 2 of those 200 cows a year with hardware sickness. If the cow doesn't recommence eating and doesn't seem perfectly all right by 5 days after the onset, take her for surgery, which is expensive but maybe not

as expensive as a cow. Ask and see.

Diseases/Infections

NOTE: Any animal that does very poorly—and you don't know why—is not meat you want to eat.

ABSCESS: An abscess is a localized infection, usually right under the skin, like a big pimple. Dynah Geissal wrote me advising, “Leave an abscess alone until it is ready to lance. At this time the hair will pull out easily near the head of the abscess. After lancing, treat with iodine. Abscesses are sometimes caused by dirty needles, so be scrupulously clean when giving shots.”

CANCER: If it's where you can see it, there'll be a hard protruding lump that just grows and grows while the rest of the animal does poorly. Make sure it's a cancer lump and not merely an infection. You do this by jabbing it with a knife. An infection runs pus; a cancer is hard clear through. If it is a cancer, take the animal away, shoot it, and dispose of the body.

CUT: Clean and then treat the cut with a product called Bag Balm, which is available from veterinary outlets. Bag Balm is also good for humans, and other cuts on your animals can be cleaned and treated with it. But use separate cans of Bag Balm for man and beast. For badly infected wounds, inject antibiotics.

INFECTIONS: Lance the wound by cutting it to let it drain. Put a healing salve like Bag Balm on it. If that isn't good enough, use antibiotic shots.

MASTITIS: For this udder infection and other dairy problems, see “Dairy Vetting” in [Chapter 10](#).

PINKEYE: People pinkeye, kitten pinkeye, and rabbit pinkeye are all disagreeable. We take the kids to the doctor for a prescription or get some Murine eyedrops; that works for kittens and baby rabbits too. Dynah Geissal says goat pinkeye is “usually caused by dusty feed but sometimes by bacteria. Treat with diluted lemon juice twice a day. This usually works, but if it doesn't, you will have to resort to the more radical treatment of injecting antibiotics into the eyelid! Pinkeye must be treated because it may lead to cancer eye, which causes blindness, severe emaciation, and death.”

Bovine Pinkeye. We have a lot of this ailment around here—it starts right after the face flies do, in late June or so, when the weather dries out and starts to turn hot. The face flies hang around a cow's eyes and drive her crazy. We try to help by soaking rags in a face-fly discourager and hanging them up on a rope so the cows can scratch themselves on it. But the best prevention is choosing a pinkeye-resistant breed of cow. Breeders have paid a lot of attention to resistance to this disease. Black Angus cows can list among their fine selling points that they are pinkeye-resistant. Shorthorns are not; I know from personal experience. Charolais are supposed to be resistant, but some still get it. Herefords are more susceptible than Black Angus.

Bovine pinkeye comes on very fast. It generally happens on only one side at a time. The eye turns white all over and looks ulcerated and awful. You'll know the instant you see the cow that something is terribly wrong. If you don't have pinkeye-treating experience, or even if you do, the best thing to do is load up the sick animal and get her to the vet immediately, because every hour really matters with this rapidly progressive disease. If you're in doubt, phone the vet first to discuss if it is what you think it is. It's a

good idea to check all the cows' eyes each morning and evening in face-fly season, as a matter of routine, to catch any pinkeye when it's just getting started. In some cases, with quick action, the vet may be able to save the eye. Or you may lose that eye but prevent the disease from spreading to the other eye. Then you've got a one-eyed cow, but otherwise she will be functional.

If you lose both the animal's eyes to pinkeye, you'll have to sell the cow for hamburger or eat it yourself, because it'll starve anyway. I know an old-timer who says the way to treat it is to get a handful of salt and rub the affected eye with all your might. Lane Morgan says her vet gave them something in a spray can (the spray was purple) that worked.

PNEUMONIA: Calves and goats get pneumonia. The symptoms are similar to the human disease. Animals with pneumonia have a very snotty nose and maybe runny eyes. They run a fever, are weak, and are obviously very sick. Their breathing is unnatural—raspy, maybe with coughing. The treatment is to keep the animal in as warm and dry a place as you can, feed frequently, and give Combiotic shots for 5 days. Coddle it a while more, because they can relapse.

Preventing Pneumonia in a Down Cow. From Barbara Stone, Stites, ID: "Our big Holstein cow went clear down during the night over the holidays, and she was down for almost 3 days. She had somehow hurt herself and couldn't get up. If you have a cow down, it's important to prevent her from getting pneumonia. It was awful cold at that time. We couldn't get her in the barn. We just had to keep old blankets and straw around her for the time she was down. We put feed and water in front of her, and she ate and drank. She finally did get up, to everyone's joy."

RED WATER: Dynah Geissal wrote me, "This disease is named for the way the urine looks when cows have it because there is blood in their urine. In goats it is detectable only with a microscope. I had 3 goats autopsied by livestock vets, one of whom told me the goat had starved to death. In fact, they do look starved. A pet vet did a fourth autopsy and found blood in the urine and then discovered the cause. After losing half my goat herd, I started inoculating and have never lost another goat to this disease. Red water is caused by liver flukes, which are carried by snails. If your goats graze or water in places that the fluke-carrying snails inhabit, they could get it. Ducks help to keep this problem under control by eating the snails. Having well-drained pastures and not allowing the goats to use natural watering places cuts way down on the problem—but inoculating eliminates it."

RINGWORM: Ringworm is a fungus. Supposedly the animal kind can't spread to humans, but I know better. First I got a spot on my arm. It kept breaking out again on my arm. We couldn't figure out where it was coming from. Then we discovered patches on Marietta, our milk cow. I'm the one in the family that milks. (Mike runs them in at night and feeds them, and I come along with the bucket and do my thing.) So it had to be more than coincidence that Marietta and I had ringworm at the same time. The doctors have a new treatment now for people ringworm, a one-shot painting that wipes it out. The ringworm eventually spread to all the cows. It took the hair off in (usually) roundish areas, leaving a kind of whitish, scaly surface.

Dynah Geissal treats goats that have ringworm with lemon juice, applied 3 times a day. I've found that iodine dissolved in glycerin is a good medicine for ringworm. You can get ringworm medicine from your vet. You paint it on once, and that's fine until you find the next spot. In the old days, they just left it alone. It was a winter affliction that the cows sloughed off in their spring molt. Another old-time remedy was to get an old rag and tie it

on a stick. Dip the rag into a can of used motor oil and run it over the ringworm areas (not near eyes).

SCOURS: Scours means animal diarrhea. Usually it's the babies who get it. Chilling, a change of food, or a bacterial infection can cause it. For treatment of a kid or calf with scours, see [Chapter 10](#). For older animals with mild scours, Dynah says she treats "with ginger fed with grain. More severe scours is treated with Kaopectate."

WHITE MUSCLE DISEASE: Dynah says, "The symptom is stiff hind legs. It occurs in selenium-deficient areas. It is prevented by feeding a mineral mix that includes selenium."

Parasites

LICE: Lice can turn up on practically anything, man or beast. And don't let anybody kid you and tell you that animal lice leave human beings alone. I know several people whose whole households have gotten horrible cases of lice from animals, in one case from a neighbor's milk cow. Animal lice don't generally make the jump to people unless you get really intimate—like leaning your head against the cow. But once you've got 'em, you have a fight on your hands. If you can help it, don't go home. Take a hot shower. Wash your hair with a strong soap. Wash all the clothes you were wearing in detergent and hot water. If still in doubt, buy a can of garden spray that's good for flying bugs (terribly strong stuff, I know, but nothing lesser than I know of is really effective) and spray your car. Take off your shoes and spray them.

If the infestation of lice is in your whole family or your house, you're going to have to go through this battle again and again. It won't be easy, but in the end you'll win. I've been through it. Wash all the clothes and bedding. Shampoo and bathe the children. Fumigate the house thoroughly. If it doesn't work, do it again. And you have my sincerest sympathy. This is one of the most miserable afflictions I can think of—and it's the same for the cow or chickens or other critters that have 'em. Malathion is an effective spray, but it's terrible inorganic stuff. A new treatment of whitewash in your animal shelter and crankcase oil on the roosts, in the case of chickens, has been known to work. Makes me itch and scratch just to write about it.

MAGGOTS: Maggots are caused by flies that lay their eggs in a wound. When the eggs hatch, the little worms live in the animal's flesh. It is a terrible sight. When I was little we had a lot of trouble with bears getting into the sheep. Often the bears succeeded only in getting part of a sheep. I remember vividly helping my daddy. He would hold the wounded sheep down while I poured the dark, thick antimaggot medicine all over where the worms were writhing in the exposed flesh. So be forewarned. If your animal has an open wound in the fly season, you must keep a salve on it or else pour an antimaggot solution over it.

WORMS: Medicine for worms can be given via an animal's food or drink, or in a shot. It depends on the animal and on the worm—the varieties of which are legion. Don't treat unless you actually have the problem.

INTRODUCTION TO BUTCHERING

For specific species butchering instructions, also see the section in this book dealing with that animal.

The tiger naturally eats nothing but meat. Man naturally can thrive on a diet of part meat which, like the tiger, we have to kill to get. I don't think much of people who say

they like to eat meat but go “ick” at the sight of a bleeding animal. Doing our own killing, cleanly and humanely, teaches us humility and reminds us of our interdependence with other species. My husband adds that there would be fewer wars if people were doing their own killing and knew what it was to have to cause death to a living creature. I’m sad, humble, and grateful for each creature that perishes for the sake of nourishing my family.

I grew up on a farm and in a climate where meat and dairy products were naturally an important part of the diet. By “naturally” I mean that as you go farther north, or farther up in altitude, you get into climates where fruits and vegetables are harder to grow, but forage crops—food for animals—like brush, grass, and hay can still do well in season. In such areas your diet naturally tends to lean away from fruits and vegetables, which become ever more limited in selection and in season as it gets colder, and toward meat and dairy products—foods that can be harvested even in snowdrifts, foods manufactured by animals that can eat grass in summer and hay in winter, 2 food sources that humans can’t eat.

Killing that provides for the ample continuation of the species is acceptable to nature. In other words, we eat the extras—especially the extra males. No one wants an adult male of these domesticated species except for meat. No one, that is, with the exception of the female (if only for a moment), so there have to be enough males for breeding. The other exception is castrated males that are work animals, namely oxen. Uncastrated males don’t make good pets, are expensive to feed, and don’t produce the milk or babies that make the females a valuable part of the farmstead ecosystem.

We also eat the females that are past reproductive age—or even younger females, if the herd has grown to a size where its natural environment couldn’t support it anyway. And we may kill to improve the genetic heritage of our surviving breeding stock—thus eliminating less hardy or less productive individuals. Killing purely for the sake of sport is wasteful unless a species has over-reproduced to the point where its ecosystem can’t

support it anyway. Don't kill members of a species that doesn't have extras.

Custom Slaughter and/or Cutting

Some people send their animals to a custom-cutter to be butchered, cut, wrapped, and quick-frozen. The cost is figured per pound and is often waived in part in return for the hide, so many pounds of the hamburger, or some such. My friend Stephen Scott wrote me: "I take the sissy way out and send them off to a professional butcher. It is not an inexpensive proposition anymore to ship pigs, have them butchered, cut up, and wrapped, and have the hams and bacon smoked, but I prefer it to the alternative. We are lucky to have a few places left that do this kind of thing in our area. Twenty years ago there were at least 10 places that would do custom butchering; now there are just 2. One of them comes out to pick the pigs up with his own truck. For the other one, you have to haul the pigs to him—haul them yourself or hire a livestock trucker to haul them for you. I don't have a trailer that will haul livestock, so I have to pay 15 bucks to have the butcher come and pick them up. We raise three pigs: one for ourselves and two that we sell. We split the hauling fee so that each one of us has to pay only 5 bucks apiece. Not a bad price considering the trouble that you can have on the road with 3 scrappy 200-lb. porkers."

Another possibility is custom slaughterers who work from a mobile rig and will visit your place for the day. If you want to hire out some or all of this work, make arrangements in advance with a local person, find out what the price will be, and make an appointment for a particular place, day and time.

CUSTOM CUT AND WRAP: Some people do their own butchering but send out the carcass to be cut and wrapped. It's easier on the animals to be slaughtered on-farm, and you'll get the organ meats fresh. Or you can hire a commercial butcher to come and do the job on-farm. In either case, you get to eat your own carefully nurtured meat, but you avoid the mess and labor of slaughter and cutting up. If you take the complete carcass to a professional butcher or to a meat locker, you can have it cut to look like the cuts at the supermarket. If you're planning on driving somewhere else with the butchered quarters in the back of your pickup, you'll want some clean old sheets to wrap the meat in, so it doesn't get dirty.

Instructions for the Meat Cutter. He'll package it just right to serve your family's size. Tell him how thick you want the meat cut, how much you want your roasts to weigh, how many steaks, chops, etc., you want wrapped in each package, what percentage you want made into burger or sausage, and if you want any of the meat cured. You may want to get the bones back. A reader wrote me, "When we send a beef to the butcher to be cut and wrapped, we request that they give us all the bones too. We pressure-cook them, let them cool, and then pick the meat off them (there's a lot!). We can the stock with some of the picked-off meat and some onion slices in each jar. It makes a great stew base and makes the budget stretch farther."

Home Butchering

QUALIFICATIONS AND PREPARATIONS: Unless you've had a college course in comparative anatomy or dissected a cat or two in a zoology course, you may not be able to distinguish one muscle bundle from another. When I was a little girl, my mother believed that every situation could be made to have educational value. As the teachers of subjects like "Hellenistic Marketing" and "Music of Ancient China" say, it's bound to be useful sooner or later; you might be surprised just when. So whenever Mother cleaned a chicken, she would call me over and have me identify all the various abdominal organs. Eventually, I struggled through 3 years of pre-med at the University of Illinois at Chicago. But

chemistry, trigonometry, and physics were my downfall. So I didn't become a doctor. But I got straight A's in all the anatomy and dissecting-type subjects. I have just listed for you my credentials for writing about meat cutting—above and beyond having done it.

"Butchering" is when you kill, skin, gut, and quarter the animal. Then you hang the quarters up to age, in the case of most animals, or merely to cool overnight, in the case of pigs. This book does not describe professional butchering; it assumes that you can probably tell bone from meat from fat—and not necessarily much more. Its essential goal is to enable you to get your meat from hoof to pan yourself, and I trust it will accomplish that. There are cuts here that you don't see in the store, but a professional butcher has lots of expensive power-cutting equipment that you don't want or need to buy. You'll understand any procedure better after you try it a few times. The school that best teaches you something is the one where you actually do it enough times to get comfortable with it. The biggest hurdle is getting started—getting the confidence that you really can do your own butchering.

I've tried hard to make the directions that follow clear and dependable. It would be even better than reading this chapter, however, if you could butcher and cut up an animal with somebody who is experienced. If you are inexperienced and must be on your own, it's a good idea to start with something small—such as a chicken or rabbit—and gradually work up, rather than trying to learn on a 1,200-lb. cow. The basic principles are the same.

In general, if you are careful with your basic preparation (don't shoot the animal if it's excited, get it thoroughly bled out, don't spill intestinal contents on the meat, get it cool, keep it clean, and don't let the meat spoil), you really can't go too far wrong. You're going to eat the meat yourself. If your steaks are triangular, they will just give you a good laugh every time you eat them.

Jacki Robinson, Reddick, FL, wrote me, "Fifteen years ago my husband and I decided to move out of the city into the country ... We bought a 5-acre postage-stamp farm that was already set up with garden space, barn, root cellar, and chicken house. After some repairs we were ready to start, and we did. We got a milk cow, a beef calf, goats, chickens, geese, guineas, ducks, bantams, pigs, and bees.

"When it came time to butcher our pig, we could get no help from any neighbors. (They were sort of close-knit and related to everyone but us. The consensus was that we would never make it.) So we went to the library. Our beautiful librarian loaned us a copy of your book ... My husband butchered our pig while I sat on top of the truck with your book telling him what to do next. The pork chops looked like triangles, and there were many unnamed pieces of meat, but it sure tasted good. After that, the neighbors were a little friendlier. I checked out your book so much that I finally bought it. Living out here is so precious to me. Growing a child and the food we eat are enriching my soul."

Once you have gotten the animal killed and the meat cut, you need to preserve it (or have a big barbecue and eat it immediately). So before you commence slaughtering, be sure to decide how you are going to preserve the meat, and be prepared to get that meat processed within the necessary time limit. This chapter contains a section describing every possible way of preserving meat, including freezing, canning, and drying. The last section tells how to make homemade soap from surplus animal fat and how to tan skins. (Candle-making info is in [Chapter 1](#).)

BOOKS AND SUPPLIES: A good one is *Basic Butchering of Livestock and Game* by John J. Mettler Jr., D.V.M. (1991). It covers beef, pigs, sheep, deer, poultry, rabbits, small game, goats, horses, and also buffalo—as well as pickling, smoking, and curing meat, and how to build a smokehouse and make sausage. *Butchering, Processing and Preservation of Meat* by Frank

G. Ashbrook contains material from USDA bulletins. Texas A&M offers meat science info and training seminars such as "Beef 101" and "Sausage School"! Contact the Rosenthal Meat Science and Technology Center, Dept. of Animal Science: 979-845-5651; fax 979-847-8615; meat.tamu.edu. The American Meat Science Ass'n lists classes, such as Pork 101, on its website: 217-356-5370; fax 217-398-4119; information@meatscience.org; www.meatscience.org.

Forschner knives are German products that are very good. They are available only from butcher supply houses. To cut up something large like a beef, a band saw really helps, but they are very expensive. We don't have one. Sometimes you can find a small saw secondhand for a bargain price. Some people make their own.

FIT TO EAT?

What's Live and Fit to Eat. Don't choose an unhealthy animal for slaughter. If you suspect an animal of being unhealthy, get it checked by a veterinarian and treat it until it's healthy again. (Then wait for the antibiotic to wear off.)

What's Dead and Fit to Eat. If you know an animal has just died, and you know why, here are your rules: don't eat an animal that died of a disease (other than a non-microbial-type disease, like foundering). Do eat an animal that died of an injury, like getting hit by a car. It would be a shame to waste the meat. If you don't know why the animal died, or if it has been dead awhile, definitely do not eat it. (When in doubt, throw it out.) As soon as possible, as much of the blood as possible must be drained out. Getting that accomplished is very important and very necessary if you want the meat to look normal and keep normally. Don't butcher or eat any animal that has received any kind of medication within the last 2 weeks or that has been recently wormed or treated for external parasites. Check the directions on the medicine container for the precise withdrawal periods after which butchering is safe. The time varies according to the particular treatment.

YOUR MEAT INSPECTION: After the slaughter and evisceration of any animal, examine the internal organs and the carcass carefully for any visible abnormalities that might suggest the unfitness of the meat for food:

1. Local bruises and injuries, enclosed abscesses, and single tumors are conditions that the professionals simply cut away and discard; the remainder of the animal is fine to use.
2. Worms in the intestinal tract are routine and don't disqualify the meat.
3. If you find inflammation of the lungs, intestines, kidneys, inner surface of the chest or abdominal cavity, or (in the case of sheep) numerous yellowish or pearl-like growths scattered throughout the organs, call your vet and discuss whether you should use the meat! (When in doubt, throw it out.)
4. If a liver has many white-filled spots on it, you have coccidiosis disease on your farm. The livers need not be fully spotted. Any slight discoloration is a sign of infection. Chickens can get it; so can various other varieties of poultry, rabbits, and sheep. Do not eat the meat of infected animals! Burn the carcass.

Butchering Meat for Sale or Trade. The Federal Meat Inspection Act requires that some meat that is to be sold or traded for human consumption must be slaughtered under inspection in an approved facility under the supervision of a state or USDA meat inspector. For more details about these regulations, see the [Chapter 9](#).

Radioactive? If they ever drop the bomb, or if a nearby nuclear power plant or nuclear

waste dump blows up, don't eat any internal organs, bone marrow, or animal skin. The muscle meat will be safe if you keep it absolutely dirt-free. Milk from dairy animals will be contaminated if your animals ate contaminated feed or drank contaminated water. It will be okay if they ate clean feed and drank clean water.

Other Poisons. Relative to the industrial-chemical era in general, if there are any poisons in the animal's system, they will wind up getting concentrated in the brain, liver, and kidneys and in the fat. *So minimize your eating of animal fat not only because of cholesterol but even more because of DDT and other chemicals!*

WHEN TO BUTCHER: Around here the best months for butchering are late October, early November, and late February. That's because then the weather is cold enough so the meat will keep, but not so cold that everything keeps freezing on you. An outdoor temperature of around 35°F is ideal, since spoilage bacteria do not grow well in such a cold environment.

Another factor in the timing of slaughter is food supply. There is often a time that's economically best for killing. For grass eaters it's when the grass gives out in the autumn, which is around the same time as when the weather gets cold enough so the meat will keep. Another economically determined time is when the critters will no longer put on much extra meat relative to the food they eat, when they're basically done growing. That's why ducklings are ready after about 10 or 12 weeks.

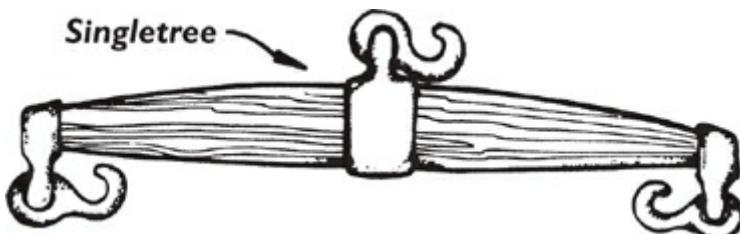

Small animals like rabbits and poultry that will go straight to the refrigerator or the table can be butchered under any weather conditions at any time of year. Larger animals that will be quickly barbecued whole, like small pigs, lambs, or kid goats, can also be butchered in summertime, even without refrigeration. But for larger animals, you'll have to consider how long it will take you to get the animal butchered, how long you want to hang it, how long it will take you to cut it up, and what plans or facilities you have to store the meat (canning, freezing, locker storage, drying, etc.).

Avoid slaughter in high winds, when dirt might be blown into the workers' eyes or dust onto the carcass. Most people avoid slaughter in hot weather, except of a small animal such as a goat. Hot-weather slaughter is best done in the late evening hours. In most families the men butcher and cut up and the women wrap, but I know some country women who take great pride in cutting up the meat themselves. Wear old and very washable clothing to butcher. Most people get blood, etc., on their clothes. Wash your hands and arms frequently.

PREPARATIONS FOR SLAUGHTER: All large animals are typically killed, skinned, and eviscerated outside and then cut up on an inside counter. Small animals may also be cleaned inside the house.

Checklist Before Large Animal's Slaughter

1. Choose ahead of time a site with clean running water handy.

2. Locate a tree with a high, healthy limb or a building with a high beam strong enough to hang the carcass from. You'll also need a block and tackle or strong rope or

singletree and hoist to raise the animal's rear end.

3. Have ready a gun or pistol (.22-caliber or higher rifle or pistol with cartridges) and know how to use it.
4. Collect a few very sharp knives and means to sharpen them again (a steel knife sharpener or Carborundum whetstone), and a meat saw. Razor-sharp knives minimize waste by enabling you to trim closely and precisely.
5. Gather buckets to hold liver and heart (you need a 4-gal. bucket for one cow's organ meat) and clean cloth or food-grade plastic to cover the animal after the carcass is skinned and eviscerated.
6. If you're butchering a larger animal, you'll also need a regular wood-cutting saw for cutting the animal in halves. The meat saw blade is too thin for that job.
7. It is also helpful to have a bucket of warm water with a heavy dash of vinegar in it for washing your hands when they get sticky, especially after you've been handling the innards and before you go back to work on the meat.
8. It's a good idea to clean and defrost your freezer before putting a large amount of meat in it. And check whether you have enough space available in your freezer. If you have a small freezer and a large animal, consider boning it out and cutting away and discarding the fat.
9. If possible, pen the animal the day before slaughtering. Do not feed it for 24 hours before killing, but do provide ample access to water during all that time. Withholding feed helps because then the guts are less bulky. Access to water helps complete bleeding out, results in brighter-colored lean meat, and makes skinning easier. But if penning isn't possible, don't worry. Your meat will still be all right.
10. The offal (butchering residue) can be awful if you don't have a plan to deal with it. See below.
11. Plan how you'll age the meat. See below.
12. If you're planning to freeze the meat, you'll need freezer paper and freezer tape, which you can get at a grocery store or from a local butcher. Have handy a crayon or marker to label your freezer packages with date and contents.

OPTIONS FOR THE AWFUL OFFAL: You could bury it in the garden, give it to the chickens, push it over a cliff, feed it to the pigs, or compost it.

Feed It. It takes chickens a long time to eat up cow innards. Pigs can take care of them right quick, but for either pigs or chickens there's a concern that eating innards reinforces the animals' parasite supplies. You can solve that problem by boiling the innards at least an hour, and preferably several, before feeding them to the animals. In that case, you need a huge pot and an outdoor place to get a fire under it. That's probably the best solution. In warmish weather, innards can get stinky pretty fast.

Compost It. Another solution is to compost the waste—innards, extra bones, hides, and blood (but not fat). Add them to your yard clippings, manure, peelings, food leftovers, feathers, and anything else organic. Mix everything with a layer of soil. Let it set a few weeks and then stir it again. But then you have to cover it in a way that guarantees some critter won't dig it up. Since some of these items decay very slowly, the delayed action continues to feed nutrients into your garden for a long time.

Remember: If not thoroughly bled out, the meat won't be pale in color. It will look "funny" and won't keep as well. And be careful to tie off rectum and to not let contents of the intestines spill onto the meat. That's how it can get contaminated with the likes of E. coli.

GENERAL PRINCIPLES OF AGING MEAT: Aging, a bacterial breakdown of complex proteins in the muscles that adds to flavor or tenderness, naturally begins when the meat is cool. If you choose to age the meat, keep it at about 40°F. Warmer temperatures increase the danger of spoilage. Colder temperatures slow down the process. Aging large animals for about 10 days should be sufficient. Deer will age in a week. Antelope should not be aged longer than 4 days. Very lean carcasses are not suitable for longer aging because they dry out too much. If the animal was less than a year old, the meat doesn't need aging at all. Don't age pork and pork-type meats (bear, wild boar, etc.).

Aging is done after skinning and gutting and before cutting up—except into halves or quarters (whichever is suitable for the size of the carcass). The aging process helps tenderize the meat and mitigate wild flavors. Small animals may be wrapped in a damp cloth and aged in your refrigerator for a day if they are young, for up to 4 days if they are old. Somewhat larger carcasses may still be small enough to be cut up and aged a while in your refrigerator. How long or whether you age large animals will probably depend a lot on the age of the meat and the temperatures the meat will be exposed to.

Wild hooved game is often hung about 10 days; it needs to be kept at 35–40°F for that period. If you have a walk-in cooler where you can hang your meat and keep the temperature above freezing but below 40°F (meat will actually turn out more tough if frozen within 24 hours of butchering), you could age it for 1 week, or 2, or as much as 3. If the weather is cool enough, let the meat hang in one of your own outbuildings with the door shut, to prevent wandering canines from helping themselves and to protect it from freezing at night. If you don't have facilities to hang the meat that long, or if the temperatures are getting too hot, by all means go ahead and cut it up. It may not be as tender as it might have been, but at least it will be edible.

About Cutting Up

CUTTING TERMINOLOGY

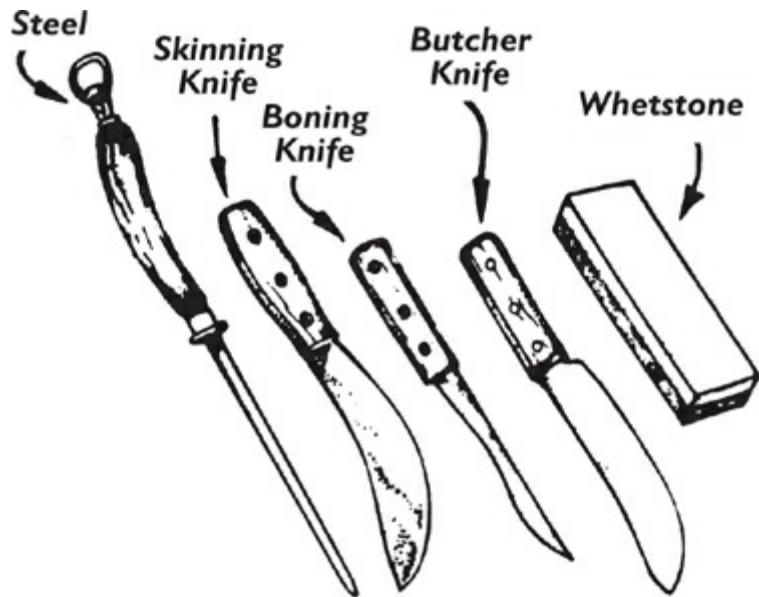

Chop: Lamb, veal, and pork terminology for what's called "steak" on a beef or elk

Cut up: To take the quarters into your house, onto the table, and cut them up into cooking-type pieces

Inside: Inside the chest and abdominal cavity

Outside: On the side where the skin was attached

Tips: Mini-steaks, possibly literally the tip of the muscle bundle

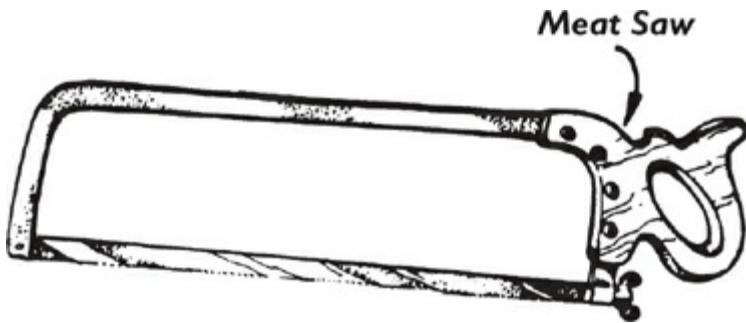

CUTTING-UP OPTIONS: Basically, you'll go one of 3 ways, or some combination thereof, with your cutting up:

1. Cut meat into chops (steaks), roasts, stew meat, and hamburger/sausage according to the part of the animal. This is the conventional way to cut meat.
2. "Bone out," which means to remove all the muscle bundles from the bone. If you have limited freezer space, if you plan to can all your meat, or if you can't stand working with a meat saw, boning out is the way to go.
3. Bone out and then grind the meat of the entire animal for hamburger/sausage. This is a frequent farmstead choice when an older animal that might be tough needs to be cut up. It gives you a good use for the meat without creating a struggle for the cook to make it usable.

THOUGHTS BEFORE YOU START CUTTING: Ask the cook about his/her preferences. Your animal is going to become spareribs, hamburger, stew meat, steaks, roasts, and soup bones. But spareribs can also be soup bones or can be cut into smaller chunks for stewing meat. Stew meat—even steaks and roasts—can be made into hamburger or sausage. Roasts can be cut into steaks by just cutting them into slices across the grain. The usual practice is to make the more tender cuts into steaks. You can learn to tell the difference. The best meat for steaks is a lighter color. It is sad but true that the least desirable cuts require the most work.

Cutting Technique. Always try to cut either outside the muscle bundle or across the grain of it (across the muscle fibers). A commercial butcher works with frozen meat and power saws. He or she can saw out all the cuts. It's best for you to first cut with the knife through the meat part and then saw with the meat saw across the remaining bone if you want to include the bone. Meat is almost impossible to saw because it's wobbly and won't hold still. If you freeze it before butchering, that problem is eliminated, but then it will be a lot harder to find your way around in the carcass and harder to cut it with a knife.

Cut Portion Sizes. The thickness of your steaks or chops is truly and purely a matter of the cook's preference, anywhere from $\frac{1}{4}$ inch to a full inch or more. Personally, I like goat and venison steaks $\frac{1}{4}$ thick (wild meat is usually cut about half the thickness of beef), beef $\frac{1}{2}$ inch, and lamb $\frac{3}{4}$ inch thick. The ideal size of your roasts depends on the size of your family. Figure out how much meat per person per meal an average roast needs to supply ($\frac{1}{2}$ lb.?) and multiply that by the number of people in your family. If some of your people are small eaters, lessen it accordingly. Add an average $\frac{1}{2}$ lb. per person for roasts that contain a bone.

Preparations for Cutting Up. Have ready 3 containers—such as cardboard boxes, enamel or stainless steel dishpans, or plastic buckets or pans—and a fourth if you plan to set aside some of the meat for jerky. One container is for the unusable trimmings you will give your cat, dog, chickens, or pigs to eat. The second is for pieces of meat that you intend to grind up for hamburger or sausage. The third is where you put the bones and ribs, which are bulky and would crowd your tabletop, until you have a chance to wrap them and put them away in the freezer. The fourth holds long, lean strips (at least 3 inches long) without too much gristle and with every bit of the fat cut away; these make the best jerky. (Note that you can't make jerky from pork because of the trichinosis threat.) You can sort these out from among the general to-be-ground-for-hamburger or sausage pile.

A big sturdy table is a good place to do the work. Everybody I know uses the kitchen table. We have a piece of plywood cut to fit the top of it for cutting-up days. You may want to also cover that with butcher paper before starting.

ORGAN MEATS: Don't age organ meats. They don't keep as well as the muscle meat. Brains, sweetbreads, kidneys, and tripe are the most perishable. Cook any or all of them within 24 hours of slaughter. The tongue, heart, and liver can last longer but should not be deliberately aged. You can store liver, heart, and tongue in your freezer.

Sweetbreads. "Sweetbreads" are the thymus gland. It looks pinkish grey and sort of spongy. I haven't included them in the regular butchering directions because most people ignore them, but the sweetbreads of calf and lamb (not pork) are edible. Lane Morgan says they're delicious. Sweetbreads are situated at the base of the neck near the heart.

Tripe. "Tripe" is the lining of the first and second stomachs of calves. I didn't mention it in the coming butchering section either, but it's also edible. "Plain tripe" means the lining of the first stomach. "Honeycomb tripe" means the lining of the second stomach and is considered better-tasting than plain tripe. You get the tripe by cutting the stomachs away from the rest of the intestines, cutting them open, and turning them inside out. Wash and rinse at least 3 times in clean water. To prepare tripe, boil at a low temperature, covered with water, until tender (4 hours or more). Then refrigerate until wanted for a recipe.

OF SUET: Suet (also called tallow) is the hardened fat around the kidneys and loins of sheep and cows. You can use hogs' intestinal fat and all sheep and calf fat for making soap and

candles and for bird feed. Suet is used in many recipes, and it's also good to feed to wild birds in cold weather. Many wild birds (especially insect-eating birds, which you want to keep around) love to get suet during the winter months. These birds can metabolize the energy in suet more efficiently than that in seeds. Be careful, however, to leave out all salt, as it will kill most small birds. You can offer suet to birds by freezing it until winter and then setting a lump in a hanging container (a wire basket or a perforated plastic bag works well for small clinging birds) or sticking it to tree bark or cones. Woodpeckers enjoy suet poured into a hole in a log. Suet poured into a coconut shell half will be eaten by all sorts of wild birds. Or you can mix in corn, seeds, or peanuts for a bird pudding!

⇒ **BASIC BIRD PUDDING** Spread seeds, grains, popcorn, cracked corn, peanuts, granola, cornmeal, cheese, oatmeal, dry cake, or what-have-you in a container. Heat suet in a double boiler and pour hot fat ($\frac{1}{2}$ to $\frac{3}{4}$ lb. of fat to 1 lb. of mixture) over mixture until it is covered. Birds need grit; ordinary sand will do. Add $\frac{1}{2}$ t. sand to $1\frac{1}{2}$ c. suet. Let set. Turn out onto a table unless you have prepared it in a tit-bell or coconut holder. In spring, when insects, worms, and new growth appear in the softened ground, stop suet feeding. For more wild bird feeding recipes, consult The Bird Table Book in Colour by Tony Soper or My Recipes Are for the Birds by Irene Cosgrove.

About Cooking and Eating Meat

Being faced with eating an entire large animal may require quite an adjustment. Maybe in the past you've learned only to cook hamburger 365 ways and are uncertain about coping with many different cuts. Don't worry: the ways to prepare and cook meat are infinite. Big hunks are roasts. Little tiny hunks are stewing meat, shish-kabob meat, or slicing meat for Chinese cooking. Medium-sized flat pieces of meat are steaks or chops. Very thick flat pieces are roasts. Bones with very little meat on them are soup bones. The ribs are "spareribs" that you bake with barbecue sauce on them. With a Dutch oven and a frying pan or wok, you'll have no trouble consuming even an entire cow. Cook the roasts and ribs in the Dutch oven with the lid on, the soups and stews in it with the lid off. Cook the flat meat in your frying pan.

RATIONING: Don't eat steaks every day the first three weeks—you'll end up eating hamburger every day the last three! Rotate. Have steak one day, then hamburger, a roast the next, then a stew, soup, or ribs. That system will make the various cuts come out about even. Or, if you want to consume less meat than that, spread the system out so you're eating the meat only every other day in the same rotation. You can be using the leftover supper meat on your off-meat days for cold cuts, hash, or ground-meat sandwiches. If you have a pig in your freezer too, add pork to your rotation. Most of the pig makes good breakfast meat. Or you can limit your meat consumption to once per day and add a couple of nights of pork roast, ribs, or chops, or add the "breakfast" pork meats to your evening meal rotation. If you use about as much pork as you do beef, you can eat up about 4 pigs while you are eating up 1 cow using this system.

TENDERNESS: Home-grown and wild meats may vary in age at butchering time and thus in tenderness. If you can't butcher your animal young, you could make hamburger or sausage out of the whole thing. The quick, hard-working old-fashioned way to tenderize is to pound the meat with a wooden meat mallet or a special steel hammer with a corrugated pressure-surface made for pounding meat. Or you can precook the meat, covered with water, for about 15 minutes. Discard that water and proceed with your regular recipe. (This process both tenderizes and floats away some of the wild, goatey or

muttony tastes.) Or cook the meat longer, or cook it a short time in a pressure cooker (15 lb. pressure for 15–20 minutes). Or marinate it, which may improve flavor as well as tenderize it. Popular marinades include a mixture of vinegar and lemon juice; grated onions and oil; tomato juice, water and lemon juice; water and vinegar; French dressing. The meat is typically soaked in the marinade in the refrigerator for 24 hours and turned in the liquid several times during that period. Or use a commercial tenderizer, which is made from a natural enzyme and will soften the toughest meat in a few minutes.

Coffee Tenderizer. Frank Womack Jr., Pomeroy, WA, wrote me, "Coffee is a means of tenderizing about the toughest meat you can get. You do not need a knife to cut roast cooked in this way. It falls apart simply using a fork. I use it making stews, also. Simply substitute leftover or fresh coffee for an equal amount of whatever fluid you use in cooking the roast. There is no taste of coffee in the meat, and the remaining fluid after cooking makes excellent gravies. Or you can soak the meat overnight in the coffee; then discard the liquid and cook in your recipe."

SECRETS OF COOKING STRONG- OR STRANGE-TASTING MEATS: Some meat may be objectionably "strong" or "strange" tasting for some eaters: older, uncastrated males, goat and mutton of any age or sex, and all wild meats. There are many ways to moderate or cover such tastes.

1. Any marinade helps.
2. Trim away all fat. This is important because the fat tends to be even stronger-tasting than the meat. Baste and fry instead with cooking oil, margarine, butter, or lard. A roast can be larded with fatty pork strips or basted with sauce to keep it from becoming dry and tough.
3. Also make sure there are no hairs on the meat; hair too carries a strong "off" taste. If you need to clean the meat, do so with a cloth dipped in vinegar. Vinegar helps dissolve clotted blood and pick up stray hairs.
4. It helps to presoak from half an hour to an hour in a solution of salt and/or vinegar.
5. Or precook 15 minutes, covered with water, and then discard water.
6. Wild-meat recipes tend to include rich marinades, stuffings of sliced onions and/or orange halves (discarded after the baking), or tasty stuffings that are served together with the meat.
7. A couple tablespoons of a tart jelly—like currant, barberry, or wild plum—in the gravy or on the plate helps any strong meat. Or serve the meat plain with a fancy fruit ketchup, such as peach. Or use other types of flavorful gravies, sauces, and heavy seasonings in general. Any recipe that involves a barbecue sauce will also camouflage an unfamiliar meat.
8. Another way to soften a strong meat's flavor is to combine the strong meat with a milder one, as in a wild meat/pork sausage combination; with potatoes, as in hash recipes; or with other bland vegetables like cabbage, cauliflower, asparagus, or breaded tomatoes.

COOKED OR RARE? Most people know about the possibility of trichina in underdone pork or *E. coli* from undercooked beef, but few know about toxo from underdone lamb. Toxoplasmosis is a parasite that can be carried in any animal, including humans, but it reproduces in cats. *Wash your hands after contact with cat litter.*

NOTE: All meat should be cooked enough to reach 160°F and change color throughout. Also wash hands after handling raw meat. When you are eating in a restaurant, check every burger or other meat. Open it up and make sure there's no pink meat at all to protect yourself and

your children from toxo, E. coli, and other diseases carried by raw meat.

NOTE: Toxoplasmosis can give anybody a “flu,” but pregnant women have to be especially careful not to eat rare or raw meat. Toxo is very serious to a fetus. It can cause blindness, retardation, or death.

Other animals besides cats can get toxo in their meat by eating cat poop that's in a grain bin or on grass. This can result in sheep with toxo cysts. Toxo cysts are killed by freezing, but the meat has to be frozen for a very long time at a very low temperature, not in the freezer compartment of your fridge. However, cooking takes care of them quickly and finally.

WILD CRITTERS

Porcupine is one kind of animal my daddy never hunted. He said that was the only kind of meat that a man who was lost in the forest without a gun had a chance of catching, because they are so slow-moving. He wanted to save them so they'd be plentiful for such a desperate man. In the years since I started this book, I've seen the numbers of various animals fall—and sometimes rise to the nuisance level again! So obey your current hunting laws, because they're carefully tuned to your local situation and needs.

I like wild animals, and I like a certain wildness in people too. I'm bothered by the extent to which writers think they have to write only what editors want, what publishers will print. I think writers have a special function and social obligation to their human community to be on the cutting edge. We need writers with bold new visions—ideas that are controversial or seemingly impossible at first glance yet may map the future. Farsighted writing that challenges the status quo tends by its nature to be unacceptable to Establishment publishing, yet it's essential to society because it articulates options. Some options are radical, some bad; but hidden in the confusion of choices is a new path—perhaps a hitherto unconsidered route, perhaps a revalued treasure of traditional living—that is the best one of all. So much important thinking appears first in small magazines or is self-published. We need to keep the doors open to these voices. And it's terribly important for our freedom of speech that people be able to publish magazines and books without submitting them to government review first, even to get a “copyright” or bar code/ISBN number to facilitate marketing.

The bottom line has to be courage. There's a plaque on my wall that I've treasured for years: "Anybody who says something is impossible is always being interrupted by someone doing it." "Impossible" is merely a relative term. One person's "impossible" is another person's "possible"—if the second person is willing to invest in the project an amount of dedication, time, and effort that the first person couldn't even imagine, much less put forth. Now, back to the topic ...

Hunting Birds with a Shotgun

Don't! As many as 3,000,000 water birds now die every year from lead poisoning, according to the Nov. 22, 1992, issue of *Awake!* magazine. Lead poisoning from waterfowl hunting is a tremendous environmental problem. The U.S. Department of the Interior estimates that for every bird that hunters kill, half a pound of lead pellets from their shotguns ends up in the ground and water. Wildlife biologists testing wetlands have discovered as many as 100,000 lead pellets per acre in the top few inches. (Lead fishing weights lost by fishermen litter the bottom of popular fishing areas.)

Waterfowl frequently eat lead pellets during their search for food. In a bird with lead poisoning, the poison reaches the heart, liver, and kidneys 3 to 10 days after it eats the lead; after another week, it is so sick that it enters a coma and soon dies. Bald eagles acquire lead poisoning by swallowing waterfowl that contain lead because they have been shot. At least 120 bald eagles have died from lead poisoning since 1966, and the rate of this type of death is increasing. Since official statistics include only eagles whose carcasses were examined for cause of death, obviously they represent only a small part of the total.

Lead-polluted land is also permanently ruined for agriculture, because any human or animal fodder that grows on it will have a high lead content. People may grow food or fodder there, not knowing of the lead, and thus risk further poisoning. I'd like to see lead-pellet shotguns made illegal. I'm totally serious. They aren't worth the environmental costs. I'd also like to see lead fishing weights made illegal. In fact, just about all uses of lead need to be outlawed. Lead poisoning is currently a worldwide long-term epidemic affecting people of all ages from conception to old age because lead is entering our bodies from our drinking water, air, and food. At best, lead exposure "merely" permanently lowers I.Q. At worst, it causes death.

PREPARING WILD BIRDS: If you do kill a wild bird for food, proceed as you would if it were a domesticated breed. Pick or skin the bird, and then remove the entrails. The bird will pick easiest while it still has as much body heat as possible, before the feathers have had a chance to set tight. See the discussion of ducks in [Chapter 9](#) for details. Cook as you would a domesticated bird. To cook a game bird in a camping setup, you can roast it by turning it on a spit slowly over a campfire, or cook in a slow to moderate Dutch or camper's oven, or (easiest of all) boil to tenderness in a stew. Wild birds are leaner than domesticated ones, and it may help a roasted one to turn it frequently, basting with margarine or a basting sauce.

NOTE: Before you cook a wild bird, consider a moment: what has that bird been eating in these polluted times? Mercury-treated seed grain? Then don't eat it! Fish from waterways polluted with dioxins, heavy metals, or radioactivity? Then don't eat either bird or fish!

Large Wild Mammals

Stay within the hunting limit. Mike and I didn't get any wild meat this last year. We were going to keep the deer on our place as pets, but we got a rude awakening. Somebody

came on our place and shot them. The same guy got the buck, the doe, and the fawn. We know because he bragged about it to a friend of ours. Kind of makes you feel that posting your property isn't such a wicked and unsociable thing to do after all!

BE PREPARED: To avoid waste (hunting is harvesting of a wild food), be prepared to deal properly with the meat. A good reference about hunting and wild meat is *Enjoy Your Game Meat: From Planning the Hunt to Eating the Bounty* by Neal Blair and Judy Hosafros (Wyoming Game and Fish Department, 1974). Another one is *Getting the Most from Your Game and Fish* by Robert Candy.

Start by taking a good sheath knife or a substantial folding knife and a small whetstone. Your folding knife blade must lock in the open position so it can't snap shut on bare knuckles. A belt ax or small hand saw will be handy. There are a number of saws on the market for the hunter. Some fold into the handle; some come in leather sheaths. Pick one of good quality. Elk bones dull a poor-quality saw in a hurry. A small block and tackle hoist can be a real timesaver. Some of these weigh as little as 2 lb. and can hoist an elk. Pack some cheesecloth sacks to put the quarters in. You can buy them at sporting goods stores or make them. Take salt too—not iodized salt but pickling salt—because even if you don't want the hide, you can give it to someone who can use it or sell it to a buyer.

Always carry fire-making equipment or matches in a waterproof container when hunting. Even in wet weather, you can always chop away some of the outside layer of a dead stump or whittle some dry kindling from pitch wood inside the soggy exterior. If you get lost late in the day, don't stumble around in the dark. Build a fire in a sheltered spot near available wood and make the most of it till daylight.

Wild meat generally has more lean than fat; the big exception is bear in the prehibernation season. And the lean of such animals as deer, elk, antelope, moose, caribou, reindeer, and small game is of greater density than the flesh of domesticated animals, maybe because they get more exercise. The age range is greater too, since domestic animals are almost always butchered in their young prime—except for hamburger-type cows or sausage pigs, whose meat is ground up, so you can't tell its age.

So wild meat may be on the tough side. Another reason for that: more care is generally given to the meat when butchering domestic than when butchering wild. What I mean is, a wild animal may have been running for, say, 2 hours during a peak hunting day as it encounters hunter after hunter. It is then cut down with a whole batch of bullets that hit it in prime meaty places, such as the front shoulder or hind hip. The animal lies for a couple of hours before being gutted, and the gutters forget to remove the testicles. Then it waits another 5 days or so in warmish weather, while the rest of the hunting party has a chance to get "theirs," before being cut up and taken to the freezer. Is it any surprise that the meat may not compare very favorably to beefsteak?

To minimize the meat's wild flavor, hunt early in the season, or else kill a female. In the large game animals, the meat of the males becomes stronger in taste as the mating season advances. Try to avoid handling the musk glands of deer, which are between the hocks and hoofs. Try to avoid killing the animal when it has been running and is very upset; such meat might be "bloodshot," not bleed out well, and thus have an off-taste. Be sure to gut it completely and as soon as possible, and don't forget to remove a male's testicles. Then halve and quarter and hang up to cool, if you aren't going anywhere for a while. The meat of any antlered game animal is called "venison."

APPROACHING A DOWNED ANIMAL: Never assume an animal is dead, even if it appears to be. Approach cautiously with your rifle ready and from a direction that will enable you to

stay away from flying hoofs and flaying antlers. Once you are sure the animal is dead, do whatever is necessary to mark the kill as yours, according to the local hunting laws.

BLEEDING OUT LARGE GAME: Any large animal—deer, elk, caribou, antelope, moose, etc.—has to be bled out, and thoroughly. Head, neck, and spine shots do not allow enough bleeding. And if the animal has been shot in the chest or abdomen, it probably won't bleed more than a little because, in that case, its blood has already run into those body cavities. So you have to cut the throat as soon as you can get to a downed animal. Beginners may find it easiest to do a side-to-side cut at the base of the neck. Pros prefer a breastbone to upward cut. Now move the animal to have its head downhill so as much blood as possible can run out the hole you made.

DEALING WITH PORKY GAME: This category is boar and bear.

NOTE: Like domestic pig, wild pig (boar) and bear meat must be cooked well done before eating.

Boar. Butcher boar, a kind of ancient wild pig, by the directions for pigs in [Chapter 11](#). Boars are comparatively lean and, because they get so much more exercise, their meat has a “wild” flavor. So consider using boar meat in wild-meat recipes (see “Recipes for Wild or Gamey-Tasting Meats”).

Bear. The old-timers cleaned a bear by sticking one hand in his mouth, grabbing his tail with the other, and turning him inside out. Nowadays we lesser mortals have to go the more mundane route of slitting and skinning off the hide—unless you find a bear without his skin. I did once.

As a little girl, I was walking down a little canyon near my home and came upon a large bear lying on the ground. I could see no wound. He appeared to be asleep. The strangest thing, though, was that he was minus his hide. I touched one leg tentatively and uncertainly. He kicked me! Well, I took off for the house yelling. My daddy was there, sharpening his knife blade. I said, “Daddy, Daddy, there’s a bear alive in the canyon and he hasn’t got his skin on.” My daddy laughed. Then he explained that there are reflexes in animals’ limbs for a little while even after they are dead.

There are now only 4 or 5 states in the Union where you can kill a bear (or an elk) any more. If you do kill a bear and want to save the fur, turn it on its back and cut the skin in a very straight line from its tail to under its lower jaw. Then cut from the lower inside of one front paw straight across to the lower inside of the other paw. Cut from paw to tail and from paw to tail on the belly side of each of the hind legs. Then peel off the bear’s hide. You can gut and quarter it and then take the meat to a custom cutter to be cleaned and cured. Or you can do it yourself, following my directions for pigs in [Chapter 11](#). “Bear

grease" means bear lard, and some people declare it's better grease than any other you'll find. You render it the same as pork lard.

You treat bear as you do pork. You can't make jerky out of bear meat because it can carry trichinosis, just like pig meat, and must always be well cooked before eating. A female bear is called a "sow." A young bear is a "shoat." The important thing about female bears and young bears, though, is not their name but their disposition. The only animal that I would tell you outright is aggressive and dangerous is a female bear with cubs. When I was a little girl, we had a man walking around town on one leg, and he was lucky to be walking at all. He made it up a tree with that one leg. Bears have the capacity to keep coming even with a bullet in the brain. You don't want to shoot one unless you're sure it can't get to you before it drops. Don't ever be one of those foolish Yellowstone Park tourist types who tries to get close and photograph that kind of bear.

If you want to thoroughly recreate an early colonial Thanksgiving dessert, make a mince pie with a filling of bear meat and dried pumpkin. Sweeten it with maple sugar and use a cornmeal crust.

» **ROASTED BEAR MEAT #1** *Rub a bear roast with sorghum on the top and sides, and roast in a Dutch oven with about $\frac{1}{2}$ inch water. This is my favorite way of making plain old pork roast, too.*

» **ROASTED BEAR MEAT #2** *Rub a bear roast with vinegar and then dry with a cloth. Rub with a mixture of bacon grease, $\frac{1}{2}$ t. poultry seasoning, $\frac{1}{2}$ t. savory salt, $\frac{1}{2}$ t. garlic powder, and $\frac{1}{2}$ t. salt. Put the meat in your Dutch oven or roaster with a little water. Cover tightly and bake at medium heat until tender. That's if you want to be able to taste everything but the bear.*

» **TERIYAKI SPARERIBS BARBECUE** *From Lane Morgan, who reports that her Alaska friends marinate bear spareribs in teriyaki sauce and then cook them suspended over a fire. The sauce tenderizes the meat and cuts the wild taste. The ribs are less greasy because the fat drips out. "Great dinner!" she says.*

DRESSING DEER, ANTELOPE, ELK (AND GOATS): These animals are all more or less closely related and similar to butcher. Remove the innards ("dress it") as soon as possible. Removing all viscera promptly will speed cooling and prevent spoilage so you'll have better-tasting meat. Arrange the animal on its back, hind legs spread. It may help to use a stick, rock, etc. to prop it in the right position. Now you have to cut the critter open from stem to stern, from neck to rear.

Of Sex and Scent. In some states, the law requires that sex identification be left attached to the carcass. If you've got that rule, cut around the scrotum or mammary gland and leave that skin attached. Sex organs won't harm the flavor. However, the scent glands may reinforce the wild flavor unless you remove them. They're on the hind legs, right below the "knee" and toward the inside (belly side) of the legs. Pros remove them carefully: secretions still on hair around the openings could get on your hands or knife blade and from there onto the meat. But most folks just settle for the wild taste.

Basic Gutting. Cut the skin in a straight line from the lower end of the breastbone down to the anus. Be careful not to cut into the intestines. You accomplish that by holding them away from the knife with your non-cutting hand as soon as the opening is large enough for you to get a hand in there. If your animal is a female with milk-filled mammarys, circumvent those and continue cutting to the rectum, but not into it. Then go back and lift and cut away the mammarys. Cut around each side of the sexual organ of a male and around each side of the rectum. Be careful not to cut into the sex organ or rectum. (Any contaminated meat would have to be cut away.) Tie off the rectum so that no contents

can escape. Let it drop into the body cavity.

You will have to cut around the edge of the muscular diaphragm that separates the abdominal cavity from the chest cavity in order to get at the lungs and heart. On an elk or moose, you may well need to use your ax or saw. Carefully reach forward in the chest cavity to cut the windpipe and gullet, which are in front of the lungs. Cutting those will free up the lungs and heart so you can pull them out of the chest cavity. Once all the contents of the chest and abdominal cavities are free, turn the animal on its side. Split the pelvic bone by inserting your knife blade into the seam between the 2 halves of the pelvis, tapping on the end of the handle and then prying downward. Again, on moose or elk, the hand ax may be necessary. Carefully roll out all the intestines, bladder, and genital organs. Also make sure any accumulated blood there is drained away. Slit the muscles holding the windpipe and gullet and pull them out.

Removing the Edible Organs. Cut the heart free from its membrane pouch. Carefully cut away the gall bladder from the liver. You'll have to throw away part of the liver to do this without cutting into the gall bladder. Then remove the liver and the 2 kidneys. You may wish to save the sheets of abdominal fat. To get the tongue, cut through the underside of the jaw deep enough so the tongue can be pulled through the opening and cut off near its base. (Don't remove the tongue if you're planning on having the head mounted.) To get the brains, the easiest way to open the skull is with a meat saw, although you can do it with an ax too. A waterproof bag is a good idea for carrying these back to camp or home. Use the organs for camp meat, if you aren't going home right away, since they won't keep as well as the muscle meat. See "Recipes for Wild or Gamey-Tasting Meats" for camp-type recipes for organ meats.

Cooling the Meat. Wild meat needs to be cooled quickly to avoid spoiling. If you intend to leave the carcass for a while, arrange it in the shade on some rocks or logs with the cavity propped open so that air can circulate through it and the body heat can dissipate. Throw a few fresh branches over it loosely to keep out birds. If you split the backbone between the shoulders with an ax, the cooling process (especially for moose or elk) will be greatly expedited. In warm weather, skin before cooling and cover the carcass or quarters in cheesecloth or cotton bags to protect it from flies. Avoid cooling in plastic or other materials that do not allow air to circulate; they could cause spoilage.

SKINNING, QUARTERING, AND PACKING: First comes a decision: To skin or not to skin? The answer is: It depends. Here are some factors to consider in this judgment call.

"Yes" to Skinning. There are practical reasons why you should skin the carcass quickly. In above-freezing weather, the meat will cool much more slowly with the hide on. In below-freezing weather, you want to finish skinning because the more recently the animal has been killed, the easier it is to skin off the hide. You also want to skin before the hide has time to freeze on, which makes it much more difficult to get off. And meat stays fresh better when the air can get to it.

"No" to Skinning. Alternate thawing and freezing will reduce meat quality. If the temperatures are fluctuating from day to night, you may want to leave the hide on to keep the meat at a more uniform temperature. If you are going to age the meat, leaving

the skin on prevents excessive drying.

How to Skin. Hanging up the animal makes skinning it easier. A “skinning knife” has a curved blade, but you can make do with any sharp hunting or butcher knife. Have some flour or cornmeal handy; if you accidentally cut into the flesh and blood starts to get onto the fur, you can apply flour or meal to the freshly cut areas to stop the blood. Skinning should be done before the skin is set on firmly. On a warm, freshly killed carcass, the skin can almost always be pulled away, and it takes just a few minutes. The skin on a cold animal must be cut away, and that greatly increases your risk of accidentally getting holes in the hide.

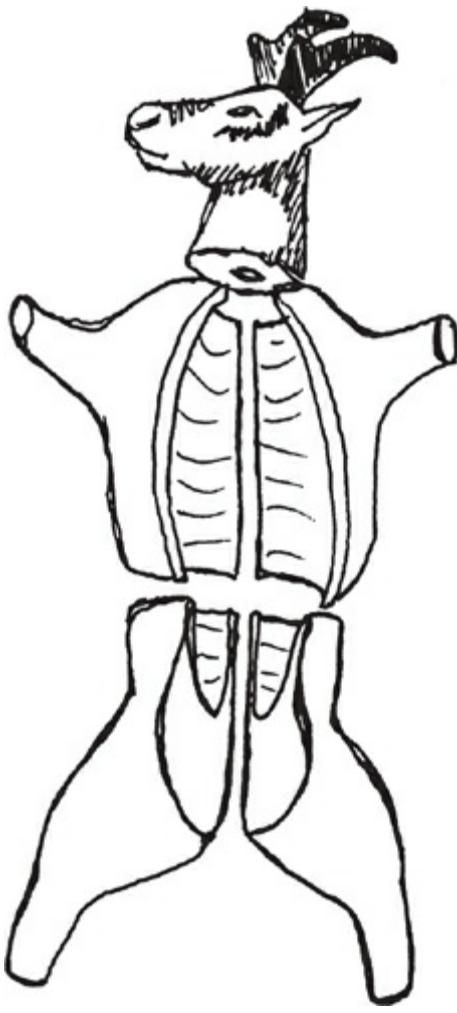

To remove the hide, cut around each of the 4 knee joints. Then slit along the inside of the leg clear up to the center cut from which you took out the viscera. Extend the belly incision on up to the neck just below the lower jaw. Take off the head by cutting completely around the neck, right behind the ears, jaws, and antlers (unless you want to save the head for mounting, in which case the directions are very different and you should come prepared with instructions from your taxidermist as to how he or she wants it done.) Slit the skin on the underside of the tail and then begin cutting the skin from the body. Like mutton, venison has a thin white layer between skin and flesh. You cut through this layer in long easy swipes with a very sharp blade. It helps to have someone pulling the skin taut while you are cutting it loose. If you intend to tan the hide, see the instructions on scraping and caring for the hide in the “Tanning” section.

Skinning Antelope. Antelope is a little tricky to skin and dress. The meat can develop a strong, gamey taste if the animal was run hard or was crippled before being killed. Pronghorn antelope should be cleaned and skinned immediately, right on the spot. Remove the entrails first; then skin. Do not get hair on the meat. Hang the carcass to allow air to circulate for at least an hour before you load it up.

Quartering. This is necessary with wild game unless you can drive to the carcass. Split the body completely in two along the backbone, working quickly to help cool it and avoid any spoiling. Quarter by cutting between the second and third rib from the rear and the vertebrae. To do this quartering, you need a meat saw or sharp ax. Place the quarters in cheesecloth sacks. If you won’t reach home for more than a day or two, salt the hide. Rub the salt all over, more on thicker places, and get into all the corners. Roll the hide and get it to the person who will tan it as soon as you can.

Packing It Out. A big buck deer will dress out to about 200–225 lb., an elk to 800 lb. You can usually pack an elk out 2 quarters to 1 horse. You probably need 3 horses for a large moose. Some people bone out the meat to get the weight down. Balance the meat on the horse’s back to spare the horse from serious injury. This is no problem as long as you pack the 2 front quarters or the 2 hindquarters from the same animal on one horse. Pack one on each side of the saddle, and fasten them down with a diamond hitch.

If you have to pack the meat yourself, don’t drag it. Cut it up into smaller parcels and make several trips carrying it on your back.

Until you can get the meat home, keep it as cool as possible. Quartering and hanging it with air circulating around it will help. On the way home your animal is better off on the trunk of the car than over the hood because the engine's heat promotes spoilage.

SECRETS OF TRIMMING MEAT

1. Chill meat as much as you can before cutting up. Any meat is easier to cut when it is cold because cold fat is firmer. Wild meat, being so lean, is especially wobbly.
2. It helps to have one person trimming fat, etc., off the cuts as another carves them off.
3. Trim away all fat because wild game fat quickly becomes rancid.
4. Unless you're lucky and the hunter got the animal in the head, wherever the bullet passed through it the meat will be messed up—torn and bloodshot (meat containing hard black bits is "bloodshot"). You must trim out all bloodshot meat, or else throw away the whole piece. Bloodshot meat doesn't look or taste good, and it spoils very easily.
5. Get rid of all the black bits. A well-bled animal shouldn't have too many.
6. If some of the meat has started to spoil, trim off the moldy areas or the parts that don't smell good. Go ahead and wrap and freeze the rest. *Such meat, however, must be cooked very promptly and thoroughly upon thawing.*
7. On wild meat, you trim away the tough paper-like outer skin from your steaks. You can cut it at each end and just rip it off across the middle.

BONING OUT: This means removing all the meat from all the bones, period. It's most feasible with a relatively small game animal. But this method, like most "methods," is rather

extreme. We bone out only a few appropriate cuts. You can save the fat for candle or soap making.

CUTTING UP THE HINDQUARTERS: These directions are for deer, elk, antelope, moose, and goat.

Haunch. This is the quarter containing the Achilles tendon, by which you were hanging the animal, and the big rear "haunch." "Haunch" means the whole hind leg of the animal. Cut off the haunch at the hip joint. It begins just below where the ribs end, and you'll have to guess at just the right spot. You'll need your meat saw to get through the bone. Now cut across the haunch in 2 places to make thirds from top to bottom.

The top (widest) third is your round steak. To make big round steaks, cut right across the grain and through the bone of the entire haunch. An easier way, which avoids having to saw across that bone for every steak, is separating the muscle bundles. The largest bundles are the "top round" and "bottom round" cuts. You can separate these two bundles if you want, and cut across into steaks or leave them attached together and cut into steaks (depending on the size of your animal and your preference). The other muscle bundle is the sirloin. Cut across the grain for your sirloin steaks.

The middle third of the haunch is generally made into a roast. Some people, however, strip it off the bone and make hamburger or jerky out of it. The long, nice strips are good for jerky. The bottom third is generally stripped of meat and the meat put into the hamburger or jerky pile. The bone can be a soup bone.

Ribs and Backstrap. What you have left of the hindquarter is the ribs and backstrap. There are 2 strips of muscle along the backbone. The strip along the outside is the backstrap (tenderloin) and is the choicest, most tender meat in the animal. You can either "bone out" these 2 muscles by cutting them away from the backbone and slicing them into steaks, or you can cut across the backbone for each steak and have both muscles represented in each steak.

If you sawed each one out you would have these cuts (using beef terminology), starting from the front end of the animal: club steaks, then T-bone steaks, and finally sirloin steaks. You can see the "T" shaped bone in the T-bone steaks. As a general guide, the first third of the backstrap will be club steaks, the middle third T-bone, and the last third sirloin. Some people make a roast of the last third instead of cutting it up for steaks; to make a roast, just leave it in one piece.

On a small animal such as a deer (a deer has about one-fourth the meat of an elk or cow), all that sawing is not worth the amount of meat you get out of it, so the 2 long muscles are generally boned out. The small inside strip is the one that would be the small piece of meat on the inside of your T-bone steak. If you bone it out, you can slice and make "tips" of it, which are fine floured and fried. You lose a little but not too much on your chop size from the boning-out process. Cut as close to the ribs and backbone as you can to minimize loss. If you decide to bone out the tenderloin, then just cut across it to make the steaks. From a small deer, the steaks are very small but good. Allow 2 or 3 for each person per meal. Some people make a roast of the sirloin instead. If you want 2 roasts, just cut it across the middle.

You can saw across the ribs and backbone to suit yourself for soup bones, spareribs, and dog food. A small deer doesn't make very good spareribs—there is so very little meat on the ribs—but you can try.

CUTTING UP THE FRONT QUARTERS

Arm. Cut the front leg from the ribs as you would a chicken thigh, pulling the bone away from the body in the joint as you cut until it is severed across the line where it joins the

chest. It should pop right out of the joint. In butchering terminology, the front leg is called the “arm.”

Saw the arm into thirds from top to bottom with your meat saw. The top third is called “blade roast.” Some people make it into hamburger because it’s a hard roast to serve and eat, especially if the animal is small. The middle third is made into an “arm roast.” Trim what meat you can from the bottom third of the leg and put it into the pile for hamburger or jerky. Put the bone of that bottom third into your bone box.

Remainder of Front Quarters. The meat along the outside of the backbone is the extension of the tenderloin muscle. Slice steak or tips out of it just like you did on the hindquarters. The rest is pretty much bone. Saw off the backbone and make it into soup bones or whatever you want. Section up the ribs for spareribs or stew meat, using the meat saw where needed.

Recipes for Wild or Gamey-Tasting Meats

For people who aren’t used to wild, “strong,” or unusual-tasting meat and want to disguise that taste, the following recipes will be helpful. They are most likely to suit small and large wild mammals but are also tasty recipes for domestic meat. In addition to these recipes, Oregon State U. Extension will sell you a booklet, “From Hunt to Home,” for \$2.50. Order from 614-292-6181; OSU, Ad S 422, Corvallis, OR 97331; <http://extension.oregonstate.edu/lane/food-preservation/publications>.

STEAK: I was raised in large part on wild meat, and our deerburger was all deer, but there are more gourmet ways to fix wild meat, starting with a simple canned deer stew, which was a childhood favorite of mine, and going from there. One fall my father was hurt in a logging accident in Oregon and had to be laid off for the rest of the winter. The little cash my folks had went for baby milk, and the rest of the diet was venison. So we never knocked venison!

A possible problem with wild meat is that its tenderness varies greatly. Tame meat is usually butchered relatively young. But wild meat might be any age—and correspondingly tough or tender. You’ll soon know the kind you have and will be able to make cooking adaptations accordingly.

Tender Ones

⇒ **FRIED WILD MEAT WITH JELLY GRAVY** Sprinkle the meat with salt and pepper or garlic salt on both sides, and then dip it into flour. Fry quickly over moderate to low heat in a little butter or oil. After 1 side is cooked, turn to brown the other side. Remove the meat from the pan. Thicken the pan drippings with 1 T. (or so) flour. Add water until it is of a suitable gravy consistency, and add 2 T. currant (or other tart) jelly. Season the gravy if your taste buds say it is needed.

⇒ **WILD STEAK, ORIENTAL** Mix together ½ c. cooking oil, 2 chopped garlic cloves, and 2 T. soy sauce. Cut about 1 lb. wild steak into cubes or strips. Let first mixture rest about an hour to get well flavored. Remove and discard seeds from 1 green pepper; then cut it into strips. Chop an onion, add 1 c. chopped celery if you have it, and get ready a couple of fresh tomatoes by slicing into chunks. This is a good one to make near the end of the garden season, when you have this stuff. Now brown the steak bits in your oil mixture; then add green pepper, onion, and celery; and cook about 7 minutes more. Dissolve 1 t. cornstarch in a little water and stir it into the mixture. Salt and pepper to taste. Add a little homemade ketchup or tomato sauce, if you have it; your fresh tomatoes; and a little more water if needed to give the mixture

a manageable consistency. Serve with cooked rice.

➲ **WILD MEAT, HAWAIIAN** Cube or cut into strips about 1 lb. wild steak. Shake the meat in a paper bag with some flour until the pieces are all coated. Brown them in enough butter to do the job. Then add $\frac{1}{2}$ c. boiling water, salt to taste, and simmer until tender. Hollow out and slice 2 green peppers. (Optional: add $\frac{1}{2}$ c. pineapple chunks.) In a separate pan make a sauce of 2 T. cornstarch, $\frac{1}{2}$ c. vinegar, 2 T. soy sauce, 2 T. brown sugar, and $\frac{1}{2}$ c. pineapple juice if you are using pineapple or water if you aren't. When the sauce is thick, pour it over the meat. Cook the entire mixture about 3 more minutes and then serve with rice.

Tough Ones

➲ **MUSTARD STEAKS** Brush both sides of 4 good-sized wild steaks with about 2 T. mustard. Sprinkle both sides of the meat with salt and pepper, and then dip both sides in flour. Brown in melted butter in your Dutch oven. Set aside. In a saucepan combine 2 T. brown sugar, 1 t. salt, 2 T. mustard, and a dash each chili powder and cayenne—and, if you have a strong digestive tract, 2 T. Worcestershire sauce, $\frac{1}{2}$ c. vinegar, $\frac{1}{2}$ c. water, and 1 c. tomato juice or $\frac{1}{2}$ c. tomato ketchup and $\frac{1}{2}$ c. water. When the sauce seems well mixed, pour it over your meat. Put the lid on the Dutch oven and bake at 350°F until done.

➲ **WILD STEAK, HUNGARIAN** Start out with enough steak for 6 people. Dip it lightly in flour; shake off the excess. Brown in a little fat. Pour into your Dutch oven. Brown several large onions, sliced, in some oil. When they're cooked to transparency, pour them over the meat. Add 1 t. salt, $\frac{1}{2}$ t. paprika, $\frac{1}{2}$ c. sour cream, $\frac{3}{4}$ c. water, and 1 bay leaf. Bake at 325°F about 2 hours.

➲ **STEAK AND WATER** Brown steaks in 2 T. shortening. Remove meat from pan. Make a gravy by adding 2 T. flour, salt and pepper to taste, and 2 c. water, after your flour has absorbed all the drippings and browned. Return steaks to pan in gravy. Cook, covered, in the oven at 300°F until tender (about 45 minutes).

Roasts: I usually cook these in a Dutch oven, usually with the lid on, usually at about 350°F but sometimes less, and I usually brown the meat in a little fat in a frying pan to just sear and seal the outside before commencing roasting. You can substitute your favorite roasting pan for my Dutch oven. Trim all the fat away from a wild roast before commencing.

If your meat is from a comparatively old, tough animal, you may prefer a first stage of simmering in a large pan of boiling water, 30 minutes per pound, or until tender. Then drain and finish "roasting." A quicker way to pre-cook is in your pressure cooker. You may have to cut the roast into several pieces to fit. Pressure-cook for 15 minutes at 15 lb. pressure. Then go ahead and "roast." It won't take long after the pre-cooking. Your results will be both delicious and tender.

➲ **WILD MOCK HAM** Bake in an airtight cooker like a Dutch oven at 350°F, 30 minutes per pound. When meat is tender, take it out. In a separate container combine $\frac{1}{2}$ c. brown sugar, 1 t. mustard, and 1 c. orange or pineapple juice (or available juice of your preference). Score outer layer of roast with knife, and pour juice mixture over it. Stud with cloves. Bake uncovered for an additional half hour, basting frequently with pan juices. Good served hot or cold.

➲ **SPICY OVEN-BAKED WILD MEAT** Combine $\frac{1}{2}$ c. flour with 1 t. salt, 1 t. curry powder, $\frac{1}{8}$ t. pepper, and $\frac{1}{8}$ t. paprika, making sure the seasonings are well distributed in the flour. Cover meat pieces (cubes, tips, small animal parts—whatever you want to cook) on all sides with the flour-seasoning mixture. Fry meat in oil or fat until well browned on all sides. Then move

meat to a baking dish, add 1 c. water, cover, and bake an hour. If you like, you can make a gravy before serving by adding flour and water to thicken liquid.

⇒ **BARBECUE-SAUCE WILD ROAST** This recipe is good for 1 entire small animal cooked whole or for a chunk of a bigger one. Cover meat with cold water, add salt, and 1 small hot pepper. Cook over low heat until just tender. Pour off the water; place meat into baking pan. Roast at moderate heat, basting often with barbecue sauce, until it looks done to suit you.

⇒ **ONION-SMOTHERED ROAST** Mix together $\frac{1}{2}$ c. flour, 1 t. salt, and $\frac{1}{2}$ t. pepper. Flour your meat pieces thoroughly in that and then fry them until browned in just enough oil. Move meat to a baking dish. Add 3 large chopped onions, and 2 bay leaves. Bake in a moderate oven until tender.

⇒ **WILD ROAST WITH DRESSING** Brown your roast in a little bacon grease or other fat. Sprinkle it with salt and pepper to suit yourself. Bake in a Dutch oven, covered for 2 hours at 300°F (assuming about a 2½-lb. roast). Make about 1 lb. bread crumbs. Combine them in a bowl with 1½ t. sage, 2 eggs, $\frac{3}{4}$ c. chopped onion, and 1 bay leaf. Add enough milk to moisten the mixture, and mix it well. Take your roast out of the oven. There will be juice in the bottom of the pan. Skim off any grease floating on top of it as best you can. Then spoon your dressing right down into the meat juice all around the roast. Cover and continue baking at 350°F for 1 hour more. To serve, remove the roast and carve it. Serve the dressing in a separate bowl. This is a favorite of mine.

⇒ **COFFEE WILD ROAST** In a wild roast, make slits big enough for sliced onions. Slice 2 onions and fit them into the slits. Make a marinade of $\frac{1}{3}$ c. vinegar and $\frac{2}{3}$ c. water; pour that over the roast. Marinate overnight in the refrigerator or other cool place. When ready to cook, drain off the marinade, brown roast in bacon fat or other oil, lay a few bacon strips across the top, sprinkle salt and pepper over, and set in your Dutch oven or roaster. Add a mixture of half coffee and half water (about 2 c. of each); keep the lid on your roaster and cook at 350°F until done.

⇒ **GREEN PEPPER WILD ROAST** I like this one a lot too. Put your wild roast, a sprinkle of salt and pepper, and 4 chopped garlic cloves (or fewer if you aren't a garlic lover) into your Dutch oven. Pour in 1 c. water, cover, and cook until done. Remove the seeds from 3 green peppers, cut them into slices, and sauté about 10 minutes in a little cooking oil. Add some of your homemade tomato ketchup, canned tomatoes, or tomato juice if you like the flavor. Pour the green pepper sauce over the meat; carve and serve.

⇒ **HERBED WILD ROAST** Combine $\frac{1}{2}$ c. flour, 2 t. marjoram, 1 t. thyme, 2 t. rosemary, and 1 cut-up clove garlic. Rub your wild roast with a little cooking oil. Sprinkle salt and pepper on it; then apply your herb mixture to it. Put the roast into your Dutch oven; add 1 c. water and 1 c. apple juice. Bake, basting occasionally, until done.

⇒ **MOOSE POT ROAST WITH MUSTARD AND TARRAGON** From cookbook author Lane Morgan! Marinate meat a few hours in red wine, raspberry or blueberry vinegar (if available), and a little soy sauce. Brown meat in a little oil. Then add a few chopped garlic cloves, a chopped onion, and 2 tomatoes (fresh, canned, or frozen). Reduce heat. Add a pinch of tarragon, 2 T. Dijon mustard, and salt and pepper to taste. You can also pour in some of the marinade, but you don't have to. Cover tightly, and simmer or bake until meat is done. The meat will make its own juice. Pour the sauce, which is fantastic, over the sliced meat and barley or rice.

➲ **WOODSMAN'S LIVER** Slice liver $\frac{1}{2}$ to 1 inch thick. It will grill quickly over a campfire on the end of a pointed stick or over a rack made of green wood. Eat plain or with salt and/or butter. A method that's a step less primitive is to brown it in a frying pan in fat. Optional: add chopped onions.

➲ **LIVER AND ONIONS** Cut liver into thin slices and soak in salted water for 1 hour. Dry slices and dredge in flour; fry in butter and add sliced onions. Fry until tender.

➲ **WOODSMAN'S HEART** Cut heart $\frac{1}{2}$ inch thick, season, baste with margarine, and broil over campfire about 3 minutes per side. A less primitive method is to fry in a pan in a little fat and season with salt and pepper. For tougher meat, roast in a Dutch oven until tender. Add vegetables (potatoes, carrots, onions) to boiled heart for a campfire stew.

➲ **STUFFED HEART** Prepare your favorite stuffing or combine instant rice, mushrooms, chopped onions, celery, salt and pepper, and beef bouillon. Cook all the stuffing ingredients in the bouillon. Clean the heart and remove membranes. Stuff the heart and bake, loosely covered, at 325°F for 15 to 20 minutes per pound of meat.

➲ **KIDNEYS** Strip away the connective membrane. Cut kidneys into walnut-size chunks. Simmer covered with water in low heat with butter, salt, cloves, and some chopped onion. Discard liquid and serve meat with mashed potatoes and/or fresh bread.

➲ **WOODSMAN'S BRAINS** When the fresh brain arrives in camp, salt it lightly and keep overnight. The next day, dip it into hot water. The outer membrane will peel off easily. Dip the brains into beaten eggs and then in crumbs, and fry in a little oil slowly until crisp outside and hot all through. Season to taste. Or mince them, add chopped green-onion tops and beaten eggs, and scramble the whole works.

➲ **TONGUE** Cover with cold, salted water and boil thoroughly, spooning off any scum that comes to the surface. When the tongue is tender, cook it; then peel off the outer skin. Good sliced thin and served with mustard or horseradish with or without bread. The tongue of a very young wild animal is so tender that it will cook up to a mush if you're not careful.

➲ **CAMPFIRE MARROW BONES** Heat them in the campfire, break them open to get at the marrow, and eat the marrow.

Small Wild Mammals

Lane Morgan suggests that I "mention the animals that are most realistic for hunting in most areas of the country—squirrels and raccoons and possum, I suppose. We could certainly use fewer possums around our place." The wise and knowledgeable Gene Logsdon, one of my favorite authors, wrote in *Gene Logsdon's Practical Skills* (published by Rodale Press, listed in the book source list in [Chapter 1](#)): "Eating wild rabbits, squirrels, groundhogs, and raccoons seems distasteful, even to those who are gulping down steak and hamburger every day. As civilization 'advances,' that part of its society that eats meat tends to restrict itself to fewer and fewer species of animals, which is quite wasteful. Earlier societies ate many more kinds of meat than we do today: in medieval Europe all manner of birds and small game were kept in captivity for meat, occupying various niches in the food web." So here are some tips to help you expand your food resources if you so choose.

HEALTH RULES FOR SMALL-ANIMAL EATERS

1. Never eat a small animal that is already dead.
2. Don't hunt an animal that isn't acting lively.
3. Even if you personally kill the animal, if, once you have a chance to inspect it more closely, it looks somehow in poor health, don't even touch it. (When in doubt, throw it out.)
4. Wild rabbits and some other small mammals may be sick with infections that can be contracted by the hunter (less likely during winter). Don't cut yourself while cleaning such animals. It's recommended that you wear rubber gloves when skinning or cleaning any small game animal, especially wild rabbits.
5. Check the animal's liver. White cyst-like spots in the liver, pea-size or smaller, indicate tularemia or coccidiosis. If you have handled an infected carcass, clean hands thoroughly with strong soap and discard the meat. *Do not eat the meat of animals with white liver spots.*
6. Don't eat brain—not even well cooked.

KERNELS: Some small mammals have small waxy or reddish glands, like kernels, situated under the forelegs, along the lower part of the backbone, and/or under the lower part of the abdomen. They are often pulled away with the skin. If not, they must be carefully cut out so as to be removed intact because if one gets cut, it will give a strong, musky taste to the meat.

SPECIAL SMALL-MAMMAL TIPS

Beaver: Cook beaver tail in the skin. Beaver tail meat is gelatinous. Use like ham with baked beans or pea soup.

Muskrat: Remove scent glands situated under both hind and forelegs.

Opossum: When skinning, remove scent glands in the small of the back and inside the forelegs.

Porcupine: Skin by starting with the unquilled belly.

Rabbit, Wild: *Wear gloves.* Remove glands from under forearms.

Raccoon: Carefully remove the brown, bean-shaped kernels under each front leg and on both sides of its backbone, similar to opossum.

Woodchuck: As part of the skinning process, carefully remove the small red scent glands located between the forelegs and the body. Because of its exceptionally strong flavor, boil wood-chuck for 20 minutes in salted water (then discard the water) before using it in any recipe.

DRESSING: Small game should be dressed as soon as possible and allowed to cool thoroughly. Remove the entrails and let the blood drain. To clean a rabbit in the field, make an incision down the belly from the vent to the breastbone, taking care not to puncture the intestines or stomach. Grasp the front feet and the head in one hand and swing the rabbit sharply downward, snapping the entrails out of the body cavity. Then reach into the chest and pull out the lungs, heart, and liver. Cut off the head and wipe the body cavity out with a cloth or dry grass.

BASIC SMALL-MAMMAL SKINNING: These directions are for when you want to use the skin. Any small game—muskrat, wild (or domestic) rabbit, squirrel, opossum, porcupine—may be dealt with as follows. Cut off the head, tail, and forepaws. Hang up the torso by the hind legs. Have those hind legs separated far enough so you'll be able to easily work between them. Cut on the backside of the leg in a straight line from the hock on one side up to the tail hole. Do the same thing on the other side. Now cut the skin from foreleg to the neck opening on one side, and then do the same on the other side. Starting from the hind end of the animal, now peel off the skin. Using pliers can help you get a better grip on the skin so you can pull hard enough to get it off. Squirrels have tough skin that clings more.

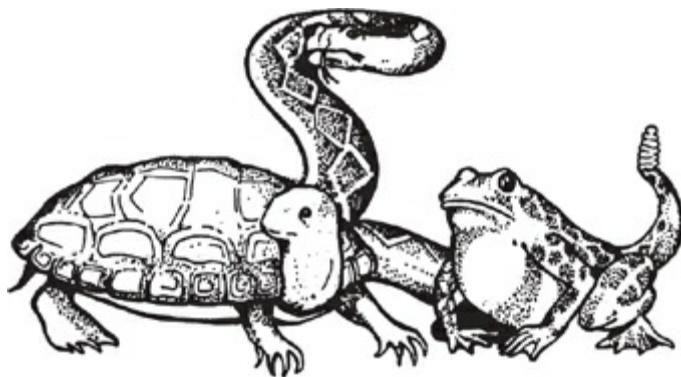

After cutting through the tail (keeping it attached to the back of the skin) and slitting the skin from the base of the tail down the back side of each hind leg and around the hocks, peel the skin off the back legs. Now stand on the tail and pull upward on both of the squirrel's hind legs. This may take a little practice, but eventually you'll be able to peel off the hide over the head and front feet. For more info and suitable recipes, see the section on rabbits in [Chapter 11](#). You can leave the skin on a wild rabbit until you cook or freeze it.

COOKING A SMALL MAMMAL: Any small game may be cooked whole or cut into pieces. Use in wild-meat recipes, rabbit recipes, chicken recipes, or any meat recipes that you feel like trying it in. See "Recipes for Wild or Gamey-Tasting Meats" for more ideas.

➲ **BRUNSWICK STEW** *This is a classic old-time small animal dish. Start with 2 lb. meat; a medium-sized bird, a large rabbit, or several squirrels will do it. Brown the meat in fat along with 1 chopped onion. Cover and boil with water or bake until meat is tender. Then add water (if more is needed), corn, tomatoes, and beans. There are infinite variations: the corn can be canned or on the ear, the beans can be lima or green, the tomatoes can be fresh or canned. Season to taste with salt and pepper. Eat when the vegetables are cooked.*

Snail, Snake, Turtle, and Frog

Here's how to prepare these critters that are neither bird, mammal, nor fish.

SNAIL: There's a lot to know about collecting and eating snails. Some are not good to eat. Some need special treatment. There are land and marine snails too, and each are different. California is good snail hunting country. Here's the necessary info (thanks to the Division of Agricultural Sciences, U. of California) for preparing the edible European brown snail or brown garden snail (*Helix aspersa*), which is called "escargot" in French but is the same as the common garden snail considered a pest in the gardens and yards of California. Also known in France as the *petit gris* or vineyard snail, it was probably first brought to the North American continent around 1850. Another edible snail found in some parts of California is the white Spanish or "milk" snail (*Otala lactea*), which is preferred by many people of southern European stock. (Ask an Italian!)

Snails have been used as food throughout the world for centuries. Edible types can be cultivated in cages placed in dooryards, basements, and even in dwellings. Snails are close relatives of the abalone, a sea snail that's also a table favorite. But the U.S. escargot is generally thought of as a garden nuisance rather than as a free, low-calorie meat crop (about 90 calories per 100 grams [3.5 oz.] of snail meat) that's also rich in protein and minerals. It would be much better to harvest and use snails for food than to poison them.

Harvesting. The brown garden snail (escargot) is about 1 to 1½ inches in diameter and ½ inch wide when mature. Mature snails are the best for cooking—there is more and tastier meat, and the shells are easier to get off. Immature snail shells are thin and hard to work with.

NOTE: Don't collect snails in areas where poisons have been used for snail control. Instead, water down the area thoroughly and wait at least 6 weeks before collecting snails.

Snail hunting is best about 2 hours after dark because snails are night creatures. Take only moving snails: that's a sign of good health. Light watering in the late afternoon before your hunt helps bring them out of hiding. You may be able to harvest them more easily during dry weather, when they seal themselves to any surface available; in citrus groves, for example, tree trunks are often covered with hundreds of snails.

Purge. *Snails collected for eating must be purged of any off-flavor or toxic materials from previously eaten food.* Put about ½ inch of damp cornmeal in the bottom of a container such as a plastic wastebasket, metal pan, or crock. Put snails in the container and cover with a ventilated top; a wire refrigerator shelf, hardware cloth, cheesecloth, or nylon netting provides plenty of air and let you observe the activity of the snails. The cover should be weighted with bricks or tied securely so the snails do not escape. Place the container in a cool, shady area and let snails purge themselves (by eating the cornmeal) for at least 72 hours. Snails can be kept in containers for a long time if the cornmeal is replaced every other day to prevent it from molding and souring. The snails will feed and then crawl up the side of the container to rest; use only active snails. *Throw away without eating those that remain inactive on the bottom.* After 72 hours the snails can be removed from the container and washed thoroughly with cold running water to remove the

cornmeal from their shells. They are now ready for blanching, another essential procedure.

Blanch. Plunge the live snails into boiling water and simmer about 15 minutes, as is done in preparing live shrimp, lobster, crab, or crawfish. (A bay leaf in the cooking water will give this operation a pleasant aroma.) The water will foam as the snails cook, so heat should be controlled to prevent the kettle from boiling over. After blanching, turn snails into a colander to drain. Then, with a toothpick, nut pick, or pointed knife, pull the snail meat from the shell. Save some shells for later use.

Remove Gall. Remove and discard the dark-colored gall, about $\frac{1}{4}$ inch long, which is found on the tail end, where the snail is attached to the shell. Wash snail meat several times under cold running water.

Frozen Snails. After purging and blanching snails, the meat may be packaged and frozen for later use or prepared according to your favorite recipe.

Preparing the Shells. Boil the empty shells for 30 minutes in water to which about $\frac{1}{4}$ t. baking soda per pint of water has been added. Drain the shells, wash them thoroughly in cold running water, and then dry them. Use them to serve snails in recipes calling for cleaned shells.

NOTE: Avoid or minimize salt and vinegar in snail recipes, because they make snail meat tough.

Snail Recipes

⇒ **SNAILS IN TOMATO SAUCE** Sauté 1 chopped medium onion, 2 crushed cloves of garlic, and $\frac{1}{2}$ c. chopped bell pepper in 2 T. oil. Add 1 lb. canned tomatoes, salt and pepper to taste, and simmer until bell pepper is tender and flavors are blended. Add 1 pt. cleaned and blanched snails and simmer 10 minutes. Serve over hot toast wedges, hot cooked rice, or hot noodles.

⇒ **BAKED SNAILS** Simmer cleaned, blanched snail meat for 10 minutes in water seasoned as desired with onion, garlic, allspice, bay leaf, etc. Toss cooked snail meat in melted butter or margarine and roll in bread or cracker crumbs seasoned with salt, pepper, and garlic powder. Place in greased shallow pan and bake in a hot oven (450°F) until brown. Sprinkle with lemon juice before serving.

⇒ **STUFFED SNAIL SHELLS** Simmer cleaned, blanched snail meat in salted water until tender. Chop snail meat, mix with minced garlic, and sauté in olive oil or margarine about 5 minutes. Stuff cleaned shells with the chopped, seasoned meat. Seal shell opening with garlic butter. Place under broiler for a few minutes until butter bubbles. Serve immediately.

⇒ **FRIED SNAILS** Simmer cleaned, blanched snail meat for 10 minutes in water seasoned as desired with salt, bay leaf, parsley, thyme, allspice, etc. Roll cooked snail meat in fine cracker or bread crumbs seasoned with salt, pepper, and garlic powder. Fry in oil until browned, as you would fried oysters. Sprinkle with lemon juice to serve. These may be served as an entree or, pierced with toothpicks, as hors d'oeuvres.

⇒ **SNAILS IN WINE SAUCE** Combine in a casserole dish 18 cleaned and blanched snails, 2 diced slices of bacon, 9 small boiling onions or $\frac{1}{2}$ c. chopped onion, 1 crushed clove garlic, 1 T. minced parsley, a pinch thyme, $\frac{1}{4}$ t. pepper, and 1 c. red wine or grape juice. Cover and bake 1 hour in a slow oven (275°F). Just before serving, thicken with a butter and flour mixture and serve over crisp toast wedges or croutons. (Serves only 3 people.)

⇒ **SNAILS IN GARLIC BUTTER** Start by creaming together until thoroughly blended 1 crushed large clove garlic, $\frac{1}{2}$ c. butter or margarine, 3 T. finely chopped parsley, 2 t. finely minced green onions with tops, $\frac{1}{4}$ t. salt, and $\frac{1}{8}$ t. pepper.

SNAKE/EEL: These instructions are for snake, but you can prepare eel the same way. Kill the snake by cutting off its head. If it's a poisonous snake, be careful not to touch the fangs, since they contain poison that can enter the bloodstream through a cut or scratch in your skin. There is no poison in the meat, which is typically very white and tender. To skin the snake, nail it down or have someone hold it by the front end with a pair of pliers. Peel off the skin as you would peel a banana. Cut open the body and take out the innards. Cut the skinned meat into 2–5-inch portions. You can split them down the backbone to make them lie flat.

➲ **FRIED SNAKE** Dip pieces into beaten egg. Roll in seasoned flour (garlic, salt, pepper) or cracker crumbs. Pan-fry or deep-fat-fry the snake. Or wrap to keep from drying out, and bake.

TURTLE: Freshwater snapping turtles are good eating but dangerous to catch. Grip the shell behind the head, so you can't get bitten. Or get it biting on a stick and then cut off its head with an ax. Let it hang head downward after beheading until bled out. Cut off all the claws. Then skin the hide down the legs to the feet, which you cut off at the joint. Small turtles can be cooked in the shell until the meat cooks free. Another school of turtle cuisine prefers to proceed by dropping the live turtle into a pan of boiling water, cooking it for about 10 minutes, and then moving it to ice-cold water for 10 more minutes. After this treatment, it will be possible to rub the skin from head, tail, and legs.

Whether you skin or boil your turtle, the next step is the same: you cut through the shell part connecting top and bottom shells. You can use a sharp knife if you have a snapper, but you'll need a saw or ax for a tougher-shelled turtle. Then pry off the bottom shell. Once the shell is off, you can easily remove the innards. After you get the turtle shelled and cleaned, cook it whole, cut it into quarters, or cut it up as you would chicken (depending on its size and the size of your cooking pans).

There's a good section on the diamondback terrapin in Gene Logsdon's *Getting Food from Water*.

➲ **DORIS'S TURTLE** Soak turtle meat 8 hours in cold salt water (important). Flour it in a mixture of unbleached white flour, salt, and pepper; brown in a frying pan; and bake 4 hours in a slow oven. Or, after browning, add 2 sliced onions and enough water to cover, and simmer until tender. Make gravy with pan juices and serve with mashed potatoes. For turtle soup, Doris does the same as above and then cools the meat and removes the bones. She chunks the meat and cooks it together with small whole new potatoes, corn, peas, carrots, celery, a bay leaf, a little curry powder, lima beans, and fresh snap beans. She adds additional seasoning to taste and sometimes tomatoes too.

FROG: The front and hind legs of bullfrogs, leopard frogs, and green marsh frogs are all edible; the rest is discarded. In Oregon the bullfrog is classified as a game fish, and there's a specific bag limit of so many per day. To prepare frog's legs, cut off the legs, remove the feet, and peel off the skin.

➲ **GOUPMET FRIED FROG'S LEGS** Season the legs with salt, pepper, and lemon juice. Dip legs into beaten egg and then into crumbs of flour. They will fry very quickly—about 3 minutes in deep fat (a wire frying basket preserves their crust). If you are pan-frying them, turn the heat low and cook 5 to 10 minutes, turning as needed, until the meat separates easily from the bones. You may substitute frog's legs in any gourmet or regular chicken or rabbit recipe.

PRESERVING MEAT

SANITIZER: You can use 1 T. chlorine bleach to 1 gallon of cool water to make a basic sanitizer with which to clean equipment, hands, and work surfaces that you have worked with raw meat on. It's important to have all those surfaces cleaned before you use them for cooked meat.

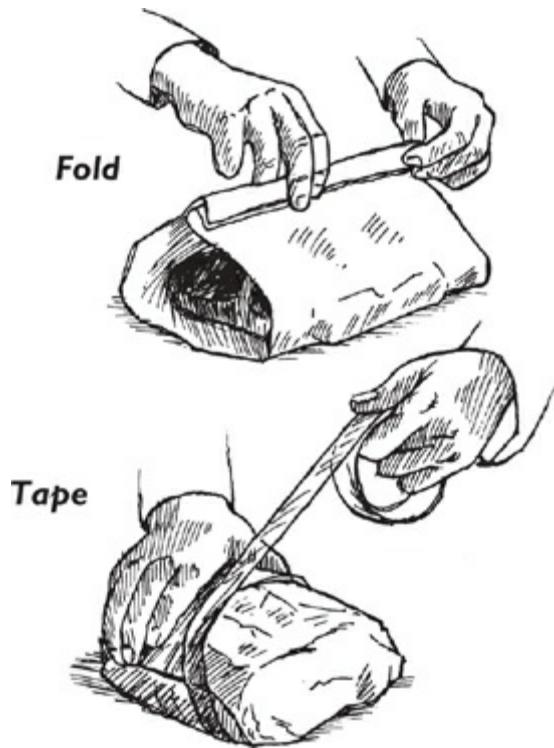

Freezing

NOTE: If you want to store meat in your freezer a long time, keep in mind that unsalted, unseasoned, unground meat keeps the longest and best.

Gone are the days when smoking, salting, and canning were the only alternatives to eating meat as soon as it was slaughtered. Freezing is perhaps the best way to preserve meat. It has virtually no effect on flavor or texture and gives you the convenience of having a variety of fresh meats in all seasons. Freezing won't keep meat forever but, estimating conservatively, at 0°F beef and lamb can be stored up to 9 months, veal keeps for 6 months, and ground meats and pork are good for 4 months. Some think that several weeks of freezing has a tenderizing effect, but a tough steak is pretty much always going to be a tough steak. Plan ahead for your freezing needs. Despite the number of home freezers that are crammed with meats and animal products, the home freezer was not designed to quickly freeze hundreds of pounds of meat at a time. If you are butchering that much meat, I would advise you to get a freezer storage locker and just keep enough meat at home for a week's meals. Or else butcher during very cold weather and let nature help with the quick freezing.

WRAPPING AND FREEZING MEAT: Immediately after cutting, meat must be properly wrapped, quickly frozen, and stored at 0°F. You'll want to freeze the meat at -10°F or lower, if possible. Put in only the amount of meat that will freeze in 24 hours, and allow ample air circulation by not overpacking the freezer. "Proper wrapping" means using moisture-proof wrap, such as heavily waxed freezer paper, and wrapping meat closely in order to keep out as much air as possible. Air in your package can result in freezer burn and rancidity of the fat.

Freezer Paper. It is shiny on one side, plain on the other. Have ready a pile of sheets of your freezer paper. To cut across the big roll of butcher paper, take a few good snips with your sharp scissors. Then, holding the paper firmly, just push the scissors on across, and it will cut like a razor. An even faster way is to measure out the length of paper needed. Then place the rolled paper on the edge of the kitchen counter or tabletop and pull the paper across the table edge. It will tear straight across.

Wrapping Procedure. Figure out how many steaks or chops your family needs per meal, and wrap just that number into each package. Place 2 layers of butcher paper or ordinary waxed paper between the individual steaks or chops. That way they'll come apart easily when you need them. Also figure out how much stew meat and how many pounds of ground meat you should put in a package. Ground meat can be stored in rolls, blocks, or ready-to-cook patties, with 2 layers of paper between. You can season meat before you freeze it, but if you expect to keep it frozen longer than 2 weeks, wait to salt it until after you thaw it. Put the meat on the shiny side of the paper—that's to keep it from sticking and from soaking the paper. Put the meat in the center of the sheet, a little nearer one corner. Fold that corner over the meat, fold in both sides, and roll the meat over and over until the paper is used up. Fasten the loose end with a strip of freezer tape. (Freezer tape is needed because regular tape doesn't hold well under freezing temperatures.) Write on the package the kind of animal (elk, beef, or whatever), the kind of cut (steak, stew, or the like), and the date.

Here is a way of double-wrapping meat that some people use. We don't because we're frugal of paper and use up the meat relatively quickly, but for an excellent wrapping method that pushes out the air and protects your meat from freezer burn over the long term, do this:

1. In center of paper, put enough meat for one meal.
2. Wipe hands clean.
3. Bring paper tops together and fold over. Tuck under ends as if wrapping a gift.
4. Get second sheet of paper. Double-wrap.
5. Tape it closed.
6. Write on the outside what is inside and how many of them.

ABOUT FREEZING AND TRICHINAE: Does freezing kill parasites? Yes, if the meat is frozen long enough—and at a sufficiently cold temperature. The kind of parasite that is hardest to kill by freezing is trichinae, which may be in bear or pork meat. The "Freezing Temp. and Time to Destroy Trichinae" table shows how to kill it by freezing. But trichinosis can

always be avoided by cooking meat, especially pork and most especially bear, to an internal temperature that destroys the trichinae parasites. *Fully cook to the point where there is no pink left at all!*

THAWING MEAT: You can thaw small amounts of frozen meat in various ways: at room temperature, in the refrigerator, at a low temperature in the oven or the cooking pot, or in the microwave. At room temperature, thawing 1 lb. meat takes 2 to 3 hours; in the refrigerator, 5 to 8 hours. Large slabs of meat should be thawed in the refrigerator.

Canning

My mother canned a lot of meat when I was a little girl, and one of my most pleasant childhood memories is of the taste of her canned venison stew. You can can any kind of meat. Chicken and rabbit may be canned on the bone, but all the bigger meats, of course, are cut away from the bone before canning. Canning is a good way to handle tough cuts because they get cooked tender in the process. *Can only fresh meat that was chilled immediately after killing and kept chilled until canning.* Don't can any meat that has turned dark or smells like it's starting to spoil!

See the canning directions in [Chapter 7](#) for info about supplies and safe methods.

PREPARING

Large Pieces of Meat. Chill the fresh meat immediately after slaughtering at 40°F or below (but don't freeze it, or you lose quality). You can hold the chilled meat for several days or can it as soon as the body heat is gone. Don't wash meat; if needed, just wipe the outside with a damp, clean cloth.

Frozen Meat. Canning frozen meat is a second-best option but if you have to, it can be done. *Don't thaw it.* Just cut into pieces with a saw and soften them in boiling water until they are soft enough to pack in jars. Cutting across the grain, remove most of the fat and reduce the meat to pieces that fit into the jars. Smaller, less tender cuts should be canned separately for stews and casseroles. Bones simmered in water make fine broth both for canning and for soups.

Strips, Cubes, or Chunks of Meat. Choose quality chilled meat. Remove excess fat. Soak strong-flavored wild meats for 30 minutes to an hour in brine water containing 1 T. salt

per quart. Rinse. Remove large bones. Then hot-pack or raw-pack.

PACKING MEAT IN JARS: You can either raw-pack or hot-pack.

NOTE: Always leave 1-inch free space (“headspace”) at the top of each jar to assure a good seal.

Raw Pack. Add 1 t. salt per quart to the jar, if desired. Pack raw meat loosely in clean hot jars, without adding any liquid. Wipe the sealing edge dry.

Hot Pack: Precook meat until rare by roasting, stewing, or browning in a small amount of fat. To brown, just place the meat in a large, shallow pan with a little water. Cover and heat until it is medium done (the pink is gone from the inside). Add 1 t. salt per quart, if desired. Loosely pack hot meat in jars with the juice, or add about 4 T. broth, water, or tomato juice (tomato juice is especially good with wild game) per quart jar. You don't need much liquid, since canning cooks more out of the meat.

PROCESSING: *Pressure-can only.* Place lids on jars and process pints 1½ hours, quarts 1½ hours. Process at 10 lb. pressure (weighted gauge) or 11 lb. pressure (dial gauge). Increase pressure for higher elevations according to the “Altitude Adjustments for Pressure Canning” table. Consult your pressure-canner manual for specific meat-canning directions. *Don't underprocess meat!*

USING: When using meats you have canned, always make sure the seal is good (listen for a rush of air, similar to the sound when you open a sealed coffee can). If you don't hear that sound, or if there is dryness, discoloration, or a bad smell, throw away the meat.

OTHER CANNED-MEAT VARIATIONS

Ground or Chopped Meat. This recipe is good for bear, beef, lamb, pork, sausage, veal, venison, etc. Use fresh, chilled meat. With venison, add 1 part high-quality pork fat to 3 or 4 parts venison before grinding. Use freshly made sausage, seasoned with salt and cayenne pepper (sage may cause a bitter off-flavor). You can add additional spices when you cook the meat for serving. Use ¾ lean meat to ¼ fat. Shape chopped meat into patties or balls or cut cased sausage into 3–4-inch links. Cook until lightly browned. Ground meat may be sautéed without shaping. Remove excess fat. Hot-pack only; fill jars with pieces and add boiling meat broth, tomato juice, or water, leaving 1-inch headspace. Add 1 t. salt per quart to the jars, if desired. Pressure-can using “Processing” directions.

Meat Patties. For ground meat, remove fat and keep meat cool while you are working. Add 1 t. salt per 1 lb. meat that you grind. Form ground meat into thin patties that will fit into jar without crumbling. Precook them in the oven at 350°F until they are medium done. Drain off the fat drippings and place patties in jar. Add enough boiling broth or water to cover them. Make sure there are no air bubbles trapped under the patties. Pressure-can using “Processing” directions.

Canned Soup Stock. A way to keep from wasting the bones is to boil them up for a soup stock and can that. Soup is a great thing to have on hand for general cooking purposes. Cook your bones, chicken, etc., until tender in lightly salted water. Then chill. Remove fat and bones. Keep the meat and sediment. Reheat and pour your boiling soup into jars. Don’t use burned pieces or bones from pork, smoked or corned meats, or fatty lamb to make stock. You can also freeze your stock, in which case you can lift the frozen fat from the top and have very lean stock. Before canning your meat or soup stock, season it with salt, a few vegetables and onion, celery leaves, bay leaf, or whatever you like. Hot-pack. Adjust lids and pressure-can using “Processing” directions.

Variable Vegetable and Meat Soup. For this soup, you use a mixture of vegetables, dried beans or peas, meat or poultry, and broth. Select, wash, and prepare dried beans or peas, meat, and vegetables as follows. Dried beans or peas: For each cup, add 3 c. water. Boil 2 minutes, remove from heat, and soak one hour. Reheat to boiling; drain. Meat: Cover with water and cook until tender. Cool and remove bones. Vegetables: Simmer several minutes until barely cooked. Broth: Meat broth, canned tomatoes, water, or a combination may be used. Season to taste. *Do not add flour, cornstarch, or any other thickening agent.*

Combine meat, vegetables, and drained beans or peas. Add sufficient broth to cover. Boil 5 minutes. Pack jars half-full with hot soup mixture. Add more hot broth to fill jar, leaving 1-inch headspace. Adjust lids and pressure-can using “Processing” directions.

Basic Canned Meat Stew. Cut up about 5 lb. meat (beef, venison, chicken) into about 1½-inch cubes. If you wish, brown in a little fat in your frying pan. Add ½ gal. chunked carrots, 1 qt. chunked onion, and 3 qt. peeled potato chunks. Add 1–2 T. salt, and pepper or other seasonings to taste. Mix together; add boiling water and heat until food is heated through. Pack hot into hot jars. Allow 1-inch headspace. Put lids on and pressure-can using “Processing” directions.

Wild Meats. Use the methods in this section, but soak the meat in a brine solution for 30 minutes to an hour before placing it in jars.

⇒ **HOME-CANNED MEAT SANDWICH** Open jar. Take out meat. Slice meat. Lay on bread. Add mustard, mayonnaise, and/or sliced pickle.

⇒ **ALMOST INSTANT CANNED BEEF DINNER** Cook 1 lb. rice. Open a jar of canned beef (or other meat). Add barbecue sauce. Heat. Serve beef sauce over the rice.

Drying

There are 2 basic ways to dry meat. The modern way is to precook, cube, and dry by sun, oven, or dehydrator. The other way—drying thin strips of raw meat, combined with salting—produces jerky.

MODERN MEAT DRYING: Prepare the meat by trimming off all the fat, boiling it until it is tender (or pressure-cooking it for 20 minutes at 15 lb. pressure), and cooling. Cut into fairly small cubes and spread on trays. Chunks larger than ½ inch square may not dry thoroughly. Dried meat is about two-thirds its original size.

Reconstituting. Pour boiling water over dried meat cubes and then simmer them for 45 minutes to return them to a tender eating consistency.

Heat Sources. You can dry it in the sun if the weather cooperates. Just place trays of cooked meat cubes in a well-ventilated place, covered to protect from insects, where the sun will shine directly on them. It may take 2 or 3 days to get the cubes hard and dry to the center. Turn the cubes several times to get all sides dry. You can also use a commercial dehydrator, a homemade dehydrator, or your oven if you have good control over the lower temperatures. The method for all these devices is the same: keep the temperature at 140°F for the first 4–6 hours, and turn and stir the cubes frequently; then reduce the temperature to 130°F and continue at that heat until the cubes are hard and dry.

Storage. Keep in an airtight jar. Remember that each time you open the jar, moisture in the air gets in. *Dried meats, especially jerky, keep only a short time at room temperature because any fat on the meat will turn rancid.*

JERKING: Indian-and pioneer-style dried meat is called “jerky.” In this case, strips of raw meat are seasoned in a salt-and-pepper brine and dried (or smoked). Some Indian tribes soaked meat in sea water to salt it before drying. Or they hung strips over a slow-burning fire to smoke-dry it.

Jerky is a homemade snack that anyone can enjoy. It’s tasty and nourishing cold, and it can be cooked into stews. I send Grandpa Emery a big jar of jerky with a red ribbon around it at Christmas because he really likes that kind of thing. It’s good for company. But like many other old-fashioned arts, you have to practice a couple of times to get comfortable with the procedures and to find out just how dry and how spicy your family likes its jerky. Modern commercial jerky is so heavily treated with seasonings and preservatives that trying to eat it as a basic food would make you sick. Meat jerked to use as a basic food should be cut in very thin strips, prepared without any salt or spices, and dried in the sun a couple of days. Good to eat, snack on, and use in stews and soups. *Freezing is the safest way to store it.*

Meats to Use. The original jerky was made of unsalted raw beef, but you can make jerky from other raw meats as long as they don’t carry parasites. But so many meats are at risk for carrying parasites that beef, deer, elk, or moose are basically the only choices you have. Use lean red meat. You can jerk any well-cooked meat. Cooked turkey and chicken make tasty jerky. Veteran meat jerkers use the poorest meat for sausage and better cuts

such as the loin and round steak for jerking. Frozen meat can be thawed and jerked at any time in its locker life, if it was put into the locker fairly promptly in the first place. About 5 lb. raw meat yields 1 lb. jerky.

Preparing Meat for Jerking. First remove all fat, bone, and visible connective tissue. Cut the remainder into strips about 5 inches long, 1 inch wide, and $\frac{1}{2}$ inch or less thick. (Or 6 inches long and $\frac{3}{4}$ inch across, or 9 inches long, or whatever you like—but remember that any piece thicker than $\frac{1}{2}$ inch will be hard to get dry.) Cut lengthwise along the muscle, not against the grain, to make the long strips. Partially frozen meat will cut more easily into proper-shaped slices. Some cooks then parboil the strips for 13 to 30 seconds, just long enough for them to change color. Some people then marinate the strips.

Seasoning. After the strips are cut but before they are dried, you season them. There are as many possible ways to do this as there are recipes for jerky, and really, they all work okay. You'll probably experiment. Mike and I never have agreed about it. The simplest method of "seasoning" is to dip the meat into salted (*not iodized*) water, but people usually want a stronger flavor. Some people use soy sauce or Worcestershire sauce as a marinade. You can soak the meat in a seasoned brine for 24 hours; then rinse briefly and hang up to dry. Or else rub or pound the seasoning in by hand, let the seasoned meat rest a few hours, and then rinse it off under the faucet. Jerked meat usually takes more seasoning than you might think because the heat of the drying process weakens the spices. Sugar, allspice, oregano, marjoram, basil, thyme, garlic powder, and Tabasco are all possibilities. Some people, when making oven-dried jerky rather than smoked jerky, fake it with that store stuff called liquid smoke.

Here are a few seasoning recipes to get you started.

➲ **PURE SALT BRINE** Make a brine of $\frac{1}{2}$ to $1\frac{1}{2}$ lb. pickling salt in 1 gal. water. Proceed as below.

➲ **SWEET BRINE** Dissolve 1 lb. pickling salt, 1 lb. brown sugar, 1 t. ground allspice, and 2 T. black pepper in 1 gal. water. Use a granite canner, crock, or plastic bucket. Soak the jerky strips in the brine for 12 hours. Weight the meat with a plate and a quart jar of water on top of the plate so that the liquid stays over it. Then rinse off in clear water. My husband prefers this recipe, but I think it is very strong. To weaken it, leave the meat in the seasoned brine a shorter time. Also, marinated meat is likely to take longer to dry than dry-seasoned meat.

➲ **FANCY FLAVOR** Combine $\frac{1}{4}$ t. pepper, $\frac{1}{4}$ t. salt, 1 t. lemon juice, and $\frac{1}{2}$ c. soy sauce.

Marinate the meat in the mixture 1 hour or longer, turning occasionally.

➲ **FALSE SMOKED JERKY** In a bowl, combine 1 c. soy sauce, $\frac{1}{4}$ c. brown sugar, and a few drops of liquid smoke for your dip.

➲ **TAMARI MARINADE** Mix 1 t. ground black pepper, 8 T. tamari (or other soy sauce), 16 crushed cloves garlic, and 4 t. wine vinegar with enough water to cover 2 lb. sliced meat. Soak meat for 4 to 6 hours in the refrigerator.

➲ **AN EASY DRY METHOD** Have ready a suitable-sized granite canner, crock, or plastic bucket. Sprinkle the bottom with salt, pepper, garlic powder, and brown sugar. Put in a layer of meat and sprinkle again. Put in another layer, and so on until you are done. Place the container in the refrigerator or some cool place and let rest 18 hours. Then remove, drain the meat thoroughly of the extracted juice, and proceed to dry it. For a mild jerky, rinse the meat before drying it. This is my favorite recipe. It makes a comparatively sweet jerky.

➲ **ANOTHER DRY METHOD** Lay the meat strips on a towel. Mix thoroughly $\frac{1}{3}$ c. brown (or white) sugar, $\frac{3}{4}$ c. salt, and 1 t. crushed black pepper. Or use $\frac{1}{2}$ c. salt and $\frac{2}{3}$ c. brown sugar. Rub in the seasoning. Juice will be coming out. Turn the strips over and repeat on the other side. Some people do this on a wooden board and pound it in. Then roll the strips in a damp (wet and then wring out) towel and leave them in the refrigerator for 8 hours. Take them out of the towel. Rinse each piece thoroughly under running water. Lay on a dry towel for 2 or 3 hours.

DRYING: After the strips of meat are seasoned, they are ready to dry. This can be done "in the field," by the heat of the sun during the day and the smoke of your campfire by night; in your smokehouse; or in your oven, depending on your preference and facilities. Just exactly how dry you want the jerky is also a matter of preference. For simple food preservation, the dryer the better, but the jerky should be dark, fibrous-looking, and slightly flexible but yet brittle enough to break apart when bent. You can stew the jerky to eat it, but people usually make it for smoking and plan to use it up soon, so they don't dry it clear out. As a snack it's nicer with some moisture left in. If some moisture is left, you'll have to keep it stored in the refrigerator. If you get your jerky too dry to suit you, you can wrap it in a damp towel and keep it in a tightly lidded gallon jar in the refrigerator to recover a little moisture.

In the Field. The meat strips can be spread on rocks or bushes on a hot day. If insects are a problem, you can cover the meat with a fine-mesh cloth, or build a smudge fire, or stand there waving your arms all day, praying for a wind. If the weather changes to rain before you're done, you'll have to take your meat indoors and wait until the sun shines again to finish. It will take about 3 days to do it this way, more or less, depending on the dryness and heat of your weather.

Wood Stove. Drying meat strips over a wood stove is a fine method for wintertime, when you use the stove a lot. Just run wires like clotheslines above the stove, so the meat can be suspended in the hot air around and above the stove. The little metal fasteners sold for hanging Christmas ornaments work fine for fastening a strip of jerky to a clothes hanger or wire.

➲ **ROBERT'S OVEN-DRIED JERKY** This is for lean cuts of beef, cooked ham, venison, chicken, or turkey. Trim off all fat and connective tissue. Cut 1½–2 lb. meat into thin slices. In a bowl, combine $\frac{1}{4}$ c. soy sauce, 1 T. Worcestershire, $\frac{1}{4}$ t. pepper, $\frac{1}{4}$ t. garlic powder, $\frac{1}{2}$ t. onion powder, and 1 t. hickory smoke-flavored salt. Stir until the seasonings are well mixed; then add meat and make sure all surfaces are coated with the seasonings. Cover and let stand

at least 1 hour. Shake off excess liquid. Arrange strips close, but not touching, on oven racks or cake racks set in shallow baking pans. Dry at 150–200°F until meat turns brown, feels hard, and is dry to the touch. Poultry will take about 5 hours; beef and venison, 4 to 7 hours. Pat off beads of oil, cool, and store in airtight containers or plastic bags in refrigerator. Makes about ½ lb jerky.

➲ **DEHYDRATOR JERKY** Place meat strips on trays without overlapping. Dry 4 hours at 140°F. Rotate the trays and turn the strips over. Continue drying for another 6 to 8 hours. Place aluminum foil or some such below the trays to catch the drippings.

➲ **MICROWAVED JERKY** This recipe is from the National Live Stock and Meat Board, which warns that microwaved jerky does not have the same long-keeping qualities of traditionally prepared jerky but will keep 4 weeks or more. Prepare your jerky as usual, cutting lengthwise with the grain into ¼-inch-thick strips. Mix thoroughly together 3 t. salt, 1 t. garlic salt, and ½ t. black pepper. Sprinkle seasoning over strips and mix in order to distribute spices as equally as possible. Arrange a load of strips flat and close together on a microwave-safe bacon rack, and cover with wax paper. Microwave on low for 22 minutes (strips keep better and dry more evenly when cooked at “low” temperature rather than at a higher setting). Now turn strips over and redistribute the driest ones to the center. Rotate rack a half turn and microwave on low again for another 22 minutes, or until jerky is dry but slightly pliable. Take out the finished jerky and repeat the same procedure with the rest of the strips until you finish them all. Let meat dry still more in open air for 24 hours before storing it in a covered container. Store in an airtight jar or sealed plastic bag (or frozen for long-term storage).

STORING JERKY: For long-term storage, jerky that's completely dry will keep very well if stored in an airtight container. I use quart jars. Just screw the lid on tight. Salt and sugar have the same preservative effect in jerky as they do in old-fashioned home-cured hams and bacon. The dryer and more heavily seasoned the jerky, the better it will keep, but I would still try to use it up within 6 months.

PEMMICAN: Real old-time pemmican was made by the pioneers from lean portions of venison, buffalo, or other meat. It was an Indian trail food that was light to carry and didn't spoil. It contained all the food elements a person needed except vitamin C, and if berries were in it, it had that too. To make it as they did, cut away the fat from the lean. Sun-dry the lean meat in thin jerky-like strips. Then pound up the jerky until you have shredded jerky. Cut the raw fat into small chunks. (This works best, of course, with a fairly firm fat.) Gradually melt them in a pan in the oven or over very low heat. Don't ever let this grease boil up.

The proportions should be 1 part lean to 1 part fat by weight. Since it takes about 5 lb. lean beef to make 1 lb. fully dried jerky, you'd start this recipe with proportions comparable to 5 lb. lean to 1 lb. fat meat. When the fat is all melted, pour it over the jerky bits; then mix the two together. It will look quite a bit like regular sausage. No salt at all should be included. Dried berries are optional. Package the pemmican in commercial sausage casings or some other waterproof container such as plastic bags. When you need it, cook it like sausage or eat it in chunks or slices like dried beef.

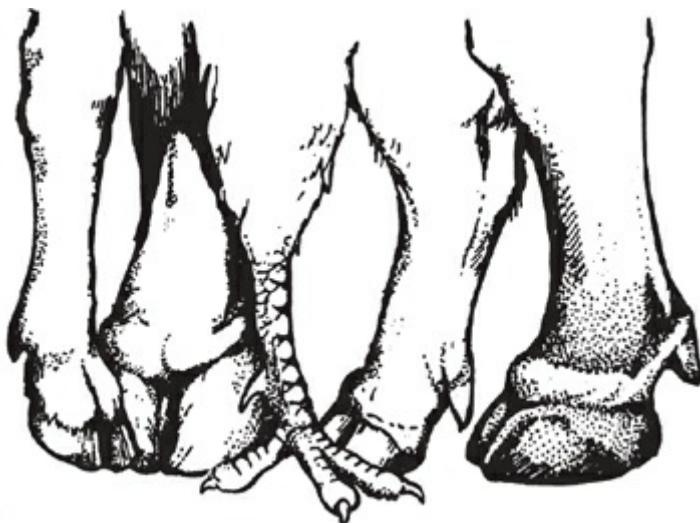

MEAT PRODUCTS

Here's an alphabetical list of some basic meat products you can make at home the old-time way.

Gelatin

By “jelly,” the old-time recipe writers meant gelatin. Now we call pectin-jellied preserves “jelly” and animal jellies “gelatin.” To Great-Grandmother they were both “jelly.” “Stock” means soup broth. Homemade gelatin is strained, clarified meat stock flavored any way you like. It sets up (jells) when it is chilled. It melts when it gets warm. To firm it, just chill again and it will set up again.

Gelatin is made from bones and ligaments. Commercial gelatin is made from skins, bones, and sinews. Feet are the boniest, ligamentiest part of the animal and not good for anything else in the kitchen. If you don’t have “4 calf’s feet” for a recipe, substitute 2 lb. or more of soup bones. “Calf’s foot jelly” is a traditional old-time dish, but you can actually make homemade gelatin from cow’s heels (the same as feet, only grown up); beef soup bones; sheep or goat legs; pig’s feet or backbone; chicken necks, heads, backs, feet; or any other bony pieces you’ve got.

I make homemade gelatin as often as I can get the makings. We butcher here at home fairly often, and friends who butcher often let me have the feet. You can’t buy feet to make jelly. Our local custom butcher is compelled by law, in the name of “health,” to put all cow’s feet from the knee down into a barrel and pour creosote over them, so he can’t sell them to me to make gelatin or even give the bones to a neighbor lady’s dog for gnawing. (That law is stupid and wasteful. By the time you’ve boiled the feet 4 to 7 hours to make gelatin, I’m sure no germs can survive.)

After trying my first homemade gelatin, I really noticed the contrast between it and the acid bite and heavy sweetness of the presweetened, preflavored commercial gelatin powder. Homemade gelatin hasn’t been bleached, preserved, or sugared. Its taste is very mild with a hint of meat flavor. I like beef and pork jelly best. My chicken jelly is a bit too chickeny, although adding extra flavoring helps disguise the chicken.

Learning how to make gelatin was a real research job for me. I started out with an antique recipe and had to experiment for a long time to figure out what was meant. Here, for you, is everything I learned about making homemade gelatin.

COOKING THE MAKINS: After butchering, you can keep feet (skin and all) and other bones for jelly making in big paper bags in your freezer until you have time to work with them. Start your jelly at least the day before you plan to use it. I’ll forewarn you — you don’t get an awful lot for your work. This is a rare and precious delicacy.

Here’s an outline of how to proceed:

1. Prepare bones. (If you’re the independent type, that means “butcher.”)

2. Cover them with water and simmer until reduced by at least one-half (4 hours or more) to get concentrated stock. (For specific directions for each kind of animal, see the following paragraphs.)
3. Chill enough to set up firmly. Remove fat from top and sediment from bottom of gelatin.
4. Clarify (complete directions given later).
5. Flavor to suit yourself (recipes later).
6. Reset, serve, and enjoy!

Calf's Foot (or Cow's Heel) Gelatin. Start with 4 calf or cow legs (or 3 or 5, if your cow is odd that way). Cut the foot off each one at the first joint above the hoof. Use a sharp knife and a lot of elbow grease (depends on how good you are at finding joints). If you cook the leg bones, too, you'll have even more gelatin, but you'll need a big kettle or you'll have to saw them in chunks with a meat saw. Put the feet in a pan of hot water and boil 15 minutes. Remove. Stir the skin away from the hoof through the top portion of the hoof, which you'll discover is soft. Cut in two between the "toes" and right on up through so that each foot is now in 2 pieces. Remove as much of the fat from between the toes as is possible. Rinse them. Put into a big pan with a gallon of cold water. Bring it gradually to a boil. Gently boil, uncovered, 6 or 7 hours. Several times, skim off the scum that rises to the top as it cooks. When the water is down to about 1 quart, take the feet out of the pan.

Strain the liquid through a cloth or fine sieve. Measure it. Put it in the refrigerator or in a cool place and let it set up. In the morning take off the fat that has accumulated on the top and quickly rinse the outside of the pan in a little hot water for a moment to loosen the jelly. Then turn it over and the jelly will slip out. Trim off the sediment from the bottom. Clarify.

Pig Gelatin. For some reason I think you get more gelatin from pig bones than from any other animal. Use the whole foot from the knee joint down. The backbone is very good for jelly making too. Leave the skin on if the hair has been scraped off. Otherwise, skin the feet. No need to cut or trim. Cover with water and boil gently 4 to 7 hours: skin, toes and all. Skim off scum and fat several times while it cooks. Strain through a sieve to get out the bones and meat (save that for other dishes). Chill overnight. If your broth doesn't jell firm enough to suit you, boil it down some more.

Mutton or Goat Gelatin. Boil leg (shank) bones of sheep or goat for 6 or 7 hours.

Chicken "Foot" Gelatin. Use the head, feet, necks and backs, if you don't need them for something else. Or if you're a purist, use just the smooth legs of birds less than a year old. With luck, about 3 pairs of feet will make a pint of jelly. Scald with boiling water and cook slowly a long time.

CLARIFYING: The clearer you can get your jelly, the more attractive the final result will be and the better it will combine with other foods in recipes. Clarifying also reduces the animal flavor. But homemade gelatin, even when well clarified, is still a little on the milky order and not crystal-clear like store gelatin. For every quart of gelatin in your pan, add $\frac{1}{2}$ c. sugar (white or brown) or honey, along with the shells and slightly beaten whites of 5 eggs (less if you're short, but it won't turn out quite as clear). Stir in the sweetening, shells, and egg whites as soon as the jelly is melted. You can leave out the sweetening if you want; it will still clarify. The following recipes are based on sweetened gelatin. Don't stir the jelly after it begins to get really warm. Let it boil 10 minutes, add $\frac{1}{2}$ c. cold water, and let boil 5 minutes longer. Take the pan off the fire, cover tightly, and let stand for $\frac{1}{2}$ hour in a warm place. Strain through several thicknesses of cloth. Dipping the cloth in hot

water and wringing it out helps prevent the jelly from setting in the cloth during the straining process. Strain while hot; otherwise it will jell in the bag. You'll probably have to apply some pressure. Wring the loose ends of the bag to force the broth through. If it isn't clear enough the first time, you can put it through the cloths again.

SETTING UP: The stiffness of your jelly depends on what part of the animal you make it from, how long you boil to concentrate it, and how much liquid you add while preparing it for table consumption. The stiffer you make it to start with, the more possibilities you have for adding flavoring later. Once you have your jelly you can divide it, using 1 part in 1 recipe and 1 part in another. If you're tasting as you go, be reassured: it tastes more like a proper gelatin after it has set up.

For the following jelly recipes, set up the jelly in your final serving molds, preferably individual ones like custard dishes, because it doesn't transfer well once set; it tends to lose shape and shine. Use cold sauces only. It melts easily. Serve chilled; it melts at room temperature. If it starts to melt on you or gets broken up, just finish melting, return it to the refrigerator, and it will again set up very nicely for you.

SECRETS OF GOOD GELATIN MAKING

1. If your gelatin does not set up, you used too much liquid for the amount of gelatin. A scant tablespoon of powdered commercial gelatin will jell with 2 c. liquid.
2. Some ingredients prevent gelatin from setting up. Pineapple, papayas, mangoes, and figs have enzymes that react with the protein in the gelatin and cause it to stay soft. Use these fruits or their juices in gelatin only if they are cooked first.
3. To keep solid ingredients from settling to the bottom, wait until the gelatin is partially set before adding them and mix them in gently, distributing evenly. Banana slices, strawberry halves, and chopped nuts and apples tend to rise to the top of gelatin. Fresh grapes, canned fruits, and orange slices tend to sink to the bottom. Use these tendencies to create layered desserts.

⇒ **MY FAVORITE GELATIN** Let jelly melt over low heat in pan. Add grape or orange juice frozen concentrate (I can make my own frozen concentrates) and lemon juice to taste. Cool the jelly. Add chopped, peeled apple and let set up again.

⇒ **COFFEE JELLY** Melt 1 c. jelly. Combine 2 t. instant coffee with 2 T. water. Add to jelly. Pour into mold and let chill to set. To make this with regular coffee, combine a very firm jelly with enough strong coffee to flavor. Add extra sweetening, if desired.

⇒ **LEMON JELLY** Combine 1 c. jelly and the juice of 1½ lemons. Strain the lemon juice through a cloth before adding it to keep the gelatin as clear as possible. Chill.

⇒ **OLD-FASHIONED WINE JELLIES** Start with a very stiff jelly. Add lemon juice and either red or white wine to taste (I prefer red). To a white wine jelly, you could add some orange juice and grated (unparaffined) orange and lemon peel. To red wine jelly, you could add red berries such as raspberries, strawberries, and currants.

⇒ **FRUIT JELLY** A thick gelatin can take the fruit directly and it will remain in suspension. Let it partly set up, and then add the fruit. In a diluted gelatin, the fruit sinks to the bottom. In that case, chill a bottom layer until firm; then add a layer of fruit and then more melted gelatin. Chill until firm again, add another fruit layer, and so on. Fresh peaches, apricots, plums, and apples are good if cooked in a little sweetened water before they go into the jelly. (Drain thoroughly before adding.) Strawberries, raspberries, grapes, cherries, chopped peeled apples, and currants can go in raw. Your own sun-or oven-dried fruits and brandied cherries are fine

too. Cut up large pieces before adding to the jelly.

JELLIES AS SAUCES FOR MEAT: Great-Grandmother served animal jellies with a sauce when she was able (the same way she served the bread varieties she called “pudding”). The easiest sauce is whipped cream. For salad-type jellies (make with raw vegetables, home sun-dried fruit, and fruit juices), serve homemade mayonnaise, sour cream, or yogurt dressing.

⇒ **VANILLA SAUCE** This is nice on a dessert jelly and uses up egg yolks left from clarifying. Scald 1 c. milk. Add a little sweetening, 2 or more egg yolks, and ½ t. cornstarch. Cook, stirring constantly, in your double boiler until it thickens. Add a bit of real vanilla flavoring. Stir until cool.

Substituting Your Gelatin. In modern recipes, use 2 c. homemade gelatin for “1 envelope” commercial gelatin, and cut back on the fluid by 2 cups.

OTHER GELATIN PRODUCTS

Homemade Meat Glaze. This adds color and flavor to soups, sauces, and gravies. To put on meat, melt the glaze over hot water and apply with a pastry brush. To make it, start with your bone stock as for homemade gelatin and boil it until greatly reduced, keeping it well skimmed. Do not clarify. Figure on boiling 1 qt. bone stock down to a cup or less, transferring it to a smaller pan as it reduces. To get a darker color, simmer the concentrated stock with caramelized sugar until it becomes like a syrup.

Bouillon “Cubes.” Make your stock and concentrate, but do not clarify. Whatever type of meat you used will be the flavor of the cubes you get. Remove fat but not sediment. When you have a well-jellied stock, you’re ready to make bouillon cubes.

1. Melt the jelly.
2. Season it strongly with your favorite soup seasonings.
3. Pour the seasoned jelly 1 inch deep into some containers you can get along without, like cans—the smaller the better.
4. Set the cans in a water bath that reaches about one-third up the side of the can. Cook on low heat at least 8 hours more, refilling the water bath as needed.
5. Chill.
6. Separate concentrate from container.
7. Wrap in foil or in paper squares cut from grocery bags.
8. Pack in jars with tight-fitting lids. Keep out of dampness.

Gravy

Good gravy to go on the potatoes can be made any time you fry or roast meat. When your meat is done, remove it from the pan. Estimate how much gravy your family can use. If you want 1 cup, pour off the grease until you have about 2 T. left, 4 T. for 2 cups, and so on. If you don’t have that much, add a little melted butter, bacon drippings, or lard. Loosen all the good brown bits in the bottom of your pan (assuming you don’t have a burnt mess, in which case salvage some grease by pouring off the top and start over in another pan), and add 2 T. whole wheat or unbleached flour per 2 T. grease.

For heaven’s sake, don’t stop to actually “measure” the hot grease and flour. You can learn to estimate close enough by looking at it, and it really doesn’t make that much difference if you use a little more or less of either. Just don’t have a whole lot of extra grease, because it will float on top of your gravy and look and taste yuk!

Over medium heat make a paste of the brown bits, grease and flour with your fork, and

let cook a couple minutes, stirring constantly. This accomplishes the browning and cooking of your flour and gives you almost an "instant" gravy. Your mashing action with the fork will break up potential lumps. Now pour in a little liquid. Stir it in until the lumps are gone; then add more and stir again until the lumps are out. Repeat until all your liquid is added. You can add more liquid each time, but start with very little. Stop adding liquid when your gravy is as thin as you want it.

For liquid, use your potato water, water from another cooked vegetable, or milk. Or juice from a pot roast or stewed chicken, if you have it. I drain the vegetable waters into the gravy (or else add them to the animal pail) and then cook that down to the wanted density. Pork-chop gravy is good with half milk and half water or all milk. Chicken gravy is good with half or all milk. Beef gravy is good with part milk or just your vegetable water. Deer, elk, and other game gravies don't get along with milk. Game gravies are much improved by adding a couple tablespoons of currant, wild plum, or some other tart jelly. For roast turkey, duck, or goose, use no milk, but add the chopped cooked giblets and the giblet broth for a delicious gravy.

If you get the gravy too thin and watery, you can boil it until it thickens enough to suit you. Finally, salt and pepper to taste. Taste it until it seems right, but don't burn your tongue! Good gravy seasonings are black pepper, onion powder, thyme, sage, marjoram, and basil. For a final garnish, sprinkle freshly chopped parsley, dill, chives, or scallions on top. Then serve to pour on your meat and mashed potatoes, rice, or thick slices of bread in a sturdy bowl with a good dipper. And put the pan to soak in the sink, so it won't be a chore to wash.

Gravy Trick. Put flour in a jar with a tight-fitting lid. Add cold water, about $1\frac{1}{2}$ times by volume. Shake by hand. Never fill jar over three-fourths full. Add to the gravy or stew slowly, stirring the whole time. From Howard Perkins, Pennsauken, NJ.

Roux. From Virginia Boegli, my high school friend who drew some of the illustrations for the early editions of this book. "I've discovered a great little French technique that really simplifies gravy. It's called roux (pronounced "roo"). A roux is a paste of about equal parts fat and flour. The fat may be drippings or butter or so forth. A roux can be blended into hot liquid without all that lumpiness. When my roasting pan has a hard brown coating after roasting meat, I like to put water in it and simmer to get all that good stuff. Then stir in a roux and seasoning—voila, it's gravy. If you want you can make a jar of roux and keep it in the refrigerator. A glob the size of a walnut thickens about a quart of gravy or a large pot of stew. If in doubt, it's easy to add a little at a time."

White Sauce. This is a meatless white gravy. It's good poured over bland vegetables such as boiled onions, cauliflower, or asparagus. I mix white sauce with diced leftover ham (omit the salt for home-cured ham) to get an extra meal out of it. To make white sauce, melt some butter in your frying pan. Soak it up with an equal measure of flour and brown a couple minutes, stirring constantly. Now gradually dilute with milk, stirring constantly. Season, and it's ready to be poured over your vegetables. Also good with cheese grated into it.

Hash

The basic hash recipe is to grind or cut into small pieces cooked meat (mutton, beef, corned beef, or what-have-you) and add diced cold boiled spuds. The usual proportion is half meat and half potato. Some people stretch it with more potato. You can add chopped onion too. Moisten with leftover gravy, soup stock, egg, or even milk or water. Season with salt and pepper. I usually make it with leftover gravy.

When you want to eat it, turn it into an oiled frying pan and bake in a hot oven until

brown, or fry on top of the stove, turning once. Slightly beaten eggs mixed with the hash will make it stick together better if you don't use gravy. If you cook an especially moist hash slowly in a covered pan for about half an hour, until there is a rich crust on the bottom, you can fold it like an omelet and serve that way. Hash is a good breakfast (or lunch) dish with eggs on the side, and it's good for using up leftovers.

⇒ **GERMAN HASH** Mix 1 c. chopped cooked beef, 1 c. chopped tart apples, 1 c. chopped boiled potatoes, 1 t. salt, and a pinch of paprika. Saute 1 small onion, chopped fine, in 3 T. butter until transparent. Add the other ingredients to the onion and butter and heat until very hot, stirring often.

⇒ **GROUND MEAT HASH** Fry 1 lb. lean ground meat with 1 T. oil until the pink color is cooked out. Add a small chopped onion and continue frying until the onion pieces are transparent, stirring as needed to separate meat. Stir in ½ t. salt, ¼ t. garlic powder, ½ t. pepper, and 4 T. soy sauce. When this mixture is thoroughly cooked and mixed, add a layer of shredded raw potato or sliced cooked potatoes. If you use the raw potato, cover pan and cook on low heat, stirring occasionally, until the potatoes are done. If using precooked potatoes, just get it hot and then serve with ketchup.

⇒ **SHEPHERD'S PIE** This old English recipe was traditionally made with sheep meat but will work with any variety, including ground meat. Have ready about 1 lb. mashed potatoes that were originally made with plenty of butter, salt, and pepper. Cut ½ lb. cold, cooked meat into thin strips. Oil a baking pan or dish, put one-third of the potatoes into the bottom of the pan, then a layer containing half the meat, then a layer with the next third of the potatoes, then a layer with the rest of the meat, and a final layer on top with the last third of the potatoes. If needed, sprinkle more seasoning on each layer as you add it. Optional: dot top of pie with butter bits, or arrange slices of tomato or bacon on it. Bake at 325°F about ½ hour or until well heated all through. Will heat faster if you preheat the potatoes with some melted butter, stirring in a frying pan until hot, before you layer them.

Mincemeat

Mincemeat belongs to the same family as fruitcakes and plum pudding—meaning that a little goes a long way. The old-timers made their crock mincemeat in late November or whenever the weather turned cold and would stay that way a few months. They kept it through those cold months in a cold place. Homemade mincemeat doesn't taste like store mincemeat at first, but the more it ages, the more it does. It's a good idea to add a little more liquor or a juice such as grape or orange just before baking a mincemeat pie. "True" mincemeat is probably the variety containing beef and suet—specifically the kind made from beef neck—but mincemeat can also be made from pork or wild meat. There are also mock varieties made from green tomatoes and raisins, or rhubarb and raisins.

Any mincemeat recipe can be stretched by adding chopped apple when you want to bake with it. A tart apple such as Winesap, Transparent, or Jonathan is best. Old-time crock mincemeats are very concentrated for the sake of easy preservation. A cup or more of chopped apples mixed with a pint of mincemeat really improves the mixture when you bake with it.

PRESERVING MINCEMEAT: Old-time crock mincemeat contained sugar, spices, vinegar, molasses, and alcohol, alone or in such combinations as to make it self-preserving. The more modern recipes I've given below aren't as strong and must be immediately canned or frozen after you make them unless you're going to eat up the mincemeat right away. To freeze mincemeat, just put in cartons and place in the freezer. If you have leftover crock

mincemeat and spring is coming, just package it up and freeze.

➲ **PORK MINCEMEAT** If you are doing your own butchering, this is one good way to use the hog's head (headcheese is another) and backbone. Boil until tender. Then skin the head, bone out the meat, and grind it up. Don't use all the fat. For each 8 lb. pork add 2½ lb. dried apples (ground and then cooked) and 3 lb. green apples, if you can get them (or 3 lb. fresh tart apples). Put 4 whole lemons and 4 peeled oranges through the grinder. Combine ground fruit, pork, 3 lb. raisins, 1 qt. vinegar, 2¾ lb. sugar, 1 T. allspice, and 1 T. cinnamon. Cook for 1 hour.

RECIPES USING MINCEMEAT

➲ **THANKSGIVING PIE** Mix 1 pt. mincemeat with 2 c. peeled, cored, chopped tart apples. Fill an unbaked pastry shell. Top with pastry. Bake 10 minutes at about 450°F and then 30 minutes at a lower temperature.

➲ **FILLED MINCEMEAT COOKIES** Blend ½ c. soft shortening, 1 c. sugar, and 2 eggs. Stir in 2 T. thick cream and 1 t. vanilla. Sift together 2½ c. flour, ½ t. soda, and ½ t. salt. Add to shortening mixture. Gather dough into a round ball and chill for 1 hour. Then roll out to about 1/16 inch thick. Cut into 3-inch rounds or squares. Put a rounded teaspoonful of mincemeat on each dough round. Fold the dough over, pressing edges together with the floured tines of a fork or with a fingertip (a square would thus become a triangle). Put the filled cookies on a greased cookie sheet. Bake at 400°F 8 to 10 minutes.

➲ **MINCEMEAT COOKIES** Cream 1 c. shortening. Add ½ c. brown sugar and blend well. Add 2 eggs and beat thoroughly. Mix ½ t. salt and 1 t. soda with 3 ½ c. flour. Alternately add 1½ c. mincemeat and the flour mixture to the liquid mixture. The liquid amount determines how liquid your mincemeat will be. You might want to add a little more or less flour to get the right cookie consistency. Finally, add ½ c. chopped nuts (more or less depending on how many you have). Mix. Drop with a spoon onto your greased cookie sheet. Bake 10 minutes at 375°F.

➲ **MINCEMEAT JELLY ROLL** Combine 2 c. sifted flour, ½ c. sugar, 1 t. salt, and ½ c. milk. Add 1 T. dry yeast dissolved in ⅓ c. lukewarm water and a beaten egg. Let rise. Punch down. Let rise again. Divide dough in half. Roll out each half to a ½-inch thickness. Spread a layer of your mincemeat over each half. Roll it up jelly-roll style. Pinch edges to seal. Let rise once more. Bake at 350°F about 30 minutes, or until nicely browned and crusty on outside.

➲ **MINCEMEAT MUFFINS** Beat 1 egg with 1¾ c. milk. Add 2 t. melted butter. Combine 3 c. whole wheat flour, 3 t. baking powder, 1 t. soda, 1 T. sugar, and 1 t. salt and then add to liquid. Add 1 c. mincemeat and 2 t. fruit juice or water. Mix it all together well. Grease your muffin tin and fill the cavities two-thirds full. Bake at 375°F for 25 minutes.

➲ **CRANBERRY MINCEMEAT PIE** Combine 1 ½ c. mincemeat-chopped apple combination,

1 ½ c. cranberry sauce, ½ c. orange juice, and 3 T. flour. Pour into an unbaked shell. Cover with a top crust. Pinch sides and brush the top with milk. Bake at 400°F 50 minutes.

⇒ **MINCEMEAT-OATMEAL COOKIES** *Sift together 1½ c. plus 2 T. flour, ¾ t. soda, and ½ t. salt. Cream ½ c. lard and then gradually add 1 c. brown sugar. Add 1 well-beaten egg and 1½ c. mincemeat. Add flour mixture gradually and then 1½ c. rolled oats. Drop by spoonfuls onto greased cookie sheet. Bake at 350°F about 15 minutes.*

⇒ **MINCEMEAT APPLES** *Try baking apples with the cores out and the cavity stuffed with mincemeat.*

⇒ **MINCEMEAT BROWN BETTY** *Make 2 c. bread crumbs, preferably from homemade whole wheat bread. Butter a bread pan. Put one-third of the crumbs in it. Add a layer of 2 peeled, sliced apples and then a layer of ½ c. mincemeat. Sprinkle over a pinch of cinnamon. Add another layer of crumbs, 2 more sliced apples, another ½ c. mincemeat, another sprinkle of cinnamon, and the remaining crumbs. Pour ½ c. orange juice over all. Dot with butter. Bake at 350°F for 30 minutes. Good with cream.*

Sandwich Mixes

These sandwich fillings are meant to be spread on homemade bread. Store-bought bread is too salty and generally “strong”-tasting for them. Any leftover meat can be made into a fine sandwich filling. Just remove bone and fat (except for old-time potted ham). Slice or grind the meat. Moisten the grindings with a salad dressing, such as mayonnaise or tartar sauce. You can make plain meat fillings this way or with the variations that follow. Croquettes are another good way to use meat leftovers. So is sliced meat warmed up in leftover gravy and served with rice or sliced boiled spuds that have been sauteed in a little butter with some chopped fresh green onion.

⇒ **HAM AND EGG** *Grind the ham with chopped hard-cooked egg. Moisten with mayonnaise or cream dressing. Add finely chopped red or green pepper and mustard.*

⇒ **HAM AND PICKLE** *Grind 2 c. ham. Mix smooth with 1 small ground pickle, 2 t. prepared mustard, 2 T. butter, and ½ t. pepper.*

⇒ **HAM AND EVERYTHING** *Mix together 1 c. chopped ham, 1 chopped hard-cooked egg, 2 T. chopped green pepper, 2 T. chopped sour pickle, and a pinch of pepper. Moisten with mayonnaise. Add thin pickle slices and strips of green pepper, if desired.*

⇒ **OLD-TIME POTTED HAM** *Grind one-third fat and two-thirds lean meat to a smooth paste. Add salt and cayenne pepper to taste. Heat and pack in small pots.*

⇒ **HAM AND CHICKEN** *Grind 1 c. cooked chicken meat, white or dark, and ½ c. cooked ham. Mince ½ c. celery and 1 T. green pepper, and mix with meat. Moisten with about ½ c. mayonnaise.*

⇒ **CHICKEN SALAD SANDWICH FILLING** *Grind cooked chicken and moisten with mayonnaise. Add crumbled crisp bacon or chopped celery.*

⇒ **CHOPPED VEAL** *Grind about 1½ c. veal and season with 1 t. salt, 1 T. lemon juice, and a little pepper and mustard, if desired.*

⇒ **CHOPPED MUTTON** *Grind until fine about 1½ c. cold mutton or lamb. Season with 1 t. salt, 1 T. pickled nasturtium seeds if you have them, 1 t. chopped fresh mint if you have it, a pinch of pepper, and 1 T. lemon juice. Good on whole wheat bread with lettuce.*

⇒ **BEEF SANDWICH SPREAD** *Grind the meat, add mayo to moisten, salt and pepper to taste,*

and stir in some chopped green onion or green pepper or pickle. Doesn't keep well, so eat it all up.

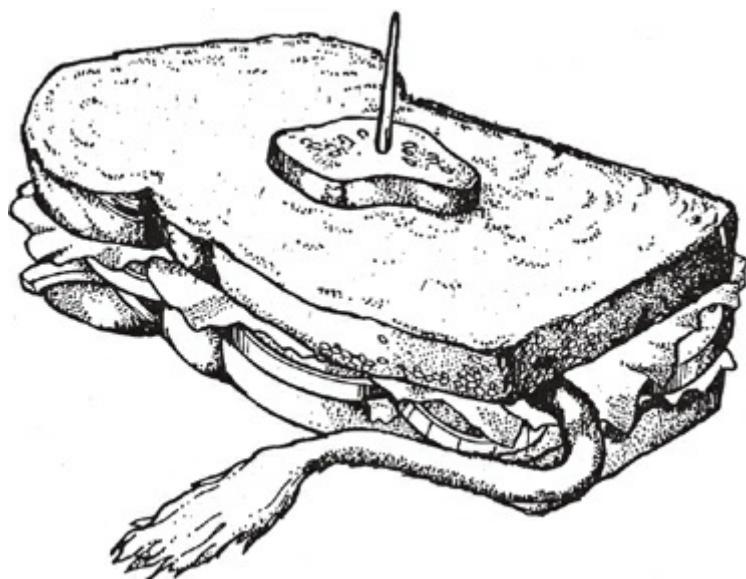

HOMEMADE LUNCH MEAT LOAF RECIPES: From Gertrude Johnson, Lamont, WA, a rare and splendid lady who says these homemade lunch loaves have no chemicals or nitrates and are inexpensive to make and very tasty.

➲ **TURKEY SANDWICH ROLL** This recipe makes lunch sandwiches for a week for a family of 3. Place 2 turkey drumsticks (or 2-2½ lb. meat), 3 carrots (scrubbed and cut into chunks), 3 ribs celery (including the leaves, scrubbed and cut into chunks), 2 medium onions (peeled and cut into chunks), 4 whole peppercorns, and salt to taste together in a large, heavy pot. Fill with enough water to cover the contents plus 1 inch more. Bring to a boil; cover and simmer about 2 hours or until the turkey is no longer attached to the bone. Remove meat and set aside until cool enough to handle.

Strain turkey broth into a bowl through a cheesecloth-lined strainer. Set the bowl aside. Discard the cheesecloth and its contents. Remove and discard the skin from the drumsticks; then remove the meat from the bones. Use your fingers to shred the meat and to check for any stray bones. Put the shredded meat into a clean saucepan. Add just enough turkey broth to pan to moisten the meat without making it soupy. Set the pan on low heat and stir to further shred the meat as much as possible. Add salt to taste. Very gradually, add enough broth to keep the meat generously moist but not soupy.

When this is heated through and seasoned to your liking (try including 2 T. dried parsley flakes or ½ c. fresh parsley and 3 thin slices of lemon), remove from heat and sprinkle 2 envelopes of unfavored gelatin on top. Stir constantly for 3 minutes. Pour mixture into a deep quart-sized, lidded container or into an 8 × 4 × 2-inch loaf pan. (Greasing is not necessary.) Cover and refrigerate overnight. When set, remove the roll from its container and cut it into slices for sandwiches. It will keep (refrigerated) for about 2 weeks. Do not freeze!

➲ **BARBECUED BEEF SANDWICH LOAF** You'll need 1½ lb. stewing beef, 1 large onion, peeled and quartered, ½ t. salt, ¼ t. pepper, ⅔ c. barbecue sauce, 2 c. water, and 2 envelopes plain gelatin. Cut beef into ½-inch cubes. Place meat in heavy pot with onion, salt, and pepper. In a separate bowl, combine barbecue sauce with water. Pour two-thirds of this mix over meat cubes. (Set the rest aside.) Bring meat mix to boil and simmer, covered, over low heat for 1 hour or until beef is very tender. Then shred beef and onion in blender, using all of the pan juices and the rest of the barbecue and water mixture. Finish as above with the gelatin, etc.

⇒ **HAM AND CHEESE LOAF** Make this when you have leftover ham (or other meat) that is in shreds and bits, unsuitable for serving. You'll need 1½ c. leftover cooked meat, water, 1 envelope (1 T.) plain gelatin, and ½ c. diced cheddar cheese. Shred, mash, and then chop ham into very small pieces in a small saucepan. Gradually stir in enough water to moisten, plus 3 T. more. Bring to a boil, remove from heat, and sprinkle gelatin on top, stirring for 3 more minutes. Let mixture reach room temperature. Then stir in cheese and pour into a lidded 2-cup plastic container. Cover and refrigerate overnight. When set, remove from container to slice for sandwiches. Do not freeze.

Sausage and Hamburger

NOTE: In the following recipes, there are no chemical preservatives, so as a safety measure, follow these instructions:

1. Use only fresh rather than aged meats.
2. After making your sausage, immediately store in a freezer that is set at 0°F or below.
3. Or preserve by canning. (Follow the directions in the "Canning" section for ground or chopped meat.)
4. Cook frozen sausages thoroughly before eating.

SUPPLIES AND BOOKS: To shop for casings, ask the custom butcher in your area. Larger cities may have stores that specialize in sausage, or your local market might order them for you from their wholesaler. If that doesn't work, check the Yellow Pages under "Meats, Custom Cutting" and "Meats, Wholesale." The Sausage Maker sells everything you need for making sausage and curing meats, including spices, tools, casings, equipment, and an instructional video/book combo deal for \$39.95. That book, *Great Sausage Recipes and Meat Curing*, by Rytek Kutas, contains 175+ sausage recipes: 888-490-8525; 716-824-5814; 1500 Clinton St., Bldg. 123, Buffalo, NY 14205; customerservice@sausagemaker.com; www.sausagemaker.com. Luhr Jensen offers a "Home Sausage Kit" with a booklet of instructions and recipes, as well as sausagemaking supplies: 877-386-3811; 541-386-3811; PO Box 297 (400 Portway Ave.), Hood River, OR 97031. Order *Home Sausage Making: Healthy Low-Salt, Low-Fat Recipes* (including poultry and fish recipes) by Charles Reavis, from Storey Books, address in [Chapter 1](#). Meat grinders and sausage makers are also available from 719-962-3228; www.cfamlyresources.com.

GRINDING AND MIXING THE MEAT: Sausage making is an important country art in this part of Idaho, maybe everywhere in the country. The arrival of late fall and butchering time on the farm means sausage time. Often it is made twice a year: in late fall and again in early spring, when some more butchering is done. In most of the small towns around here, it is a public operation as well as a private one. The communities have an annual sausagemaking bee followed by a big sausage feed.

Hamburger Making. "Hamburger" is ground meat with whatever percentage of fat added or left out that you prefer. The precise point at which ground meat stops being "hamburger" and becomes "sausage" is vague. If pork is added, the result is generally called "sausage." Hamburger and sausage are basic meat foods, a way to make use of all your meat scraps. When you butcher wild animals and small animals like goat, you get so many odds and ends of meat pieces (especially if you are boning out the meat), that ground-meat recipes are the answer. Grinding also solves the problem of using tough, old animals. And ground meat is easy to heavily and thoroughly season, so it also can solve

the problem of what to do with strong-tasting meats. Hamburger and sausage can be heavily or lightly seasoned—whatever you prefer. Besides the seasoning, you can add water and fat. Ground meat that is all lean can often benefit from a little added water, about 1 T. water per 1 lb. lean meat.

NOTE: The following sections usually refer to “sausage,” but some of it applies equally to hamburger.

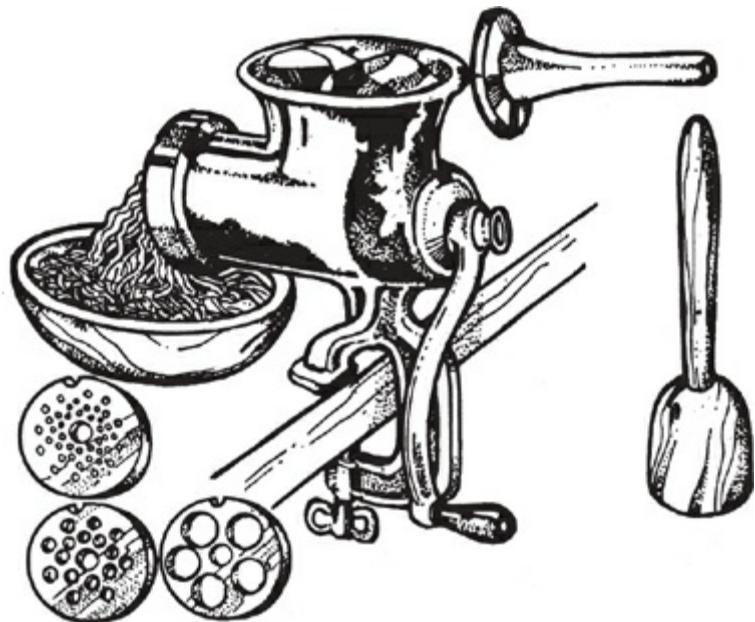

Adding Fat. To any hamburger or sausage, you have the option of adding fat. If you choose to do so, choose a soft, low-cholesterol fat such as pork fat. Don’t use a strong-tasting (high-cholesterol) fat like venison or goat. *Don’t use mutton fat.* You don’t have to add fat. You can make all-lean hamburgers, and they will be delicious and cook fine. But in the past it has been popular to add pork to nonpork meats because the pork seems to bind the meat together while cooking and improve its flavor. If you add fat, make sure the fat and meat are well mixed before you package the hamburger or sausage. You can knead the mixture with your hands until the fat and lean are distributed equally.

Grinding. To make sausage, one thing you must have, or have access to, is a meat grinder. The best grinder for sausage is one with a choice of coarse ($\frac{1}{2}$ -inch holes) and fine ($\frac{1}{8}$ -inch holes) plates. Don’t plan on using one of those small home-style meat grinders to make your sausage. I made that mistake. They just can’t handle the job. Even if you keep the screw as tight as it will go, which helps, you end up getting some steel flavor in your meat. You have to keep tightening the screw because it keeps slipping. And sooner or later the grinder starts getting stringy ligaments wound around the outlet, and finally it gums up completely and is immobilized. It helps some to trim out as many of the ligaments as possible, but there’s no way to get them all.

Better than trying to grind sausage in a little home grinder is to take a dishpan or two of it to your local butcher. But check first to see if the butcher feels able to do it for you. There are so many new laws now that discriminate against home-butchered meats that he or she may not want to take the chance.

It helps to use a larger model of meat grinder (Food Grinder Pro, \$100, or Stainless Steel Meat Grinder, \$150, from Back to Basics, 866-290-1851). Or mail-order a sausage grinder and stuffer from Lehman’s (888-438-5346; www.lehmans.com); they sell other sausagemaking equipment, too. A typical bargain grinder has the 2 disks for fine or coarse grinding and a 7/8-inch stuffer attachment. It’s crank-operated. Power grinders are the nicest of all, if you have the kind of handyman who can hook up a washing-machine motor to anything.

Before you grind the meat, trim it from the bones and cut away all gristle and blood clots. Cut it into strips, whether it is fat or lean. Put your fat in one pile and your lean in another to help you have a notion of proportions. You’re supposed to use one-third fat and two-thirds lean, and you can kind of judge that with your eye. I don’t see much use in the fat part, however, so I generally just use whatever fat comes along of its own accord, and the fat that I can easily cut out goes into the rendering pail.

Seasoning. Some people grind their meat coarse and then add the seasoning and grind again. But it's too much struggle to grind more than once, and it's easier to mix the seasoning with the meat before grinding than after. So do it like this. Cut the meat in strips. Lay it out on a mixing surface, such as a sheet of freezer paper with the wax side up. Sprinkle the seasoning over and mix with your hands. Sprinkle again and mix again until you have it well mixed. You can season about 20 lb. at a time this way. It's much easier than working with it ground.

Now grind. If you have a very good grinder, you can form your ground sausage into fist-sized balls and put them through the grinder again. It really helps to have a wooden "follower," which is a basic cylindrical meat pusher, so you don't grind your fingers but do hold the sausage in the grinder.

If you aren't sure of your seasoning amounts, make a little sausage cake up on the spot, fry it, and eat it. Then you can adjust the seasoning of the rest accordingly. Don't taste raw pork because it's been known to carry trichinae, a parasite that causes a horrific disease. A woman at my college got it after eating several hot dogs in Chicago. She got really sick and had to quit school. I can't imagine our home-grown pork having any such thing because pigs get it from eating infected meat, and I know where everything that our pigs eat comes from. Nevertheless, it's a good idea not to taste raw pork.

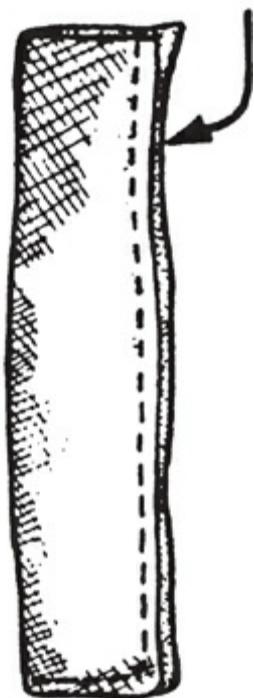

If you decide to add more seasoning to your already ground meat, mix it in a big kettle. Get ready by washing both hands clear up to your elbows, and then plunge in. Knead as for bread dough, picking up from the bottom, pulling up over the side to the top, and punching into the center. In a moment give the kettle a quarter turn and continue. Some people grind the meat coarse, add the seasoning, and then grind it fine. That's okay if you have a good power grinder.

The seasoning can be as simple as salt and pepper. Or it can be a very, very complex mixture. Morton Brothers (the salt people) makes a sausage seasoning that's sold in our local grocery stores. Some people add a little Tenderquick to their seasoning; some make it all from scratch. The commercial seasonings contain a lot of spices blended with salt as well as monosodium glutamate and preservatives. Use 8 oz. seasoning per 24 lb. meat for strongly seasoned sausage. For a milder sausage, use 8 oz. for 35 lb. meat. I've tried just grinding and freezing the sausage plain and then seasoning it right before I cook it, but it doesn't have the best flavor that way. The seasoning needs a chance to work in.

ABOUT CASINGS: You travel one of 2 basic routes, the easy one or the hard one, in shaping the

ground seasoned meat into sausage. The easy way is to make patties. Sausage that is seasoned and frozen in breakfast-sized packages, which you can simply thaw, shape into patties, and fry (or sausage-fry and then can), is just as much sausage as the kind that's stuffed into casings, and it's a lot easier to make. The harder option is to stuff the mixture into casings. Stuffing casings is extra work and expense (or time if you clean your own casings). At home I usually just wrap my sausage in freezer paper, enough per package for a meal, and that's it. But at the big hog-butchering and sausagemaking bees, I've enjoyed the adventure of doing the real thing. At these bees, while the men butcher the hogs, the women clean the small intestines, and those become the sausage casings. They make sausage and stuff the casings and then smoke them in a little smokehouse right there.

***Homemade
Muslin Casing***

You can use plastic, muslin, or gut casings. Casings are sold by the "hank," which is a 1½-lb. package that is supposed to stuff about 100 lb. of sausage. You don't eat the plastic casings, of course, or the muslin ones. But when you make sausage with casing made from the natural gut, you eat the casing too. Plastic casings used to be readily available but are hard to get now. They were sold in 1-inch, 2-inch, and 4-inch sizes. Two-inch was generally the most satisfactory.

Making Muslin Casings. *Don't dry sausage in these. You have to strip the muslin off first.* Sew 8 × 18-inch strips of muslin. This allows for a ½-inch seam. Fold and sew up 1 end and turn inside out. Firmly pack the sausage in there. Be sure there are no air pockets, because air pockets may cause mold to grow on the inside of the casings. Tie the top with a heavy cord and give it a loop to hang up the sausage. Be sure to dip your muslin casings in water and wring them out before starting to stuff them. If you don't have a sausage stuffer, you can spoon sausage into big casings like these.

MAKING NATURAL CASINGS: There are 3 kinds of natural casings, and a really good sausage stuffer has 3 nozzle sizes. Little-pig size (what they call link sausage) is about 2 inches long and ½ inch wide and is a sheep casing. Beef casings are used to hold salami-type sausages. Pork casings make traditional "sausage" sausages. A hank of pork casings is

supposed to stuff 100 lb. of pig—but about 85 lb. is more likely. Sheep casing will take 50 lb. Beef casing will take a lot. You can buy natural casings in quantity and keep them in your freezer. I have a friend who kept hers there for 3 years before they were all used up, and they kept fine. Soak them in warm water before stuffing.

Making natural casings is cold, tedious, hard work, and it's not for the squeamish. You need a fairly low faucet or hose that runs water on the ground, a knife to cut the gut when it shows a hole or tears, and a set of knitting needles. If you are going to clean casings, it's doubly important that the animal not be fed for 24 hours before butchering. The casing is made from the small intestine of the animal (sheep, cow, or pig). If there is food in there, it makes a lot of extra work to get it out.

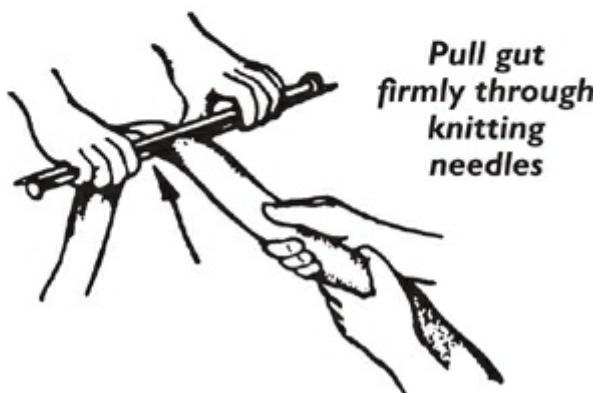

If you are planning to save casings, it's a good idea to keep your pigs especially well wormed. (Worm medicine is a liquid that you mix with a gallon of water and have them drink.) Not only is it disagreeable being in the same vicinity as a bunch of 6-inch-long, husky, writhing, white roundworms, but they also make holes in the intestine. A really infested pig will have a gut like a sieve.

1. Cut the small intestine off where it starts below the stomach, and cut it on the other end where it is about to connect up with the large intestine. You'll have to rescue it from the general pile of innards. Put it in a big dishpan.
2. Carry it over to your faucet or hose. Strip it between your fingers or between knitting needles to remove as much of the contents as possible—food, worms, or whatevers. Just let them spill out on the ground. Then rinse them off under running water. This is where the agony starts, because sausage and butchering weather is cold weather, but you have to do all this work with your bare hands because the gut is delicate and so is the job. Your cold, wet hands will be in a state of near-paralysis after the first 10 minutes. It's not so bad if you're doing just 1 gut, but if you're doing more than one, it's nice to have somebody working with you so you can take turns freezing your hands working with the casings or thawing them out over the nearest fire.
3. You have the gut contents stripped out as best you can and the outside rinsed off under your faucet. Now you're going to turn the entire gut inside out. There's a neat trick to this turning. Practice beforehand in the house with something like a sock, when your hands are warm and dry, till you feel you'll be able to do it even with wet, frozen hands and a slippery gut:
 - a. Take a sock.
 - b. Hold it upside down.
 - c. Start turning it inside out.
4. Keep in mind that if it was a gut rather than a sock, it would be about 25 feet long and slippery. The way to get it turned inside out is by water pressure. The hard part is getting it started. Returning to the sock, if you turn socks inside out like I do, you have your thumbs in a sort of pocket you've made all the way around. Now you're going to run your water into that pocket. Since the gut is waterproof, the water pressure going into the pocket will push on it and draw more and more of the gut inside out until you're clear to the end. If you run into a wormhole or the gut starts to tear, you lose your water pressure as the water starts to leak out the hole. In that case, cut the gut at the point of the leakage and start over again with the part that hasn't been turned yet.
4. Put your turned, cleaned casings in a pan. Now get 2 knitting needles. Put 1 end of the cleaned gut between the knitting needles. Have somebody hold the needles tightly

together while another pulls the casing through between them.

*Turn gut inside out
using water pressure*

*Pull gut
firmly through
knitting
needles*

5. Rinse them some more.

6. Store in cold water if you're going to use them soon. Otherwise freeze them. Soak in warm water before using.

➲ **CHITTERLINGS** *This is a Southern name for casings used as a meat dish. Having gotten them this far, you soak them in vinegar to remove the smell and then cook.*

STUFFING THE CASINGS: The stuffer is basically a nozzle with a container on top, fixed so you can put pressure on the contents. The pressure forces the sausage out through the nozzle and into the casing. The simplest sort is just a funnel. You hold the casing under the funnel and push it through with your hand. The usual sausage grinder has a stuffer attachment. Using the attachment, you turn the crank to force the sausage out of the nozzle into the casing until it is full. Pack the casing as tightly as possible. At the sausagemaking bees they have a special big crank-operated sausage stuffer, but that's not practical for one individual or family.

If you're going to have only one stuffer size, it's better to have it too small than too large. Really nice stuffers have 3 nozzles for the basic casing sizes, but ordinary ones have just one size, $\frac{3}{8}$ inch in diameter. It has to be small enough that the smallest casing can easily slip over the end of the nozzle.

Step-by-Step Guide to Stuffing Casings

1. Separate out a length of casing.
2. Put the entire casing over the nozzle of the stuffer.
3. Pinch the free end shut with your left hand.
4. Have a helper run the stuffer. The casing will unfold itself as the sausage is forced into it. To make a round sausage, fill about an 18-inch to 2-foot length. To stop the stuffer, crank it quickly backward a half turn of the crank.
5. Pull off a little empty length of casing. Cut the casing.

6. Put the 2 loose ends of the sausage casing together, forming a ring. Tie the ends together with twine or a stout soft white string. If you plan to hang the sausage to smoke it, tie another knot between the 2 free ends of your twine so you have a little ring of string for hanging it up. Your sausage should be long enough to make a comfortable circle and touch end to end. Round sausages smoke best because they can't stick together, twist, or flip.

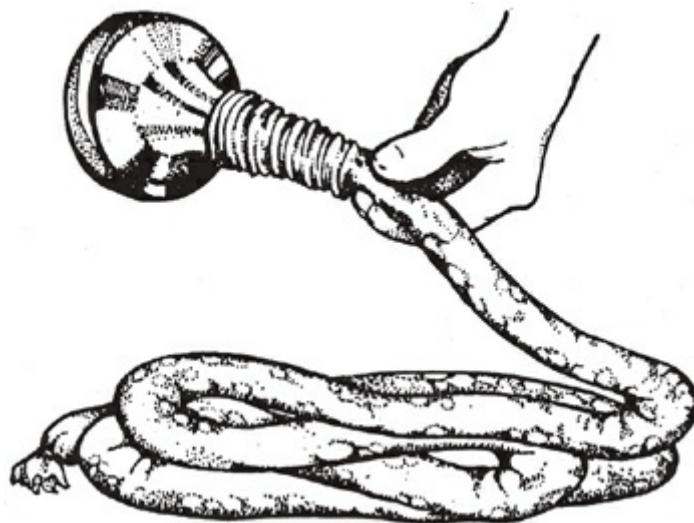

If a casing breaks with sausage in it, set it aside for the time being and restuff it later.

To make short links rather than rings, start as before. Let fill about 5 inches, or as long as you prefer. Stop filling. Twist casing several times around to make a thorough obstruction. Commence filling again, and so on. Cut off when you have enough to tie in a circle. (Takes about three.) Tie as before. If you don't tie them in a circle, you'll have to tie between each link. Three inches long is nicest, but you have to be pretty good at it to make them that short.

A butcher doesn't even need to stop the machine but can just keep the links flowing across the table.

Another way to do it is to make very long links and freeze them. Then you can just break off what you need.

Stuffing Using a Funnel. Use a funnel with a $\frac{3}{4}$ -inch opening. Put the wet casing over the funnel end. Push meat down the funnel into the casing, regulating the thickness as it goes in. Make 5 inches long. Twist funnel around to form link. Continue pushing meat in until used up. Puncture with a skewer to let air out.

SAUSAGE RECIPES

NOTE: Sausage made from these recipes should be preserved by freezing or canning.

➲ **HEALTHY HOMEMADE SAUSAGE** For the healthiest sausage, omit salt and reduce fat. Using a mortar and pestle or your blender, make a powder from your spices and add that spice mixture to the ground meat.

➲ **CLASSIC SAUSAGE** Simply grind your meat scraps and add one-fourth to one-third pork fat and seasonings (salt, pepper, sage, optional red pepper) or one-third preseasoned pork sausage. Classic all-pork sausage is made of pork trimmings—one-third fat to two-thirds lean.

➲ **CARLA'S DIGESTIBLE SAUSAGE** I'm always in a rush, so we just grind the sausage, season it, bag up in the usual meal-sized lot, and put it in the freezer. Just grind up the pork trimmings, using only one-fourth fat. Add hefty amounts of salt, garlic salt, onion salt, dried parsley, sage, and thyme. Leave out the pepper, red pepper, cinnamon, allspice, and so on.

This tastes absolutely sausagey and has no bad aftereffects for even the most sensitive eater. I never seem to be able to keep sausage on hand. It gets used up faster than any other part of the pig.

➲ **PLAIN PORK SAUSAGE** Take 10 lb. fresh pork, 5 T. salt, 2 T. sage, and 2 T. black pepper. Grind together. Mix thoroughly some more afterwards to make sure the spices are evenly distributed.

➲ **OLD-TIME GARLIC SAUSAGE** Combine 20 lb. beef, 40 lb. pork, 1 ground onion, 4 T. garlic juice, 2 c. salt, $\frac{1}{2}$ c. brown sugar, and $\frac{1}{2}$ c. pepper. Mix thoroughly. Set out overnight so part of the liquid can evaporate. Stuff in casings. Smoke with apple wood 12 hours or until casings are somewhat dry.

➲ **BREAKFAST HERBIE LEAN SAUSAGE** For every pound of lean ground meat add $\frac{1}{8}$ t. pepper, $\frac{1}{2}$ t. marjoram, $\frac{1}{2}$ t. thyme, $\frac{1}{4}$ t. sage, and $1\frac{1}{2}$ t. savory or $\frac{1}{2}$ t. coriander seed. Mix all together thoroughly. Let rest in refrigerator overnight to help seasonings get well absorbed. Shape into patties, fry, and enjoy.

➲ **SPICY SAUSAGE** Sample recipe: combine 4 lb. pork (one-third fat, two-thirds lean), 5 t. salt, 4 t. sage, 2 t. pepper, $\frac{1}{2}$ t. red pepper, $\frac{1}{2}$ t. cloves or 1 t. nutmeg, and 1 t. sugar. Full-scale recipe: combine 100 lb. pork, $1\frac{3}{4}$ lb. salt, 3 oz. sage, 3 oz. pepper, $\frac{1}{2}$ oz. red pepper, and $\frac{1}{2}$ oz. cloves or 1 oz. nutmeg.

➲ **MARJORAM-MACE BULK SAUSAGE** Take 85 lb. lean pork, 15 lb. beef, $1\frac{1}{2}$ lb. salt, 4 oz. pepper, 1 oz. red pepper, 1 oz. marjoram, and 1 oz. mace. Cut all meat into small pieces, sprinkle seasoning over, and grind with small plate. Store for 24 hours. Add enough water so you can knead the mixture well. Make into patties; stuff casings and freeze; or smoke and then freeze.

➲ **SEASONED SAUSAGE** First mix your seasonings; then mix seasonings into meat. For each $2\frac{1}{2}$ lb. ground meat, combine $2\frac{1}{2}$ t. sage, $\frac{1}{2}$ t. thyme, $\frac{1}{2}$ t. cayenne, $\frac{3}{4}$ t. pepper, $\frac{1}{2}$ t. garlic powder, $\frac{1}{2}$ bay leaf, crushed, and a dash of celery seed.

➲ **PIZZA SAUSAGE** Combine 10 lb. pork, almost all lean if you can manage it, $\frac{1}{2}$ c. salt, 1 t. pepper, 1 t. crushed chili pepper, and 3 t. fennel seeds. Mix in seasonings. Grind. It will keep in refrigerator about 2 weeks. To cook, cut into patties and fry slowly or bake at 350°F for 45 minutes. Good with tomato sauce and spaghetti. Crumble as it fries to put on pizza.

➲ **BOLOGNA** This traditional sausage is made of a mixture of ground beef and ground pork. You could make it if you were butchering both a beef and a pig. That's a pretty natural thing to do come weather cold enough for slaughtering. By then we're low on all kinds of meat. You can substitute mutton or lamb for beef in this type of recipe. The proportion of pork lean and fat to beef can vary, according to taste and convenience, from as little as 5 lb. pork to 20 lb. beef to as much as 15 lb. pork to 20 lb. beef. So to a certain extent, it can just be a matter of how many pounds of beef and pork scraps you have. You might want to save a lot of your beef hamburger, though, to be plain old hamburger, and the same with pork. The nicest mixture is probably 2 lb. lean beef to 2 lb. lean pork with some fat pork (not more than 1 lb.) thrown in. Season with sausage seasonings and grind. Use 1 t. seasoning per 1 lb. meat. If you want to put together your own seasoning, try salt, pepper, garlic, onion, coriander, and mace. Water is added in the proportion of 3 or 4 pt. per 25 lb. meat. Bologna is traditionally stuffed into beef casings, smoked, and then cooked. Remember to soak the casings before stuffing them. Smoke the bologna for 2 to 3 hours. Then simmer the bologna just below the boiling point until it floats—15 to 30 minutes. Chill in cold water and hang to drip in a cool place. Then you can

freeze it.

➲ **LIVER SAUSAGE** Along with seasoned pork sausage and blood sausage, this is one of the most popular country sausage recipes around here. Boil 5 lb. pork liver for 1 hour. Strain and discard broth. Cover 5 lb. lean pork and 5 lb. pork skin with water. Add 3 bay leaves, 6 whole cloves, and 1 onion. Boil for 2 hours. Skim the fat from the broth. Remove the meat and cool the broth. Grind the liver and the meat. Add salt, pepper, and garlic salt to taste. Add enough of the broth to moisten the mixture well. Stuff into casings and boil 1 hour. Then keep in refrigerator or freezer. This recipe makes enough to stuff only about 6 casings. Don't smoke liver sausage.

The above recipe is pretty heavy on the liver side. Most liver sausage contains only 10–20 percent liver. You can add your pork head, tongue, and the like to it. In that case, go ahead and cook all the meat except the liver just the way you would for scrapple—until it can be easily separated from the bones. Then cut the livers deeply with a knife and add them for the last 10 minutes. Don't overcook the variety meats. It all gets cooked again in the casings anyway. For 100 lb. meat use 2 lb. salt, 2 oz. pepper, 1 oz. sage, $\frac{1}{2}$ oz. red pepper, and 1 oz. allspice. Mix in the seasonings and grind the meat until it's ready to stuff into the soaked casings. Stuff, tie, and simmer in water until it floats (10–30 minutes). Cool, chill, and hang up to drain. Freeze.

➲ **SALAMI** This is made from meat that might be tough and need grinding or that tastes like a wild meat you aren't used to. The spiciness covers the taste. Don't use any fat from wild meat, except bear, since the wild flavor is generally concentrated in the fat. Wild sausage that's part pork or pork sausage makes a fine breakfast sausage. Wild meat is generally extremely lean, so you can combine it with really fatty pieces of pork and it will benefit. You can use one-fourth to one-third pork. Season and grind up. Then I just bag it up, tie with the wires, and freeze. Each bag holds enough for a breakfast. When we have plenty of wild meat and pork, I make salami by the kettleful. Season with commercial seasoning, 1 t. per pound, or use your own formula. You can add black whole peppers after your grinding to make it authentic. Sage, allspice, garlic, ground cardamom seed, and onion salt are all good in it. After the meat is seasoned, you can stuff it into casings if you like. Smoke about 48 hours (smoking is no substitute for cooking, however). Freeze it and cook it when you are ready for a sausage meal.

➲ **POTATO SAUSAGE** This recipe was sent to me by the Johnsons of Wheaton, IL. Use 4 lb. ground beef and 2 lb. ground pork. Peel and grate potatoes until you get about 1 qt. grated potato. Use some of the liquid that drains off the grated potatoes so that the mixture is like a soft meat loaf. Grind 3 large onions and add. Add salt, pepper, and ground allspice to taste— $\frac{1}{2}$ to 1 t. The flavor should be subtle. Put this mixture in sausage casings. Don't pack too tightly. Tie the ends. Simmer in salted boiling water for $\frac{1}{2}$ to 1 hour. Freeze. To cook, put in a shallow pan in the oven and brown at 375°F for about 10 minutes.

➲ **BLOOD SAUSAGE** This recipe makes about 30 lb. sausage. Take 7 lb. fresh pork (cook the day before and save broth), 1 bundle casings (well washed and soaked in water), 3 lb. rice (cooked almost done), 2 lb. barley (also precooked the day of use), $\frac{1}{2}$ c. cinnamon, 1 t. cloves, $1\frac{1}{2}$ t. allspice, $\frac{1}{2}$ c. marjoram, 3 T. pepper, $\frac{1}{2}$ c. salt, and 2 qt. fresh beef or pork blood.

It is probably better to use beef or lamb casings, and the sausage will taste better if you use beef blood. The meat used should be mostly pork; a little beef can be added. Fresh pork hocks, shanks, shoulder, or meat from the hog's head works great. Fat must be left with it, since it is a necessary ingredient. All ingredients should be ready ahead of time.

Blood should be caught in a manner that keeps it clean. Add a little salt to keep it from setting, or stir it. The best way to get a cow or pig's blood is to shoot the animal and then quickly hoist

it. Cut the jugular vein in the neck—or, if you're a real expert, go straight to the aorta coming out of the heart. Press the neck of a jar to the animal's neck to catch the blood as it pours out. To get blood from an unhoisted beef or pig, just hold the pan so as to catch blood after cutting it open. One hog will give about 1½ to 2 gal. blood. Don't get blood from nose or mouth. Keep pan under animal, and keep stirring for at least 5 minutes; otherwise the blood will congeal into a lump, and you want to keep it liquid. If you have snow, pack the jar with snow to cool it. Grind meat and fat. Warm broth. Mix meat, broth, warm rice, barley, and blood. If blood has set, grind it and then mix in. Add spices. Mix thoroughly. Mixture must be quite warm to put in casings. Don't pack casings too full. Have a kettle of water boiling. Tie casings, leaving room for expansion. Drop a few at a time into the water. Cook about 10 minutes. Test by pricking it with a needle. If juice is clear, take out and cool. Wrap for freezer.

My family enjoys this fried crisp or put on a cookie sheet or shallow pan in a hot oven until crisp. We use it for either breakfast or dinner. It is very expensive to buy, and what we do buy never seems very good.

⇒ **GERMAN FRANKS** Take 5 lb. veal without bones, 5 lb. pork (no fat), 8 lb. lard, 13 grams (½ oz.) salt per pound of meat, 3 grams (1/10 oz.) pepper per pound of meat, and ½ nutmeg per pound of meat. Grind meat very fine together with salt, pepper, and seasoning. Mix well after the grinding. Put into clean intestines and make 6-inch pieces. Prick with fork. Franks will keep a while in refrigerator.

⇒ **KIELBASA (POLISH SAUSAGE)** Combine 1½ lb. pork loin or Boston butt, ½ lb. veal, salt and pepper, 1 clove garlic (crushed), and 1 t. crushed marjoram, if wanted. Run meat through coarse grinder. Add 3 or 4 T. water, garlic, salt and pepper to taste, and marjoram. Mix thoroughly and stuff casing. It is now ready to smoke. Or just place in baking dish and cover with water. Bake at 325 to 350°F until water is absorbed.

⇒ **DRY ITALIAN SAUSAGE** Take 5 lb. freshly butchered ground pork butt, 2 t. black pepper, 1 clove garlic (chopped), 1 wine glass of red table wine, 1 T. salt, 1 T. fennel seed, and 1 t. ground hot pepper. Blend well and store in refrigerator overnight. The next day, stuff in casings. Then freeze, or hang up to dry in cool, ventilated room for 1 week and then freeze. Some people add ground onions to sausage.

⇒ **ROSEMARY SAUSAGE** Take 1 lb. pork 1 lb. beef, 1 lb. veal, 1 lb. suet, 1 T. salt, 1 t. black pepper, 2 t. rosemary (ground or chopped), ½ t. thyme, ½ t. marjoram, ½ t. freshly grated nutmeg, and casings. Finely grind first 4 ingredients. Add remaining ingredients and mix well. Put into casing and tie every 4 inches, or form into patties and refrigerate.

⇒ **DUTCH “POUTDEN”** Use a Dutch oven or a large pan with a cover. Cut or chop up the following ingredients, working from the bottom of the pan to the top. On the bottom make a layer of potatoes, then carrots, then onions, then apples, then cabbage (cut in chunks), and then mettwurst or any good smoked sausage (cut in small pieces). Add 1 to 2 c. water, salt, and pepper. Boil until mushy. Can be served as it comes or mashed together.

⇒ **SWEET AND SPICY SAUSAGE** To 4 lb. pork trimmings, add 5 t. salt, 4 t. sage, 2 t. black pepper, ½ t. ground cloves, and 1 t. sugar.

Canning Sausage. See the Ground or Chopped Meat recipe in the "Canning" section.

Preparing Hamburger or Sausage to Be Frozen. Mix together your desired meat, fat, and seasoning ingredients. Then decide if you want to freeze it in clumps, patties, or rolls. For clumps, divide into the sizes you want, wrap, label, and freeze. For patties, divide meat into $\frac{1}{2}$ -lb. balls and press into flat patties (or use a hamburger press). Package for freezer the desired number of patties per package. Separate the patties by a double thickness of wax paper. Wrap, label, and freeze. When thawed, these patties can be broiled, pan-fried, or baked in gravy. For rolls, shape meat into cylinders of a diameter and length that will feed all of your family for 1 meal. Wrap, label, and freeze; when you defrost a roll, cut into slices. Rolls slice better if they have some fat content or if all-lean meat is mixed with a little water.

Soups from Meat

CONSOMME: Prepare for the pot a chicken that weighs about 4 lb. Saw about 2 lb. worth of beef bones into pieces. Cut up 2 lb. beef. Put everything in a covered kettle and add water to cover. Let it all soak an hour; then put over the fire and bring quickly to the boiling point. Reduce heat at once to simmering and cook 6 or 7 hours. In the last hour of cooking, add 1 T. salt, $\frac{1}{2}$ c. carrots, $\frac{1}{2}$ c. onion, $\frac{1}{2}$ c. celery, 1 t. peppercorns, 2 whole cloves, 1 allspice berry, 1 small bay leaf, 2 sprigs parsley, 1 sprig thyme, 1 sprig savory, and 1 sprig marjoram. Cut the vegetables into reasonable-sized pieces. At the end of the last half hour of cooking, strain the soup. Then chill it. When it's cold, remove any fat that has solidified on the surface. Clarify by reheating with 2 slightly beaten egg whites, stirring constantly until it boils. Boil 5 minutes. Then let stand until it settles. Strain through 2 thicknesses of cheesecloth.

BOUILLON: Use $3\frac{1}{2}$ lb. beef. Put in a pan with water and let stand an hour. Then put over heat in covered pot and bring to boiling point. Skim off scum. Reduce heat and simmer 3 hours. Chop 1 onion, 1 carrot, 1 sprig parsley, and 2 stalks celery and add to soup with $\frac{1}{2}$ bay leaf, 2 cloves, 6 peppercorns, and 1 t. salt. Let simmer an hour more. Strain into a bowl and chill. Remove fat when it is firm and clarify for consomme.

BONES: No matter how closely trimmed, bones can be cooked for a delicious and nutritious broth. Fill a large pressure cooker or canner with trimmed bones, half-fill it with water, and cook at 15 lb. pressure for 1 hour. After the pressure has dropped, strain the broth into another kettle and pick off any meat still on the bones. Chill the broth and remove the fat from the top. The remnants of meat and broth can be either frozen or canned. Use the bones as dog treats or bury them in the orchard or garden, where they will serve as time-released fertilizers.

By-Products: SOAP AND TANNED HIDES

There's no need to waste anything from your animals.

Soap Making

Soap is nothing more than a mixture of fats or oils with lye and water. Although soap has been a part of human life for at least the last 2,000 years, its commercial history is very short. Before people learned the connection between bacteria and disease and figured out that soap killed bacteria, cleanliness was not a popular concept. But by the mid-19th century, innumerable fat-lye soaps were on the market, some made with animal fats and others with palm kernel oil, which lathers more easily than tallow soap. These days,

commercial soaps and detergents are so plentiful that homemade soaps are a handicraft.

The idea of making one's own soap is attractive for several reasons. First, it is the only way to really know what you are rubbing on your hands or soaking your clothes in. Makers of commercial soap detergents don't list all their ingredients on the package. Those of us who are concerned about ecology have to dislike the detrimental effects of the commercial synthetic detergents that have been widely used since just after World War II. (Although soaps in large concentrations can poison marine life, this rarely happens because the soap decomposes readily.) Second, soap is another use for the byproducts of slaughtering your animals, making the proposition of raising stock that much more economically efficient. Third, the cost of making homemade soap is much less than that of buying commercial soaps.

Homemade soap leaves clothes with a lovely clean smell. (Use about 1½ c. per load, or more if you're planning on putting a lot of clothes through the same water.) I like homemade soap for dishwashing, too. Here's my testimonial: my glasses have been shinier and my silverware sparklier since I started washing them with homemade soap. I can also see the soap in the rinse water for the dishes because it turns gray very quickly—an advantage over detergents, which are so clear that you think you have washed them away, but you end up eating them! Homemade soap works okay in lukewarm water if you can give a halfway ample hot rinse. It's also fine for human bodies if it is properly aged. You can wash your face and take baths with it. You can use the leftover water to irrigate garden or flowers, since the soap has no additives that harm the environment. And homemade soap is a bargain!

If you wonder what using homemade soap flakes is like, just buy some White King. As far as I can tell, it's identical to homemade! Of course, homemade soap doesn't contain the bleach that is present in so many detergents now, so your clothes won't look "white" unless you add a bleaching agent separately to the water. Or you can make your soap with bleach. Homemade soap won't work well in a very hard water unless you use some borax to hold down the "curding." You can put borax in when you make the soap. Using liquid bleach will also help hold down the curds.

BOOKS ON SOAP MAKING: *The Art of Soap Making: A Complete Introduction to the History and Craft of Fine Soapmaking* by Merilyn Mohm (1979); Dorothy Richter's *Make Your Own Soap! Plain and Fancy* (1974); and *The Natural Soap Book* by Susan Miller Cavitch are available from 719-962-3228; www.cfamlyresources.com. *Milk-Based Soaps* by Casey

Makela; *The Soapmaker's Companion* by Susan Miller Cavitch; *The Handmade Soap Book*, by Melinda Coss; *Making Natural Liquid Soaps* and *Making Transparent Soap*, both by Catherine Failor; and *Melt & Mold Soap Crafting* by C. Kaila Westerman are available from Storey Books (address in [Chapter 1](#)).

The most recent is Elaine C. White's *Soap Recipes: Seventy Tried-and-True Ways to Make Soap with Herbs, Beeswax, and Vegetable Oils*. Order her book from Valley Hills Press, 1864 Ridgeland Dr., Starkville, MS 39759 or online retailers such as www.amazon.com.

SOAP-MAKING SUPPLIES: A homemade bar of soap can be a work of art and/or a way of making money.

K & W Popcorn ships 5-gal. coconut oil or 35-lb. bags: 660-359-2030; PO Box 275, 710 E. 24th St., Trenton, MO 64683; www.kwpopcorn.com.

Liberty Natural Products, 20949 S. Harris Rd., Oregon City, OR 97045; 800-289-8427; fax 503-631-2424; www.libertynatural.com. Wholesale only; \$50 minimum. They sell essential oils, soapmaking fats, herbs, clays, etc.

Lorann Oils offers molds for soap and candies, essential oils, flavorings, and specialty ingredients for soap-, candle-, and food-crafters: 4518 Aurelius Rd., Lansing, MI 48909; 888-456-7266; 517-882-0215; fax 517-882-0507; customercare@lorannoils.com; www.lorannoils.com.

SunFeather Natural Soap Company, 1551 State Hwy. 72, Potsdam, NY 13676; 800-276-1365; fax 315-265-2902; www.sunsoap.com, offers soapmaking books, supplies, and equipment. Free color catalog.

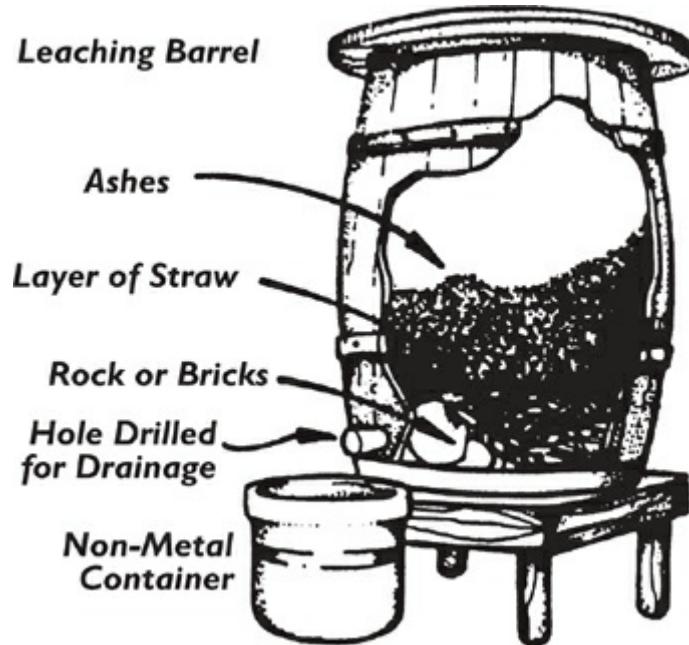

HOT WATER, COLD WATER, HARD WATER: Homemade soap is good for washing if you are able to wash in hot water. It isn't good for washing dishes or clothes in cold water, though, because it doesn't dissolve easily, even if you make it into soap flakes. If you use it to wash dishes in hard water, it leaves a ring around the sink. Hard water contains calcium, magnesium, and iron, which, with soap, form compounds, or "curds," that resemble sticky gum. Use borax or washing soda to soften hard water before adding soap. Make sure the soap is dissolved before you add clothes or dishes. Otherwise you risk having little particles of undissolved soap left among your clothes. A really good hand rinse will easily get rid of those particles, but automatic washers aren't built to handle that. You'll have to agitate the water to dissolve the flakes into solution and produce suds. Use water as hot as your hands can stand—or hotter. Great-Grandmother literally boiled her clothes with homemade soap in a big iron pot over a fire in the backyard on washday. But then, practically everything her family wore was cotton.

SOAP JELLY: You can solve the dissolving difficulty by heating, or adding hot water to, a concentrated soap mixture, stirring it into solution, and then cooling. The old-timers called this dissolved soap "soap jelly" and made it ahead. They used it in washing machines and for washing dishes because soap jelly easily melts in hot water and makes thick suds. To make soap jelly, you cut 1 lb. hard soap into fine shavings and add 1 gal. water. Boil about 10 minutes and then cool. Keep soap jelly covered to prevent drying out. A reader told me an even easier way. She puts homemade soap bars into a few gallon glass jars and pours hot water over. Every day or so she drains off the liquid into a plastic pail, and that liquid is soap jelly.

Buying Lye. You can buy lye from the cleaning agents section of a regular supermarket. If they don't carry it, ask. They can order it for you. It may be called sodium hydroxide or caustic soda. Store lye is sold in cans, usually containing about 13 oz., under several

different brand names. Note the sodium hydroxide content. It should be 94–98 percent. Lye for soap is different from the lye used for drain openers, which has nitrates and other additives. There is usually a soap recipe on the lye can. Most lye companies will send you further information on soap making upon request.

Making Lye. Use ashes from hardwoods, if possible, such as oak, walnut, or fruit wood, since they make a stronger, better lye. Pine, fir, and other evergreens are soft woods. Put the wood ashes in a barrel with a small opening near the base to let the water “leach” through. Set the barrel so that you can put a container under the hole. If your wooden tub or barrel doesn’t have a hole, bore one with a drill on the side near the bottom of the barrel. Before putting in your ashes, put several clean rocks or bricks inside the container by the hole and then add a generous layer of straw, if you have it—hay or grass, if you don’t. Then you can add your ashes. You can just let them accumulate until you want lye or until your container is full. The most efficient way of proceeding is to then add soft water to your barrel until water begins to run from the tap (this may take awhile). Then plug the tap hole with a cork plug (home brewer’s supply houses have them) or something, and let it soak a few days. If you have extra ashes, you can add more ashes and water as the first layer settles in the barrel from the wetting. In 3 days, open the plug and have a wooden tub, crock, or glass container ready to catch the trickle of lye water emerging from the opening.

Lye Concentration. Store lye is just fine if you follow the directions. For homemade lye, put in an egg or potato. If it floats enough that a piece about the size of a quarter is exposed on the surface, the lye is about right for soap making. If it sinks, the lye water needs to be leached another time through fresh ashes or else boiled down until the concentration is strong enough. If your lye isn’t strong enough, you’ll make soft soap as the pioneers did. Knowing how much homemade lye to use in soap making requires experience. Excess lye makes a coarse, flinty soap that will crumble when shaved and burn you when used. Soap should have a smooth, velvety texture that curls when shaved. If any free lye is present, the soap “bites” when touched with the tongue.

Lye for Cleaning. You can use lye as a cleaning fluid for washing garbage cans; hog, dairy, and poultry housing; and other problem areas. Use about $2\frac{1}{2}$ c. liquid lye or 1 can commercial crystals per 10 gal. warm water, or as you like it. In days past, lye was poured down rat holes and also used in making hominy.

FATS FOR SOAP: Since soaps and candles both use tallow, pioneer families often produced both at the same time. The grease must be pure, clean, and fresh (or frozen) to obtain soap with a clean, wholesome odor. By "toilet" soap, the old-timers meant soap using fat from butchering rather than drippings; it was a whiter, better-quality soap. "Saddle soap" meant an all-mutton or beef tallow soap. Such a soap was valuable as a cleaner and preserver of leather.

Six pounds of fat and 1 can of lye will make about 9 lb. of soap. Mutton (sheep) or goat tallow (fat) is the hardest of all animal fats, having the highest melting point. Used alone, mutton or goat fat makes a hard, dry soap unless you add extra water or mix the hard fat with softer ones like lard, goose grease, or chicken fat. Beef tallow, once the preferred fat for soap, is next in hardness and also should be mixed with softer fat or additional water. One pound of untrimmed beef fat will get you 1 c. tallow. Lard (pig fat) makes fine soap, giving you 2 c. fat for every pound of meat, although it may be a little soft. Poultry fat is too soft when used alone, so it should be mixed with harder fats. Meat fryings, cracklings, meat trimmings, and other refuse fat must be first clarified and desalted.

You can use any animal or vegetable fat (even salad oil), but not mineral oil. Tallow alone produces a hard soap without much lather. Adding vegetable oils improves the texture. The best vegetable oil by far is coconut oil, which produces a fine sudsing soap similar to a "shaving" soap. (All-lard soap is similar; you can use the coconut oil soap recipe to make it.) Soap made from vegetable oils or soft fats requires less water and needs to dry longer than soap made from tallow. Cottonseed oil is difficult to work with and results in a soft soap, while olive oil is better for soap making than other vegetable oils.

Store your fat in a cool, dry place while you accumulate enough for soap making. When you do have enough, make it into soap promptly, because fat will become rancid over time, and rancid fat has to be cured of that problem before it can be used (more on that later). Soap improves with age; fat doesn't.

To accumulate fats, each day save your fats of all kinds. If you boil meat, cool the pot of liquid and remove the fat. Then put the accumulated fat on and melt it. Cook long enough to get all the water out (if you don't, it will mold or spoil). Then fold several thicknesses of cheesecloth or any loose-weave cotton, and strain the melted fat. Always be careful when handling hot fat, since it can burn you. Keep all fat in a tightly lidded pan, away from any strong-smelling stuff, until you are ready to make soap. You may want to freeze it, but if you can store it in a cool place, it will keep for several weeks.

Rendering Fat. Render any surplus fat from butchering or fatty trimmings from cutting up. Grind the fat or cut it into pieces. Put it into a large kettle on top of the stove or in a large pan in the oven. Add about 1 qt. water for each 10 lb. fat. Use a moderate temperature and stir occasionally. When the fat is liquefied and the solids (cracklings) are brown and settling, carefully strain the fat. You may want to do this more than once. Your soap will be as white as your fat is. If your fat is not pure enough, you may end up with yellow soap with an unpleasant odor. If you do not want to strain the fat, scrape the sediment off its bottom, pour off the liquid, and repeat as necessary. Years ago, old-timers had a "fat press" for pressing out lard or tallow. It was an iron kettle about 1½ feet in diameter, with a sieve in the bottom and a big dasher that fit over it and could be screwed down tight to put pressure on the cracklings.

Clarifying Drippings and Removing Salt. Put the leftover cooking grease into a kettle with an equal amount of water. Use a large pot so it won't be likely to boil over. The day before soap making is a good time to do this. Bring to a boil, stir, and add 1 qt. cold water for each 1 gal. drippings. Stir to break up any lumps. When the water boils, let it set and

settle. Then cool and skim fat from surface with skimmer, or refrigerate and clean the cake of fat as described above, or strain. Repeat these procedures until you are satisfied with the condition of your grease. I would advise not even bothering with leftover grease that has absorbed strong smells, but sometimes you can cut the effect by adding a little lemon or vinegar to an amount of water equal to half the amount of fat and boiling them together. (Soft fats that won't get firm even when refrigerated have to be skimmed, of course.)

Removing Rancidity. Boil the sour or rancid fat in a mixture of 5 parts water to 1 part vinegar. Cool and skim fat, or refrigerate and remove fat cake. Remelt the fat; for each gallon of fat, add 1 qt. cold water. Stir slightly. Cool and skim fat or remove fat cake. Repeat as necessary. Fat that is rancid is fine for soap making but not for eating ever again.

OTHER SOAP INGREDIENTS

Water. Water is a basic ingredient of soap making. You need pure water, free of chemicals that can combine with the lye. Don't use hard water unless you neutralize the chemicals in it with washing soda. "Hard water" means water with minerals dissolved in it. Rainwater isn't hard, but almost all water from springs, wells, or rivers is, in varying degrees. Measure the water into enameled, wooden, or crockery containers that are easily handled.

You can test how hard your water is by making a solution of denatured alcohol or wood alcohol and pure soap. At room temperature, mix in soap a bit at a time until the solution is nearly thick. Then find 2 identical small medicine bottles or spice containers. Put rainwater or distilled water in one and the test water in the other. Use an eye dropper to add soap solution to the distilled water. Shake frequently. The idea is to get suds to cover the water surface for 1 minute after the bottle is laid on its side. If you then add the same number of drops to the test water, shaking, you can see how long the suds last there. Soft water will produce a minute's worth of suds; hard water will not.

Perfume. Perfumes like oil of sassafras, oil of lavender, and oil of lemon may be added to soap. They used to be cheap, but not any more. Oil of citronella is sometimes suggested, but I wouldn't use it. It's an excellent insect repellent, however. Never use perfumes containing alcohol—they will not last and may cause separation. Experiment to learn just how strong you want your soap to smell. For a start you might use, per 15 lb. tallow: 4 t. oil of sassafras; 2 t. oil of lavender; 1 t. oil of lemon; 1 t. oil of cloves; 1 t. oil of almond; 2 t. oil of pine; or $\frac{1}{2}$ t. rose geranium oil.

You can make your own rose geranium perfume by making a tea of the rose geranium leaves and adding it to your soap. All soap readily absorbs odors, desirable or undesirable, so it can be perfumed simply by placing with it the petals of any favorite flower or perfume, if you have yet not added a scent.

Coloring. Uncolored soap is fine. A light yellow or marbled effect can be made with liquid butter coloring. You can make your own pink coloring by adding an extract of the blossoms of pink roses or tulips. A green color can be had by pounding the tops of beets (or spinach, parsley, etc.) to extract a few drops of the juice and adding it to the water. (For more ideas, see the section on making food colorings in [Chapter 5.](#))

Borax. Borax quickens the sudsing action of soap because it helps to hold down homemade soap's tendency to curd in hard water and it's a natural fabric softener. Because they used borax, the old-timers could hang their clothes on a line and they'd come out soft.

Since chemically, borax doesn't play any role in the soap recipe—it's just a physical

additive—using more or less doesn't affect the quality of your soap a bit. I've seen recipes with anywhere from 2 T. to 3 c. borax per can of lye. You can buy it at your grocery store. The exact amount you should add depends on how hard your water is. You can make a batch one way and see how it washes, and then either add or subtract borax the next time according to what you learn. Or you can leave the borax out of the soap recipe completely and add it at the time you wash clothes. That will give you a good notion of just how much borax to include the next time you make soap.

Air. If you want your soap to float, fold air into it when it begins to have a creamy consistency. You fold in air just as you would fold an egg white into a cake mixture. Test for floating by flicking a few drops on cold water.

Rosin. Adding rosin to soap increases its lathering ability but makes the soap darker and softer. Rosin soap is okay for laundry. Add 8 oz. crushed rosin to 5½ lb. fat and heat until the rosin melts or is dissolved in the fat. Cool fat to 100°F and add 90 lye solution made of 1 can lye dissolved in 2½ pt. water.

SAPONIFICATION: Soap making is a chemical process. When lye and fat are brought together under the right conditions, they react to make soap, which is an alkali salt of fatty acids and glycerin. The process is called "saponification." It may take several weeks for complete saponification to take place. This is one reason that aging is so important in soap making. Soon after it is made, soap actually contains some free lye, but the longer it ages, the less likely it is to contain any free lye. Soap made from lard or soap that has been boiled requires longer aging before it becomes hard and ready for use. Once it is saponified, the soap will never separate into fat and lye again. In homemade soap, the glycerin is left in. In commercial soap making, it is separated and sold.

LYE TO FAT TO WATER

To make good soap you need correct proportions of these basic soap ingredients.

Lye

Fat

Water

Cold Process. The process I use to make soap is the cold process. To make the very best soap (mine is not), use exact weights, measures, and temperatures. A dairy (floating) thermometer and household scales are useful. Soap has to have the right proportion of fat to alkali. Too much fat makes for an ineffective emulsifier, but too much alkali will make soap that's too harsh, especially for skin. The saponification has to be nearly complete. Free fat can become rancid, smelly brown spots on your soap. Free bits of lye can burn the skin.

Combine lye, water, and fat (see "Lye to Fat to Water" table for proportions). First add the lye slowly to your water when making a solution from the lye crystals, and then add the lye solution slowly to the melted fat. Stir evenly, preferably only in one direction. Rapid addition of the lye to your fat, or of the fat to the lye, can cause separation. So can jerky, uneven stirring. Boiled, or hot-process, soap is probably superior to the kind I describe here, but it's a lot trickier to make. Use an enameled kettle, never aluminum.

Confused already? This will help.

The Basic Steps of Soap Making

1. Slowly add 1 can lye to 5 c. cold water in an earthenware or unchipped enameled or "ceramic on steel" container. Steel or aluminum under the enamel is okay. Don't use cast iron. Ask at a kitchenware store or at a homesteader's supplier if you are not sure what pot to use.

Mix lye and water outdoors or near open windows, because the mixing produces heat. There will be strong fumes that you can see. Try not to breathe them; they'll make you cough. Don't use anything but a wooden spoon to stir. Be careful not to splash it on your skin. Stir constantly until the lye crystals are all dissolved. Now let it cool. Cool the lye solution to 70–75°F if your fat is lard (pig fat), 90–95°F for an all-tallow soap.

2. Heat 10 c. melted fat. A relatively large proportion of fat gives you a milder soap. If the temperature of the lye water (including borax if it's in your recipe) is about 75 to 80°F at the time of mixing with the melted fat, the fat should be heated to the appropriate temperature, as shown in the "Heating Fat" table. Too high a

temperature darkens the color of the soap and may keep it from setting.

HEATING FAT

Type of Fat

Temperature

Vegetable oil

110–115°F

Bear

115°F

Goose

115°F

Pork

120°F

Beef

130°F

Deer

130°F

Sheep

130°F

3. Pour the fat slowly into the lye water when you have each at the right temperature.

4. Add your borax, perfume, coloring, or other extras at this point.

5. Stir in one direction until you have soap. This usually takes about 15 minutes, but it could happen in 5 minutes or take an hour, depending on temperature. If you have waited for your ingredients to cool, you should have no problem. If you're having a setting problem, you might try setting the mixing container in cold water. If, on the other hand, the soap starts setting on the edges, stir faster or even beat it. Soap starts out dark-colored; as you stir, it gets somewhat lighter in color. When all the lye gets mixed with all the fat, saponification happens. You'll notice a cloudiness first. It's ready to pour when it is like thick pea soup, and drops that are trailed from the spoon stand momentarily on the surface of it. It's also ready if the stirring spoon will stand by itself in the middle. If you pour too soon, the soap may separate into 2 layers, the bottom hard and brittle and the top greasy. But if you wait too long, you'll end up with incomplete, odd-shaped bars with air pockets.

6. Pour into molds. Scrape all the mixture out of the bowl. Your soap will be a little dark when first made but will turn white in a week.

This sounds like a lot of work, but it isn't after you make a couple of batches. All these little things will soon come naturally. There are infinite variations on this procedure, but it's the one I know best and it's relatively simple. It makes a good basic raw (cold, not cooked) soap for soap flakes with which to wash dishes and clothes. But later on, I have some even easier ones for you that readers have sent me.

OF LYE—READ THIS!

1. Lye is caustic soda. It burns, even in tiny flakes. Lye in the eyes or on skin or clothing can cause severe burns. Obviously, you should not swallow it.

2. Keep children and animals away from lye.
3. The fumes of lye in water can burn your throat and chest. Work in a well-ventilated space, outside or near a window. Don't breathe the fumes!
4. Keep newspapers handy to sop up spills.
5. Don't keep lye or a lye solution in metal; lye reacts with metal. Don't put it in aluminum, because it will react with the aluminum. Don't put it in tin, iron, or stainless steel. It's best contained in plastic, glass, stoneware, or unchipped enamel.
6. Be careful with glass. Water and lye can heat enough to break glass.
7. Measuring spoons of stainless steel are okay, but cups should be glass or heat-resistant plastic. Utensils exposed to lye should be enamel, crockery, glass, or wood—and they should never be used for anything else. Rinsing utensils after they have been in a lye solution makes them safe to handle, but remnants of lye in cracks can contaminate foods.
8. Use only wooden spoons. A slotted spoon is good for stirring. Better yet, stirring with a piece of kindling will save spoiling a good wooden spoon.
9. Never add hot, or even warm, water to canned store-bought lye crystals. They heat up anyway when combined with water, and the hot water will cause spattering.
10. For protection when making soap, wear rubber gloves and keep a bowl of vinegar nearby, so if you spatter lye on your hands or arms, you can dip them immediately into the vinegar to neutralize it.

First Aid for Lye Burns

Be extremely careful when working with lye. If lye comes in contact with human skin, it causes a chemical burn. Flush immediately with water. If it is not flushed, it will continue to burn. If possible, add a little salt to the water. If water is not available, use soda water or soda pop—they're better than nothing. If, after 5 to 10 minutes your skin is still red and painful, seek burn care in a hospital emergency room.

If lye is swallowed, call 911. Swallowing lye can be fatal. When swallowed, it burns the esophagus, so vomiting (which may be inevitable) should be avoided. Take milk or ice cream to help neutralize the lye's chemical reaction. Although vinegar, orange juice, and so forth also neutralize lye, they should *not* be ingested because the combination creates heat. This rise in temperature will burn physically in addition to the chemical burn.

If lye gets into the eye, call 911. Flush the eye immediately with water; add salt to the water if possible. Again, use milk if available, to neutralize the chemical reaction. Most likely you should get to an emergency room as soon as possible. Do *not* use vinegar or boric acid solution.

But the best advice is: Be Careful!

SOAP MOLDS: What you can best use for a mold depends on whether you're planning to make soap flakes or bar soap. For soap flakes, you can use anything except metal containers for a mold—serving bowls, enamel pans, wooden boxes, plastic containers, and cottage cheese cartons (handy because you can cut them off when you're done). Avoid containers with paint or dyes that the soap could absorb. Have your molds ready before you start, and expect to dispose of them once the soap hardens. Grease the molds with Vaseline and then pour the soap carefully into the mold. Smooth the top surfaces with a plastic spatula.

Keep setting soap away from the heat. It takes from a few hours to several days for the soap to harden enough to be removed, and it shrinks as it hardens. Soaps with higher amounts of soft fats will take longer to dry. To get it out of the mold, slip a paring knife around the edge and pry some. The longer it sets, the easier it is to get out. The Vaseline gives the soap a nice surface finish. Let the soap dry at room temperature for about 2 weeks, but keep it from freezing, since that stops the curing process and produces a too-soft soap.

To make flakes, use a grater with medium holes, or put the soap through a food chopper, or shave with a knife. Once the flakes are completely dry and hard, you can store them in a cardboard box, paper bag, or what-have-you.

Although the soap is soft and easy to flake immediately, let it age as long as possible before making flakes. The longer the soap has aged, or cured, the more complete the saponification and the less the risk of free lye. Five-year-old soap crumbles into something very much like detergent in consistency. Age soap in an open box in open air for 8 or 10 months or a year if you can. Don't allow the soap to freeze for at least the first 2 weeks. The best curing is at room temperature. If you're desperate, the soap can be used after a month has passed. If you grate it prematurely and find that it still has so much moisture in it that it comes out lumpy, you can rush it by first flaking and then drying it in a 150°F oven. When thoroughly dry, pulverize it.

To mold bar soap, pour soap that is ready to mold into a soaked wooden box lined with a cotton cloth that has been wetted and then wrung as dry as possible. Or you could use Plexiglas or glass pans lined with wax paper, or milk cartons. If you have molds the size of soap bars, those are most convenient of all. You can construct an open wooden grid that fits into a box and makes several bars of soap at the same time. Cover with cardboard and then with a rug or blanket to retain heat while the soap is texturing out. Some people cut the blocks into bars only a few hours after pouring. If you do this, be careful. The

saponification is probably not complete, and the lye in the solution can still burn you. Some people prefer to leave the soap molds undisturbed for at least 24 hours before cutting and piling. Others take a knife and score the soap into bars a few hours after making, let it sit overnight, and then turn them out on a board and finish breaking the cuts so the bars will separate nicely. When well set, remove the soap and cut into convenient-sized cakes. To remove the soap from a mold made of a damp box lined with cotton, just lift the soap by the ends of the overhanging cloth lining. Pile the bars on top of each other so air circulates around each cake. The soap can be neatly cut by wrapping it once with a fine wire such as piano or guitar wire, crossing the ends, and pulling.

Many of the commercial molds for decorative candles can be used to make soap too. Just avoid the metal ones. Those molds that shape the top of the soap must be pressed tightly since soap hardens more slowly than wax, especially in a closed mold. Remove the soap before it is completely hard so you can smooth the edges and fix any small flaws. Remember that the soap is still fairly caustic at this stage.

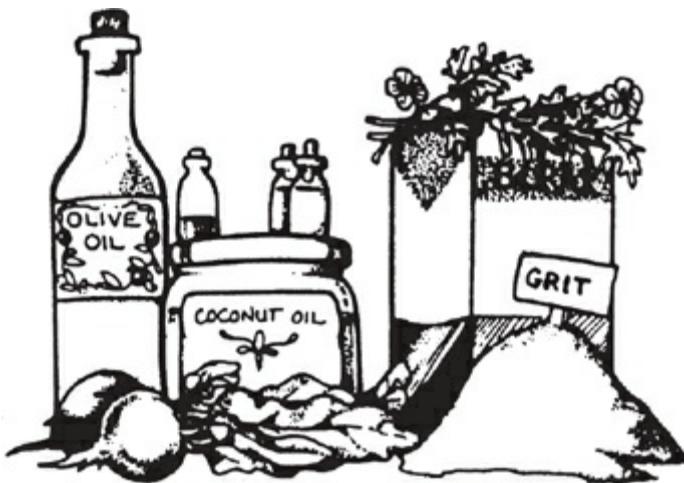

Soap on a Rope. Double a washable cord and wrap the ends with thread for 2 inches. Stick this end into setting soap and let harden.

STORING BAR SOAP: After the soap has completely dried, you can wrap it in wax paper, tissue, plastic wrap, or paper envelopes. Colored papers may stain the soap. Aluminum may interact with the alkalis. Scents will fade from soaps unless they are wrapped.

➲ **GERTRUDE JOHNSON'S BOILED SOAP WITH BLEACH** Gertrude Johnson of Lamont, WA, wrote me, "I've made soap for years, but mine never turned out to my satisfaction until I ran across this recipe. Start with 10 c. melted fat (lard and suet is a good combination), and stir in 1 c. liquid bleach until well blended. Dissolve 1 can lye in 6 qt. water (don't use aluminum pan). Do this outdoors, being careful not to breathe the fumes or splash any liquid on your hands, face, or arms. Stir with wooden spoon or paddle until well dissolved. Stir the bleach/fat mixture into the lye solution and stir well again. Set aside for 4 to 6 days, stirring frequently.

It will start out thin and watery, but by the fourth or fifth day it will be solid to the bottom of your old canner (my soap kettle). Put on the stove and melt, and then boil over medium heat, stirring all the while, until melted and thick like honey. Pour into molds, cover, and let cool. Cut into bars. Store in a dry place for several months to cure. I just grate this and then melt it in water to make thick suds to use in my automatic washer, and it makes my clothes clean-smelling and white. Besides, the suds don't ruin the soil and water as detergents do." Since I first published Gertrude's recipe, lots of people have written to tell me what good soap it made for them.

➲ **VIOLET'S SOAPMAKING TECHNIQUE** Violet Stewart is a wonderful pioneer lady from Okay, OK, who has helped me a lot with the writing of this book. She wrote me, "Weigh fat. I make only small batches at a time since it is easier to handle. Granite pots are best to use. Do not use glass or aluminum. Aluminum will turn soap dark—besides, it ruins the aluminum; lye eats it. Melt the fat and do not let it get hot, just melted. Set aside and measure out 2½ pt. cold water for 6 lb. melted fat. Measure water into pot large enough to hold the amount. Slowly add 1 can of commercial lye and stir with a wooden stick that's long enough so that lye doesn't spatter on your hand. Stir gently until lye dissolves. Pour in your 6 lb. melted fat, stirring gently while pouring the fat. Fat must never be hot or it may explode when added to lye. Keep moving gently for about 20 minutes, and it will get about like honey. The fat should feel warm to the hand. Have molds ready. Pour soap into molds and put where draft will not hit it. Each batch makes 9 lb. finished soap. I make it every time I get 6 lb. clean fat."

➲ **ABRASIVE SOAP** To make a regular mechanic's soap, add pumice stone, emery dust, or Tripoli powder. Castor oil or some other light mineral oil is also needed to prevent the abrasive from settling. Dissolve 3 lb. homemade soap in 6 c. water (more if the soap is very dry). Add 1 T. borax and 3 oz. castor oil or other light mineral oil. When cooled to a creamy consistency, work in 5 lb. pumice stone powder. Pour into widemouthed jars or cans, cover tightly, and use as a paste. Or pour into a mold and, when hard, cut into cakes. Or you can add 5 to 6 lb. of the abrasive to the regular soap mixture when it thickens, and stir until thoroughly blended.

➲ **FLOWER SOAP** Take 4 packed c. fragrant flowers (such as rose, cherry, or apple), 4 c. rendered tallow, 2 c. cold soft water, vegetable oil, and $\frac{1}{2}$ c. plus 2 T. lye flakes. Gather flowers just before you make the soap. Immerse them in the melted tallow. Heat for an hour just at the melting point. Allow to harden overnight and then remelt (don't overheat) and strain. Add enough vegetable oil to flower tallow to total 5 cups. Cool. Stir lye into cold water until dissolved. Grease molds with vaseline. Proceed to cool, mix, and mold as for any other soap.

➲ **"CASTILE" SOAP** This one is a very high-grade soap: use 24 oz. olive oil, 38 oz. good tallow, and 24 oz. coconut oil. Have fats at 90°F. Use 1 can lye and 2 pt. water cooled to 90°F. Follow basic soapmaking procedures to complete.

➲ **COCONUT OIL SOAP** A pure coconut oil soap gives a very profuse but thin lather. For a thicker lather, use part tallow. Pure coconut oil soap is made by using 1 can lye, 4½ lb. coconut oil, and 2½ pt. water. Have lye solution at 70°F, oil at 130°F. Follow basic soapmaking procedures to complete.

➲ **ELAINE WHITE'S LARD OR BEEF FAT SOAP** Weigh out 16 oz. lard or beef tallow, 2.3 oz. lye, and 6 fluid oz ($\frac{3}{4}$ c.) water. Lye/water and fat temperatures should combine to be about 120°F. Leave in mold a day. Age 3 weeks.

➲ **GOAT MILK SOAP** Pour 10 c. goat milk into a large bowl. Add 10½ oz. lye, stirring gently. Allow to cool to 85°F. Add 8 t. borax, 6 oz. glycerin, and mix. Add 3½ lb. lard which has been warmed to 90°F. Beat on low for 15 minutes. Let sit 5 minutes. Beat on low for another 15 minutes. Let set 5 minutes. Beat on low 5 minutes. Watch closely because this soap sometimes thickens up suddenly. Pour into a mold. Leave for 24 hours. Remove from mold. Cut into bars. Air dry 3 to 4 weeks.

➲ **MYSTERY PALM OIL SOAP** This recipe was sent to me by Randee Greenwald, a Peace Corps volunteer working in Cameroon, a country in western Africa. Like many Westerners in non-Western settings, Randee wrote me to say this book had been useful and to help me make

it more so. She shared her soap recipe, adapted to the local village economy. This recipe requires 5 liters water, 5 liters palm oil, and 500 grams (17.5 oz.) caustic soda. (A liter is just a bit more than a quart.) "Palm oil can be produced in the villages. The oil has to be cooked first. It takes anywhere from $\frac{1}{2}$ hour to an hour to cook out all the impurities. It then must be allowed to cool awhile. The caustic soda must be bought in town. Using a plastic bucket, add the caustic soda to the water and stir until it's dissolved. Let it cool for a couple of minutes and add the oil."

Now here this recipe runs into a problem. A mouse chewed off a bit of the edge of the letter during the years I stored it waiting to write this new edition. After the gnawed-away place, it continues: "... ached [be bleached?] first—and takes anywhere from $\frac{1}{2}$ hour to an hour to cook out and stir ... [another mouse-eaten chunk, blank?] with a wooden stick. This takes quite some time—an hour or more. You know when the soap ... [is done?] when your arms break or when you stop and it does not separate. You can leave the mixture in the plastic bucket or pour it into molds. It takes about 3 weeks to dry." (Anybody who can supply the mystery words, I'd love to hear from you!)

NATURAL SUDSING AGENTS: A number of plants (mostly tropical) produce a substance called saponin that can enhance the sudsing quality of handmade soap. Saponin is commonly obtained from soapbark, a South American tree, but a few saponin-yielding plants grow in the northern United States and Canada as well. *Saponaria officinalis*, a common weed known as chimney pink, soapwort, bruisewort, bouncing bet, or latherwort, has an abundance of saponin in its roots. It has dense pink and white flowers in late summer and early fall. Although all parts of the plant have saponin, you can dig up the roots and crush them in water to obtain a foam that is good for cleansing silk and wool. Another plant that has saponin is *Saponaria ocymoides*, a small pink-flowered perennial. Sweet pepperbush, a species of white alder, grows along the coast in the United States and in lower Canada, mostly in swamps. Lamb's quarters, a summer weed, also has the soaping agent. And finally, quinoa growers have to get rid of the saponin before eating their grain. To extract saponin, crush or grind the plants, boil them in alcohol, and strain the hot liquid. While it's cooling, it will produce a white crumbly powder that easily suds in water.

Tanning

Animal skin, when fresh and unworked, has 3 layers. The outer skin is called "scarf skin" by tanners; it comes off with the hair. The middle skin is called "grain." The underskin is called the "flesh." The scarf skin peels off naturally. The flesh you scrape off. The grain is what, combined with tannin or other substances, produces leather. Grain is made up of interlaced bundles of gelatinous fibers more or less filled with fluid matter. In the tanning process the fluid is eliminated, leaving only the fibrous portion that can be affected by the tanning substance(s). The loss of this fluid is what reduces the weight of the skin.

Tanning is a long, hard process. Sometimes you may be more successful than others. Some techniques may suit you better than others. The ways to do it are as varied as the end products. When you tan a skin, you're converting an easily decomposed substance, skin, to one which resists putrefaction—leather.

TANNING SUPPLIES AND SERVICES: To ship a hide, put it into some sort of mailing container and send by motor freight, parcel post, or UPS to the tannery of your choice. Include instructions for what you want done to it.

Braintan.com equals Matt and Michelle Richards. They sell books, tanning supplies,

tools, and info on making buckskin, leather, and furs. 10398 Takilma Rd., Cave Junction, OR 97523; matt@braintan.com; www.braintan.com; 888-443-3826. Their amazing website contains 250 + pages of articles, tutorials, an online, ongoing forum, sources for tools, books, videos, finished skins, and more traditional tanning info than you knew existed.

Bucks County Fur Products tans to order (send SASE): PO Box 204, Quakertown, PA 18951; 215-536-6614. Good service.

Eagle Feather Trading Post offers pre-1800 patterns for homemade buckskin clothing, Indian craft supplies, Mountain Man, rendezvous, and survival supplies: 801-393-3911; fax 801-393-4647; 168 W. 12th St., Ogden, UT 84404; www.eaglefeathertrading.com.

Hanson's Leather sells supplies, tools, patterns, and books for making traditional leather clothing and goods: 6900 Andressen Rd., Sheridan, CA 95681; 530-933-1232; fax 530-633-0193; hansons@succeed.net; www.hansons.net.

L & M Fur and Woolen Enterprises Inc.: 103 Erie Ave., Quakertown, PA 18951; send SASE for info on their custom tanning.

Stern Tanning Co.'s Jeff Stern will gladly tan your hides: 877-783-7682; 414-578-8640; 4010 W. Douglas Ave., Milwaukee, WI 53209; info@sterntanning.com; www.sterntanning.com.

Tandy Leather Co. sells leatherworking supplies: leathers, tanning kits, tools, dyes, hardware, and books, including Stohlman's encyclopedia series on the manufacture of leather products: 800-433-3201; 817-872-3200; 3847 East Loop 820 South, Ft. Worth, TX 76119: www.tandyleather.com.

Van Dyke's offers a wide variety of tanning chemicals, oils, softening and pickling agents for home or commercial use, plus a complete line of tools, fleshers, leather, felt, and accessories. Free mailorder catalog: 800-787-3355 (customer service); 800-843-3320 (orders); fax 704-279-8958; PO Box 480, Granite Quarry, NC 28072; www.vandykestaxidermy.com.

INFO ON TANNING: Subscribe to *The Leather Crafters & Saddlers Journal* to network and learn about serious leatherworking: supplies, patterns, machines, step-by-step instructions, etc.: \$32/yr for 6 issues: 715-362-5393; 222 Blackburn St., Rhinelander, WI 54501-2902; journal@newnorth.net; www.leathercraftersjournal.com. You'll find good directions for tanning sheepskins in the Spring 1984 issue of *The Black Sheep Newsletter*, available for \$1.95 from *Shepherd* magazine (address in [Chapter 11](#), "Bee, Rabbit, Sheep, and Pig").

Good books on tanning include *Home Book of Taxidermy and Tanning* by Gerald J. Grantz (1969) and *Leather Makin'—A Manual of Primitive and Modern Leather Skills* by Larry J. Wells. A good book on making things from leather is *Brendan's Leather Book* by Brendan Smith (Outer Straubville Press, 1972). *Home Tanning and Leather Making Guide* by A. B. Farnham (1959) is a guide to home tanning of leathers using chemicals or old-time bark tanning. *Leather: Preparation & Tanning by Traditional Methods* by Lotta Rahme describes the traditional tanning methods of Canadian Native Americans and the Sami Laplanders in northern Sweden: \$19.95; call/fax 503-735-3942; 7549 N. Fenwick, Portland, OR 97217; tcl@teleport.com; www.teleport.com/~tcl. *Primitive Wilderness Living & Survival Skills*, by John and Geri McPherson, describes dry-scrape brain tanning in [Chapter 1](#) of their excellent book.

The Shoe Trades Publishing Co. publishes and/or sells the *Leather Manufacturer Directory*

and many books on leather processes such as *Manual of Shoemaking. The Fundamentals of Leather Manufacturing* by Prof. Dr. E. Heidemann is a new book that covers the great extension in tanning knowledge of recent years: collagen, keratin, and elastin chemistry; mechanisms of enzyme action; microbiology; chemistry of vegetable and synthetic tanstuffs, fat liquors, and dyestuffs, etc. The *Leather Technician's Handbook* by J. H. Sharphouse is the newly revised text for England's famous "Leathersellers College" written by world-renowned leather scientists, dealing with all steps of the tanning process. Shoe Trades Publishing Co. also offers *Theory and Practice of Leather Manufacture* and the *Complete Handbook of Leathercrafting*: 514-457-8787; PO Box 198, Cambridge, MA 02140-0002; www.shoetrades.com.

THE BASICS

Vocabulary

Bating solution: A solution for neutralizing the hide after dehairing in limewater.

Buckskin: A dehaired leather tanned by Indian methods.

Dehair: To remove hair from the hide. You have a choice of several dehairing methods.

Flesh (v.): To scrape off every bit of meat, fat, and "flesh" from the hide. (See "Fleshing" section.)

Green hide: An untanned hide.

Hide: The skin of a large, adult animal.

Hide-relaxing compound: A do-it-yourself formula is to wash and soak hide in hot borax solution until you can feel it's not so stiff.

Neat's-foot oil: Fat skimmed off after hoofs and hide trimmings have been boiled down in water for so many hours that they set solid as a "gelatin." (You can get it from a shoe store.)

Pelt: A sheepskin.

Prime: Of skins that you want to keep the hair on, from an animal killed during the cold months.

Rawhide: A leather produced without chemicals—not truly tanned, because it is never very pliable except when wet.

Salinometer: An instrument that measures the salt concentration in your solution.

Scarf skin (striffin): The outer layer of the skin. It cannot be tanned.

Scores: Cuts.

Skin: The skin of a smaller animal (the skin of a larger animal is called a hide).

Sleeker: An instrument for smoothing the hide.

Unprime: Of skins that you want to keep the hair on, from animals killed during the warm season.

Skin Weights. The kind of leather that you can make depends on the size and weight of the skin you start with. Commercial tanneries have equipment that can split a heavy hide into layers of lighter leather, but you can't do that without a special shaving tool available from tanning suppliers. So if you want light leather for gloves, bags, or garments, you have to start with the skin of a small animal such as a sheep, calf, goat, or deer. The finished leather is generally just a bit thicker than an untanned hide. The hide of a full-grown cow will start out weighing 60 lb. or more (which is a word to the wise about just what sort of a job it is hefting one of those around to tan it!). To make heavy belting,

shoe-sole, or harness leather, you must start out with a hide weighing over 50 lb. Lace leather, small belting, and straps are made from a hide of 20 to 40 lb., which would be the skin from a light-to medium-sized cow. Calfskins, which average around 7 or 8 lb. in weight, are used for boot and shoe uppers and heavy gloves.

Season. The season affects the ultimate use of the skin, too. The best leather comes from animals taken in the summer and fall. Winter hides are less firm and are weakened by having grown all that hair, and the hair is just an extra chore if you don't want it. On the other hand, the best hair-on skins are those taken during the winter, when the animal has its heavier winter coat of fur. A fine, fur-bearing skin would be tanned to take advantage of the fur.

Species. Deer is not recommended for hair-on tanning because its hair becomes brittle and sheds. Angora goatskins are often tanned with the fleece on for rugs. With the hair and scarf skin off, they make fine light leathers. As for cowhides, rather than struggle with such a heavy hide all in one piece, tanners traditionally make big cowhides into 4 separate strips for tanning. The hide is cut down the back to make 2 halves. Then each half is cut again in the nose-to-tail fashion. The back strips are a heavier leather when finished than the belly strips. The splitting of the back strip from the belly strip is generally done at the break of the flank, which makes the back strip about twice as wide as the belly one.

A BASIC OVERVIEW: Start small—for instance, with a few rabbit hides. It will take around 2 weeks to finish them. Here are the basic steps:

1. Soak in fleshing solution.
2. Carefully scrape off all bits of flesh, fat, and membrane without tearing the skin.
3. Soak a week in a tanning solution.
4. Dry them slowly at the same time as you work them by hand so they don't get stiff (too quick a dry means you must rewet and start over).
5. Oil hide with neat's-foot oil.
6. Store flesh side to flesh side for a month. Then they'll be soft and ready to sew.

Skinning and Storing. Making leather or fur starts with properly skinning and storing your animal. If you plan to make a rug, the traditional way is to first cut the animal's skin down the center of the belly, from the throat (below the mouth) to the base of the tail. Then cut along the inside of each leg, from the foot straight up to the belly cut, and remove the skin in 1 piece. (See "Skinning, Quartering, and Packing" under "Wild Critters" for skinning instructions.) If you want to do hair-on tanning, be careful not to get blood on the fur. If you are skinning in the woods in winter, you can wipe bloody places on the fur with snow to get them clean.

Fleshing. Once the animal is skinned, you must scrape all pieces of flesh and fat from the skin. If they are left on, the salt won't penetrate and the hair will slip while in the later curing process. Special tools are advertised in tanning-supply catalogs, but you can use a knife. Just be careful not to make holes in your hide. This is a preliminary, superficial operation, as distinguished from the more serious scraping that comes later.

Freezing. If you have a deep freeze, just pop the skin in there until you're ready for the next step. You can store a hide at 0°F for a month.

Salting. If you are planning to make home-cured rawhide or buckskin, don't salt the skin; otherwise, spread it out flat, fur side down. Dampen the hide if it has dried. Rub salt liberally into the flesh side of the skin, about $\frac{1}{2}$ inch all over the hide. Be sure and get salt

into all the crannies and especially in places where the hide is thick. If you have several hides, you can salt them in layers—that is, you can spread out a hide, salt it, then put another on top, salt it, and so on. You can use any kind of salt; fine table or dairy salt is best. The basic principle of salting is that you can't use too much salt. Then roll the skin(s) up tight and let cure. The salting sets up the skin so that you can get right down to the hair roots when you flesh. *Always roll hides destined for hair-on tanning fur side in.*

For skins that you are planning to send to a mailorder tannery, just leave them rolled up to cure for a few hours. Then turn the scalp flesh side out, resalt, stretch, and partly dry in shade. *Never let skins destined for fur-on tanning dry in folds, as the hair will slip.* When partly dry, roll up flesh side out and ship at once. *Roll before skins get too dry and hard to roll.*

For skins to be tanned at home, store in a cool, dry place and leave the salt on at least 4 days. Seven days is better to hold the hides a second week. Shake, drain, resalt, and reroll. Don't store them too long. If they spoil, you've lost that skin, because it's just about impossible to get the bad smell out again.

Drying. Do this step if you are planning on storing your hide even longer, or if you are planning to send it to a mailorder tannery. Otherwise, skip it. For hair-on tanning, don't ever let the sun get on your hide, and don't let it dry in folds. Give the salted skin a good shake to get off the excess salt. For hair-on tanning, hang the skin to dry somewhere under cover. You can hang your hide by making a hole in it and putting a rope through it, or just by hanging it over something. After it has hung to dry a while, it turns white and gets progressively harder. The salted skin stores better if it is dried completely in the sun, but if you do that, when you get ready for the next step, you must resoak it from 1 to 6 hours in water and then give it a good scraping on the flesh side to remove the glaze that otherwise would prevent your tanning solution from soaking into the hide. Scrape with a dull knife or broken glass.

TANNING RECIPES

Bark-Tanned Leather. Old-fashioned bark-tanned sole and harness leather is the finest leather known, but it requires 120 lb. of finely ground oak or hemlock bark for each cowhide treated. I don't have the recipe, although I've heard it was in USDA Farmers Bulletin #1334.

Unslaked Lime and Sulfuric Acid. After a preliminary fleshing to remove large hunks of flesh and fat, the skin should be rolled up in salt (see "Skinning and Storing" section) for 2 weeks in warm weather, 3 in winter.

Then flesh it right down to the root hairs to remove all the tissue paper-like membrane. If you want your hide tanned without the hair, the next step is to remove the hair or fur. Otherwise this step can be skipped. Remove hair by soaking the pelt in a milk of lime solution. Put 6 to 8 lb. of unslaked (caustic) lime in a wooden barrel or plastic garbage can. Slowly add 1 qt. water and stir. Do not add so much water at one time that it stops the slaking action, and don't let the solution splash on your skin or eyes. (That will cause a burn.) If working in a plastic can, don't let the heat build up enough to melt the container. After slaking is complete, add 2 gal. clear cold water, mix thoroughly, submerge hide, and cover container. Stir 3 or 4 times daily and test hair each day. When the hair can be rubbed off (not pulled off), the process is complete. A deerskin requires about 3 days.

Remove the skin from the solution and scrape in the direction of the hair with a square-edged tool, such as the back of a knife. Scrape the hair uniformly, and wash out all the lime with fresh water. You cannot overwash it at this point. If you don't get the lime

solution out, it will continue to eat up your hide. If you live along a creek, the ideal way to get rid of the lime is to hang the hide out in the riffle for 3–4 days. You can further neutralize it by soaking in a solution of $\frac{1}{2}$ gal. vinegar to 20 gal. water.

The pickling solution is prepared by first filling a plastic container with as much water as necessary to cover the hide without crowding it. While stirring, slowly add $1\frac{1}{2}$ liquid oz. commercial sulfuric acid (65–70 percent) for each gallon of water in the container. (The Indians used urine as a pickling acid.) Do not pour water into the acid; it causes a violent reaction. (If any acid splashes on you, wash it off immediately.) Now stir in all the rock salt the solution will dissolve. Place the hide in the solution and move it around so that the solution reaches every part of it. Let it soak, stirring it daily for 4 or 5 days or as long as necessary to bleach the skin white. Test by cutting off a small strip of the hide along one edge to see if it is white clear through. Then wash it thoroughly and press it dry. (You can squeegee it out on your fleshing beam.)

Now take the amount of water that will completely cover the hide, and mix in as much baking or washing soda as the water will hold in solution. Soak the hide in this for an hour to completely neutralize the acid. When this is done, rinse out the soda solution thoroughly, and wring the hide out as much as possible by hand. Thoroughly rub the flesh side of the hide with a mixture of neat's-foot oil and beef tallow. Then wash the skin with cold water and detergent, and hang to dry again. When it is almost dry and still somewhat flexible, work the skin back and forth over the edge of a board or square iron bar, flesh side down, to soften it. Pull and stretch the leather in every direction until it is white, dry, and pliable. If the skin feels too oily, fine hardwood sawdust can be worked into it and then brushed off. Charlie Wilkes of Hillside, NJ, sent me that recipe, and I appreciate it.

Salt-Alum Tan. Before tanning a large hide, split it lengthwise down the center to make 2 easily handled pieces. Soak and cleanse the sides in a wooden or fiberglass tank (or a 30-gal. plastic trash can). Allow them to soak for 18 hours. Flesh the skins thoroughly, removing every bit of flesh, fat, and gristle. Remove the hair by soaking the skins in a solution of 10 lb. hydrated lime in 5 gal. water. Add more water to completely submerge the hide and soak the skins for 10 to 14 days. Move the skins around and stir several times a day. When the hair slips off easily by hand rubbing, remove the skins and lay them over a beam. Now you can take off the rest of the hair along with the thin top layer of skin in which the hair grows.

The salt-alum solution is widely used to tan leather. But if you don't do it correctly, the leather may be stiff and hard; if so, repeat the process. Dissolve 5 lb. salt and 2 lb. alum in 5 gal. warm water, and then cool the solution before immersing the hide. Stir several times a day for 6 to 10 days. Tanning is complete when a thick sliver of skin cut from the edge shows the same light color throughout its thickness. Rinse the tanned hide thoroughly and hang to dry. Work the flesh side vigorously over the fleshing beam or the edge of the board. Keep the hide damp, and roll it up until it is pliable. This must be done several times until the hide is flexible as cloth. The final step is to rub a little warmed neat's-foot oil into the dampened leather. Then work it over the beam once more. The product will be a leather than stays supple even when it gets wet.

Salt-Alum Dry Cure for Small Pelts. To get a long-lasting fur, you had best send your pelts to a professional tanner. But if you just want a simple home cure to give you a usable small skin, rub fresh skins (only the flesh side) with a mixture of 1 part salt and 1 part alum. Dry for 3 days in a cool shaded place. Remove all the dried fatty tissue and trim the edges of the pelts. Wash in a mild soap and rinse out suds. Don't twist or wring. Hang the wet hides over a clothesline with the fur inside. Keep them out of the sun; it can

stiffen them by drying them too quickly. Fluff the fur several times over the 2 or 3 days they take to dry. Rub neat's-foot oil or saddle soap onto the skin side. The more you rub, the softer the pelt will be.

Salt-Alum Brine Cure for Small Pelts. Rub each skin thoroughly with salt. In a container, cover the skins for 4 days in a cool place. Take the skins out and scrape the skin side until all fat and gristle are gone. Mix 2 lb. salt, 1 lb. alum, and 2 gal. water to make the brine. (Double or triple if necessary.) Soak the skins in the brine for 2 weeks. Then wash them in soap or detergent and dry them on a line in the shade for 2 days. Fluff the fur several times and be sure the hide is completely dry before rubbing neat's-foot oil or saddle soap onto the skin side.

Tanning a Snake Skin. Young Missy Kolb of Mt. Airy, MD, wrote me of shooting a copperhead that lay coiled up in her horse barn. She noticed this book didn't tell how to tan a snakeskin, so she sent me her instructions! "To tan a snake, split the skin along its stomach from head to tail (unless you *want* the belly to show, in which case you split along the spine). Peel the skin like a catfish (except use fingers, not pliers). Scrape it out as much as possible with a spoon and let it dry out a little. Mix 1 part denatured alcohol and 1 part glycerine and paint it on both sides. Then spread skin out flat on a pine board. Put another pine board on top and weight it heavily with rocks or blocks. Paint both sides every day *at the same time each day* (meaning you leave 24 hours between paintings) for 7 days. On the eighth day it is ready to be a belt, hatband, etc.!!" Thank you, Missy!

Tanning Kits. If you want to try one of the sophisticated chemical tans, probably the best way to start is with a mailorder tanning kit. But please note ...

NOTE: Many tanning chemicals are very dangerous. Don't breathe the dust. Keep them off your skin and out of your mouth. Some have very pretty colors—don't let your children get hold of them!

HAVING A SKIN COMMERCIALLY TANNED: If you plan to have the actual tanning done elsewhere, the hide should first be fleshed, salted, and dried according to the directions at the beginning of this section and then mailed to the tannery. The finished hide will be returned to you for final cutting and sewing into your rug, vest, or whatever. Many commercial taxidermists use these mailorder tanneries rather than doing their own tanning. Some places are also willing to make "buckskin," which in this case means hairless leather suitable for making gloves and the like. The price depends on the size and type of hide. For example, a bear cub hide would be cheaper to tan than a big bear hide. The wholesale price is generally a third less than retail.

Shipping Hides. Put the hide into some sort of mailing container and send by motor freight, parcel post or UPS to the tannery of your choice. Be sure to include instructions.

USES FOR HAIR: Hair from hides is removed by the lime process described under tanning. If you want to use the hair for upholstering, wash it through several waters until clean, and then dry in a warm place. It may then be used to stuff cushions and couches as desired.

RAWHIDE: Rawhide and buckskin tanning (see next section) are the 2 processes most appropriate in a really primitive situation. The biggest drawback of rawhide is that after you're all done, it can lose its shape if it happens to get soaked again. The biggest problem with home-tanned buckskin is that it smells bad.

You can make rawhide entirely of easily available natural materials. (You can't use a skin that has been salted to make rawhide.) Properly speaking, rawhide isn't "leather," but it is potentially very useful. It is shaped when wet and then dried. Once it dries, it holds that shape and will be tight and hard. If something made of wood cracks or if you

want to fasten wood pieces together with a nonmetal material, bind them with damp rawhide and then let it dry. Rawhide can be made into a rope by cutting in strips and plaiting. To plait rawhide, first soak the strips until soft. Keep them damp while you're plaiting, and grease the rope after you're done to keep it from getting too stiff.

You can also make buckets, baskets, or other containers from rawhide. Cut the rawhide to the shape you need. Then soak until soft and sew up, using thin strips of rawhide for thread. Fill with dry sand and let dry, or put over a wooden form that is the shape you want it to be and let dry. When dry, your rawhide container will be really sturdy.

Now that you know what rawhide is good for, you might want to make some.

1. Get your hide. It's most convenient to work with that of a small animal such as a calf.

If the skin has already been dried, you'll have to soak and scrape it until soft before proceeding.

2. Trim off unwanted flesh and fat with a sharp knife (don't cut the skin!). Then use either the paste or container method to get the hair off. With the paste method, lay the skin, hair side up, on a clean surface and sprinkle about an inch of dry wood ashes over every part of it. Work the ashes well into the hair and then wet by sprinkling with the softest water you can get hold of—rainwater if possible. Fold the hide, ash paste and all, hair side in, into a tight bundle. Tie the bundle with a rope. Wrap with wet burlap that you can keep wet, or bury your hide bundle in moist earth. It will take about 3 days for the hair to get loose enough for the next step.

If you have a wooden or crockery container big enough for the job, you can soak the hide instead of making paste. In that case, soak in caustic lime or a weak lye made by mixing wood ashes and water. Leave it in the solution until the hair is slipping.

3. Rinse the hide thoroughly. Proceed to dehair and flesh it. You need a surface to put the hide on and a scraper. You could buy a fleshing tool or make one. A table knife blade is the right kind of blade. If you can remove the knife from its handle and set it into a piece of wood, so you can have a handle on each side of the blade, you have a perfect fleshing tool. Lacking that, even a rib bone will work as a scraper. But if you're going to get serious about tanning, a good farrier's tool for fleshing is worth having.

Fix yourself a beam to work the hide on. A log or half log (the round edges are the really important part) or even a 2 × 8-inch plank, rounded off, will do. Set the beam on legs at a 45° angle, bracing it well. One end can rest on the ground. Equip yourself with a bucket of water for rinsing. Throw the hide over the beam with the end falling off the tip, so you can press your body against the hide and hold it on the beam while your hands are occupied with the fleshing tool. Have the tail end of the skin toward you as you scrape to avoid catching your fleshing tool on the hair roots and cutting into the skin. Wear a waterproof apron and scrape downwards. Scrape the flesh side with your scraper, moving the hide around as necessary to flesh it all. Then turn it over to the hair side, now with the neck end toward you, and scrape off the hair and scarf skin at the same time.

4. Wash the dehaired hide thoroughly, stretch it to its full extent, and fasten for drying. You can nail it to the side of a building if you do it high enough so animals can't get at it. If you're planning to make a lot of rawhide or buckskin, rig yourself up a frame to lace it on. Make the frame out of wood strong enough to hold up against a good bit of pull and big enough to go around the outside of your stretched-out hide with room to spare. Then thread a $\frac{1}{4}$ -inch rope or what-have-you through the edge of the hide, then around the outside of the frame, back in and through the hide, around the frame again, and so on until you have the whole skin stretched. Keep your framed hide where animals can't get at it. If you find the hide stretching, keep taking up the slack until it is tight as a drum. Don't dry your rawhide in direct sunlight. Find a shady spot where air can circulate around it for best results.
5. When the skin is bone-dry, you have rawhide. For an extra, optional finishing touch, you could go over both sides of the skin with sandpaper, pumice, or sandstone to smooth down rough spots and give it an even texture. When you want to use some, just cut off what you want, soak 10 to 12 hours until workable, and shape as already described. Another way to soften rawhide is by making a mixture of 1 part neat's-foot oil and 1 part tallow, or use any animal grease and work it into the rawhide as you work it on your beam.

BUCKSKIN: The best information on buckskin making is available from Matt Richards in his recent book, *Deerskins into Buckskins: How to Tan with Natural Materials, a Field Guide for Hunters and Gatherers* (10398 Takilma Rd., Cave Junction, OR 97523; www.braintan.com; \$15 plus \$3 s/h). Like rawhide, buckskin is not, properly speaking, either "tanned" or a "leather." It's useless for harness or binding because it stretches so badly if wet. It tends to have an odor. On the other hand, it can be made relatively quickly without any store-bought stuff. It's soft as chamois but stronger and warmer than cloth, and it protects your skin against briars as well as denim does. You can wash it like cloth, squeezing the soapy water right through. Indians, hunters, and pioneers wore buckskin moccasins and clothes year-round, but it was considered low-class stuff.

You can make buckskin from deer, calf, sheep, or goat, but sheep isn't too desirable because it doesn't wear as well as the others. Deer and elk are the easiest to handle. Technically, "buckskin" means skin in which the grain fibers have been separated and softened by continuous pulling and stretching while drying, rather than by chemical action, and are preserved in that separated and softened condition by grease and by having been smoked. If buckskin gets wet it stiffens up again, but it can be resoftened by

working with the hands.

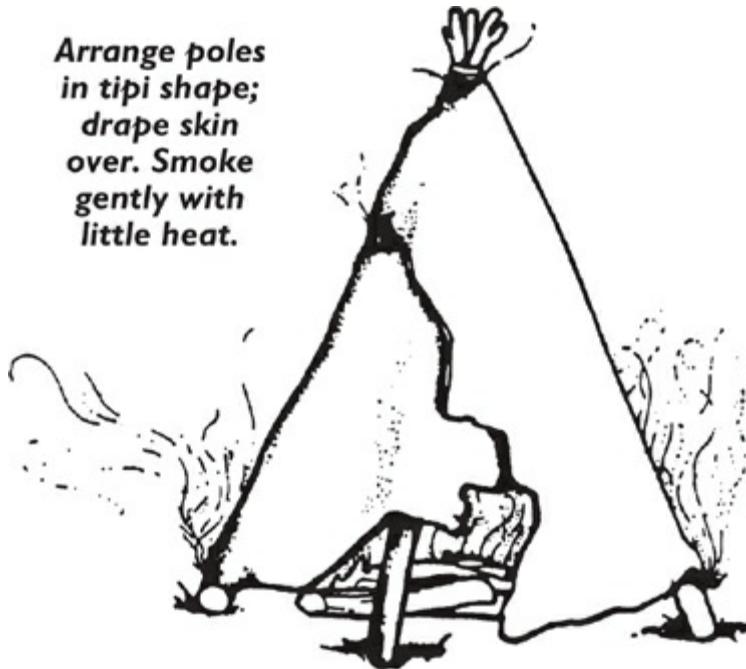

1. Don't salt skins to be made into buckskin. Soak them in plain water until the hair rubs off easily. Keep the water in a warm place, if possible, and keep an eye on the skins so you'll know when they're ready. Stir at least once a day. If your hair won't slip, add wood ashes to make a weak lye solution. In this case, remember to rinse well before proceeding (see warnings about lye under "Soap Making"). Don't try to take the hair off until it comes off easily. You won't rot your hide by soaking it a little longer. When it's ready, you should be able to just rub the hair off with your hand.
2. When the hair is slipping, throw the skin over the beam that was described under "Rawhide" and commence working with your fleshing tool. Have the hide's neck up toward you, and work the flesh down the beam away from you.
3. You can use either the brains or soft-soap method for this stage, as follows:

Brains method: Make a paste with warm water and the skull contents (the brain) of the animal. You can add any animal grease if you're afraid you won't have enough for the job, but generally each animal has enough brain to treat its size of hide. The brain paste is applied warm to both sides of the hide. If you are worried that the brains won't keep while the hide is soaking, mix them with moss, make into patty shapes, and dry out by sun, fire, or oven. To get the paste on both sides, you'll need to lace the skin in a frame the same way you do with rawhide. Apply paste. Remove from frame, roll flesh side in, and store in a cool place for 2 days. Rinse well and wring as dry as possible. For detailed info, order the 52-minute video *Brain Tanning Bison Robes the Native American Way* by Larry Belitz (who is also a tipi expert: "Sioux Replications"). Or order his illustrated booklet, "Step-by-Step, Brain Tanning the Sioux Way": HCR-52, Box 176, Hot Springs, SD 57747; 605-745-3902; or at www.braintan.com.

Soft-soap method: Soft soap is soap made with a weak lye solution. If you aren't a soap maker, shave up a bar of yellow laundry soap and dissolve it in water. Use 2 c. soft soap or 1 bar of laundry soap to about 2½ to 3 gal. hot water. Begin by rinsing your hide well. Then work it as it dries. Grease it with animal fat. Then put it into the warm soft-soap solution. Soak the skin in it for 4 or 5 days. Remove skin and rinse again. Work while drying again, according to direction in step 4 under "Rawhide." The hide must now be continuously worked while it is drying. If you let the hide get dry in the middle of the job, it will get stiff and you'll have to dampen it again. Try not to get it too wet or you'll have to wait for the extra water to dry out. It can be pulled over the end of your beam or a stump and scraped with sharp stones or shells if you don't have metal tools. Or pull back and forth over a fence post with a wedge-shaped top. A small hide can be worked entirely by hand. A large one just about requires some kind of system, such as 2 people pulling it back and forth over a beam. The important thing is to somehow pull, twist, and stretch that hide in every possible direction to loosen the fibers of the grain. It is this procedure that makes the skin buckskin. You're done when the buckskin is almost as flexible as cloth. It should be easy to squeeze water right through the skin. If it isn't soft or you have hard spots, moisten and work while drying again until you are satisfied.

4. The final step is to smoke the buckskin. Before smoking, it's optional to go over the flesh side with sandpaper for any roughness. The smoking improves both the durability and appearance of the buckskin. There isn't any one absolutely fixed, correct way to do it. If you have a regular smokehouse, spread out the skin in there by stretching it horizontally. You can smoke several skins at once by arranging them

in layers. Or you can fasten large hides together in a tent shape and build a small fire right under them. For the "tent," make a cone of small poles tied around the neck at the top, tipi style. Then arrange your hides over that. Burn green hardwood if you can get it. Don't use soft (pitchy) woods. Willow, birch, and alder are okay. The Indians used green willow, which makes the buckskin yellow. The smoking process will take 1 or 2 days. Don't scorch the skin. You'll have to turn it over and smoke the other side when the inside is done. The buckskin is finished when it is colored a deep yellow or light brown.

Blankets, Rugs, and Clothes from Skins

CUTTING SKINS: If the hair is on, always cut from the hairless side and let the knife ride through the hair so you don't shorten it. Use a sharp knife or scalpel depending on how heavy your hide is.

SEWING SKINS: You can hand-sew leather seams with a "glover's needle." You can hand-sew using silk, heavy-duty mercerized nylon thread, heavy waxed linen thread, or dental floss. In general the thicker the leather, the tougher the thread you'll use. Some leather workers sew their thread through a cake of beeswax to help it slip through the subsequent leather. For fancy work, where it will show, use the clear nylon that is like a fishing leader; when sewing a skin onto a backing of felt, use a heavy, colored thread to match the felt color.

Machine-Sewing Leather. Rabbit hides that have been worked to soft enough can be machine-sewn. For bigger or less-soft hides, you must sew by hand or use a special needle designed for piercing leathers, called a "leather-point" or "15 by 2" needle. It has a wedge-shaped point rather than a round one and makes a clean cut. There are different sizes of leather-point needles for leathers of different weights. It's advised to use size 11 for light leather, 14 for medium, and 16 for heavyweight. Homemade skins tend to be medium to heavyweight leathers.

To sew thick leathers on your sewing machine, you also will benefit from loosening the presser foot so it doesn't press down too hard. The thicker the skin, the fewer stitches you set it for: 12 per inch on lightest leathers, 7–10 on mediums, 7–8 on heavyweights. There are special heavy-duty sewing machines for large-scale leather working. Or you may be able to have the sewing done for you; check with shoe repair shops, taxidermists, or saddle

shops.

Mending Cuts. Check the skin for cuts and mend them. If you have a bullet hole, cut away enough skin to change the shape of the hole from a circle to a diamond; it will look better after it's sewn up. If the fur has a bad spot, you can patch it using a baseball stitch over the top and back through again.

WASHING LEATHER OR SHEEPSKIN: Wash in lukewarm water and pin on a clothesline to dry. It might get stiff, so start when half-dry and rub to soften. *Don't dry in a dryer.*

MAKING FUR THINGS: You can lay a pattern on your fur, trace, and cut it out. You can sew together several small skins to make a robe, parka, vest, cap, or whatever you want. You can sew fur to the back of woolen mittens for extra warmth. Rugs and robes are probably the easiest things to make.

Make a Fur Rug. The easiest way is to just use a crude salt-tanned hide laid on the floor, wool side up. Such simple hides can also be used as lap robes, blankets, bed pads, truck and tractor seat covers, and so on. A more finished rug is made by cutting the skin to your preferred shape and trimming off the ragged edges. Draw around the skin to get your pattern, and then cut a piece of felt (or whatever material) about 1½ inches larger than the skin all around. The edges of the felt are generally cut in a zigzag with pinking shears for attractiveness. For extra warmth you can put in a layer of quilting batt between the skin and the felt. Attach the felt to the skin by catch-stitching along the edges. Sew from the back. If you can, try to keep your stitches from going clear through the hide. If your rug has a tail with it, that is usually not bordered unless it is short.

A Robe. This is usually around 60 × 70 inches. One horse-hide, one cowhide, 2 or 3 yearling cowhides, 8 calf hides, or 6 to 10 sheepskins or goatskins will give you a robe. You can use either sheared or unsheared sheepskins. You'll want to make sure that the fur or wool is clean and that tangles and burrs are brushed out. A robe can be unlined, but it is always nicer with a flannel or felt lining sewed on the way you make a fur rug.

Fur Slippers. Choose or cut out a piece of fur or sheepskin at least 4 inches longer than your foot and wide enough so that when you stand on the piece with 1 foot and fold the sides upward on each side of that foot, they reach at least 2 inches above your ankle protrusion. Now sew the backside of your slippers up where the backside of your heel will be. Cut to fit, and sew together the part that will go over the front of your foot. Hem down a 2-inch "collar" around your ankle, and run a leather thong or elastic through the opening to help hold your slippers on.

Woven Fur Blanket. You can make a blanket from many small skins, such as rabbit skins, by tanning them and cutting into strips about 2 inches wide. Sew together end to end until you have strips long enough to form the warp and woof of a basket-style woven blanket. Join the ends with the overhand baseball stitch and make sure that the fur is running the same way along each strip. The more strips you have, the bigger your blanket can be. When you have enough, fasten into place on a frame the strip that will form the warp. Interweave the woof, but not too tight. Put a piece of outing flannel on the back, and stitch together as if you were making a quilt.

Other Fur Products. You can make mittens, moccasins, shoes, and sheepskin coats. Leatherworking manuals and other books can give you more patterns. There is probably a leathercrafts shop in your region where you can find guidance.

Horns

Horns are composed of a hard material that can be turned into a variety of useful and

decorative objects. You can experiment and turn pieces of horn into buttons, beads, decorative inlays, knife handles, and even zipper pulls.

FOOD FROM WATER

As public oceans and rivers more and more double as toxic dumping grounds for every city or country that can get at them, regular commercial water creatures are ever riskier to eat. The so-called FDA seafood inspection program actually inspects only 1 lb. of fish for every 160,000 lb. we eat. And the FDA seal of approval is false security anyway because the FDA has toxic limits for only a dozen or so modern poisons—even though biochemists know there are hundreds that today's fish may carry. And as increasing numbers of the world's people chase fish, the supply grows ever shorter.

The answer is growing your own food from water—in water you know is pure, using food you know is safe to enter the food chain—or buying the equivalent. Growing food from water, or “aquaculture,” has been part of family farming in many places around the world for centuries. But now small-scale fish farming is booming more than ever, and rightly so. You can grow more of this healthy, low-fat, heartprotecting protein in a smaller space than any other variety of animal on your homestead! Water farmers grow clams, mollusks, catfish, yellow perch, bluegills, bullheads, crayfish, bass, trout, carp, tilapia, mosquito fish, and others. They market them as human food, bait, or as stock for other people's food-growing or ornamental ponds or fish-bowls. As always, it's best to start small and get experience before you invest heavily.

Almost anybody can do some water farming. You can raise catfish in just a barrel! If you have as much as 10 acres and a water supply, you have room for several fish culture ponds. Fish can be part of the natural ecosystem on your homestead, with meat-eating fish eating discarded innards and algae-eaters profiting from pig and poultry manure used to fertilize the pond. Or you can feed them commercial fish feed made from residues of the agricultural industry. Or both.

HELP FOR SICK WATER CRITTERS

UAPB Cooperative Extension Program; Larry W. Dorman, Extension Fisheries Specialist; 870-265-5440, ext. 2712; fax 870-265-2750; 523 Hwy 65 & 82, Lake Village, AR 71653; ldorman@uaex.edu.

ONLINE INFO

aquanic.org takes you to the Aquaculture Network Information Center (AquaNIC).

agebb.missouri.edu/mac leads to the Missouri Alternatives Center website.

MAGAZINES: *Aquaculture North America* is published 6 times per year and serves the “aquaculture industry professionals of North America.” It's \$29.95 for one year: 4623 William Head Rd., Victoria, BC V9C 3Y7, CANADA; 250-474-3982; fax 250-478-3979; www.aquaculturenorthamerica.com.

Austasia Aquaculture magazine promotes aquaculture in the Australasian and Asian regions. It covers all aspects of this vast industry in that region, including regular columns

by industry specialists. Their delightful website is at www.austasiaaquaculture.com.au.

North American Journal of Aquaculture, formerly *The Progressive Fish-Culturist*, is a specialty aquaculture magazine available from the American Fisheries Society. Call for subscription info; 800-354-1420; www.fisheries.org. *Farm Pond Harvest* encourages private-party readers as well as commercial growers. A subscription is \$15/year from 1390 N. 14500 E. Rd., Momence, IL 60954; www.farmpondmagazine.com. Their back issues from 1967 to the present contain a wealth of information on aquaculture. Despite their name, they also cover saltwater fish, shellfish, bullfrogs, etc., but their emphasis is on the family fish pond.

UNIVERSITY AND EXTENSION HELP: Aquaculture, like the rest of modern agribusiness, is spurred on by university Ph.D.s and USDA researchers and specialists providing tech services to corporate and also independent food growers. It is a huge, profitable, and often very technical part of the food-producing industry. Subscribers to *Aquaculture Magazine* also get a yearly *Buyer's Guide and Industry Directory* (300 pp.). This is a great resource for anybody interested in aquaculture, beginner to expert. For example, it lists name, phone number, and often the e-mail address of all the Extension Agent aquaculture experts! There are one or more in every state, beginning with Jeff Allred of the Alabama Fish Farming Center (529 Centreville St., Greensboro, AL 36744; 334-624-4016; fax 334-624-4050), and ending with Joe Hiller, U. of Arizona (520-621-7621; jghiller@cals.arizona.edu).

Want to learn this business? Study at the School of Fisheries at the University of Washington, the U. of Idaho, Louisiana State U., Auburn U., or Texas A&M at Corpus Christi (361-825-5700; lsci.tamucc.edu/mari). All have outstanding aquaculture programs.

Since 1980, the U.S. government has heavily funded aquaculture research and development. There are five regional centers from which these funds and services are administered:

Center for Tropical and Subtropical Aquaculture: The Oceanic Institute, 808-259-8395; 41-202 Kalanianaole Hwy., Waimanalo, HI 96795; www.ctsa.org; www.oceaninstitute.org; www.oceaninstitute.org.

North Central Regional Aquaculture Center: Michigan State U., 517-353-1962; fax 517-353-7181; 13 Natural Resources Bldg., East Lansing, MI 48824-1222; www.ncrac.org.

Northeast Regional Aquaculture Center: U. Maryland; 301-405-6085; fax 301-314-9412; 2113 Animal Sciences Bldg., College Park, MD 20742-2317; www.nrac.umd.edu.

Southern Regional Aquaculture Center: 662-686-3285; fax 662-686-3320; 127 Experiment Station Rd., PO Box 197, Stoneville, MS 38776; www.msstate.edu/dept/srac/.

Western Regional Aquaculture Center: 206-543-4291; School of Fisheries, U. of Washington, Box 355020, Seattle, WA 98195; www.fish.washington.edu/wrac.

BOOKS AND PAMPHLETS: *Fundamentals of Aquaculture* by James Avault Jr. is a 900+-page step-by-step guide to commercial aquaculture covering pond construction, feeding, disease control, etc., available from AVA Publishing (see book dealers). Gene Logsdon's *Getting Food from Water: A Guide to Backyard Aquaculture* is an American classic. He covers beach harvesting, pond building, stream management, pond fish management, waterfowl, garden pools, etc. *Aquaculture: The Farming and Husbandry of Freshwater and Marine*

Organisms by Bardach, McLarney, and Ryther is an older, in-depth book. *A Fish and Vegetable Grower for All Seasons*, by Robert E. Huke and Robert W. Sherwin, covers the aquaculture/solar greenhouse (raising vegetables) combo.

Other books: *Farming the Waters* by Peter Limburg; *The New Field Book of Freshwater Life* by Elsie B. Klots; *World Fish Farming: Cultivation and Economics* by E. Evan Brown; *Trout Farming Handbook* by S. Dumond Sedgwick; *Koi of the World: Japanese Colored Carp* by Dr. Herbert Axelrod; *Creative Fishing* by Charles J. Farmer; *Fish and Invertebrate Culture* by S. Spotte; *Home Aquaculture: A Guide to Backyard Fish Farming* by S. D. Van Gorder and D. J. Strange. Two basic British books on the subject are *Fish Farming* by C. F. Hickling and *Backyard Fish Farming* by Bryant, Jauncey, and Atack.

The USDA is pushing family water farming and offers special resource numbers. Call their center for aquaculture, aquatic ecology, and fisheries at 202-690-0082. Various government agencies offer bunches of pamphlets on building farm ponds, fish management, and raising bait fish, almost all available online (afsic.nal.usda.gov/nal_display/index.php). Government is a good partner in this area. They'll help you plan a pond and may even help stock it through the Bureau of Sports Fisheries and Wildlife. (Check to see whether you need a fish stocking permit.)

AQUACULTURE BOOK DEALERS

Aquatic EcoSystems: 877-347-4788; 2395 Apopka Blvd., Apopka, FL 32703;
www.aquaticeco.com.

Aquatic Promotions: 305-247-0460; PO Box 700166, Miami, FL 33170-0166.

AVA Publishing: 225-763-9656; fax 225-766-0728; PO Box 84060, Baton Rouge, LA 70884-4060; AVApub@cox.net; www.AVApub.com.

Miami Aquaculture: 561-364-5999; fax 561-364-7748; 805 N. Federal Hwy., Boynton Beach, FL 33435; www.miami-aquaculture.com.

Seacoast Information Services: 401-364-6960; fax 401-364-9757; 135 Auburn Dr., Charlestown, RI 02813; www.aquanet.com.

AQUACULTURE SUPPLIES AND PUMPS: A commercial fish farmer might have to buy all kinds of expensive, fancy items, but you can make do with recycled materials and shop for used, bargain items. Here are some suppliers.

Aquaculture Research/Environmental Associates (AREA), PO Box 901303, Homestead, FL 33090-1303; 305-248-4205; fax 305-248-1756; www.areainc.com. Offers a large, free black-and-white catalog full of graphs and numbers that are mostly Greek to me but probably would be fascinating to a commercial fish grower. They can help you construct a hatchery, look for ways to get more fish from your ponds, aerate your water, have live-haul tanks, etc. They offer floating docks, etc., for shellfish farmers. AREA provides design assistance, including size, piping layout, valves, and cost estimate, at no charge.

Dempster Industries: PO Box 848, Beatrice, NE 68310; 402-223-4026;
www.dempsterinc.com.

Flowlight Solar Pumps, made by Windy Dankoff; order from Northern Arizona Wind and Sun: www.solar-electric.com; 800-383-0195.

Independent Sun Power: HC 85, Box 21, Tryon, NE 69167; 308-587-2468;
www.independent-sun-power.com. Solar electric water-pumping equipment.

Photocomm: 930 Idaho Maryland Rd., Grass Valley, CA 95945; 800-544-6466.

The Ram Co.: 512 Dillard Hill Road, Lowesville, VA 22967; 800-227-8511;
www.theramcompany.com.

Solar Components Corp. offers for \$2 a 64-page catalog of solar, greenhouse, aquaculture, and energy-saving supplies; 121 Valley St., Manchester, NH 03103-6230; 603-668-8186; www.solar-components.com.

Sunelco: PO Box 1499, Hamilton, MT 59840; 888-786-3526; www.sunelco.com.

AQUACULTURE CAN BE DONE IN THE CITY TOO! Read *The Integral Urban House*, an account of a 2-story Berkeley house that the Farallones Institute turned into a center to demonstrate “urban-scale appropriate technology”—including a 2,000-gallon concrete pool in the backyard containing black bullhead catfish, bluegills, and Sacramento catfish, with the power for water filtration and recycling provided by a windmill-operated pump.

Mariculture

This word refers to harvesting food from beaches—from the “intertidal zone” where sometimes the land is covered by ocean water and sometimes it isn’t. Lots of algae, shellfish, and sea vegetables grow there. If you don’t have a pollution risk in your area, this area has tremendous food potential. See *The Sea Vegetable Book* by Judith Cooper Madlener for info on gathering and using sea vegetables, and try *Sea Vegetable Recipes from the Oregon Coast* by Evelyn McConaughey (2 volumes!) for ways to use them. *Seaweed in Agriculture and Horticulture*, edited by B. and G. Rateaver, describes traditional seaweed use in Europe, how to make seaweed extracts, etc. Nori seaweed can be grown on nets suspended under a raft in shallow sea water. Its culture also can be combined with raft culture for shellfish and fish.

RAFT CULTURE: Raising shellfish using rafts and/or floating pens is big business now. The first raft culture was done by a shipwrecked Irish sailor. He suspended a net into the water between 2 poles to catch sea birds, left it there, and then found out that mussels had fastened themselves to it while it was under water at high tide. Now the Washington State Department of Natural Resources, which supervises many acres of tidelands, leases sites to individuals and provides aquaculture advice. The techniques for farming shellfish have been around for only the last few years. It’s an exciting new field for small growers.

SHELLFISH: For growing shellfish, it’s handy to live right on the edge of the ocean. Or you can lease a few acres of open water from the Department of Natural Resources and tether a raft over it.

Red Tide. *Don’t go out to gather shellfish without knowing about red tide and being sure that the critters are safe to eat.* “Red tide” is an algae bloom that can occur from late spring to fall. It’s toxic to humans, although shellfish thrive on it. Shellfish on a diet of red tide are no good for human eating until they’ve gotten it out of their systems. Any filter-feeding shellfish—oysters, mussels, etc.—can have this problem. *Harvest only when the government in your area says it’s safe to or, if without expert advice, harvest only in winter.*

Mussels. You start out by buying mussel seed (there is a specialist in northern California who grows oyster, clam, and mussel seed under laboratory conditions). Seed for about 1 million mussels costs about \$1,000 and can be contained in a coffee cup. After “planted,” only about 10 percent survive predations of flatworms, starfish, and other dangers to baby mussels, but that still leaves 100,000—so many that thinning may be necessary. They’re ready in a year and can be harvested from September to June. They’ll keep well, even out of water, as long as a week if kept cold and damp. To cook, remove the byssus

(silky filaments by which they attach themselves to rocks), scrub the shells clean and drop them, shells and all, into boiling water. Or steam. (Don't overcook.) Then make a chowder of mussel meat in tomato juice. Or combine chopped mussel meat with pasta. Kamilche Sea Farms is a commercial mussel-growing operation: 360-427-5774; fax 360-427-0610; SE 2741 Bloomfield Rd., Shelton, WA 98584-8640; info@kamilcheseafarms.com; www.kamilcheseafarms.com.

Oysters and Clams. You harvest these with a shovel at night, by lantern light, at extra low tide. Best results in windy, cold, rainy weather. But worth it! Aside from the harvesting method, oysters and clams are similar to mussels. You could model your oyster farm on the Jolly Roger Oyster Co., which grows bottom-cultured oysters: 360-665-4111; PO Box 309, Ocean Park, WA 98640; www.jollyrogeroysters.com.

Greenhouse / Hydroponics / Aquaculture Combo

Water can be used in a greenhouse for supplemental heating and cooling. It's cheap and readily available, and it stores more heat in less space than any other commonly available heat-storage material. Greenhouse water can be recycled to raise edible fish or to do hydroponic gardening. *Fish Farming in Your Solar Greenhouse* by William Head and Jon Splane explains how to use greenhouse water as a heat-storage material for growing fish and how to use the leftover food and body wastes of fish to grow vegetables. Thus all you must buy or obtain is fish food (for tilapia and catfish), and your crop is both vegetables and mature fish. William Head also wrote *Gardening Under Cover*, from which I quote ([this page](#)-[this page](#)):

"In this system, fish supply the fertilizer for the plants in the form of uneaten food and nitrogen-rich waste byproducts, and the plants help to keep the water clean by absorbing nutrients from the fish water. Ideally, additional fertilizers are not needed and equipment costs may be minimized. We have had both success and failure, trying to make the concept work ... [after failure] we redesigned the entire hydroponic system, incorporating a method called the Nutried Film Technique (NFT)."

"NFT can grow crops on much lower nutrient levels than are required in other hydroponic systems. This is particularly important for hydroponic designs that use only the relatively low nutrient levels of an aquaculture system. A shallow stream of nutrient water is circulated through a dense mat of plant roots. The upper roots in the mat are exposed to moist air. This provides both abundant nutrients and oxygen to the roots ..."

"The aquaculture tank was stocked with 60 small channel catfish (*Ictalurus punctatus*) and 120 African perch (*Tilapia mossambica*) ... The fish were fed twice daily with a commercial fish pellet (Purina trout chow). The plants were irrigated entirely with the aquaculture water. During a 7½-month testing period, 90 pounds of edible fish were harvested, and each of the 24 tomato plants had an average yield of 9 pounds of tomatoes. Tomato plants of the same variety that were raised in the greenhouse soil yielded about 7 pounds of fruit per plant ... this design required less labor than crops growing in the soil beds, and we never had to worry about watering the plants. Water flowed freely along the pipes throughout the testing period."

For more information, see the sections on greenhouses and hydroponics in [Chapter 2](#). The New Alchemy Institute has done particularly useful research in this area. In the above-quoted book, Head wrote ([this page](#)), "New Alchemy's best hydroponic trial has produced about 2.3 pounds of vegetables per pound of fish food, plus the edible fish."

Pond Fish Farming

Some raise them for fun and family food, some as a business. A pond can provide

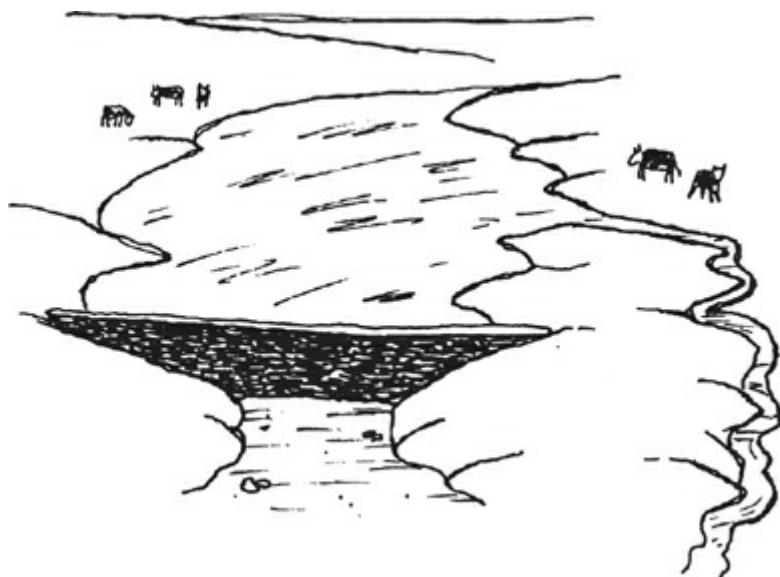

irrigation water for your garden and orchard and a place for the kids to catch frogs and turtles, swim in summer, and skate in winter. If you plant a pond's banks with nuts, fruits, and Christmas trees, you get an extra dividend. And you can have waterfowl enjoying the top of the water. There are more than 2,000,000 farm fish ponds around this country. Stephen Scott wrote me, "I have, just this past year, begun to raise fish in very small ponds. I feed them worms and frogs, which we have in abundance. The ponds are hand-dug affairs, 24 feet in diameter and about 5 feet deep. They are spring-fed, and the fish seem to be growing surprisingly fast."

On the other hand, Lane Morgan carps, "Farm fish may be fed subtherapeutic doses of antibiotics, like other livestock. Farm fish and hatchery fish are crowded and stressed, like 'factory farm' livestock, and they suffer health problems and may be medicated accordingly. Also, the farms cause pollution problems, not to mention that the escapees that breed with wild fish can mess up the intricately adapted genetic responses of the wild species. I guess fish farms have their place, but I'm not a big fan."

Check out *Earth Ponds* by Tim Matson; "Ponds for Water Supply and Recreation" by the Soil Conservation Service, USDA Handbook No. 387; *Management of Lakes and Ponds* by George W. Bennett; *Ponds: Their Wildlife and Upkeep* by Robert Burton; *Ponds and Water Gardens* by Bill Heritage (Poole, Dorset, England: Blandford Press); and Garden Way's booklet "Build a Pond for Food & Fun." The USDA publication, "Ponds—Planning, Design, Construction" is comprehensive and available online at www.in.nrcs.usda.gov/pdf%20files/PONDS.pdf.

STEP-BY-STEP POND BUILDING

1. Assess Soil, Water, Topography, Etc.. For a good fish pond, you need a reliable supply of clean water and a situation where either it doesn't flood or you can arrange drainage to compensate for flooding. Your soil must be capable of holding water on both the proposed pond bottom and the sides, or else you'll have to line it with Bentonite or some such. You need enough spring flow, well water, or runoff to fill the pond in a year or less and to replace water lost from seepage and evaporation.

The ideal water source is a well, because then you will have no unwanted fish, no flood problems, and no muddiness. Well water, however, is no guarantee against pesticide pollution. Your well flow should be fast enough to fill your pond in a week or so, to replace water lost through evaporation in hot weather, and to supply oxygenated water. A problem with springs is that they often fluctuate seasonally—check on that. If oxygen

level is not adequate, you just aerate the water. Water source also affects water temperature, which affects the fish species you can grow. In summer temperate zones, a surface runoff water source means warm water. Water from a well or spring means "cold" water. If there are fish in the spring water, you just filter it to keep them out. Stream water needs to be filtered to keep out other fish too.

2. Get Permits. Check with the local branch of the USDA Soil Conservation Service. Your land must contain a site considered suitable for impounding water. On most sizable places, there are one or more sites that can pass muster. Your pond can be viewed as a water storage or even wetlands restoration. If you have a swampy area that's growing cattails, you can use that. But first you need to get an appropriate permit or, more likely, permits.

3. Plan Size. Don't be easily discouraged. You can raise channel catfish in a barrel! But bigger ponds are easier to manage and succeed with. A warm-water pond for bass and bluegill fun fishing needs be at least an acre in size. Trout ponds are recommended to be at least $\frac{1}{3}$ acre, though I've seen a very good one that was smaller. But surface area is vital relative to depth because it helps oxygen, which fish need to breathe, get into the water. At the other extreme, 15 acres is considered to be the maximum desirable size.

4. Plan Depth. Shallow water is a problem because weeds grow in it. In ponds stocked with bass and bluegill, those weeds protect small fish from the bass. Shallow water also causes mosquito problems. A pond is easier to manage if it has no shallow water. Deepening and/or filling will eliminate those shallow edges. A minimum depth of 2 feet is good, but 3 feet is better. So your pond needs deep sides to discourage plant growth but a smooth bottom if you plan to harvest by seining. Water 10 feet deep—or more—will allow the fish population to stay comfortable in winter. Where the pond will be covered with ice for a month or more and winter fishkills are frequent, water depth may need to be as much as 20 feet. If your pond depends on seasonal rains for its water supply, water should be at least 10 or 12 feet deep over a fourth or more of the pond area. A shallow bottom is desirable for bluegill and bass to nest in. Throughout most of the South, an average depth of 3 to 4 feet is adequate for fish growth; no more fish can be grown by providing additional depth.

5. Plan Spillway and Drainage. The emergency spillway to prevent floodwater from going over the dam should be designed to keep the flow shallow. This prevents big fish from swimming out and unwanted fish from swimming in. To prevent unwanted fish from entering the pond from downstream, a 24-to 36-inch vertical overfall in the emergency spillway should also be used. A drainpipe is useful and is required by law in many states. It should be large enough to drain the pond in 5 to 10 days. An overflow pipe or trickle tube connected to the drainpipe keeps the normal water level a few inches below the spillway. This reduces erosion of the spillway and prevents excessive loss of fingerlings soon after the pond is first stocked. A device to take outflow from the bottom rather than the top helps warm the pond early in the spring, may save fertilizer, and may permit fertilizing in spring when the flow is heaviest. Plan your water cycle if the water will be aerated or filtered.

6. Clear Trees/Brush. Most trees and brush should be removed from the area to be covered with water. If possible, remove stumps and snags from the pond bottom. This leaves the bottom smooth for seining, which may be required for good management. Clearing trees and brush from a strip 20 to 30 feet around the pond reduces the amount of leaves that fall into the pond. Leaves discolor water and encourage growth of algae, and decaying leaves may cause oxygen depletion in the water. A cleared strip also provides a grassy bank for fishing.

7. Dig/Fill. A demolition expert could dynamite out some deep holes in it for you. Or if you have a meandering river on or beside your property that has left a former meander now abandoned, part of the meander might be blocked off for a waterfowl area for you. Or you can dig a pond from scratch with a bulldozer. There are many different ways to build a new water area or develop an existing one. A “raceway” is one nice way to raise trout; water flows downhill from one pondlet to another.

8. Stock Pond with Fish. Before stocking, eliminate all wild fish from your pond and drainage area to keep them from competing with the stocked fish for space, oxygen, and food. Draining the pond does it. Choose your fish species to stock based on the temperature of your water, its depth, what you have to feed, and what you want to eat. You can stock with a single species such as trout or with a combination of species, such as bass with bluegill. Private and certain state and federal hatcheries provide fish for stocking. You can get info on sources of fish for stocking from the Soil Conservation Service, Extension Service, Fish and Wildlife Service, and your state fish and wildlife agency. How many fish depends on the species you choose, your water, and whether you want to do supplementary feeding. Prices are reasonable; for example, tilapia fry (50 will fit in a teaspoon) are about 17 cents per 1,000, 14 cents per 5,000 [1992].

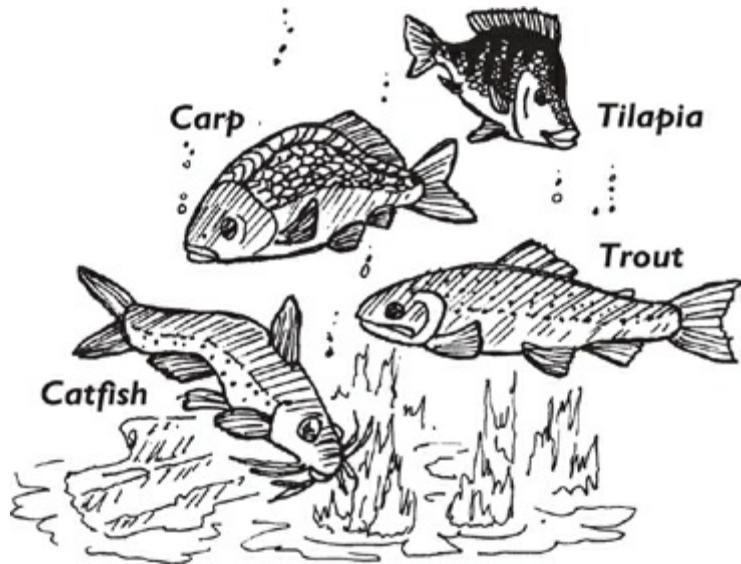

9. Do Long-Term Fish Pond Management. Intensive management with carefully figured and faithful fertilizing and supplemental feeding gives you the maximum harvests, but it can also be costly and time-consuming.

10. Breed Fish. This is an optional step. Hatching and raising fingerlings takes knowledge and attention. I'm not going that deep here, but if you want to learn how, the info is out there. You can even get a degree in fisheries management from the University of Washington!

A CHOICE OF FISH TO STOCK

Large-Mouth Bass and Bluegill. Every imaginable fish combination has been tried by fishery scientists. This is the one that works best. These are the species most commonly stocked in warm-water (80°F or more) ponds. Red-ear sunfish may be added for variety and to lessen the risk of the fish population getting unbalanced. The bluegill and red-ear sunfish provide food for the bass. The bluegills eat insects that eat pond plankton. The bass eat bluegills (and baby bass). With this combo, properly managed, you'll have good fishing for years. Alabama ponds that won't be supplementally fed are generally stocked with 50 bass and 500 bluegill per surface acre. With supplemental feeding you can stock with 100 to 150 bass and 1,000 to 1,500 bluegill per surface acre.

To keep your pond species in balance, the first year return all fish caught. The second year you can take out 80 lb. bluegill per acre, but still no bass. From the third year on, take 80 lb. bluegill per acre and 20 to 25 lb. bass per acre. When handling fish that will be returned, wet your hands to preserve the slimy protective coating of the fish.

Carp. These warm-water (80°F or above) fish don't need running water and are very good to eat. If the water gets too cold for their liking, they will hibernate at the bottom. Originally from China, carp has been a domesticated fish for millennia. There are several varieties. The grass carp is a vegetarian. It prefers green grass and vegetables—all kinds of freshly cut land grasses, weeds if not too tough, leaves of some trees, all kinds of fresh vegetables, rice bran, and bean meal. The others are carnivorous but are not the biting, chewing sort; they suck in food from the pond bottom. The black carp needs a diet of snails. The silver carp eats plankton. You drop manure or night soil into a carp pond. The fish don't eat it, but other critters do, and then the carp eat them.

⇒ **BROILED CARP** Clean carp and cut into pieces. Sprinkle the pieces with lemon juice. Broil, turning once, for 25 minutes. Sprinkle salt on it and serve.

Catfish. Catfish are warm-water fish that prefer 80°F and above. They're good in more southern areas and do well in farm ponds. They grow well in water 70°F or more, slowly in 60–70° water, hardly at all in water colder than 60°F. They do well in a pond about 2½ feet deep at the shallow end and sloped to 4 or 6 feet at the outlet. You can stock with blue, channel, or white. Channel are easy to raise and easy to manage because they seldom reproduce in a farm pond. Catfish that do reproduce can result in pond overpopulation—more and more fish that are smaller and smaller in size. You can raise catfish in a combo. If your pond tends to become infested with unwanted fish, the answer is actually to also stock it with large-mouth bass and fathead minnows. The minnows feed the bass, which get big enough to eat up the undesirable fish; thus you get the maximum yield of catfish.

Once your pond is stocked with fingerlings, the fish come up at feeding time and compete for the feed you throw them. They can get to be 6-pounders. Harvest by regular fishing pole, seining, traps, or lift nets. Four to six feet deep is good for them.

Crayfish. These taste like lobster, are ready for harvest in less than a year, and will thrive in almost any pond, lake, stream, or swamp anywhere in the continental United States. They can live on hay supplemented with garden-cull roughage. There is a growing commercial market for them.

Although known as "crawfish," these are correctly called "crayfish." They are freshwater crustaceans that resemble the lobster but are usually smaller. Little creeks around here have them. To catch them, you grab the crawdad in the middle with 2 fingers. Press the front pincers together and drop it into a bag. They're usually quite small, so it takes a lot—several dozen or so—to make a meal. For plain crawdad, just drop the live crawdad

into boiling salted water and boil 5 minutes. Then serve. You pick off the shell and pick out the meat using toothpicks—sort of a poor man's lobster. For larger ones, pull out tail fin and intestinal vein. For tastier crawdad, add a chopped onion and chopped dill weed to the boiling salt water and serve with a garlic-seasoned melted-butter dip on the side. Crawdads are good served with biscuits.

Tilapia. Tilapia are very easy to raise. They can even survive in water without oxygen because they can come to the surface and gulp air. They are very disease-resistant and gain about 1½ lb. in 6 months if generously fed. Tilapia are algae feeders. The female holds her fertilized eggs in her mouth and broods them there for 3 weeks until her fry hatch out. She doesn't eat during that time. For about 3 weeks after hatching, the fry will hide in mum's mouth when afraid, so during that time she still doesn't eat much and loses weight. So tilapia raisers try to prevent spawning by hand-separating males from females. Tilapia taste good and sell well to pricey restaurants and grocery stores.

Trout. Rainbow and brook are the trout varieties usually stocked in ponds because they're available, easy to manage, and easy to catch. You need a dependable supply of year-round good-quality water—from a well, spring, or stream. You need good water circulation—a minimum flow of 450 gallons per minute. You can stock either kind or both. If you're stocking trout, don't put in any other species of fish. Trout just aren't able to compete successfully. This is a cold-water (70°F or less) fish. Stock a natural pond with no more than 500 half-pound trout per surface acre per year. With supplemental feeding you can stock 2,000 per year. With good management, your pond should reach its carrying capacity in pounds of fish within a year after stocking.

During the second year, trout don't grow much unless the pond is fished enough to make room. Fishing is good for the crop! Each fish you take out lets the remaining ones gain weight faster. You can start fishing as soon as the trout are 6 to 8 inches long—about 6 to 10 months after stocking the pond with fingerlings. By early in the second year, they'll be 12 to 14 inches long and weigh about 1 lb., and they'll continue to gain weight. But only a small percentage of the trout you stock will live more than 2 years. At the end of 3 years, just a few large trout will remain, a number far below the carrying capacity of your pool. Time to start over.

Cleaning Trout. Keep the trout out of the water and away from the bank long enough to make sure it is dead. There are various ways to clean it. Start from the 2 fins behind the anal vent. Cut them off around the vent and cut forward to the neck. Then pull out and discard the internal organs and scrape out the bloody membrane tissue along the backbone with your fingernail. That tissue is the fish's kidney. Rinse in water.

The head is handy if you want to carry the fish with you on a forked stick, with one branch through the gill flap and out the mouth, or if you have an almost-too-small-to-be-legal fish. If you want to take off the head, cut it right back of the gill flaps. There is no need to scale a trout. Put it on ice, if possible, while you're waiting to either cook or freeze it.

Wilderness Trout. I once fried 3 small trout on a flat rock heated in my campfire. I had no salt, pepper, flour, or anything else to add, but I remember those trout from an isolated mountain lake as one of the best meals of my life. I was 16 years old. I had ridden 15 miles before that meal and had 15 miles yet to go. Makes for a good appetite!

➲ **QUICK TROUT** Season inside and out with salt and pepper. Roll in flour or cornmeal until coated inside and out, or dip in beaten egg and crumbs. Fry in oil or lard. It will cook very quickly. Turn once. Watch to prevent burning.

➲ **DUTCH OVEN TROUT** Partly precook 5 slices of bacon in a frying pan. Preheat your Dutch oven and pour the bacon grease into the bottom of it. Put the trout in a layer to cover the bottom (about 4 medium-sized ones). Sprinkle with salt and pepper to taste. Lay the bacon over the trout. Put the lid on and cook in the oven at medium heat about 15 minutes. Serve with lemon wedges, if you can get them.

➲ **PLANKED LARGE TROUT** A Victorian delight. Place fish whole on hot greased plank (hickory, oak, or ash— $1\frac{1}{2}$ inches thick). Sprinkle with salt, pepper, and melted butter. Bake at 400°F an average of 15 minutes per pound for whole fish. When almost done, arrange a border of hot mashed potatoes around it. Brown under broiler. Surround with hot vegetables. Garnish. Serve on plank at the table.

Eating Trout. Peel the skin off the top side (it's tasty too!). Very carefully, and in the best light you have, separate meat from bones—each person for himself. But do it for the smaller children, and don't give any trout to toddlers lest you goof and get a tiny bone in it, on which they might choke. Peel the meat slowly and carefully from the side using your fingers for best results, or a fork if you're squeamish. Peel from the head toward the tail and from above the backbone moving down, and cut along the ribs in order to avoid dislodging the fine rib bones from their connection with the backbone. If they do get loose with the meat, it's a real nuisance trying to pick them out one by one, and it's very easy to miss one. With practice, you can lift the whole side of flesh up off the little rib bones. Do the same to the other side of the fish, and you have your good eating ready.

Other Fish. Other cold-water (70°F or below) fish you might want to raise in your pond are muskellunge and northern pike. Another possible warm-water (80°F or above) fish choice is buffalofish. There are other varieties, like the bluegill and redeye sunfish, that are stocked to feed not humans but fish that will then be human food.

Fish Food: As with feeding any other livestock, there's a choice ranging from home-grown to ultracommercial feeds. Even among commercial feeds there are choices. You can choose feeds that have no preservatives, artificial colors, fixatives, synthetics, or pesticides.

Fertilizer. "Fertilizer" feeds the algae, which feeds the fish. You fertilize before the growing season for warm-water fish. In the extreme South, fertilizer can be applied year-round, but the fish-growing season decreases progressively toward the North, so fertilization is less effective in the northern states and may even do more harm than good. Too much fertilization can cause oxygen shortage and fishkills, especially if you also have an ice cover. Where fertilization works, ponds need refertilization any time during the growing season that a white object can be seen 18 inches or more below the water's surface. (If the pond is fertile enough, the resulting algae bloom will obscure an object at that depth.) As many as 12 fertilizer applications per year can be of benefit to maintain that fertility. You fertilize with animal or people manure or other organic products.

Supplemental Feeding. In trout ponds, this can raise production from 100 lb. per acre to 1,000–2,000 lb. per acre. Feeds are sold as finely ground mash and as floating or sinking pellets. Or you can make home-grown feed by offering chopped meats, wheat, whey, greens, and earthworms; watch what they take and what they don't, and be guided by that.

OTHER POND MANAGEMENT TASKS: Keep an eye on what the waterweeds are doing. Maintain a balanced fish population if you're keeping a combo. Be aware of the possibility of fish diseases. Maintain good water quality.

Preserving Food from Water

Use top-quality, fresh meat. Process for preservation as soon as possible after you catch (or buy) it. The longer you wait, the poorer the quality will be. To prevent spoilage, keep fish and shellfish cold—on ice or in your refrigerator. Handle raw seafood safely. Raw seafood may contain microorganisms that cause food poisoning. These bacteria are destroyed by heating the seafood before eating. Make sure that you wash your hands, utensils, and work surfaces (such as cutting boards) after handling raw seafood. Don't let raw seafood come into contact with cooked seafood.

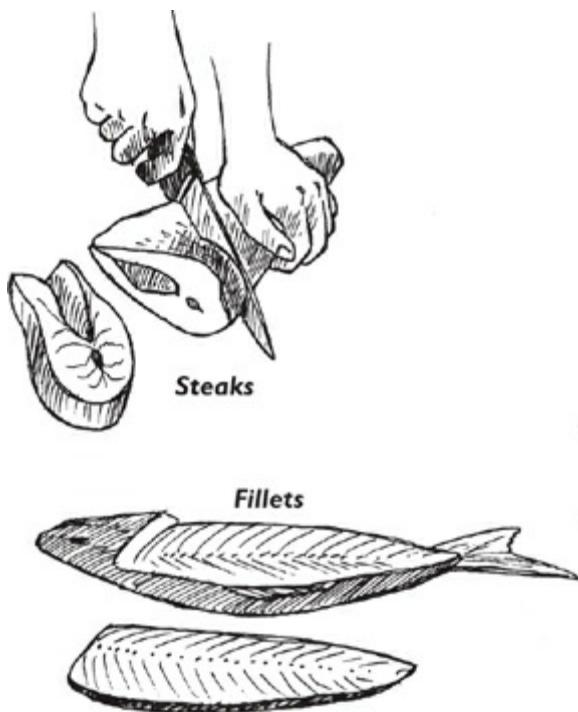

Keep live shellfish (clams, oysters, mussels) moist and cold. Place them in a bowl, cover with a wet cloth, and store in the refrigerator. Keep fish on ice. Avoid rough handling. Don't stack fish on top of one another—this causes crushing and bruising, which speeds up spoilage. Keep live crab cool. *The Great American Seafood Cookbook* by Susan Hermann Loomis (New York: Workman Publishing, 1988) has good illustrations of filleting and cleaning and good info on wild seafood.

FREEZING FISH: Fish may be frozen whole as they come from the water, or whole but “drawn” (with the entrails removed). Drawn fish are best for freezing because they take less storage space.

Cleaning Scaly Fish. Soak the fish for a few minutes in cold water. Next, hold it down so it can't slide, and scrape using a dull knife from the rear end toward the head. The scales near the base of the fins and head are trickiest to get.

Removing Entrails. Switch from the dull knife you used for scaling to a sharp knife. Slit the belly from vent to gills. Remove the head by cutting above the collarbone. Scoop out and discard the innards. Break the backbone over the edge of the cutting board or table. Remove the dorsal or large back fin by cutting the flesh along each side and pulling out the fin. Never trim off the fins with shears or a knife because the bones at the base of the fin will be left in the fish. Wash the fish thoroughly in cold running water. You can leave the tail on a small fish. It will ordinarily be cooked whole. Rinse your scaled and cleaned fish in cold, running water. Your fish will keep better if you don't soak it in water after cleaning.

Steaks and Fillets. Large fish are cut crosswise into steaks or lengthwise into fillets for cooking. Cut steaks about $\frac{3}{4}$ inch thick. Fillets are a bit more complex. A fish's side bones are inside next to its cavity. So you make a boneless fillet by cutting the meat away from the backbone, tail to head, with a sharp knife, until you can lift the meat off the bones in 1 piece. With a sharp knife, cut down the back of the fish from the tail to the head. Then cut down to the backbone just above the collarbone. Turn the knife flat and cut the flesh along the backbone to the tail, allowing the knife to run over the rib bones. Lift off the entire side of the fish in 1 piece, freeing the fillet at the tail. Turn the fish over and cut fillet from the other side, resulting in 2 fillets—one from each side of the fish.

If you wish, you may skin the fillets. To do that, lay a fillet flat on your cutting board, skin side down. Hold the tail end with your fingers, and cut through the flesh to the skin. Flatten the knife on the skin and cut the flesh away from the skin by running the knife forward while holding the free end of the skin firmly between your fingers.

Preparing Catfish. Nail the fish through the head to something firm. Cut through the skin around the front end. Pull the skin down to the tail. Pliers can help you get a good grip on it. Then cut off head and tail and remove entrails.

Brine Dip. Commercial packers give fish steaks and fillets a 30 second dip in a 5-percent salt solution ($\frac{2}{3}$ c. salt per 1 gal. water) before wrapping and freezing. It helps preserve them.

Wrapping Fish for Freezing. Wrap in a covering that's resistant to water vapor. Try to make the package airtight to prevent drying. Place 2 layers of waxed paper between individual chops, steaks, and fillets so that individual frozen pieces can be separated easily. Wrap in freezer paper on the outside. Or put them in a milk carton or similar container full of water and freeze fish and water together. The water keeps them from drying out.

The Freezing. Spread packages. Turn control to coldest position. For quickest freezing, place packages against freezing plates or coils or in fast-freeze section of freezer. Store at 0°F or below. You can cook without thawing; it will just take a little extra cooking time. Or thaw first and then bread and fry, or stuff. Cook immediately after thawing.

STEP-BY-STEP FISH CANNING: This info is from Pacific Northwest Extension.

NOTE: *Do not can smoked seafood; freeze it instead.*

1. When you catch fish, remove viscera at once. Chill the cleaned fish until you're ready to can.
2. Before you can, remove head, tail, and fins.
3. Wash fish carefully, removing all blood.
4. Split fish lengthwise. Cut into lengths suitable for jars. (About 1 lb. of fish will fill one half-pint jar.)
5. Pack fish tightly into pint or half-pint jars, leaving 1-inch headspace. *Do not can fish*

or shellfish in quarts. You may add 1 t. salt per pint. You can also add lemon juice, vinegar, salt, or oil (1–3 T. vegetable oil or fresh-type dressing per pint) as you wish.

6. Adjust lids. Wipe jar rims clean with a wet paper towel before putting on the lid. Moisten towel with vinegar when you pack fatty fish such as tuna and salmon.
7. Process half-pints and pints for 100 minutes *in a pressure canner* at 10 lb. pressure (weighted gauge) or 11 lb. pressure (dial gauge). Increase pressure for higher elevations as shown in the “Altitude Adjustments for Pressure Canning” table in “Preserving Meat.”

Eating Home-Canned Food from Water. *Before tasting home-canned seafood, examine for spoilage.* Bulging jar lids, spurting liquid, an “off” odor, or mold show that the food is not safe to eat. *Do not taste or eat questionable food.* For an extra margin of safety, heat any home-canned seafood before you eat it. Boiling the seafood, covered, for 10 minutes will destroy bot toxin. Or you can preserve texture by baking. To do that, remove lid and insert a meat thermometer upright into the center of the fish. The tip should be at the approximate center of the fish. Cover the jar loosely with foil and place in an oven preheated to 350°F. Remove the jar from the oven when the thermometer registers 185°F. You’ll need about 30 to 35 minutes. Let the jar stand at room temperature for about 30 minutes. This will let the temperature become uniform throughout the jar. Serve the fish hot or refrigerate immediately for later use.

NOTE: If you prepare canned fish in a casserole, bake at 350°F and check the internal temperature at the end of the cooking time as described above for jar.

My favorite animal in my whole long life was the half-Shetland pony I rode as a child, Shorty Bill. I'll never forget the night that horse saved my life. Or was it my father who did?

Shorty Bill was half the size of a regular horse. I rode him every day to a country school 2 miles down the road, there and home again after school. One late fall day I took a notion to ride him from school directly over the mountain instead of going by the road. I let myself through the gate across from the little schoolhouse, and Shorty and I didn't have another fence from there to home. We were on what you might call open range. We slowly moved up out of Bracket Creek Canyon, where the school was, into the treeless exposed top of the mountain that lay between the school and my home.

As I rode, dusk fell early. Then, without warning, out of the gray sky came a true blizzard. The snow began to fall thicker and thicker—big white flakes, and with them utter black darkness. The wind howled and whined in my ears, pushing against my pony's body and mine. I couldn't even see my pony's ears ahead of me. Though I was warmly dressed, as always, I started to feel a real chill on my face.

There was no light, no road, no fence to follow. No sound but the wind. I was a little girl of about 8 with no hope in the world but my pony. I knew those blizzards. It might snow for days and nights, and when it stopped there could easily be 4 feet of snow on the ground. I had gone out with my father the morning after a band of freshly sheared ewes and lambs had gotten caught in a blizzard. I'd watched as he frantically searched for rounded mounds in the surface of the snow and then dug down through its smothering, chilling blanket. But the sheep and lambs he found were all dead.

I remembered that and, for a moment, I was very frightened. What could I do? Who would help me? There was nobody.

Then I remembered my daddy once saying to me, soon after he gave me my horse, “If you ever get lost with Shorty Bill, just let him have his head.” (That means let him choose

and go where he wants.) "Horses have senses that people don't, and can't even understand. He'll take you home." I heard those words again in my mind just as clearly as if he were there with me, saying them for the first time. I was so grateful that Daddy had bothered to give me the bit of advice that now was the only hope I had. It had to be my answer. There was no other way. It had to be Shorty Bill who took me home. But was Daddy right? Could Shorty Bill find his way even in this storm? The storm wouldn't kill him even if he didn't find his way home. His body was so big and strong and warm. But it could kill me.

Nothing to do but trust and obey. Obey my father. In a sense, obey Shorty Bill. So I let him have his head: I simply let the reins hang slack instead of putting pressure on his mouth and neck to inform him which way I wanted him to go. Now he could go any way he wanted to. He would soon realize that.

Having given up the "steering," I instead concentrated all my efforts on keeping warm and hanging on. I made myself as small a target for the freezing wind as I could, hunching over my pony's back with my head low, my chin snuggled as deep into my coat as I could get, trying to shelter my face from the wind.

We went a very long time like that. Shorty wasn't one to hurry. He was old as horses go. He moved along steadily, though, and I felt soothed by his steady rocking motion, almost sleepy, except I had to make myself stay awake enough to hang on tight. I don't know how long it was, some hours ...

Suddenly he stopped. That did scare me. As long as he was moving, I could still hope that he was taking me home. Now I peered up and out from my coat collar's shelter to a wonderful sight: I could just barely see the shine of a light. It was the one outside the barn. My daddy was there, standing out in the freezing cold, right under the light, right by the barn door. He must have been waiting for us. He walked quickly over and lifted me off Shorty Bill with one great swoop of his strong arms. He hugged me wordlessly to his chest for a long moment. Then he took Shorty Bill into the barn's wind-sheltered warmth, took off his saddle and bridle, and gave him an extra-big serving of oats for his dinner.

Whenever I remember that journey on Shorty's back, lost in the storm, I think about trust. Who you trust. How you trust when there is nothing else to do. And how that trust can bring you safely home. Whenever I think of that, I think that going home to Heaven must be like that. You trust because there is nothing else to do anyway. And your trust brings you safely home. I've felt that I was in darkness many times since that ride. But there's a hand that holds mine and an invisible light that goes before me. Guiding, guarding all the way. Though it be even the valley of the shadow of death.

INTRODUCTION

Although my mother could turn out good food on the old wood cookstove and wasn't discouraged by all sorts of country problems, no part of the barnyard was ever really her thing except the chicken house. She loved her chickens and they seemed to love her. I love all the animals, including the big ones, but Mother was terrified of them. I remember one time Daddy had to be away overnight. Mother assured him that, just for once, she could manage to milk the cow. Well, I awoke the next morning to hear her hollering desperately outside the window. I ran to look, and there she was, perched on the very top of a fence post, balancing up there in some mysterious way while our gentle milk cow stood close by, patiently waiting to be taken on into the barn. Mother was convinced she was under attack.

I'll never forget that scene because, although I'm lean like the Harshbarger side of the family (my full maiden name was Carlotta Louise Harshbarger; "Carla" is a nickname), Mother always packed quite a bit of weight, and her getting on top of that fence post was an achievement. If you don't believe me, just go out and try to stand on top of a wooden fence post—no matter how much you weigh.

Every spring Mother had baby chickens living in a cardboard box back of the wood stove. One year Daddy added a bathroom with a bathtub in it on to the house. Afterwards, Mother moved the spring chicks to the bathtub once they outgrew the cardboard box, until it was warm enough for them to be outside. We took our spring baths in a big round metal tub on the kitchen floor, just like we'd done before we had plumbing.

Mother had a wonderful healing touch with sick animals. I saw her revive an almost-dead baby chick that had suffered some crisis of illness or injury. She would work the stiff little legs and wings up and down until circulation was restored. Then she'd wrap the chick in a soft white dish-towel (white from being boiled in lye water on top of the stove) and put it in a little box near the stove, wherever a wave of her experienced arm told her the brooding temperature was just right.

The chickens loved my mother. They got all her kitchen scraps. Daddy could feed the pigs on whatever else there was—the chickens had first rights. And they appreciated this. They laid eggs aplenty for us. If Mother went to town shopping and stayed away too long, the chickens would get restless and manage somehow to get the front door open. Mother would walk in and find chickens roosting all over—on the kitchen stove, the table, in cupboards. And they would all fly up and squawk at the sight of us, feathers and droppings going every which way.

I'll never forget the taste of Mother's fried chicken. First she'd have me go out and catch and kill a couple birds (she never could bring herself to come out of the house until that part was over). Then she'd appear with a big bucket of scalding water, and we'd pluck, clean, and cut up the birds together. That very night for supper we'd eat them. Mother turned up her nose at chicken that was over 12 hours from the hoof to the pan. She didn't have a deep freeze. She canned lots of venison, but her chicken was always absolutely fresh.

CHICKENS

NOTE: The following section on chickens contains basic information relevant to all poultry varieties. In the other poultry sections that follow, only data that is different from the information in this section is covered.

Getting Started: Information and Supplies

POULTRY PERIODICALS: Most U.S. rural-living magazines have occasional articles on poultry—the most common homestead animal. And also ...

Feather Fancier Newspaper is a Canadian newspaper focused on purebred poultry,

pigeons, waterfowl, pheasants, etc.; \$20 US/yr; sample \$2; 519-542-6859; fax 519-542-4168; 5739 Telfer Rd., Sarnia, Ontario N7T 7H2, CANADA;
featherfancier@ebtech.net; www.featherfancier.on.ca.

National Poultry News is no longer in print, but the website is still available as a resource for poultry information. From it you can link to many articles or purchase books. Contact Glenda L. Heywood, Editor: 207 13th Ave., Brookings, SD 57006; www.nationalpoultrynews.com

BASIC PRINCIPLES OF ECONOMIC CHICKEN MANAGEMENT

1. Start your flock with quality chicks, bought from a local hatchery or mail-ordered, or incubate your own eggs.
2. Choose your best caretaking schedule: a small egg flock year-round, or a big meat-production for a few months a year (or both). Choose a broiler breed for your fryers, a good laying breed for your layers, or a quality meat-eggs breed and eventually raise your own.
3. Feed your cockerels or capons only long enough to get them to the eating size you want, butcher them yourself, and then can or freeze them, so that you won't have to feed them any longer than necessary.
4. Use home-grown feeds when possible: pasture, household, and garden scraps; surplus milk; garden squash and mangel beets raised and cooked for your birds' winter veggies ...
5. Feed your birds a generous (and diversified) diet. To a real extent, the more they eat, the more they grow, and the more they lay. Make sure your birds have adequate ventilation, space, sunshine, and gravel for their gizzards.
6. Buy or raise some new pullet chicks every year; periodically cull your existing flock of layers carefully and send to the stew pot any birds that are performing poorly.
7. Shovel out the chicken house at least twice a year, age the manure in your compost heap, and then use it to enrich your garden soil.
8. Sell your surplus eggs direct to other householders at a reasonable profit to help pay for the cash expenses of poultry-keeping.
9. Preserving eggs evens out the spring surplus with the winter shortage and enables you to get along feeding fewer laying hens.
10. Keep basic records so you know where your greatest expenses and best profits are.

The Poultry Press is available monthly from 765-827-0932; PO Box 542, Connersville, IN 47331-0542. Cost is \$26/yr; \$74/3 yrs; sample copy \$3; www.poultryspress.com.

Poultry Times: If agribusiness concepts don't stick in your craw, to understand the

commercial poultry production scene, and for good disease articles with solutions, spend \$18 for a year's subscription to *Poultry Times*; 770-536-2476; fax 770-532-4894; 345 Green St. NW, PO Box 1338, Gainesville, GA 30503;

www.poultryandeggnews.com. A commercial farm poultryman in your neighborhood would be a breeder (who sells eggs to hatcheries), a hatcheryman (who sells just-hatched birds to growers), or a grower (who sells eggs and/or broilers to processors and distributors). But *Poultry Times* will ask further: whether you're a broiler processor, egg packer and processor, hatcheryman, broiler or layer producer, commercial egg producer, turkey producer, feed manufacturer, flock serviceman, hatching egg producer (breeder), supplier to the poultry industry, turkey processor, started pullet raiser, ag college, veterinarian, government, financial advisor (banker), or nutritionist (poultry feed component specialist). Its calendar lists poultry specialty conventions, conferences, seminars, and short courses—all aimed at the for-profit, large-scale poultry operation.

POULTRY CLUBS, MUSEUMS, AND TOURS: The American Poultry Association offers membership, quarterly newsletters, and an annual yearbook and show awards for \$10/yr. Contact Pat Horstman, Sec-Treas; 724-729-3459; PO Box 306, Burgettstown, PA 15021; www.amerpoultryassn.com. The Society for Preservation of Poultry Antiquities promotes endangered and rare poultry worldwide and also unites collectors of antique poultry equipment; www.feathersite.com/Poultry/SPPA/SPPA.html. Get a Membership Breeders Directory and four bulletins for \$15/yr. The Maine Alternative Poultry Association (MAPA) organizes growers with less than 2,000 laying hens or less than 10,000 meat birds; www.maineppoultrygrowers.org.

The National Poultry Museum at Bonner Springs, KS, is part of the National Agricultural Museum. It displays thousands of antiques representing the poultry industry's heritage; www.aghalloffame.com. Or visit the American Poultry Historical Society: Dr. Lou Arrington, Secretary, 260 Animal Sciences Bldg., 1675 Observatory Dr., Madison, WI 53706. Overseas, visit the Dutch Poultry Museum in Barnveld, Holland.

POULTRY SUPPLIES: For small flock service, look in your local Yellow Pages under "Feed Dealers" or "Poultry." Your local feed salesperson can be an invaluable source of advice to help you get started and keep you going, as well as supply information on commercial feeds and basic components of build-it-yourself feed rations and general livestock supplies. Hatcheries, local or mail-order (listed below), often sell specialized books and poultry equipment for family flocks.

Brower Equipment offers a free catalog of brooders, bulbs, cages, waterers, and feeders: 319-469-4141; 800-553-1791; fax 319-469-4402; Hwy. 16 W., PO Box 2000, Houghton, IA 52631; sales@hawkeyesteel.com; www.browerequip.com.

EggCartons.com sells poultry supplies, especially egg cartons (pulp or foam) sized for chicken or duck eggs, \$37.50/250, etc.: 888-852-5340; fax 877-455-4647; PO Box 302, Manchaug, MA 01526-0302; info@eggcartons.com; www.eggcartons.com.

Foy's Pigeon Supplies sells general poultry supplies. Free catalog: 877-355-7727; 3185 Bennett's Run Rd., Beaver Falls, PA 15010; www.foyspigeonsupplies.com.

G & M Sales of Virginia sells poultry feeders, etc.: 800-296-9156; 540-433-9156; fax 540-433-4818; 4562 S. Valley Pike, Harrisonburg, VA 22801; sales@gmsalesofva.com; www.gmsalesofva.com.

GQF Mfg. Co. Quail & Poultry Equipment offers incubators, brooders, waterers, canders, and much more! 912-236-0651; fax 912-234-9978; PO Box 1552, Savannah,

GA 31402-1552; sales@www.gqfmfg.com; www.gqfmfg.com.

Rocky Top General Store sells poultry and gamefowl supplies, antique tools, coal/gas/wood stoves, farm/pet supplies, grain mixtures, kerosene heaters, etc., by mail-order or in-store: 865-882-8867; fax 865-882-9056; PO Box 1006, Harriman, TN 37748; rockytopgen@msn.com; www.rockytopgen.com/.

Smith Poultry and Game Bird Supply sells poultry books, incubators and brooders, medications, vitamins, wormers, and watering supplies; 14000 W. 215th St., Bucyrus, KS 66013; 913-879-2587; fax 913-533-2497; smith@poultrysupplies.com; www.poultrysupplies.com.

Stromberg's Unlimited sells poultry-keeping supplies, poultry stock, incubators, chicken pickers, books. Free catalog: 800-720-1134; 218-587-2222; fax 218-587-4230; Box 400, Pine River, MN 56474; info@strombergschicken.com; strombergschickens.com.

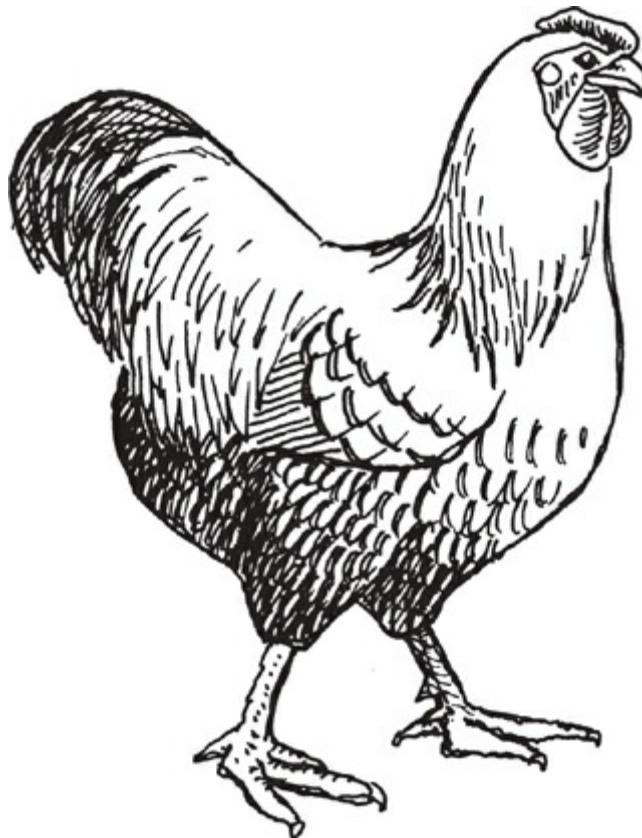

Val Products is a multinational manufacturer in this field: 717-392-3978; fax 717-392-8947; 2599 Old Philadelphia Pike, Bird-in-Hand, PA 17505; chick@valproducts.com; www.val-co.com.

Poultry Books: *Raising Chickens* by Cynthia Haynes (1985) is fairly recent and carefully researched. *Raising Poultry the Modern Way* by Leonard S. Mercia (updated 1990) is a long-time classic for those who want a commercial operator's approach. If your interest is in a few chickens kept as pets or show stock in a suburban setting, read *Bantams: A Complete Pet Owner's Manual* by Helga Fritzsche (1985), translated from its original German edition. Other useful books are *Chickens in Your Backyard* by Rick and Gail Luttmann; *Raising Poultry Successfully* by Will Graves (1985), which covers chickens, ducks and geese; *Starting Right with Poultry* by G. T. Klein (1973); *The Complete Handbook of Poultry Keeping* by Stuart Banks (1979); *Raising Turkeys, Ducks, Geese, Pigeons and Guineas* by Cynthia Haynes (1987); *The Family Poultry Flock*, edited by Lee Schwarz (1981); *Raising Small Meat Animals: Efficient Home Production of Cornish Game Hens, Chicken Broilers, Turkey Roasters, Rabbits and Squabs* by Victor Michael Giamattei; and *Producing Eggs and Chickens with the Minimum of Purchased Feed* by Ed Robinson (1972).

Chicken Breeds

Here is a description of the different kinds of chickens, sorted out in various ways to help you make sense of it. To me, the most important aspects of a chicken are ranging, mothering ability, and climate suitability. But there's a bird for everybody's needs here. Browse until you find your perfect match. But first a useful definition: "sex links."

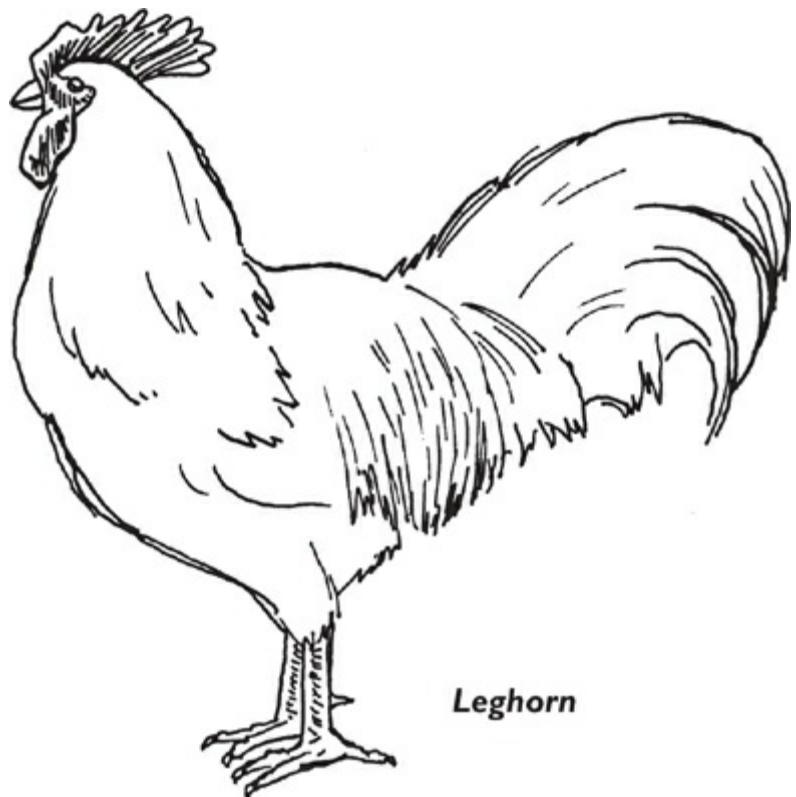

Sex links exist in various breeds and are always worth considering. Sex links are the offspring of the crossing (mating) of a "gold" (red, buff, brown ...) male with a "silver" (Wyandotte, Plymouth Rock, Sussex, Brahma) female. The chicks will be sex differentiated by color: males, cream or white; females, buff or red. The sex links generally belong to the "heavy" size category (see "Heavy Chickens" below). Keep in mind—if you are planning to incubate your own eggs—that they are hybrids, and crosses do not breed true. That means the chicks will not turn out like the parents. (Only pure breeds breed true.) The Black Sex Link is a meat-eggs hybrid gotten by mating a Rhode Island Red rooster to a Barred Plymouth Rock hen. The Red Sex Link has a Rhode Island father and a White Leghorn hen mother. Hatcheries like to see sex links because of the fact that cockerels and pullets are different colors at hatching, and that saves the hatchery time, which is money, in determining the sex.

Wyandotte

GOOD EGG LAYERS: The most efficient layers of all come from carefully selected genetic lines of chickens that have been developed for commercial egg production. The Leghorn is the old-timer in this field. White Leghorns are the best known, but Leghorns also come in brown, buff, red, and the black-patterned Columbian. Other modern breeds that lay as well as, or even a little better than, the Leghorn, are the New Hampshire, Golden Sex Link, WhelpLine, and Barred Plymouth Rock. All these breeds, including the Leghorn, will lay between 245 and 255 eggs per year under good management. The best egg-laying breeds grow relatively slowly and eat a lot relative to the weight they put on. You can't have both top egg production and most efficient meat production from the same line of birds. It is also worth noting that at least 2 duck breeds, the Khaki-Campbell and the Indian Runner, lay eggs as dependably as these chickens.

EGG COLOR: Brown eggs are exactly the same inside as white ones. To find out what color egg a breed lays—if no one tells you and you care—just ask. In most places, brown eggs sell for 2–10 cents a dozen more than white eggs. In general, the smaller (Mediterranean-derived) breeds—Leghorns, Minorcas, Anconas—lay white-shelled eggs; the larger (American) breeds lay brown. The major English-developed breeds—Cornish, Orpington, and Sussex—are brown-egg layers, as are the Asiatic chickens—Brahma, Cochin, Langshan. Purebred Araucanas, chickens from South America, lay eggs in the purple to pink range. If an Araucana is mated with a brown-egg layer, half the offspring will lay eggs with dusky shells. If an Araucana is mated to a white-egg layer, half the offspring will lay eggs with light blue shells. An individual hen won't change colors. Whatever color she first lays will be what you'll always get from her.

Leghorn

SIZE: Chickens come in broiler, giant, heavy, light, and bantam weights. The concept helps sort out most of them, though many breeds now have both a large variety and a bantam variety.

BROILERS. These are your basic meat birds. The ideal broiler is now expected to gain 4 lb. in 8 weeks and then go into the deep freeze. It used to be that meat birds were either extra roosters or culled hens. Then came a period when caponized cockerels were the popular meat birds. Now extra male chicks of egg-specialist breeds are frequently destroyed at the hatchery because, even at bargain-basement prices, they aren't the bargain that broiler chicks are if what you want is meat. Broilers grow phenomenally fast because they've been carefully selected from genetic lines that have maximum feed-to-flesh conversion ratios. That means with a broiler, 2 lb. of feed turn into 1 lb. of meat in just 3 weeks. The best laying breeds, on the other hand, would have to eat around 6 lb. of feed to gain a pound, and it would take longer than 3 weeks. Another way to put it is that your broiler will eat twice as much feed as the other breed, but you'll be done and putting it in your deep freeze 3 months sooner than you would the regular heavy breed. Probably the maximum farm efficiency is to have a good egg-laying dual-purpose (American) breed and raise some extra broiler chicks every year for the bulk of your meat birds. Don't let broilers grow older than 12 weeks because by then they've put on all their meat and mainly acquire fat.

Any "giant" or "Cornish" or "Cornish cross" or "jumbo" or "broiler" is a broiler. The hatchery catalog will make it clear to you which of their breed names means "broiler." The Cornish-Rock is a hybrid of a Cornish rooster and a White Plymouth Rock hen. A friend who raised a batch told me they dressed out between 7 and 8 lb. at 12 weeks old. She said they made good roasters because of that sizable cavity to stuff and had huge breasts and lots of white meat. Hubbard Roasters are another rapid-growing, large-breasted bird. None of these breeds makes good layers because they eat so much more per egg they lay than a good layer does, and they don't lay as well.

Giants. Many sources rate Black Giants and Jersey White Giants as "heavy" chickens, but to me they fit best here, along with Cornish. Their capons may grow to 15 lb. The giants

and Cornish are a little slower to mature than heavy breed birds or broilers. If you want to breed your own broilers, a purebred Cornish rooster mated to heavy-breed hens will produce acceptable meat-type offspring. Hatchery broilers come from carefully developed genetic lines that are protected, sometimes even patented. These birds do mate naturally, but only if they're on a lean diet, eating only about 70 percent of what they'd like to have. Cornish roosters do have a problem breeding because of their top heaviness. You have to pick your roosters carefully and not let them get too heavy. The small birds that you see in grocery store meat displays called "Cornish game hens" are Cornish Rocks that were butchered at 4 weeks of age. Butcher them at 2 lb. live weight to get the proper "Cornish game hen" dressed weight (1 ½ lb.). Get more info, including sources to buy Cornish hens, at www.acahady.com/icba.html.

Heavy Chickens. These also make good fryers and roasters and stay put behind a fence. Your extra roosters and overage hens are meaty enough to make butchering worthwhile. They ordinarily eat more and lay slightly bigger eggs than lighter breeds. It is among the heavy chickens of "American" descent that you find your good combination meat-and-eggs barnyard breeds. They don't grow as much meat as the giants, nor as fast, but their size is not shabby, and many of them are top-of-the-line egg-layers, too. Butcher these breeds at 16–20 weeks of age.

Rhode Island Reds, Production Reds, Plymouth Rocks, White Rocks, Barred Rock, Wyandottes, and New Hampshires fall into this category. Chicken breeds that were developed in England and fit in this weight group are the Australorp, Dorking, Orpington, and Sussex. The Buff Orpington is an exceptionally gentle bird that is a good bet to set when the warm weather comes. The non-bantamized Asiatic chickens—Brahma, Cochin, and Langshan—belong here because of their characteristically large bodies; they also have feathered shanks and heavy bones, and they lay brown eggs. Hen weights range from 6 ½ lb. for a mature Wyandotte, Rhode Island Red, New Hampshire, or Black Australorp hen, to 7 ½ lb. for a mature Barred Plymouth Rock, White Plymouth Rock, or Black Minorca hen. (The Black Minorca is the largest member of the Mediterranean group of egg breeds, but by weight it belongs here.) The naked-necked Turken grows to be 6 lb. or more.

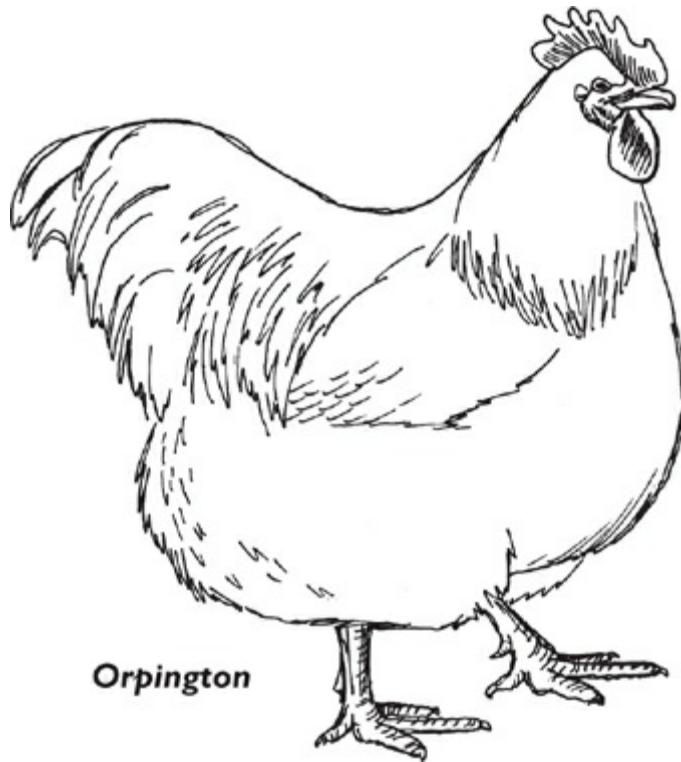

Light Breeds. These are the Leghorn and other Mediterranean-derived chickens, plus the Araucana—which is as lean as the Leghorn and still has all its brooding instincts—and the American-developed WhelpLine, a 5-lb. hen. The Houdan is an old-time French-developed light breed. California Gray, Sicilian Buttercups, Minorcas, White Faced Spanish, Blue Andalusians, and Anconas are other light breeds. The Sicilian Buttercups and Houdans are especially good layers. The lights are somewhat more nervous in temperament than the heavy breeds, which are better with children. The high-strung lights don't tame easily. A hen typically weighs 4–4 ½ lb. Leghorn roosters make passable fryers, though they are smaller than Reds or Rocks. Leghorns, or Leghorn varieties, are the general favorite of commercial egg operations. The white eggs sell better and color better at Easter. The smaller size means the chicken eats less per egg produced (though the eggs are slightly smaller). The production-oriented Leghorn gets a lot of bad press among homesteaders, but the fact remains that half a century of selection effort has gone into those birds to achieve ideal cost-efficient egg production. Lane Morgan, writer, gardener, and chicken-raiser, summed it up for me nicely: "Leghorns might be a good choice if you are raising a flock in confinement, on commercial food. I've had a Leghorn laying flock, and they certainly do lay, but I just didn't enjoy their company much. Incidentally, I find Araucanas much calmer and more sensible than Leghorns; I personally wouldn't lump them with

other hysterical light breeds."

Bantams. A "bantam" is the bantam weight—a very small bird, smaller even than a Leghorn and about one-third to one-fourth the size of a large chicken. There are dozens of types and colors of them with wonderfully varying size, color, and plumage patterns, and they are popular as show birds for the county fair. There's a considerable size range among the different varieties. La Fleche is the heaviest with a 3-lb. cock. Silkies and Faverolles are a little over 2 lb. (cock); Chochin and Ancona cocks are a little over 1 ½ lb. The hen typically weighs slightly less. The black Silky was domesticated in China 4,000 years ago, the Chabos and Cochins 1,000 years ago. In addition to these ancient breeds, there are many new breeds of dwarfed commercials and other modern chickens, as well as ever-evolving new varieties of selections and crosses being developed for the hobby and show markets, mainly selected for their lovely or interesting feathers.

Bantams require less room and less feed than larger chickens. They provide less meat and their eggs are small, though actually large in proportion to the bird's body weight. (In a recipe, 3 bantam eggs equal 2 regular eggs.) Some breeds will lay almost as many eggs as a commercial chicken (La Fleche, 200/year; Amrock, 200/year; Ancona, 180-200/year), but most lay less than that; the Sebright and Game varieties rank at the bottom for egg-laying (50–80/year). These breeds are not the most efficient egg-layers, nor do they offer the most efficient feed-growth conversion ratios, but there is one important quality about some of them that merits consideration: many of these chicken varieties will readily brood and be good mothers. The majority of the modern bantam breeds, like the modern breeds from which they were dwarfed, do not reproduce naturally—they must be incubated. The traditional bantam hen, on the other hand, will virtually insist on becoming a mother, and is such fun to watch, and such a good mother, you'd probably be willing to allow it. To own such a bantam hen, choose a variety that has high ratings for broodiness, mothering, and foster-mothering ability: Ancona, Cochin, Silkies, Brahma, and Faverolle. Silkies and Cochins are also outstanding for their tranquil dispositions.

You can start out with just 2 bantams, male and female, and they'll do the rest. Or start out with just a bantam hen, and a regular-size rooster. Then, with genetic luck, her pullet offspring will have the mothering ability of a bantam and grow to more nearly the size of a large chicken. The older bantam breeds are also typically healthy (they can make it through almost anything) and cute, with lots of personality, and are great foragers, as well as good incubating machines for their or any other chicken's fertile eggs. A disadvantage to running bantams (which many folks call "banties") together with a general flock, if you're hatching your own eggs, is that the bantam roosters are so wonderful at doing their thing that soon you'll have all half bantams—which is not good from the meat point of view. You can avoid that by eating the bantam roosters. Bantams are too small to be proper fryers, but they stew okay. A risk with these born foragers is that they'll become totally independent of you and roost in places you disapprove of, and you'll only be able to catch one with a .22.

You may want to join the American Bantam Association and get their quarterly newsletter: PO Box 127, Augusta, NJ 07822; fax 973-383-8633; aba@bantamclub.com; www.bantamclub.com. They publish 19 books on bantams.

CLIMATES: If you live in the frozen North, the heavily feathered, heavy-breed Brahmans, Cochins, Orpingtons, Black Giants, and Wyandottes are worth considering because they are heartier and lay better in cold weather than more lightly feathered breeds. In general, the heavy breeds are the best for cold climates. Neither the broilers nor the light weights tolerate cold well. Frozen combs are a special hazard for cold-climate flocks. In unheated housing, large combs can tend to freeze, which causes lowered egg production from hens and a temporary end to the fertility of roosters in breeder flocks. So avoid buying such large-comb birds as the White Leghorn. A cold-climate bird is best adapted if it has a very close-fitting "rose" comb. The Mediterranean-derived breeds adapt well to warm or hot climates.

BREEDS FOR RANGING: In general, don't buy any white birds if you have predator problems and expect your chickens to range free at least part of the time. They stand out too much. An alert, active variety handles predators better. Regular size Anconas, Brown Leghorns, and Dark Cornish, and old-time bantam breeds are well spoken of in this regard. Araucanas, too.

SETTERS AND NON-SETTERS: Most chicken breeds have had the instinct to set and mother completely bred out of them, but some still have it. If your basic interest is egg production, broody hens are a nuisance. If you like the tradition of a natural chicken family you have to pick one of the breeds that can still handle that assignment. Breeds that will set are Orpingtons (Buff are best mothers), Turkens, Partridge Rocks, Buff Rocks, Speckled Sussex, Dark Cornish, Columbian Wyandottes, Buff Cochins, Partridge Cochins, and Light Brahma, and any of the good bantam mothering breeds.

BREEDS FOR FLY-TYING AND FEATHER-JEWELRY: Raise Barred Rocks for the Grizzlies, Blue Andalusians for the Duns (only half of their offspring will be blue, even when breeding true), Silver Penciled Rocks or Wyandottes for the Badgers, and buff, brown, and red

breeds for other lovely feathers.

RARE BREEDS: The American Livestock Breeds Conservancy (Box 477, Pittsboro, NC 27312; 919-542-5704; www.albc-usa.org) classifies as “rare” those poultry breeds with 500 or fewer females and fewer than 3 sources. As of 1993, Ancona, Black Minorca, Delaware, Dominique, White Jersey Giant, White Wyandotte chickens, the Pilgrim goose, and the (unimproved) Bronze turkey were “rare.” The ALBC classifies as “minor” breeds those with 2,000 or fewer females, and 5 or fewer sources, or a concentration of the breeding population in fewer than 3 sources: Black Jersey Giant, Brown Leghorn chickens, and the Khaki Campbell duck. They classify as “watch” breeds those with 2,000–20,000 females, but fewer than 10 sources, or a declining number of sources. “Watch” poultry breeds are Barred Plymouth Rock, Black Australorp, New Hampshire, Rhode Island Red (old-type), Rouen duck, and Toulouse goose. In addition to the ALBC and regular mail order poultry-outlet offerings (listed below), you can locate unusual breeds by asking around locally. Or contact the American Poultry Association, which publishes *Standard of Perfection*, a show-oriented guide to chicken varieties; 724-729-3459; 133 Millville St., Mendon, MA 01756; www.amerpoultryassn.com.

Starting by Buying Adult Birds

The cheapest way to start a flock is to order chicks from a hatchery and raise them yourself. That virtually guarantees you a disease-and parasite-free flock to start with. And it eliminates the possibility that somebody is selling you their culls. Furthermore, moving from one home to another tends to throw adult layers into a molt, which will end laying for a while. Nevertheless, you can buy adult birds from neighbors, local commercial sources, and mail-order sources—and there may be circumstances under which so doing will be your best choice. This type of transaction is most likely to occur with fancy breeds and breeding stock in general. I’ll tell you how to do this now and later describe how to obtain and manage baby chicks, or hatch your own chicks by incubator or mother hen.

HEALTH: Buy only healthy individuals. To make sure of that, check out the following points before you buy:

1. Look to see if they have skin or feather parasites. Do this by taking along a little magnifying glass and peering among the underarm feathers down by the skin.
2. Combs and wattles should be shiny red (unless the hen is broody or mothering). Eyes should be alert and bright. Feathers should be smooth and shiny.
3. Droppings should be well-formed rather than loose, and without the pinkish tinge of blood.
4. The birds should be busily eating, dusting, or preening—generally active and curious. If they are quiet, with feathers fluffed out, they are not healthy.

BRINGING NEW BIRDS HOME: If you have no other chickens and the new ones are healthy, and if you give their housing a good lye-cleaning before they are moved into it, and if you make sure they don’t run on ground that other poultry have used within the past 3 years, there’s a good chance the new birds will stay healthy. If possible, bring your new birds home near sundown. No matter what time of day you end up bringing them home, confine them in your chicken house until they’ve gone to roost there. Then keep them penned up for the next few days with plenty of food and water available. After a few nights of requiring them to roost where you want them to, their habit will be set and they’ll consider it home. Then you can open the outside door.

INTRODUCING NEWCOMERS TO AN ESTABLISHED FLOCK: Birds can be very cruel to unknown individuals. To bring in such a stranger, he/she would have to be approximately the same size as the rest of the flock's members. Pen the new one(s) where the old ones can see them for about 3 weeks. Then "accidentally" leave the cage door open and keep a distant eye on what happens next. Lane Morgan said, "When I have to introduce new birds to an established flock, and I don't have the option of keeping them separate but in view for weeks, I do 2 things. I put the new birds in at night, so they have roosted together before they have a chance to fight, and for a few days I evict the old birds into their yard every morning, leaving the new one or ones in the inside pen with the food and water. The new ones get a chance to eat in peace and to take possession of the new space, and when the established birds are let back in, they are too busy eating and drinking to make a lot of trouble."

TAMING BIRDS: To tame new birds, get them to eat from your hand. And pet them on cheeks, head, and neck, and get them accustomed to being gently carried by you. But you may not want to tame birds whose life cycle will be strictly utilitarian.

Starting by Buying Chicks

The subject of raising chicks is so complex I scarcely know where to begin: With the chicken who lays and sets on and mothers her own? With the egg that you collect and incubate artificially and then raise the resulting chicks like a batch from the mail-order hatchery? Or with the chick that has just arrived in the mail and first of all needs the warmth of a brooder? I am guessing that most people nowadays get their chicks mail-order, so I'm starting with that. Afterwards, I'll tell you how to hatch your own in an incubator, and, last of all, how to let a mother hen do it the old-time way.

MAIL-ORDER CHICKS: These are incubator chicks that have been grown at commercial regional hatcheries and are sent through the regular mail to you if you've placed an order for them. It takes 21 days to hatch chicks, so you order and pay for them ahead of time. The earlier you get your order in, the better. Some hatcheries give price breaks for early ordering. Some get booked to capacity in the rush season and can't accept more orders. Some rarer species get sold out way ahead of time. Hatches are scheduled for early in the week. You may want to order all your chicks at once—or to work with a smaller number at a time in a smaller brooder space and raise several batches—maybe one in February, one in April, and one in October. To start a large number of chicks and not have to worry so much about chilling in colder climates, the ideal time to get them is around July 15. At that time of year you could probably raise any number of chicks without even a heat lamp, if your nights are warm.

How MANY? You should always have at least a pair of poultry—chickens, or any other domesticated birds—and a trio (a cock and 2 hens, preferably) is better; they really get lonely and don't thrive without the companionship of another bird. But you'll probably start with more than that if you start with chicks. Most hatcheries won't ship fewer than 25 chicks at a time. That's because it requires at least that many to create enough body heat to keep the chicks warm enough during their journey from the hatchery to you. Chickens get along best if they were raised together, so it would simplify your life to start your intended flock all together and at the same time.

CHICKS FOR LAYING HENS: An average hen will lay 220 eggs per year. A typical family needs 2 laying hens per family member to supply them with plentiful eggs. So you'll order 25–50 chicks of a breed that lays well and has good food-egg production conversion efficiency. After the ninth edition of this book, Lane Morgan took me to task: "In these cholesterol-conscious days, that number seems high to me. We have done fine with one layer per person and have had enough extra eggs to supply a neighbor. With a 60-watt bulb on a timer, they lay all winter—not a lot but enough." She's right.

When placing your order, you'll also have to choose whether you want to buy all pullets, "straight run," or cockerels. Sometimes called "hatch run," straight run means mixed-sex chicks. If you buy specifically one sex or the other, pullets of good egg-laying breeds may cost you from 2-8 times as much as cockerels. But, if your main interest is in eggs, they'll be worth it. If you buy straight run, you've got to figure out for yourself when they get big enough what sex each is and treat them accordingly. (All, or most, of the cockerels would go into the meat count.) You'll get about 50 percent of each sex. You'll probably lose a few of the chicks you order to general hazards of the growing-up process. The remainder will become your flock of laying hens. So buy 50 straight-run chicks for every 20 laying hens you want. If you already have a flock of layers, the most economical practice is to replace around two-thirds of the poorest layers of them each year with new pullets. If you like keeping old friends around though, there's nothing in the rules to prevent you.

Pullet Chicks and Time of Year Hatched. If you buy pullet chicks in January, February, March, or April, they will mature while the days are still getting longer, and that will stimulate them to mature sexually and promptly commence laying. They will continue laying through winter and on to the end of the next summer. Or they may have a late molt that first year. Such pullet laying, though they'll at first lay smaller and fewer eggs than more mature birds, can compensate for the molting time of older birds. Pullets that come into full production at a relatively young age do have a statistically greater

tendency to prolapse (part of the tube comes out with the egg). But you'll probably never encounter that in a small flock. Usually they will be fine and finish up their growth normally, together with their egg-laying. Pullets that mature after the days have stopped getting longer will not commence laying until the following spring. These late-laying pullets do lay more eggs, bigger ones, and more fertile eggs with less chance of poor health because they have come to full maturity before commencing laying. In that case, you would order chicks to come in July.

CHICKS FOR MEAT: How many days a year do you want to eat chicken? Once a week? Order 50 quick-growing birds to be raised and processed for the freezer as soon as they reach the target weight. Twice a week? Make that 100 of them. Or, if you're not used to thinking of it by the bird or have a small family, 15 chickens per year per member of your family is a conservative estimate. Remember to include the cockerels from your laying stock (if you're getting straight run) in your count. Lane Morgan again: "A 10–12-week-old Cornish cross is big. Our family of 4 gets at least 2 meals out of it, which affects menu planning and butchering quotas."

If your interest is to get birds for roasting and frying, the broiler breeds are a shortcut to that end. Or try a straight run of a heavy breed. You may get offered a great bargain in cockerels (generally Leghorns). Don't jump at it unless you have lots of virtually free food to give them. It might be called something like "Super Bargains" or "Assorted Surplus." It takes so many more pounds of feed to grow a Leghorn to eating size than it does a broiler breed that the money you save on Leghorn cockerels at the outset is more than offset by the extra feeding expense. Such light-breed cockerels, if not bought by the uninformed, will end up in dog food or livestock food or ground up for fertilizer.

HATCHERY SEXING: Sex-classified chicks are sorted at the hatchery by vent-sexing specialists who work with a lighted magnifying glass strapped to their heads. Accuracy is not absolute—only about 90–95 percent—which is really very good, considering how little they have to base a decision on.

OF DEBEAKING AND DUBBING: The hatchery may offer to "debeak" and "dub" the birds for a small additional fee. I would decline, on the grounds that the expense to you and trauma to the bird is not necessary if you are going to raise them in a halfway humane manner. Nevertheless, here's the data on debeaking and dubbing.

Debeaking. Debeaked birds have about half of the top beak cut off and the end tip of the lower one. At the hatchery this is done with an electrical device that cuts and heat-cauterizes at the same time. You can debeak birds yourself with wire cutters, goat nail trimmers, pit-tooth nippers, or some such. The reason many big production operations have their chicks debeaked is because the natural end of a chick's top beak has a sharp down-curving extension with which they can peck other birds and with which they are said to fling some food out of the trough, causing waste. Objections to debeaking are that debeaked chicks are not as able to drink water and eat food, that they look mutilated and ugly, and that the beak is likely to grow out again anyway, requiring a repeat of the debeaking process. Most small holders, whose birds will not live with the extreme stress and crowding of huge commercial flocks, do not have their chicks debeaked.

Dubbing. "Dubbing" is cutting the bird's comb off close to the head. If it is done to older birds, both comb and wattles will be dubbed, but with mature birds considerable bleeding is a problem. The argument is that this prevents frozen combs. Since frozen combs occur only in severe cold and inadequate housing, and in certain large combed breeds, it really is a rare problem. Furthermore, it is mainly the cock who is at risk from a frozen comb,

because his comb stands up. Large-combed hens have a comb that folds over on itself and that helps keep it warm. Dubbing prevents the bird from naturally making enough Vitamin D from the sunlight to be independent of artificial rations—because they do that in their comb, their only unfeathered, unscaled part. Furthermore, if you don't like a large comb, choose one of the many breeds with a small, close-to-the-head "rose" comb. You can do the dubbing yourself using an ordinary sharp scissors to decomb baby chicks. (Dub older birds using tin snips or commercial dubbing shears.) Better yet—to dubbing—just say, "No."

ARRIVAL AND INSPECTION: The ordered birds, after hatching, are immediately shipped by whatever method will get them to the destination within 36–48 hours. Stay in touch with your postal carrier when you're expecting. You may get a phone call from the post office with a background of melodic cheeping. Open your parcel at once in the presence of a postal employee. Count all the live birds. If there are dead birds or if the number you received is not equal to the number you paid for, have the problem verified by the postal employee in writing to the hatchery immediately. They'll make good on it with replacement stock for you.

Places to Buy or Order Poultry

FEED-STORE CHICKS: At Kendrick, the feed store doesn't sell chicks, but apparently in many other places it does. Lane Morgan said, "You don't say much about buying chicks from the feed store, but that's what I do. Find out what day their birds will arrive, and make your purchase several days later. That way someone else, probably with better equipment, has fed and sheltered the babies through those first touchy days. I've gotten 2-week-old birds for the same price as newborns, which saves a lot in food and hassle. This is a specially good deal for turkeys, since they are expensive and accident prone."

MAIL-ORDER SOURCES, MIDWEST

Brooding Chicks

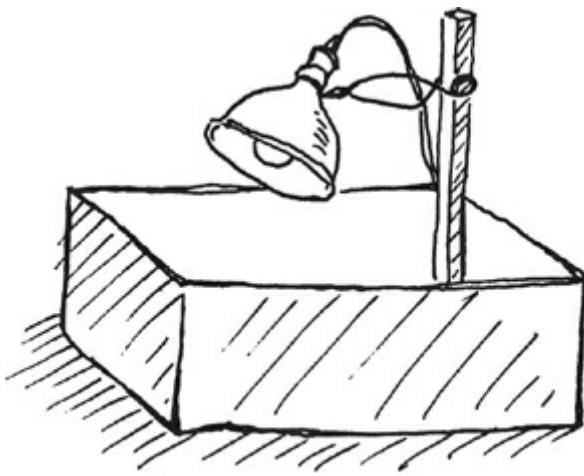

If you wait to order your young birds until local temperatures are quite stably warm—and if you have a draft-free place for the chicks—you can make do with a minimal source of heat their first week or so at night and that's it. This is the closest thing you could have to a non-brooding option. If you're going to raise chicks, you've got to learn at least a little about brooding them.
