INTRODUCTION TO BROODER STRUCTURES: Newborn chicks are tiny, fragile, and fluffy. The basic characteristics of an adequate brooder setup for your chicks are warm, dry, draft-free, clean and cleanable, escape-proof, safe from predators, and expandable. But it doesn't have to be expensive. Lane Morgan advised, "Distinguish between the ideal and good-enough reality. I've had good results with very funky setups, but then I never raise very many at a time." My mother started her chicks by the wood stove, then put them in the bathtub, then moved them to a shed. Many small growers start them in a basement or garage for 3–4 weeks, then finish them in a garage or shed. Big commercial growers may be brooding in narrow 100-foot brooder houses, one end blocked off by a plastic curtain, which is gradually moved down to make more room.

Whether you have borrowed chicks, bought them, or home-incubated them, your first concern, once they appear in your life, is to supply a mother's warmth. That's what brooders are all about. If your chicks are to be brooded in a special room or small building, it should be tightly constructed, insulated, without drafts, and able to hold a uniform temperature. And yet there should be ventilation enough to move moisture and waste gases out without losing too much heat. If you choose a room (or build a room) in an outbuilding that doesn't have electricity, you can use a heavy-duty extension cord to get power out there. If there is a risk of transmitting disease or parasites in your brooder house, give it a thorough cleaning about 2 weeks before the chicks arrive. Then let it air out a while; fresh, strong, cleaning agents can burn chicks' feet and eyes.

You can buy various styles: a battery brooder that is like a lidded box with a thermostat and heater, or a hover-type brooder that hangs from a ceiling in a brooder room and can handle large numbers of birds of any size. (The "hover" is a very large reflector around the bulb that keeps the heat focused down at the floor level.) Or you can make a homemade brooder. Or you can take the minimalist option.

Homemade Cardboard-Box Brooder. The typical homemade incubator involves a light with foil focuser, or heat lamp (or a box just the right distance from a heat source for the temperature you need if you have no electricity). If a bulb is used for heating, keep in mind that infrared is better than white-light because the birds are less likely to pick at each other under infrared. A cardboard box 30 inches square with high sides, situated in a room where the temperature doesn't drop below 65°F, with a 69-watt light bulb shining from overhead could handle 50 chicks to start. Make sure you're not using the type of bulb for indoor suntanning. Chicks can sunburn, too. And don't use a high-wattage bulb, like a 100-watt, because that could be too hot, and bright light in a brooder can result in excessive picking. Such a heat-box arrangement is your brooder.

Homemade Brooder

Covering a half to a third of the box top will also retain heat in the hover area. It's ideal to have a 6-by 8-foot space for 100 brooder chicks to allow some growing room.

Adding a "Room." You can add space for chicks who have started out in a cardboard box by cutting out one side of the box and taping on other boxes, as needed, to create additional "run" space, and to provide space in which to offer food and water. Where you cut away the side of the box, hang a piece of cloth. That helps keep heat in the hover box, and the chicks will run in and out of its warmth through the inch or two you leave between the bottom of the cloth partition and the bottom of the box, just as if they were running to and from the warmth of a hovering mother hen.

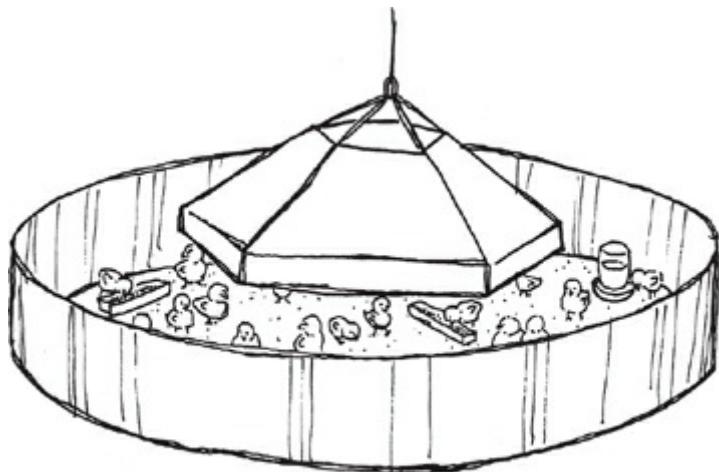

NOTE: Don't start a fire! This may happen if you have the light bulb too close to flammable litter. Check on this by putting your hand about 2 inches above the brooder floor under the heat. If your skin feels uncomfortably hot, lower the wattage or raise the light or some such. Don't completely cover a brooder. The heat will build up in there and can kill chicks or cause a fire. Overheated chicks will pant.

The Brooder House. A 250-watt infrared lamp, suspended about 18 inches above the floor level, will brood 75 chicks. Large brooder operations use a row of such bulbs with their individual hover areas. An advantage of using more than one bulb is that if one burns out, there is an alternative source of heat in the room. Inside this warm, draft-free building, arrange a little pen with sides made of whatever you want to rig up, and over it hang your heat light from the ceiling.

Chick Fencing. The chicks need boundaries to limit their area at first, help them find their food and water, and keep them from wandering very far from the source of heat. Naturally, you need chick fencing only if you're brooding in an otherwise open area. If you're brooding a small number of chicks in something like a box, it already has sides. Baby chicks can't be put behind chicken wire; they're so little they'll walk right through it. You can buy a wire with finer mesh if you want to use that in your brooder design. You can't use anything very low to fence them in. Baby chicks can fly over short obstacles by the time they're a week old. One good system is to cut cardboard boxes into long sections at least a foot high, then tape or staple the sections together in a circular shape. Make it sturdy enough so it can't possibly fall over. The circle is so the chicks won't have a corner to crowd in, which could result in smothered chicks if you have more than a few in there. And it prevents drafts and keeps them close to the warmth, which should be focused at the center of the circle. Start out with the fencing 3-4 feet out from the heat source. Day by day, as they grow in size and endurance, you can keep adjusting their "fencing" outwards. After a few weeks, your chicks have outgrown the need for fencing and you can

remove it and let them run all over their pen's area.

Commercial Brooders. You can purchase a ready-made brooder in the size that is practical for you. There is wonderful brooder equipment sold: infrared heat lamp brooders, or big commercial gas brooders and other nonelectric styles. The most common and inexpensive style for small-scale brooding is an infrared light with a metal reflector to focus the light and prevent ceiling condensation from dripping on the bulb and exploding it, and a heavy guard wire under the bulb so that if the light fell the bulb wouldn't touch litter and start a fire. Another common brooder-style is the hover-type brooder, which looks like a small flying saucer suspended from the brooder room ceiling on a chain. Larger brooders are equipped with thermostats to control their heating. The principle of a brooder's operation is simple, and directions will come with your equipment.

Hover-Type Brooder

Wood Stove Brooding. If you have no electricity or fossil fuels, you can still keep chicks warm. Put the chicks in a cardboard box. Put that cardboard box into a larger cardboard box that has a layer of hay, or some other similar insulating material along the bottom; insulate between the walls, too. Cover most of the top with a cloth or some other insulating layer (allow ventilation!). Put the box at a suitable distance from your source of heat. If that isn't warm enough—and in cold weather, or on cold nights—fill a large jar full of very hot water. Wrap it in a towel to prevent burns, and place in the center of the box. Refill with hot water as needed. Check your baby chicks often, including several times a night, until they have outgrown that necessity.

Solar Brooding. The concentration of America's poultry industry in Sun Belt states is partly because of chickens' dependence on warmth, more so than any other livestock. Solar poultry brooding research has been done by the government, and solar brooding has been found to be technically feasible. For details, see *Raising Chickens* by Cynthia Haynes (see "Poultry Books").

TEMPERATURE CONTROL: Turn on the brooder the day before its occupants are to arrive and check to see if you can get the desired temperature.

Checking the Brooder Temperature. To control the temperature in any style of brooder, first you have to know what it is. Use a drugstore human-type oral thermometer or a brooder thermometer (mail-order from poultry suppliers for about \$3). An oral thermometer is the most accurate sort. (Be sure and shake it down and wait long enough for the temperature to register fully.) Lay the thermometer just at the edge of the brooder's heat circle. When using a light for warmth, you adjust to get the right temperature by

raising or lowering the light until the temperature where the chicks are, around the edge of the heat circle, is 95°F (but not if you're raising broiler chicks; see next paragraph). (Or you can put a smaller bulb into your light-heat socket.) An experienced brooder knows by a wave of the hand if the temperature is about right. The first week or two, while the chicks are at their most fragile, it wouldn't hurt to get up 2 or 3 times a night and check on them.

Broiler chicks should start at 85°F. They don't tolerate heat as well as other breeds—need less brooding and more ventilation.

Chick Behavior and Estimating Temperature. Chick behavior, after they are one week old, is a very accurate indicator of temperature conditions in your brooder (before one week use a thermometer). If it isn't warm enough, they'll huddle directly under the heat source (or in a cold corner). Comfortable chicks make contented chirps. They may signal chilliness with a shrill peeping that says, "Mother, I need you!" If it's too hot in the heat circle under the lamp, they avoid it. They may also spread their wings and pant. Under ideal conditions the chicks will form a circle around the edge of the brooder heat. They won't be in the absolute center. If they are gathering at one side of the brooder, the problem may be a draft. Keep in mind that whenever a door opens, cold air may rush in at floor level—which is where the chicks are. And that draft can instantly and invisibly sweep away the accumulated heat from under the brooder.

Decreasing the Heat. As the chicks grow older, they need less warmth. You decrease the heat 5 degrees a week by raising the heat source, say, 2 inches per week, until it gets down around 70°F. With an electronic brooder, you lower the temperature by changing the setting of the thermostat. Thus their second week you'll have them at 90°F, their third at 85°F, their fourth at 80°F, their fifth at 75°F, and then their sixth at 70°F.

Weaning Completely from the Heat. After the 70°F point (they'll be 6 weeks old), your brooder temperature depends to a large extent on your outside weather conditions. Probably you'll start to turn their heat-source off during the day, but put it back on at night. At this stage, with warm weather outside, you won't be needing the brooder any more at all, except perhaps if the nights are cool. Chicks come out of the egg with fuzz, then gradually grow feathers. In prolonged heat, they actually feather out a little more slowly. Their first feathers are a transitional set; they grow the "real" ones later. Exactly when you turn their heat completely off depends on what the weather conditions outside are and how completely your birds have feathered out—probably a few weeks after you began to turn the heat off in the daytime; it's a judgment call. But I'm getting ahead of the story here. Let's go back to what those baby chicks need.

CHICKS AND LIGHT: For the first week it will help your chicks to be in a lighted area 24 hours a day. It's during this period that they learn where the food, water, and warmth areas are. But make the night light only about 15 watts, since bright lights for brooding tend to create a pecking problem (they are also an inefficient and expensive heat source). Keeping chicks in a dimly lit place and using only small wattage green or red light bulbs in brooders will relieve a pecking problem. Chicks who have been raised under a brooder light, white or infrared, have to be gradually and gently introduced to true darkness when the time comes. They've been accustomed to associating light with warmth and safety, and they may be frightened when the light is gone and pile up and smother one another.

OF FLOORING, CHICK LITTER, AND SPRADDLE LEGS: You don't want the chicks to eat their own droppings. And you don't want them to eat the litter. And you don't want them to slip on their flooring. In the first few days of a chick's life, it is quite vulnerable to developing

spraddle legs from slippery flooring. Long-legged varieties are most susceptible. Those early days their leg cartilage has not yet hardened and can easily be gotten out of position. Straw and flat newspaper are the slipperiest surfaces and the most likely to cause spraddle legs; their legs begin to turn sideways at the joint until finally they are turning straight out from each side. There is no cure for spraddle legs.

Safe Flooring. The shipping pads in the bottom of chick mail-order boxes are designed to prevent spraddle legs. For the first week or so you'll want to come up with your own system. Thus, a good covering is clean burlap sacking. Put clean sacking down daily. Or clean rags. (If you wash these, don't load them with bleach. The bleach could interact with material in the feces and result in poisonous gases.) If you are using a battery brooder with a wire bottom and the chicks are so small their legs are slipping through, cover the floor of it with your clean rags for the time being, changing it as needed for sanitation. If you use rags, make sure there are no loose threads that could get wound around a chick and kill or cripple it.

Newspaper Floor Covering. Later, once your chicks have definitely learned what is and isn't food, and their legs have grown strong, you may want to evolve to a thick layer of newspapers. This helps prevent them from eating feces since every day you roll up and take away as many layers of the paper as necessary to make their flooring clean and dry again. Don't use any colored pages as they are loaded with lead. Don't let the newspapers get wet and slippery. If you put a layer of shredded newspaper on top of the flat newspaper it will be more absorbent and will eliminate the slippery factor. Just tear the newspaper in strips, stir it up, and lay it down.

NOTE: Don't ever use newspapers as floor covering for ducklings, goslings, or turkey pouls.

Loose Litter: Another option is loose litter, about 2 inches deep. It should be an organic, absorbent material—not straw, which is not absorbent. Don't use sawdust or sand as litter. Sometimes the birds will eat too much of it instead of their food and get an impacted crop and/or gizzard and starve. Sawdust also can become wet and moldy and cause disease. Hay or wood shavings, 2 or 3 inches deep, are good. The basic rule is to use litter pieces that are too big to fit into a chick's mouth—that way you're safe from them eating it—unless it's something utterly harmless, like potting soil, and that actually does work fine. If you use loose litter, turn it daily and remove wet areas. Small chicks are at risk from diarrhea organisms that thrive in wet litter. Large ones that cannot roost and must bed down in their litter (Cornish crosses) especially need it to be kept dry, clean, and fluffy to prevent them from developing dirty breast feathers and breast skin irritations. Once the chicks are 4 weeks old you can keep them safely on almost anything. *Note: Some disinfectant and fragrance sprays will kill chicks.*

Chick Dust. If your initial brooder arrangement is inside your home, soon you'll be wanting to move them elsewhere, for the sake of cleanliness and your health. Baby chicks create a powdery, disagreeable dust that gets everywhere in their environment and is difficult to live with and to keep up with. Small traces of bird protein exit with the bowels. The droppings dry to a powder. Those droppings also tend to contain a microorganism that can cause problems for humans and other creatures who breathe it. Also, chicks molt twice while they are growing up. The first molt is their loss of the fine down they wore at hatching. Shed down, dried droppings, and chick feed all contribute to the chick dust. People who work with birds a lot are subject to hypersensitivity pneumonitis (an allergic reaction in the lungs), also and variously known as bird fancier's, pigeon breeder's, breeder's, or handler's lung disease. Bird feces may also carry an irritating microscopic life form that if it dries, turns to dust, and becomes airborne, can put long-time handlers at

higher risk for cancer and any lung disease. This is true of all birds, from parakeets and parrots on; in fact, this latter problem is associated with birds that are kept in the house rather than with barnyard fowl.

NOTE: If you are at all concerned about this possibility or bothered by the chick dust, don't keep birds in your house, and please do wear a dust mask while in the same room with and working with your chicks or adult birds.

SICK AND DEAD BABY CHICKS: It's important to observe your young poultry closely every day. Professionals expect a 2–3 percent mortality rate for chicks. If you find a sick one, separate it from the rest and try TLC (tender, loving care), isolation, and warmth in its own private little hospital box. If you find a dead one, remove it from the pen and bury or burn the body.

HOUSING FOR THE OLDER CHICK: Brooder chicks grow rapidly, and as they grow they require more space. So your chicks will likely go through a series of different brooder arrangements. One common plan is 3-step housing: full-scale brooding for day-old to 6-week-old chicks (6-week-old chicks need twice the space day-olds do); less protective brooding arrangements from 6 weeks to 2 months; then a final shift to your regular chicken house for the pullets. The precise transition ages can vary a lot with your own particular situation. One option is to use a portable coop as a transition home for young birds that have outgrown the brooder, but are not yet ready for the chicken house. In experimental new housing arrangements, you can tell if they're chilled by watching to see if they huddle. If they are acting cold, you need to change something to provide more heat, like with a light bulb. Broilers will go directly from the transition housing to your deep freeze. They'll be ready at 7–10 weeks—whenever they reach 3–4 lb. (the exact weight goal and length of time to get there depends on your breed of bird and its diet). That will probably take about 8 weeks on commercial feed, a few weeks longer on home-devised diet.

Roosting Chicks. Chickens have the urge to roost from age 5 weeks on, and will hop up on a perch to sleep if it's available. Roosts (a long pole works well) 6 inches apart with about a 4-inch space for each bird will be suitable. Their first perch can be as high as a foot. They can hop farther as they get older. Roosts slanted from floor to wall like a ladder help them gradually make the grade. Some growers don't provide broilers with roosts because they say some birds scrape those big breasts on the roosts. They let them sleep on a floor. But Lane Morgan disagrees: "Even my Cornish stupids will roost if I give them a low enough roost. I encourage their roosting because they stay cleaner and it conserves space in their house at night."

Moving into the Chicken House. It's best to delay the chicks' joining of the regular flock until they're big enough that getting picked on won't be a risk to life and limb. Somewhere between 10 and 12 weeks after hatching, you can put them out with your other chickens, depending on their size, the weather, and how well insulated or warmed your chicken house is. Move pullets into the hen house before they begin to lay to prevent throwing them out of the mood, as any major change is likely to do that to chickens. Pullets that are moved after laying has commenced may stop laying and go into a molt. To move larger birds from one housing to another, do so at night, placing them on the roosts in their new quarters so they'll have slept there a night before they go out the door in the morning. That helps them know where home is. If they're still not sure the next night, shoo them in there again, and shut them in for the night. If they're reluctant to go in, let them get a little hungry, then feed them in there.

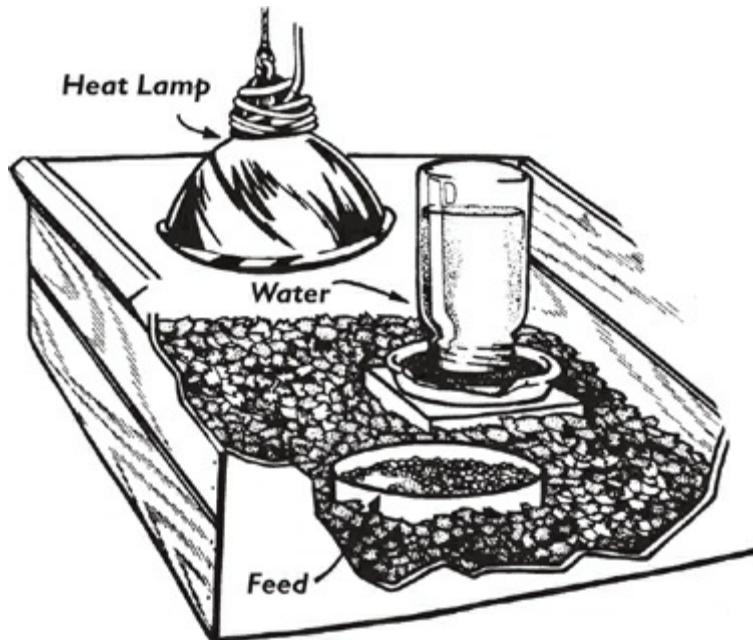

CHICK AGE AND APPEARANCE: When the chicks are a little more than 4 weeks and a few days old, you'll be able to distinguish the cockerels, who have grown pink combs and clearly visible wattles, from the pullets, who grow and color their decorations slightly later. The final adult plumage starts to grow when the bird is 12 weeks old and will be finished coming in by 16 weeks. To make a pet out of your bird, this 12–16-week period is a good time to carry and pet it frequently. Be gentle, and the fowl will learn to trust you and be your friend.

Chick Water

WATERER TYPES: To make a homemade chick waterer, fill a quart jar with water. Put a shallow bowl upside down over the open mouth of it like a cover. The bowl's diameter should be only a little more than that of the jar top. Quickly turn the whole thing upside down outside the chick pen. The jar will slop for a moment. Slip a match or toothpick under one edge of the jar to keep the water flowing as the chicks need it. Set it down in the chick pen like that. There are also well-designed commercial waterers (and feeders) available mail-order from poultry specialists or from your local feed store. You need a minimum of two 1-gal. waterers per 100 chicks. By the time they're a month old, you'd find it convenient to be using a 5-gal. waterer per 100 chicks. Lane Morgan advised me, "You can buy a plastic base that works with a quart jar. If you use commercial plastic gallon waterers, I'd say get the kind with prongs and slots, not the kind where the top screws all the way onto the base. The screw kind never screws on right."

TEACH THEM HOW TO DRINK: Give mail-order chicks food and water immediately after they arrive. Water first—it's most important—then feed. (Unless the chicks arrive to you chilled, in which case warmth is the first priority.) At first your chicks may not realize what to do with the water. When you move them from the mail-order carton into their brooder house arrangement is a good time to teach drinking. Gently and briefly dip their beaks into the water, one by one. They'll quickly catch on. Then others will imitate the ones you showed how. They dip their beaks in, then tilt their heads back and slightly open their beaks to swallow. Separate the ones who have learned how from the ones who have yet to learn and give the slow learners another dip. If the chicks arrived to you chilled, warm them and then serve them lukewarm water with just a little sugar dissolved in it.

KEEP THEIR WATER CLEAN: Chicks drink a lot (about 2 ½ times as much water by volume as the food they consume), so make sure that drinking water is always available to them, and that their water supply is kept clean. To do that you'll need to clean and change their water supply at least a couple of times a day, and disinfect the containers once a week in some hot and soapy water or—most powerfully—by boiling them. Put their water supply as far as possible from their food supply so they don't get their feet gummed up with spilled chick food that has gotten damp and stuck to them. Change the newspapers lining the bottom of their housing once or even twice a day to keep their floor dry from water spills and droppings. Be careful you don't spill water into the chick pen, because eating wet food or droppings at this age can make them sick. If they do get into wet food and it sticks onto their feet, or if droppings cling to their rear ends, you need to clean it off very gently. Apply Vaseline where you cleaned them and keep an eye on those chicks after returning them to make sure they don't get into difficulties again.

WATER SUPPLEMENTS: You can buy vitamin and electrolyte supplements to add to your chick water. You don't have to have these, but they don't hurt and may help. There is a special home-grown supplement for the fast-growing broiler chicks, which is helpful to them. The broilers need extra Vitamin D₃ to avoid rickets and crippled legs because of their extremely speedy growth. Cod liver oil added to their drinking water from day 5 to about 4 weeks does the job. Just pour a few drops on the surface of their drinking water daily. You'll need about 4 oz. to supply 25 chicks for that 3-week period. Don't give before day 5 because that might cause diarrhea. After that, if you're giving too much and they get looser bowels, cut back. Or make sure they get lots of direct sunshine.

CHICK WATER DON'TS

1. Don't give water in containers with edges over an inch high.
2. Don't use a container deep enough that a chick could fall in and drown. (If they can, they will.)
3. Don't use a container that chicks could tilt or tip over by jumping up and perching on the edge.
4. Don't have an arrangement that allows any chick droppings to get into the water.
5. Don't give ice-cold water. (Serve it lukewarm, baby-bottle temperature.)
6. Don't let chick drinking water run out.
7. Don't put the water (or food) directly under the heat lamp.

Chick Food

If you have hatched your own chicks, rather than bought them, they won't be hungry right away and shouldn't be fed prematurely. Once you see them start pecking at their litter or flooring, it's time to feed them. (They should be watered before they are fed.) Have feed ready when you put mail-order chicks into their first brooder. And have their litter (if you are using organic litter) covered with newspapers, which are covered with cloth the first 4 days—until they've learned what's food. Mail-order chicks may have been hatched 3 days when they arrive and be ravenously hungry and start eating litter in their instinctive, but uninformed, search for nourishment—which at best would cause them indigestion and at worst, death. Young chicks instinctively peck at anything that is at the same level they're

standing on. So, for the first few days or week, feed them on paper plates, pieces of cardboard, newspapers, or in the bottom part of egg cases or small box tops to maximize access to proper feed and encourage them to learn how pleasant eating the right stuff is.

Once they learn to eat food, you can feed them in tuna-size cans or jar lids, or shift them to commercially made trough feeders or other suitable containers. Don't place feeders right under the heat center. Instead, place them like spokes on a wheel, with their main portion out of the central heat area and waterers between them. Plan one inch of feeding space per chick. But by the time they're a month old they'll be needing 3 inches of feeding space per bird, so you'll need double the amount of feeder length they required at the beginning. At any time, you want an arrangement they can get at, but not walk in. And one that won't allow them to waste feed by scratching it out of the container. They also have a tendency to toss it out with their beaks. It will help in that regard if you don't fill their troughs over half full. Research has shown that any poultry, given full-to-the-brim feeders, will waste about $\frac{1}{3}$ of the contents! If their feeders are only $\frac{3}{4}$ full, waste drops to about 1/10 of the contents. At $\frac{1}{2}$ full, waste is down to more like 1/20. They should clean out one batch before you give them another, so stale feed won't accumulate at the bottom of their feeder. The birds will be put off by the presence of stale feed and won't eat as much, and it could end up causing them diarrhea. Keep feed before them virtually all the time, for at least the first 6 weeks and preferably longer. Check the food supply several times a day.

Diet Options: When feeding chicks you have 3 choices. You can use commercial feed all the way; feed commercial chick starter at the beginning, phasing into a home-devised diet; or use home-formulated feed all the way. Chickens also need pebbles (grit) to help their gizzards digest food. It's not necessary at this time to feed grit with commercial mash; chickens of any age being fed an all-mash ration can make it without grit. If the feed includes some coarse material or is a home-devised diet, add a very little sand sprinkled over the top. Or you can buy a product called "chick grit." You'll have to increase the size of their grit as they get older. Warning: Consuming too much grit and/or litter will impact the chick crop and gizzard, causing the chick to starve.

Commercial Chick Feed. Whether there is something intrinsically evil about buying feed ready-mixed is a matter of opinion. It's true you can never be completely sure of what's in there. The feed industry considers listing complete amounts of ingredients to be giving away trade formulas, and it doesn't do so. The feed's true "protein" could be from ground cull baby chicks, feathers, slaughterhouse discarded poultry heads and feet, and so forth. Commercial feeds must be bought in bulk for greatest economy. Industry sources say they shouldn't be stored for more than 3 weeks, but in the real world people store them longer. If you can buy your commercial feed only in 100-lb. quantities, as is frequently true, and you have only a few young birds, you may have them ready for grower ration when you still have half a sack of starter left. The practical wisdom in that situation is to keep on feeding the starter until the sack is empty, and then move them to growers ration. Starter rations are actually the highest in protein of all the types.

Commercial feed comes in 3 sizes: mash, crumbles, and pellet. Chicks tend to scatter and waste the mash, and it's so powdery it's difficult for them to swallow. The pellets are too large for them, so crumbles are best. (You can feed pellets if you mash them.) Feed all they'll eat. Most people have the best success using the commercial starter. Chicks will eat heartily and grow fast. You can continue feeding your chickens with commercial products, moving from the "chick starter," when they are 5 or 6 weeks old, to "growing mash," and from that to the "laying mash," according to directions on the package or feed-store

advice. When you move the chicks from one ration to another, take a week to do it, thus making the change gradually: 25 percent new feed at first, phasing into 50 percent and, finally, 75 percent. There is a particular formula of high-protein feed for the fast-growing broilers. Don't feed laying mash too early to your pullets; feed it from about 5 months on.

Starter-Feed Antibiotic. The starter feed contains antibiotic. Chick starter feeds are available at 2 levels of antibiotic content: low and high. If you are able to get prepared chick feed that doesn't have any antibiotic at all in it, it would be less expensive. That antibiotic and expense are 2 reasons why many chicken-owners wish to shift their birds to home-based feed quickly. You can shift any time. Lane Morgan uses antibiotic-laced feed only the first week, then shifts. By then the chicks have more natural resistance to infection. The longer you use the medicated chick starter feed, the more you risk birds becoming antibiotic-dependent and unable to be healthy on their own. "Growing" and "finishing" commercial feeds do not ordinarily contain antibiotics. To be sure, read the feed bag label. Your bird should be off antibiotics for at least 5 days before slaughter, and preferably more.

From Commercial Feed to a Home-Based Diet. Anywhere from the chicks' fourth day on, begin to offer fresh, finely chopped greens as part of their diet, along with finely cracked grain. Barley, wheat, and oats are good. The plain grain should be no more than 5 percent of the diet at first, but you can gradually increase it, and increase the size of the grain bits. Supply sand for grit, then shift to a larger size grit when they are about 8 weeks old. By this age also you can have them completely shifted to the diet described under "protein" in the chicken-food section that comes in a few pages.

Home-Grown Diet All the Way. A young chick eats only a thimbleful of food per day, and that small quantity must supply all its different and complex dietary requirements. Supply a menu made up of 2 parts finely ground wheat, corn (not too much corn), and oats, combined; one part protein—such as fish meal, meat meal, a daily small portion of canned cat food, chopped hard-boiled or scrambled eggs, clabbered milk, yogurt, cottage cheese, or worms, bugs, and grubs (a combination of these is best of all; from variety comes nutritional adequacy); and one part a variety of greens: alfalfa meal, alfalfa leaves, or fresh green stuff—comfrey, chard, clover, lettuce, dandelion, cress, chives, grass, spinach, weeds (finely chopped). Other good diet components for your chicks could be wheat germ, sunflower seeds, powdered seaweed, powdered milk, and linseed meal. Their diet should be about 20 percent protein. To collect worms and bugs for them, lay boards on the ground in your garden, or wherever the harvesting is best, at evening. In the morning pick them up and serve what's alive and gathered underneath them to the chicks. Never mind how disgusting it looks to you. The chicks will love it.

Their necessary Vitamin A comes in the green stuff. They'll also need ground eggshells and/or oyster shell (unless there is another source of calcium in their diet), fine grit or sand for their gizzards, and a sprinkle of salt. As they grow they'll need coarser grit, and can handle coarser grain. After their fourth week, they can eat their grain whole. If they aren't getting any sunshine from which to manufacture Vitamin D, they'll have to have cod-liver oil, or some other form of D. You might ask how this chick diet differs from that suggested for mature birds: it doesn't—except that chicks need proportionately a little more protein and calcium, and they need their grain broken up to start with. (A mother hen breaks it up for them.)

When your weather is warm and sunny, you can let them out to pasture on clean ground after the sun has dried all the dew off the grass—briefly, at first, longer as they get older. Small chicks tire easily and need to rest and get warmed again. Watch carefully as a

mother hen would that they don't get chilled or become a meal to a bird of prey or a domestic cat. And perhaps provide a box on its side for shade and coziness.

But keep in mind that chickens, like any other critters, can get spoiled and picky as to what they will and won't eat.

CHICK HEALTH PROBLEMS

Chick Diarrhea, or Coccidiosis. This is a widespread problem for young poultry but is much less common in home flocks than in commercial ones. Coccidiosis is caused by a protozoan parasite that birds pick up from feces. There are many varieties of *Coccidia*, some of which make birds sick and some of which don't. Most varieties trouble only one type of bird and not the others. Symptoms of a serious attack are blood in the droppings and an obviously sick bird. To prevent it: avoid overcrowding, feed a balanced diet, keep food available. Commercial, medicated feeds contain medicine at a low level to permit the birds to develop immunity, or at a high level to control the disease completely. In the absence of such medication, manage your chicks in such a way as to minimize the possibility that they will eat litter or droppings. Refill water containers more than once a day, and sterilize the water containers once a week. Keep the litter dry; remove any portions that have gotten wet. Coccidiosis is more likely to strike in damp, chilly weather, so keep young birds dry and warm.

A home remedy for coccidiosis is to add 1 T. plain vinegar per quart drinking water for 3 days or until the chick droppings look normal again. (Don't give cod liver oil while giving vinegar.) Conspicuously sick or weak chicks that are being persecuted by stronger siblings should be separated into a special hospital-brooder box until they can get their strength back. Dead chicks should be removed from the pen immediately and burned or disposed of in a way that couldn't spread disease to the others.

Pasted Vent. This can be caused by chilling when the chicks are being shipped, although the pasted vent occurs a few days later. You'll notice a chick whose hind end is glopped up with droppings stuck to the vent area. It needs to be cleaned off gently. You can pick it off dry, but it is easier to hold the chick's hind end under lukewarm running water and gently massage loose the dried feces. The fluff around the vent will pull away too, which is a bit hard on the chick, but that can't be helped. After the cleaning, apply Vaseline to the area. Dry the chick's down with a hair-dryer or some such before you put it back with the others.

Picking at Each Other. Penny Anderson of Aitkin, MN, advises me: "If you have chicks picking at each other, cover the picked area thickly with Vaseline so when they pick they get a beak full of goo. Easiest to just put Vaseline on all the chicks' tails when the feathers are starting to come out. I've only had this trouble a couple of times. Haven't figured out why since they have always had a big pen, plenty of light, etc."

Hatching Eggs in an Incubator

The most productive modern chicken breeds (in terms of meat and eggs) are carefully selected genetic strains that won't go broody. So if you want more of them, you have to buy them again from the commercial hatchery—or incubate their eggs yourself. Home incubation is actually a practical option, especially with the inexpensive, but functional, small incubators available for sale. Even the smallest size, which will hold about a dozen eggs, can keep them adequately warm, humidified, and turning. Nevertheless, you're bound to have some eggs that don't hatch. Fifty percent is a poor hatch rate, 70 percent about average, and 85–90 percent is very good. If you have an incubator and can buy fertile eggs locally for reasonable prices, it's probably cheaper than mail-ordering.

OF EGGS AND HEREDITY: Look carefully to see whether one end of the egg is pointy or round. Pointy-ended eggs make roasters, says Ellinor Nurnberg of Ontario, Canada. Round-ended ones make hens. This method is 90% accurate. If you collect eggs from hybrids and crosses the offspring will not be like the parents. Raise purebred chickens of a kind you like. Then you know what you have, and you know what you're going to get. To raise crosses you'd have to do your own crossing by finding out what 2 kinds of chickens result in the cross you want, and then breed them. Whatever roosters, hens, and eggs you choose, choose the best: birds that conform to their established breed characteristics for fancy breeds, and birds that carry desirable traits of egg-laying, egg size, good health for egg-meat production breeds. If you're breeding from birds who are in their first laying season ever, wait to begin storing eggs for incubation until the hens have been laying several weeks. The first eggs tend to be smaller and less uniform in size, with lower fertility rates.

GETTING HATCHABLE EGGS

Diet. For prime hatchability of your eggs be sure to feed your breeding birds a diet high in protein with plenty of greens and comparatively little grain. The bird, if offered excessive grain, tends to fill up on it, like a kid with junk food, when what she really needs are the protein and greens. Laying mash is not a suitable feed for birds you want to hatch chicks from, but there is a special commercial feed for them called "breeder's ration." Free-running birds will do fine, or you can offer the home-based diet (see "Protein"). Both the roosters and hens involved also need to be fed regularly and generously since a rooster's reaction to loss of body weight from short rations can be sterility, and a hen's reaction is to quit laying for a long time. In general, the more eggs a hen is laying, the more likely her eggs are to be good hatchers, because she's in such prime health. The lighter the yolk, the less hatchable your eggs will tend to be.

Rooster. If you don't have a rooster among your chickens, none of the eggs will hatch; you need that daddy chicken for fertile eggs. This is elementary birds-and-bees data, but I've met city folks who've never stopped to consider such details. Furthermore, the younger the rooster, the more likely his eggs will be fertile. (And the younger the hen, the more likely her eggs will be fertile.) A young light-breed rooster can fertilize a harem of 10–20 hens, while an old rooster can keep up with only 5–10 hens. A heavy-breed rooster, even a young one, shouldn't be assigned more than 8–12 hens. A bantam rooster is best matched with a harem of from 2–5 hens. Getting the right number of roosters for your hens takes delicate guesswork. Too many roosters causes the egg-fertility rate to go down, because then they spend more time fighting with each other than they do courting—or the egg production can go down because the hens are getting hassled too much. If there is only 1 hen per rooster, she can end up in really bad shape from too much mounting. And your hen must be compatible with your rooster, because some hens, to some roosters, will say "No."

A rooster with a frozen comb won't be sexually active until his comb heals up, which can take several weeks. A molting rooster isn't interested either. Birds in batteries basically don't reproduce naturally, because of the low ceiling. You have to raise the roof, or artificially inseminate (see "Artificial Insemination" under "Turkeys").

For a fertile egg the hen needs to have been inseminated no sooner than 24 hours before laying, and no later than 2 to 3 weeks. There is no way to look at an egg and know if that egg's mother has had a passionate embrace from a rooster in the required time frame. You'd just have to hope for the best and proceed. Once incubation has begun you can tell if the egg is fertile by candling it (see "Candling the Eggs"). But if you have

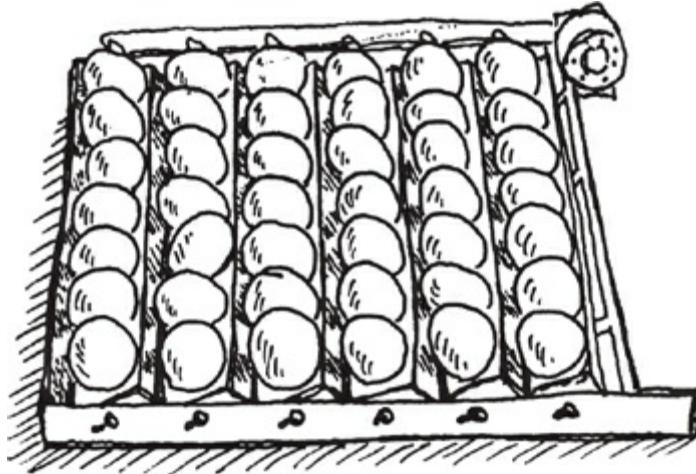

actually seen the rooster mounting hens, you can start collecting eggs. A rooster has no penis. He breeds by simply pressing his vent to the hen's and extruding semen into it.

Daylight. No matter what the age of your rooster, he will be more fertile between March and May than he is during the other months of the year. More daylight causes his semen output to increase. Commercial egg-laying breeds may lay year-round; more natural breeds begin laying in February and will have fertilized eggs by March or April. That's because it takes the rooster longer to get going and become fertile than it does the hen. You can cause a rooster to get fertile earlier by extending his hours of light to 14 hours per day and warming him to 60°F. Five weeks after that change, approximately, he will get in the mood. It takes the hen 2 or 3 weeks after the days get long enough to have fertile eggs.

Handling and Labeling Eggs-in-Waiting. Gather them before night, if your nights are chilly, to keep them from possibly harmful low temperatures. Handle the eggs very gently and keep them either on their side or with the large end up—never with the small end up as that may cause the air cell located in the large end to rupture. Choose normal shaped, normal sized, uncracked ones. Don't wash eggs-in-waiting. The water could carry the very bacteria you're trying to avoid through the shell's pores and into the egg. If something on the egg shell is a real problem, buff it off gently. Yet very dirty eggs have been washed by desperate owners (less than 3 minutes in water 110-115°F), and the chicks lived to peep the tale. If you are incubating eggs from a variety of poultry breeds, it may help you to write on each egg—in pencil—a code designation for the breed. Write on the small end of the egg, because the large end gets broken away in the hatching process. You might write, for example, "M" for mallard and "L" for Leghorn. If you are keeping track of different genetic lines of the same breed you can give each pen a different number. In that case, you might have L1, L2, and L3, for eggs from 3 different pens of Leghorns.

Storing Eggs-in-Waiting. Placing the eggs in egg cartons works nicely, at a temperature of 45–60°F, in a place that has at least reasonable humidity. That temperature won't kill the embryo, but it will keep it from commencing development. Don't store them in an air-conditioned room. Air conditioning removes moisture, which is bad for the eggs. The temperature of your household refrigerator is probably lower than desirable and would reduce hatchability. Don't let the eggs that you plan to incubate go below 40°F, which will kill the embryo, or above 80°F, which would cause a slow growth of the embryo that weakens and eventually kills it. Actually, the embryo starts to develop at any temperature above 68°F, but the growth rate becomes a major risk above 80°F. Eggs that are going to be incubated should be turned or tipped 3 times a day. The easy way to accomplish that is by raising one end of the egg carton. Then, next time, raise the other end. Start incubating eggs from 1 to 14 days after laying, better in the first week than in the second.

INCUBATOR TYPES: You can order incubating equipment to handle almost any number of eggs—from a dozen to 75,000. Most incubators are electric, but there are nonelectric (kerosene, oil) models available. Each incubator comes supplied with detailed directions, and they'll work best if you follow those instructions very carefully. If you have a new incubator, set it up and level it. Run it a couple days to be certain it's working as it should. Test to see if it's keeping the temperature you want. Make sure the moisture pan has water. Before using an incubator that has been used before, clean it carefully. Or you can make a homemade incubator.

Drawer from Incubator

Homemade Incubator. The proper brooding temperature for almost all varieties of eggs is 99.75°F (which is just exactly the temperature under a mama hen). The most primitive homemade incubator is something like a bucket with eggs in it. The eggs are wrapped in a cloth and a light bulb is suspended over the top. This is the least likely to work, and yet I know of people who have hatched chicks with exactly such an arrangement. What you're striving toward is a heat source that can keep about a 2-or 3-square-foot area at approximately that 99.75°F. You can make a better box-style incubator out of a Styrofoam cooler, or a cardboard or plywood box. If you make the top side of glass, you'll be able to watch the hatching. A plywood incubator with a 40-watt light bulb should be about 11 inches high, 11 inches wide, and 16 inches long, with a hinged front side for a door. With 3/8-inch ventilation holes on each side—near the top of 2 sides, near the bottom of the other two—you get a natural air circulation inside your incubator. The eggs should be placed in a tray made of wire mesh fastened to a wooden frame 2 inches off the bottom. A water pan should be placed on the bottom of the incubator underneath the eggs. To test the temperature of the incubator lay a human oral thermometer among the eggs. It's all quite adjustable: the wattage of your bulb, the material and size of the box—so long as you end up with the temperature you want in the place you want it.

Commercial Incubators. If you're buying an incubator, you must first choose between a still-air incubator and a circulated-air incubator. The still-air incubators are the smallest—with capacities of about 1,100 eggs—and least expensive. Still-air incubators depend on gravity to move air through vents on the top and bottom of the incubator. The operating temperature of a still-air incubator is always set a little higher than that of a forced-draft machine—101.5–102.75°F, depending on the variety of egg. (If you don't know the recommended temperature, go with 102°F, and you'll probably be fine.) You have to be home every day at certain times to turn the eggs. The cheapest, smallest models of all do not have a thermostat and are poorly insulated. Just as with incubating with a light bulb, this is not as cost-efficient or reliable as using more sophisticated equipment. The Hova Bator Incubators are well thought of for hatching small batches of eggs. Incubators that turn the eggs for you generally use either a mechanism that rolls the eggs or actually physically turns them. Avoid the "rollers" because eggs tend to get cracked.

Circulated or "forced" air incubators are used by large commercial hatcheries. They have fans that move air around the eggs. They cost more but give you better hatching percentages because of the improved control of the incubator environment and because the eggs are turned in a tray rather than rolled. With automatic egg-turning you are a lot freer to be away from home. Big models can hatch very large quantities of eggs.

Humidaire incubators are expensive but give high-quality service. If you are planning to hatch very small eggs such as quail, ask your supplier for special advice on your incubator model.

HUMIDITY: During incubation eggs lose some weight due to evaporation of the contents. The presence of humidity helps control that loss. Humidity helps your eggs to hatch. Too much humidity, however, results in a chick too large to work its way out of the shell. Too little humidity results in a chick that is glued in there.

Measuring Humidity. Measuring incubator humidity is done with a wet-bulb thermometer. "Relative humidity" is determined by comparing the difference between the dry-bulb temperature reading and the wet-bulb reading. If the recommended relative humidity is 62 percent (correct for large turkey eggs during the first 25 days), then at a dry bulb reading of 99.5°F, the wet-bulb reading will be 87.5°F. If you have a hygrometer you can measure the humidity in your incubator air. You're aiming for a wet-bulb reading of 85–87°F the first 18 days of incubation (60 percent relative humidity), and 89–90°F the last 3 days (70 percent relative humidity).

Increasing Humidity. Incubator operators generally try to raise the humidity the last few days of the process. If the relative humidity wanted is 70 percent (correct for the last 3 days of turkey eggs) then the machine will be set at 99.5°F, and you'll be looking for a wet-bulb reading of about 90°F. Humidity in still-air incubators usually comes from an evaporation pan in the bottom of the machine. A soaked sponge sitting in the pan can increase humidity. If the weather is dry or the incubator is opened frequently you can supplement humidity by using a sprayer that emits a fine lukewarm water mist. Humidity is added by increasing the amount of evaporation area or by changing the ventilation; reducing the ventilation increases the humidity, and, in turn, increasing the ventilation decreases the humidity.

INCUBATOR TEMPERATURE: The room in which you keep an incubator should be well-ventilated and at a temperature of around 60–70°F. Incubators (and brooders) are engineered to raise normal room temperature of about 70°F up to the required temperature, and they don't work properly in an unheated building and/or in cold weather. So don't let your incubator sit in the sunshine, or near a heater, near a window, or in a draft because any of those might be more than the heat control system can handle. Don't let the eggs ever get over 103°F. That would probably kill them. A forced-air incubator should be set for 99.5°F; a still-air model is set for 102°F.

ADJUSTING TEMPERATURE SETTING: Each variety of bird has a specific number of days needed to hatch its eggs. If your eggs hatch in fewer than that number of days, it suggests that the incubator temperature was set a little too high. Lower that setting 0.5–1°F and incubate another batch of that variety of egg. On the other hand, if your eggs took longer than the predicted number of days, then you should raise the incubator temperature the same amount. After several trial runs of this sort, you'll know the best temperature to set your incubator at in your particular environment.

Cooling. Most incubators are modeled on the original hen, and they cool the eggs 15 minutes a day—for 5 minutes at a time—which may or may not help. Circulated-air incubators are equipped with cooling systems. So if the heat system gets turned off for a while, don't panic. Maybe it was like a mother hen leaving the eggs once a day to get food and water. Quite likely the eggs will be all right, though maybe a day later in hatching. If the electricity should go off for a long time while you're incubating, try to

keep the eggs warm anyway, by enclosing the incubator in a down sleeping bag, or moving it near an alternative heat source.

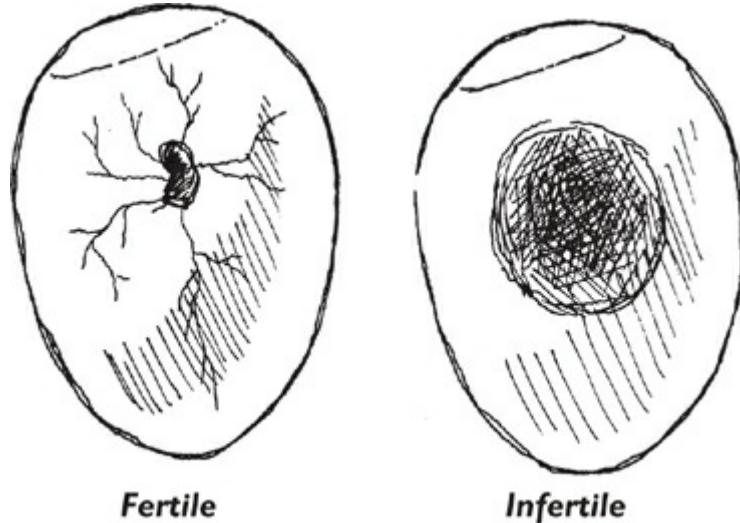

TURNING THE EGG: Faithful, frequent turning is essential to the embryo's proper development. A hen on the nest instinctively does that too. Not turning the egg regularly can result in a crippled or deformed chick, the death of the embryo, or a chick that can't hatch out properly (this is because turning prevents the embryo from sticking to the surrounding membrane, which can happen if it stays in one position too long).

1. Turn the egg from a fourth to halfway around at least 3 or 5 times a day. This helps the network of fine blood vessels through which an embryo breathes to finish developing. Some incubators automatically turn the eggs once an hour.
2. The odd number of turns will ensure that the eggs will be on opposite "sides" during the long nights, rather than always resting in the same position.
3. The way to tell where you're at is to mark an "X" on the egg and turn the mark up one time and down the next.
4. Any time you write on an egg, use a pencil, not a ball-point pen or marker pen. Ink may be absorbed through the shell pores and may harm the embryo.
5. Be extremely careful not to cause shock or jarring to the egg when you turn it, especially in its first 24 hours, when certain delicate blood vessels are just forming. Some incubator operators skip that first day completely, not even opening the incubator door once, and start the turnings with day 2.
6. After the eighteenth day of incubation, quit turning the eggs. If you are hatching the eggs of a species other than chickens, quit turning 3 days before their expected hatching date.
7. From the tenth day on, make sure that the large end of the egg is at least somewhat up. Around the twelfth to fourteenth days, the chick takes a lengthwise position in the egg. If the small end of the egg is up at this stage the chick develops with its head in that end. With its head in the small end, a chick may manage to pip (peck a hole in) the shell, but it's practically impossible for it to hatch clear out. In a broody hen's nest, under natural circumstances, an egg lying flat will just naturally have the larger end a little more elevated. In the incubator you consciously have to make sure it's like that.

VENTILATION: Whether you're using a homemade incubator or a commercial one, you need ventilation for it, because the developing baby chicks are taking in oxygen and breathing out carbon dioxide right through tiny holes in the shell. Without an adequate air supply, the embryo will suffocate.

CANDLING THE EGGS: Candling, once done with a candle, is achieved by shining a powerful light through the egg in a dark room. Specific designs vary widely. You can use a slide projector, or a small box with a 40-watt light bulb enclosed in it, the insides covered with black paper, and just 1 opening, slightly smaller than egg-sized, through which you view the egg. You can buy a commercially designed candling box. Any method that enables you to thus examine an egg against a bright light in a dark room will work for white-shelled eggs; brown-shelled eggs take a longer time, but you can eventually identify an embryo in them too. The darker the egg's color, the harder it is to make out what is going on in there. To test eggs, hold each one up against the opening through which the light is coming, broad end upward (always!), and peer through it.

There is no way to know for sure that an egg is fertile without candling it. (Or opening it.) Some growers candle after 72 hours of incubation, when the fertile eggs have a typical blood vessel formation that looks like a spider. Some growers don't candle until 3 days before the scheduled hatch. (Eggs removed for being infertile at 72 hours or at 9 days can still be eaten.) Eggs in which the embryo has died and is now rotting must be removed because that process releases harmful gases and uses up incubator oxygen, and the spoiling egg may explode and scatter bacteria-loaded glop on normally developing eggs. If you're candling the eggs of a setting hen, do it while she's on her daily break. You may candle at any time you're concerned that the chick embryos might have been harmed by something. In such a case, wait several days after the trauma, to give the egg a chance to recover or perish, then candle.

Candling Signs. When you candle an egg, you will see one of the following: A clear egg means the egg is infertile or the embryo's development stopped very early. Remove it from incubator. A dark haze or grayish clouds mean the egg is rotting. (Note: At 2 weeks of incubation, fertile and normally developing eggs will be nearly dark throughout.) A dark red circle with no veins means the embryo has died. A fine network of veins radiating from a dark center means the embryo is developing normally.

If you candle a few days before hatching is expected, the fertile eggs will permit light only through the large end of the egg. The rest of it will appear dark or black in color.

THE PIPPING: Somewhere between the 19th and 22nd day of incubation, your egg will hatch—if it's going to. The chick has been getting food and water from the yolk, and oxygen from the air that comes in through the shell's pores. It took in calcium from the shell to help form its bones. The last thing the chick does before pipping (to “pip” is to make a hole in the shell) is to, over the last several days before hatching, draw the yolk into its body. The yolk goes in through its connection (like an umbilical connection) to the chick's lower abdomen. The drawn-in yolk makes the chick's abdomen bulge. The chick has to finish pulling the yolk sac into itself through its umbilical opening, and then grow that opening closed. At the same time, the chick swallows what is left of the egg's white. (That's why chicks can be sent by mail—that yolk can nourish them for as long as 72 hours after hatching.)

Starting as early as the eighteenth day, the baby chick may begin picking at its shell from the inside. It pecks its way through to the egg's air space and takes a breath. Once the chick's head is in the air space you can hear it loudly peeping inside the shell. The ready-to-hatch chick has an “egg tooth,” which is a sharp little extension on the end of its

beak. (A few days after hatching, the egg tooth drops off.) On the 21st day, or thereabouts, depending on if the incubation was a little cooler or warmer than normal, the chick pecks a small hole in the shell. It has pipped. Incidentally, it's important that you leave the eggs completely alone during this pipping and hatching period; avoid even opening the incubator.

THE HATCHING: Making the hole to the egg's air space was hard work for the chick. It's tired now and goes to sleep for hours. When it awakens it goes back to work on the hole, pecking eagerly. As it pecks, it is gradually rotating its body inside the egg. The effect is that the crack it is creating gradually comes to extend in a straight line, which gets longer and longer until it is almost all the way around the egg. Then the chick gives a powerful kick with its big feet and it is out of the shell. It takes the chick from several hours to a day or two to get from pipped to clear out of the shell, and then a couple hours more, once it gets free, to finish drying off. When the chick is first out of the shell it is wet and tired. Don't try to help it free or rush the process. If you peel the shell off for the chick, thinking to help, the chick will probably be even worse off. It may still be in the process of drawing the last of the yolk into its body. (Note: Helping a chick out of the egg has been done, but it's a delicate business needing a knowledgeable person.) If a significant number of your chicks pip, but don't finish coming out of the egg, your humidity was too low. (Raise the humidity level the last 3 days before the hatching.)

The just-hatched chick rests on its stomach for a little while, and if you didn't know better, you might think it was sick. When the chick first tries to walk, it can't. It hobbles, using its wings to help. The chick gradually dries and gains strength. After they hatch, leave chicks in the incubator until they finish drying off and get fluffy (12–24 hours). They don't need food yet, and it can actually harm them to be fed too soon. Baby chicks can scamper about as soon as they are rested and dried off from hatching. Then you can move them to your brooder. Clean the incubator thoroughly before storing it.

SEXING DAY-OLD CHICKS: To get started at doing your own chick vent sexing you need a magnifying glass and the book called *Sexing*, compiled by Mr. Stromberg, published and sold by Stromberg Publishing Company, Pine River, MN 56474. It's very thorough, covers sexing many varieties of poultry, and includes diagrams and photos.

Chickens That Hatch Their Own Eggs

“Setting” or “brooding” are words that mark that dramatic turning point when a hen decides to start her family. Then she stops just laying her eggs and walking away, and instead she stays to sit on them, keep them warm, and so incubate out a family. It's desirable or undesirable—depending on whether you want chicks or eggs. Or whether you want her to incubate or your machine to incubate. You can recognize a broody because her manner of speech changes from the everyday sing-song to a lower-pitched “come here” cluck that she will use to call her chicks. There's no known way to force a hen to get broody. A dimly lit, private, comfy nest with several eggs in it may help incline her that way. When I was young, several of the hens in my mother's flock would be broody at any one time. Five years ago you might get 5 hens that would go broody from a flock of 50 commercial-breed layers. Now scarcely one out of a 100 of them will try. And the one that does is likely to forget all about it after a few days on the nest, get up, walk away, and not return. If you want a hen to hatch out some eggs, you'd be best off choosing one from among the breeds that are known to still have genes for that behavior. (See the breed descriptions at the beginning of this chapter.)

A good reference on this subject is *Bantams: A Complete Pet Owner's Manual* by Helga Fritzsche.

THE BROODING: Just as soon as the weather starts to get nice, your broody-capable hen begins to want to set. A roaming chicken may make a nest in some secret place where she thinks it will be dry and safe and far from all the fleas and mites that may infest a chicken house. (Young birds are extra vulnerable to ectoparasites.) Or, in a hen house, she may choose the place where she is used to laying her eggs. She begins to lay eggs in the nest, an egg a day. Each day, before and after her laying, she sits a little longer on there. Under natural conditions a good setting hen will lay 10–14 eggs in her nest. There may be more than 1 hen laying in the same nest. Or you may not want every one of those eggs to be set. In that case, mark with a pencil the ones you're going to let her set and take the rest. When she's ready to incubate the eggs seriously, she may perfect her nest by picking feathers off her breast with her beak; these feathers will help insulate the nest. By exposing breast skin she is also able to share her body heat more efficiently with the eggs.

Once a hen has begun to set, you can, if she is in an absolutely unacceptable place, try to move her (carefully!) to a more suitable brooding nest that you have prepared. But brooding hens need to be undisturbed, and the move itself may cause her to give it up because of the disturbance. If you have more than 1 hen setting at a time, it helps if they are reasonably far from each other, perhaps in separate portable coops. But, again, it's risky to move them. Another preparation might be to sprinkle the setting hen with a louse-repellent powder, once you separate her from the rest of them.

Nest Design. The brooding nest should be roomy enough that the hen can turn around in it and turn her eggs, and near enough to the ground that the chicks won't take a disastrous fall overboard once they hatch—although they are very light and tend to survive such falls well. (After they are hatched you'll take away the nest so that then the chicks can easily enter and leave their shelter together with their mother.) The typical human-designed egg-laying nest is not the best egg-brooding nest. Chickens are descended from ground-nesting species, rather than tree-nesting ones. An ideal nest is a little wooden house about 15 inches square and at least 16 inches deep, with the top roofed and the front side open. It sits directly on the ground. The ideal nesting material is grass turf. You can make a nest by laying the turf grass-side down, or grass-side up, or you can make a thicker nest by cutting 2 turfs of the right size, then placing their dirt sides together and placing them inside. In either case, pound down the center of the nest sufficiently to make it into a shallow saucer-shape so that the eggs won't roll out. And moisten it with water.

Eggs Per Hen. A large hen that can cover and keep warm 14 regular-sized eggs will have to be given proportionately fewer if some of them are exceptionally large: 6–7 turkey eggs, 9–11 duck eggs, 4–5 goose eggs. Those numbers are not absolute but average: it all comes down to how large—and well-feathered—the bird is, and how large the eggs are. Insofar as possible, match egg size to bird. A small bantam hen finds a goose egg awkward to sit on; large birds are likely to break very small eggs (like quail). A bantam hen that isn't heavily feathered may be able to cover only 8 eggs or so. Don't give a hen more eggs than she can adequately cover. If you do, you may lose the whole clutch, because she rotates eggs from the inside to the outside of the nest, so they'd all get chilled sooner or later. You can try the clutch on for size so to speak: give the eggs to her, and then look to see if she can cover them all. If you have goose eggs under a hen, you'll have to turn them 3 times a day yourself, because they are too big and heavy for a chicken to get properly turned.

Eggs-in-Waiting. Some chicken-owners, anxious to assist nature, collect the eggs and care for them as with incubator eggs-in-waiting until the hen actually commences setting. Since it's impossible to predict exactly what day she'll go broody, such eggs are marked with pencil stating the date collected. When the hen does commence setting, you supply her with a clutch selected from the eggs fresh enough to be the best bets for hatchability.

Egg Adoption. After a hen has begun to set, on one of the first few nights she stays on the nest, slip the eggs to be adopted under her late at night. It can be disastrous to put eggs under her after she's already been setting very many days because after 23 or more days of faithful egg-attendance, the hen may say "to-Hell-with-it" and leave the nest. On the other hand, many modern hens have such a weakened broody instinct that they are not dependable brooders and will soon give up and leave the eggs anyway. If you're worried your hen might not be dependable, let her set on fake eggs for a few days. Take her off the eggs a couple times. If she gets back on the nest each time, she's a good bet and deserves some real eggs to hatch. While she's setting, she will be very protective of her eggs and upset with you as soon as she realizes you're planning to do something under her. She'll peck at you with her hard little beak, and it can do damage. Wear a heavy shirt with long sleeves. You could wear a mitten, but I'd rather take a peck than take a chance with fumbling the eggs. Place them carefully under her, one by one, giving her a chance to receive and arrange to her satisfaction each individual one.

Inter-Species Brooding and Mothering. If you have commercial breeds as well as ones that will go broody, you can put their eggs under the broody hen. Setting hens of breeds that are good broodies and good mothers will hatch and try to mother even large eggs like those of ducks or geese, although they will get quite unhappy when those "chicks" jump into water and swim. If you want an egg to be adopted, follow the rules for eggs-in-waiting. Rare eggs that you're eager to try hatching can be kept for 4–5 weeks—until you have a broody hen that's just starting to set a clutch of eggs. The long wait will lower hatchability, but you might still get offspring. If there are eggs hatching at widely varying times, the hen may choose to follow an existing family and give up on the unhatched eggs. (It may help to take the first few hatchlings into the house for nurturing.) If all the eggs are low hatchers, she may give up before they're done. As you get to know your hens better, you'll learn which you can count on to stay with it for a long incubation.

Days to Hatch. Chicken eggs, all breeds, take an average of 21 days to hatch. That's exactly 3 weeks. But the length of time for a specific egg can vary from 19 to 22 days or more. If the hen continued laying eggs for a few days after she started setting, chicks may appear for a day or two. Or maybe another hen laid eggs in the nest during some of the brooder's time off the nest. Those will also hatch later. Any eggs left after the brooder gives up probably aren't going to hatch at all. A difficulty of inter-species egg adoption is that various eggs will have varying days to hatch. Pheasant, Bobwhite quail, and Chukar partridge eggs take 23–25 days to hatch. Guinea eggs take 26–28 days. Turkey, duck, and peafowl eggs take 28 days. Goose eggs take 29–31 days. Muscovy duck eggs take 33–35 days, and swan eggs take 35–37 days.

Human body warmth is just right to hatch eggs. Women of ample mammary endowment have incubated eggs kept between their breasts for the necessary number of days!

The Brooding Routine. Now your hen has her final clutch of eggs to brood. She sets on the nest for 3 weeks. On the first night she stays on the eggs, you can start counting toward 21. Many times a day she turns each egg in her nest very carefully halfway over and rotates eggs on the outside of the nest to the inside—which ensures equal sharing of

the warmest and coolest locations in her nest by all the eggs. The broody hen is a willing martyr. She eats very little. She loses weight and her feathers get duller. She's very irritable toward visitors: she clucks, ruffles her feathers, even pecks at them. Now that she's seriously setting, she leaves her nest only once a day for food and water. She'll be gone only about 15 minutes, or maybe a half hour, if the weather is warm and the sun is shining so she doesn't worry as much about the eggs' chilling. Like a chick in the egg, a setting hen is receiving nourishment independently because, once she starts to set, she stops laying and instead begins to absorb the food energy stored in her conveyer belt of formerly developing eggs. Yet it's a friendly, helpful act to also leave fresh food and clean water close by for her. Her feeding excursion is a good time for you to peek and see what her nest looks like. But don't handle her eggs or nest while she's gone. Too much of a foreign scent around could cause her to leave that nest and refuse to return to it again.

She talks to her chicks while they're still in the egg and has a good sense of what's going on with them in there. If something like a severe thunderstorm or a prolonged chilling kills all the chicks in their eggs, the hen will know it. Be careful you don't accidentally shut a setting hen away from her eggs. She'll be frantic, and with good reason. Nevertheless, eggs that have been uncovered a night are not necessarily dead, though it may set the hatching back a day. The last 24 hours before hatching, she won't leave her nest even for the usual food and water recess.

Humidity Assistance. You can help keep the humidity right by keeping the earth between the 2 turfs damp. If the weather is seriously dry, you can also help the hen by adding humidity. Some growers do that by spraying her eggs with a light mist of lukewarm water once a day, while she is on her break, starting on the 16th day. Other growers believe that spraying water on incubating chicken eggs promotes fungal growth and embryonic death and suggest instead flotation of the eggs—on the 19th day of incubation—in water that is exactly 97°F and for only 1 minute. But in real life it doesn't have to be that exact. Certain other species require even more humidity and even stronger measures. (See "The Waterfowl: Ducks and Geese.")

THE MOTHERING

Taking in the First-Hatched Chicks. A newly hatched chick is wet and could be fatally chilled if the mother isn't sitting on it to dry it and keep it warm. Some folks feel it's best to take the first-hatched chicks into the house—once they're safely separated from the egg and dried off. That's to save the hen the conflict of wondering if she should sit on the remaining eggs or follow lively chicks that have jumped out of the nest and are out in the cold peeping mournfully and maybe dying of chill. For just a few chicks that soon will be returned to the mother, keep them in a warm, dark place in the house—maybe in a box lined with newspaper and partly covered with warm cloth. Put the box where the brooding temperature is right, near a heater or under a light. Give them food and water using the general directions for chick care. It can also be a favor to the hen to pull out from under her the abandoned shells of fully hatched chicks.

Returning Chicks or Adoption. Return your borrowed chicks, if possible, the first night after the hatching is finished and the hen has been moving about with her chicks. This is also the time to give her any chicks you want adopted. A hen can mother more chicks than she can hatch. She can mother as many as she can hover over and cover when they need warmth. She doesn't literally sit on top of them; instead she stands and covers them—a blanket of warm feathers fluffed out all around them—plus dispenses the heat coming directly off the bare spots on her breast where she pulled out her feathers. Hens have been known to bring up as many as 25 chicks. So, if you have access to orphan chicks, or your

own incubator chicks, or mail-order chicks, and if the timing is right, you can add them to the hen's family at this stage. The important thing is that your chicks, to be successfully adopted, have to be the same age as the hen's own chicks—preferably just 1 or 2 days old. Older chicks won't be as likely to obey the hen, and the hen will be more likely to reject them.

Putting Chicks Under a Hen. To accomplish the return or adoption of chicks is just like adding eggs-in-waiting to a hen's clutch. You wait until late at night, then slip each chick under her. The chick will be attracted to her warmth and will nestle under her. She'll fluff up more as needed and cuddle the new ones together with her others. To give chicks to a hen who has been allowed to set on fake eggs, put the chicks under her as above, taking away a dummy egg after each chick has been placed under her. You can't get a chicken to adopt chicks unless first she has become broody and set for 3 weeks or so. That's when she gets her mothering instinct activated. She might kill chicks given to her prematurely. These things have to unfold naturally, and there's a time for this and a time for that.

Chick Rejection and Obedience. Check the next day to see if she's rejected a chick. She does that by pecking at it whenever it comes near. It will soon give up and go hide its head because she won't peck at it if its bright eyes aren't showing. You can try to put the outcast chick under another hen, or raise it yourself in the house. You can't change chicks from one hen to another if their original mother is nearby in the same poultry flock. The chicks will remember the sound of their own mother's voice and always want to go back to her. And if you did inter-species brooding, you can't count on the young of very different species—guineas, wild ducks, peafowl—to follow and obey a hen mother. You have to watch and see if the babies are successfully bonding to the adoptive parent. If not, you'll have to mother them yourself.

Chicken Mothering, Food/Water. Hens, especially ones who are descended from a line of mothers who hatched and mothered their own chicks, can be very wise mothers. After only a few hours, the chicks know their mother. She teaches her chicks to come when called and to eat and drink. (Make food and water available. If it seems like it's taking time for the chicks to get started, remember they are equipped at hatching for 3 days in a desert. But if she's an inexperienced or inadequate mother, you can help by showing the chicks how to nourish themselves, same as for brooder chicks.) An experienced mother cracks seeds that are too large for the chicks in her beak and feeds them the small pieces. She teaches them what is and isn't good to eat. She'll find a bug, put it down where she wants them to gather, call the chicks, and tell them if it is or isn't good food.

Chicken Mothering, Protection. She watches carefully to see if the chicks are getting chilled and need to be called under her for a warming up, and to make sure she hasn't lost track of one. She can be fearless in defense of her babies. She can be dangerous to pet rabbits or guinea pigs that might happen to be in the area. An angry bantam fluffs out her feathers to the max to make herself look much bigger than she really is. She'll stand her ground against a far larger animal, making little pecking charges to try to drive it off. Unfortunately, a mother hen's blindly aggressive behavior may also extend to other mother hens—in which case chicks sometimes get trampled in the conflict, or may even be pecked by the other mother. (That's why it's wise to establish such families on opposite sides of your barnyard, or in separate coops.) She teaches her babies to be careful when cats come around and to look out for hawks.

Separation from Mother. A lost, scared chick sounds the alarm with a very distinctive, loud, "Peep, peep, peep." That's their S.O.S., and whoever is mother—you or the hen—better hurry and see what the problem is. A common serious problem occurs when 1 chick gets trapped somehow away from the group. The hen is torn; she doesn't want to leave the rest of her chicks unprotected, unwarmed, and alone, yet she doesn't want to abandon the separated one. In a case like that, you should interfere. It's generally as simple as lifting the isolated chick over some kind of barrier.

Housing for a Hen and Chicks: Keep the chicks away from the chicken house to start with, both to protect them from vermin and to prevent them from being pecked by larger birds, who can be very cruel. Or a predator, such as a roaming cat, might get a chick. You have 3 choices for housing: leave them alone to tough it out and hope for the best, start them in a big cardboard box or A-frame and then gradually set them free, or start them in a chicken coop or subdivided pen and keep them living like that quite a while. Chicken coop containment is especially wise with a chicken mother who is just learning the ropes herself, not having been raised by a natural mother. She may not know enough to encourage her chicks to keep warm. Leaving them alone is the riskiest option.

Cardboard Box or A-Frame Housing. You can place hen and chicks in a large cardboard box with a chicken-wire cover. Such a box should have appropriate litter, food, and water.

It doesn't need a heat source. The hen will hover over the chicks when they need it to warm them. The big problems with box-housing are the small size and fragile construction. Instead, you may want to build an old-time A-frame chicken coop, the size of which is about 4 feet by 4 feet. It has no bottom, and no nest in it; anything else is too difficult for the chicks to get in and out of. There are slats across the opening, close enough together to keep the hen in, and aviary netting or a 6-inch board across the bottom to keep the chicks in. You can gradually phase some freedom into this setting by leaving hen and chicks shut in there for a couple of days, then letting them out together in the daytime and shutting them in again at night. In the A-frame, make available water in a chick-waterer and baby chick starter food. Arrange things so the babies don't get their feet wet. After 10 days or so you can let the cooped hen and chicks do whatever they want and they'll probably be fine.

Chicken Coop. The last option is a classic chicken coop. A coop ensures that the mother and her chicks don't get separated (unless a chick squeezes through the wire and gets lost). Move the family into the coop at the end of a week in the cardboard box or the A-frame, or, better yet, situate the A-frame right inside the coop and at the end of the first week, or whenever weather is suitable, just pull the board or netting off that keeps the chicks and their mother inside their house and let them have the freedom of the coop. A coop can be created by subdividing space from a regular chicken house or large bird pen or by creating a special portable unit. Ideal is a portable ground pen enclosing a little roofed box house (A-framed or rectangular) in which the hen can hover over her babies.

Good dimensions are 4 feet wide by about 6 feet long and 2 ½ feet high, with a wooden frame and a hinged roof. The house for such a coop can be built onto the end of it. If it has a low wooden floor and a swinging door, you can just shoo the family into it and shut the door when you want to move them. That way the coop itself doesn't have to have a bottom, which helps keep the grass under it nicer and more accessible to the birds. In good weather, put the coop right outside, moving it whenever the grass underneath seems significantly soiled or trampled. The coop should allow sunshine to enter, yet have spots of shade, and the little house should be rain-proof and heavy enough not to blow over in a wind. If the weather is cold, damp, or uncertain, put the coop in a sheltered place—inside your barn or in a shed. A coop of this design has other uses too. You can use it to isolate purebred birds for controlled breeding, or to isolate a sick bird, or to isolate newly purchased birds that are still in their quarantine period, or to house transition-size young birds.

A SECOND FAMILY: It's almost unheard of now for chickens to set more than once a year, and that's a shame. The old-time hard-working bantam hens used to have as many as 4 families a year. After raising one family, when the early spring chicks were about 2 months old and could find their own food and get along without their mother, she chose a new nesting place, pecking and scolding the youngsters if they came near her. They would give up on being mothered and join the general flock. (Even if she doesn't want to set again, feel free to take the mother away when the chicks are 8 weeks old, or older. They will now be fine without her and can be treated like transition-age chicks from the brooder.) Such a talented chicken mother would begin laying again. When she had enough eggs she'd get broody, set again, and start another family. If I were a breeder of household poultry, I'd select for that characteristic alone!

Chicken Housing

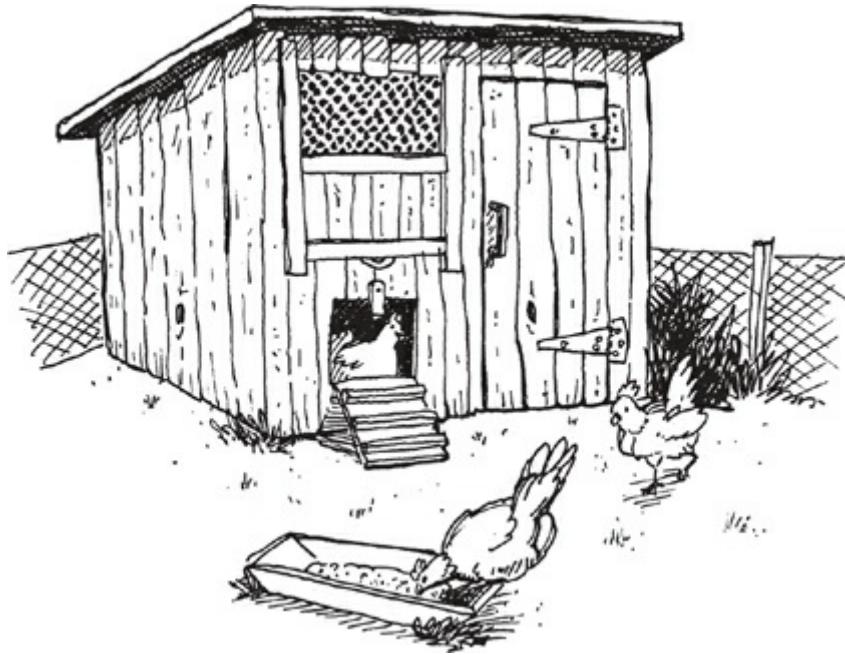

Chicken houses—and all the features that go into and around them—are a big topic. Some

chickens have to spend their lives in very cramped quarters.

BATTERIES: Some commercial operators keep their birds in small, individual, stacked wire cages called “batteries.” A battery-housed bird is never threatened by anything except boredom and inactivity. Batteries can’t be used unless they’re inside a warm building, even if they have a self-heating component. The baby chicks live in pens 5 tiers high; when they’ve grown larger they’re moved to somewhat bigger cages stacked 3 tiers high. Food and water are provided in troughs at the edge of the tray. Battery cages can be bought ready-made or you can make them. They’re certainly economical of space, but many people consider them an abomination because they don’t allow a chicken to do the things chickens normally do—like scratching, dusting, sunning themselves, roosting at night, and moving around in the daytime to explore, socialize, and mate.

But even the freest ranging chickens need, and want, shelter from bad weather and night-roaming predators, for chickens are sound sleepers to the point of helplessness.

How Much Housing Space Per Bird? If your chickens will be roaming free during the day, they need only a relatively small shelter in which to sleep at night—big enough to hold their roosts. Totally confined birds, on the other hand, need much more space to avoid overcrowding them. Larger breeds need more space than smaller ones. Many birds need more space than few birds. Your bird population may be cyclical: a large crop of broilers in the spring plus your layers, but only the layers in wintertime. Figure 5–8 square feet per bird for fully confined birds in a small flock, 4 square feet per bird for a larger flock. By using a temporary chicken-wire partition, you can divide a chicken house into 2 parts during its busy cycle: one-half for the broiler crop and spring pullets being raised for replacement layers, the other half for your layers.

Using an Existing Chicken House: Check first for rodent holes; nail metal over them. Check the roof for leaks and fix as needed. Sweep the dirt out. If the building has been used to house birds in the last 3 years, give it a good cleaning before you move your own birds in. (Follow directions under “Cleaning Your Chicken House.”)

Adapting an Existing Outbuilding: To renovate an outbuilding, choose one with a rat-proof floor, walls, and roof, that can keep out rain and has windows or some kind of openings for light and air. In a cold climate, it should not be drafty. In a hot climate, it should have

good ventilation during the summer. You can put your chicken house inside a larger building—a large shed or barn—using existing walls where suitable and adding new ones as appropriate. Or you can build it against the outside of a larger building such as a lean-to shed (on the south side if possible).

BUILDING A CHICKEN HOUSE: Keep in mind that you want a short walking distance from your home to the chicken house, because you may be going there several times a day. Situate the building so that it will be convenient for you when cleaning day comes and you want to cart the accumulated manure and litter away. Plan where you will store the feed. Art Boe is an ex-Alaska fisherman, off-and-on building contractor, former high-school science teacher, South Dakota farm boy, cow milker, and friend. His wife is a second-grade teacher and has had an Emery in her class about every other year. Here are Art's directions for building the ideal chicken house:

You'll probably need a local building permit to build a from-scratch chicken house. You can get very detailed plans from chicken books, magazine articles, state agricultural colleges, etc. A simple pole or frame building, shed type, is adequate. You can manage with a space as small as 6 by 8 feet for a dozen chickens, or 10 by 12 feet for 30–40 of them, or 20 by 40 feet for 250, which is a commercial-sized operation. Plan ahead for how you're going to clean out the manure. That means you'll probably want the roof high enough so you can get inside and shovel manure out comfortably. Slope the roof, say from 7 feet in front to 6 feet in the back, to help water run off. The rule of thumb is 1 foot of drop for each 8 feet of roof—more if you live in snow country where piled-up snow could collapse your roof.

Of Windows and Light. You'll want windows on the south side in northern climates, with enough roof overhang to keep out the hottest summer sun. To be most effective the roof overhang must slant down over the windows, creating a "V" (upside-down) or "cowl." Such a window-overhang combination will keep out the summer sun, let in the winter sun, and protect the front wall from rain. Install windows across a third to a quarter of the wall on the south side, made so that you can remove the glass in summer for additional ventilation, or easily open and close them from the outside. Windows are especially important for poultry because the male's fertility and the female's egg production are both affected by the presence or absence of light—so you want to maximize their exposure to light.

Ventilation. The more chickens you have in a house together, the more warm and moist the air is going to be in there. Chickens, especially confined ones, suffer in very hot weather and may die if the temperature in their house gets too high. They have a high respiratory rate and a high body temperature—they need proportionately more oxygen. They do not excrete sweat or urine (though their droppings are moist). A chicken breathes out her excess moisture. Moisture that doesn't have a chance to circulate out of the chicken house causes wet litter, which in turn can result in breast blisters and manure burns. In a warm chicken house, the ammonia from the manure becomes very strong, and in a very short time can result in ammonia blinding and serious respiratory damage if adequate ventilation for a confined flock is not provided. Ammonia poisoning can also retard growth, reduce egg laying, cause foot pad burns, and encourage staph infection.

So the chicken house needs ventilation enough to get oxygen in and also to get ammonia and moisture out. You will need some ventilation even in winter—windows that drop down or tip in and can be opened at least a crack. In cold weather it's best to have the ventilation on one side, to the south, to prevent chilling cross drafts. In warm climates or hot weather, you'll want to be able to open up both sides of the chicken house to get

cross-drafts. Chicken wire on the inside will hold in the chickens and keep out predators and wild birds, which can carry parasites and diseases that chickens can contract. Don't use fly screens to cover the chicken house windows; they don't let enough air through to do the job in hot weather.

Climate Zones and Chicken Housing. In very warm climates like southern Texas, the southern Gulf states, and Florida, chicken houses typically have wire walls that can be covered with tarp or plastic curtains in case of windy or cool weather, and they are located under a shade tree. In the rest of the southern United States and on the extreme west coast, chicken houses are typically uninsulated and have large front openings that can be covered with plastic or windows in stormy or cold weather. (Or you can construct a more "regular" house for them—but have a screen door, screened windows, and extra screened openings in both peaks of both walls for ventilation in hot weather.)

Eastern, Midwestern, and Rocky Mountain-area chicken houses need to be well insulated (double walls with a 1 ½-inch insulation layer between them), tightly constructed, and protected from the wind. You can insulate your chicken house cheaply—by gluing Styrofoam to the walls and ceiling. In yet colder climates—such as Montana, the Dakotas, the Great Lakes area, and northern New England—the chicken house can benefit from even thicker insulation and electrical heating (at least a light left on) during severe winter weather. In interior Alaska, chicken houses may be built underground!

Of Insulation and Electricity. The birds will be warmer in winter if you insulate your chicken house and if it is small enough with a low-enough roof to keep the warm air near the chickens, who make quite a bit of heat themselves. Insulate by building the walls in 2 layers with air space in the middle. Air is an insulator. Or put commercial insulation material in the middle. Or fill that wall space with some different, available insulating material. Don't spend a fortune on a chicken house unless you have it to spend. For cold climates, one or more light bulbs burning at night can prevent frost-bitten combs and wattles on the roosters and help keep drinking water from freezing. With electric warmth in the chicken house, young birds can leave the brooder and be moved into the big house at earlier ages. You'll also find electricity useful if you live where winter nights are long and you want to push your chickens to maximum year-round production by leaving the lights on. On the other hand, you don't have to wire the chicken house. It's cheaper and simpler not to, and you'll still get eggs.

The Floor: Dirt, Wood, or Concrete. For a dirt floor, first level your ground, and then just build your house on top of that. You may be able to get along with a dirt floor, but they're hard to clean, hard to keep dry, and vulnerable to weasels and rats tunneling in; also, parasites in the ground can be harder to get rid of. Another option is a wooden floor. Building it up off the ground prevents rats from hiding underneath and gnawing through it. If rats do gnaw a hole in the floor or wall, nail sheet metal—or a tin can lid—firmly over the hole to block it. A wooden floor is warmer than dirt and dries from underneath. Chickens make a lot of moisture. But wood can warp and rot. You could reinforce a wood floor by making it of 2 layers, with building paper or insulation board between them. The other option is a concrete floor. Slope a concrete floor about 4 inches from back (where the roosts are) toward the front of your chicken house.

LITTER: You can go 3 different ways with this: Use a foot of litter to start with. Or build up litter by starting with 2 or 3 inches and then gradually adding more throughout the year in layers atop of what's already there to a total of as much as 2 feet. Or use a thin layer, which is cleaned out and replaced every week or two. This litter is very important—don't skip it. It gives the chickens something to scratch and prevents their droppings from

adhering to the chicken-house floor. The litter dilutes the “strength” of the chicken manure. For chickens in a cold climate, built up litter insulates their floor, and the decomposition and fermentation processes inside it actually provide heat for them. For the same reason, when warm weather comes the chickens will be cooler and more comfortable if you get the old litter out of there and provide fresh.

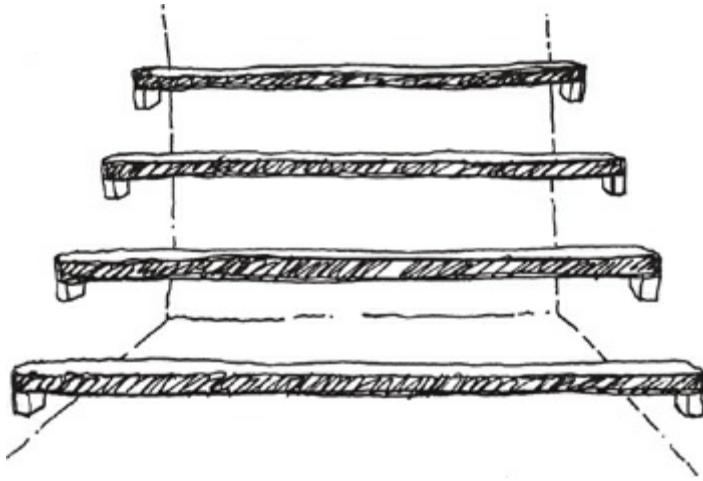

Litter Materials. Soft wood shavings, peat moss, sugar cane fiber, or some such shredded organic material is best. You can use hay, preferably that rejected by the cows. But not sawdust because it tends to be so dusty it is hard on your chickens’ respiratory systems. And do not use oak shavings because they are toxic.

NOTE: Don’t let the litter mold! Moldy litter can result in a serious poultry disease in which the mold organisms actually move into the birds’ respiratory and digestive systems and live there. The mold organisms can also damage your health.

Stirring the Litter. Some chicken-raisers stir together the shavings and manure every couple weeks with a rake. That stirring prevents the litter from packing and promotes drying since the litter has to absorb a lot of moisture from the chicken droppings. Then when it comes time to clean out the chicken house, the litter is already more than half-composted. Other owners just let it stack up until they can’t stand the sight of it any more, or the garden is going to be wanting it, and then they take it all out in a big 1-day ordeal. If you leave it alone more than a few months, the manure gets quite compacted, and it will be like spading a garden to cut it loose and get it out of there.

NESTS: This is something (anything) like a wooden box, about 10 inches square, with a top and sides, but open at 1 side for the hen to enter. A slit in the top helps ventilate the nest. A slanted top prevents roosting on the nesting box with its attendant manure collection. Cover half the open side with wood, or cover all the open side with a curtain of cloth that’s slit to let a chicken hop through. It should be relatively dim inside. Hens like dark, comfy, private places to do their thing in. An instant nesting place can be made by leaning a sheet of plywood, or anything similar, against the chicken-house wall. They’ll lay between the sheet and the wall. Put hay, chopped straw, wood shavings, or some such, in the nesting place for the hen to nestle down in. Change the nest litter occasionally, when it gets dirty. Nail a nesting box, 2 feet high or so, up on your chicken-house wall. You can put them in a row. Supply 1 nesting box for each 4 layers—more or less. Pullets, just laying their first eggs, are liable to drop them anywhere, and that can’t be helped. Some hens may be tempted to make a nest in a corner of your hen house on the floor. That is a problem because it may result in the development of egg-eating. Stop it by picking up the eggs and clearing away the “nest.”

Roosts: You’ll want roosts in your chicken house. The chickens will fly up there and perch, curling their toes around the roost to hang on. (That’s why it’s handiest for them if you use a pole or round the top edges somewhat.) If you don’t have a chicken house, your chickens will fly up onto rafters or into trees—if they can fly—as soon as they get big enough to fly that high. Since they sleep unbelievably soundly, chickens have an instinct to pick a very protected place to do it in.

Building Roosts. Basically, the perch is a long pole, 2–3 inches in diameter, set 2–4 feet off the chicken house floor. The best perch isn't made of really smooth material; the birds would have trouble hanging on. And it would be firmly nailed in place, so it can't turn. An easy-built roost is just a 2 × 4, about 12 feet long, nailed across 1 or more corners of the chicken house, as needed. But don't put roosts right on top of each other. Birds drop feces in the night. Arrange the roosts in such a way that the droppings have a clear fall to the floor. The roosts are best when they are no closer than 18 inches to a wall. Allow about 18 inches perching room per adult, heavy-breed bird. In cold weather they'll crowd and take less room as they huddle together to keep each other warm. The area right under the roosts will collect more chicken manure than all the rest of your chicken house combined. Some growers recess the area under the roosts to separate the deposits there from the rest of the litter. That arrangement is called a "droppings pit." Some growers fence the pit at top and sides with chicken wire to keep the birds from getting into it.

Roost Height. The height needs to be right for your particular birds. High-flying bantams will like it on the high side. (If unconfined, such high-flying bantams are likely to perch in your orchard instead of the chicken house. If you let them do that a few nights, they'll want to keep doing it. It's just a matter of your preference, whether they should or not.) Yokohamas, with their lovely long trailing tails, need high perches to keep their tails out of the droppings. Bantams that don't fly much, feather-footed breeds, and Chabos need perches no higher than 1 foot. For average meat-eggs breeds, if you have enough birds to need more than 1 roost, you can put them one behind the other in rising order, like separated staircase steps, at 2-, 3-, and 4-foot levels.

PEOPLE DOORS: You need a people door from the outside into the chicken yard, and a people door from the chicken yard into the chicken house. Or a people door from the outside into the chicken house directly, and then one from the chicken house into the chicken yard. Another useful door is a lengthwise one along the floor right behind the chicken's roosting area. That one would allow you to frequently rake out the manure from where it builds up under the roosts. Some classy chicken houses have special hinged doors that open directly into nesting boxes and allow you to gather eggs without entering the chicken house. It's all a matter of your preference.

CHICKEN DOORS: You'll want separate doors for your chickens: little bird-sized doors (about a foot square) that are shut easily from the outside. That way, in chilly weather you can leave their doors open but close the people-sized door to minimize cold drafts. Also, for free-running chickens, such a small door keeps out large stray dogs. As an extra protective measure, close that little door at dark, after they've all gone in to sleep—because some

night-predators are small enough to slip in through it and can make a dreadful carnage of the sleeping chickens. On the other hand, unless you leave plenty of food and water inside the chicken house before you go to bed, you'll need to get up early in the morning (chicken time is early indeed!) and open it again.

Chicken-Sized Door Design. It should be about half a foot above floor level so litter doesn't escape from it. One handy style of door is a plain flat piece of wood that slides up and down in wooden grooves. Another style is attached at the top by nailed-on leather straps or metal hinges and is held up during the daytime by a loop of twine that can be hooked on a nail situated at just the right height above. Yet another style combines a door and walkway down. You make it by sawing out your door and letting it fall to the outside, drawbridge style, during the day, then drawing it back and fastening it shut at night. If you don't have that style chicken-door and your chicken entrance is not at ground level, then you could make a separate walkway by providing a board for the birds to walk up from ground to door level. Strips of wood nailed crosswise on the board an inch apart will help them get traction in wet weather.

CHICKEN-YARD OPTIONS: Basically, you have 4 outdoor options: a sun porch, a fenced dirt yard, a fenced pasture (regular or rotated), or free-running.

Sun Porch. Most chicken owners don't have the option of letting their poultry run completely free, but they want them to have some outdoor time. The most protective choice would be a sun porch. This is an outside pen or an inside pen with an attached outside run. The outside part is built at least a foot off the ground, and it has chicken-wire sides and top, and a floor of small wire mesh or wooden slats—which allows manure to fall through onto the ground below. This allows poultry to get sunshine and fresh air and prevents them from eating feces or dirt. Such a pen can be dependably sanitized. The use of a sun porch is best if you have very disease-vulnerable stock or are in a disease-or parasite-ridden area. Chickens usually don't require that much protection. Turkeys sometimes do. (See "Sunporch" under "Turkeys" for more information.)

Fenced Yard: Yarding reduces confinement stress problems: cannibalism, feather-picking, egg-eating. And chickens just plain enjoy basking in sunshine (to make their Vitamin D) and benefit from exercise. Your chicken yard should be planned so that it has a portion that will be shaded and a portion that will be in the sunshine. In coldest climates, they'll be using their yard in the warmer months. Then, in extremely cold, stormy, or snowy weather, you shut the door to the chicken yard and keep them completely inside. Feed them inside the chicken house. Or, if you choose to feed them in the yard, use a covered-style feeder to keep out rainwater. A small chicken yard is a dirt yard. If it wasn't dirt to start with, it will be soon. A dirt yard is nicer if you cover it with litter. Chickens love to scratch in litter; scatter some kind of mulching material. That will also help keep it nice looking and good smelling and will inhibit possible health problems associated with wet, muddy yarding. Straw, tree leaves (not black locust—poisonous), or ground corn stalks and cobs, are cheap, fine sorts of yard litter. You then periodically add the yard litter to your compost pile, together with its nitrogen load.

Pasture. This is an excellent option. See "Water and Food for Chickens (and Other Adult Fowl)." Free-ranging is covered there, too.

Fencing for Chickens. "Chicken wire" has smaller holes than the "woven wire" you use to fence in larger animals. Chicken wire isn't as stiff as woven wire, so it takes more structure to hold it up. Posts set in the ground will corner the chicken yard. On the sides place a post about every 5 feet. Then stretch the wire around the outside, tightening it by

pulling on the 3 or 4 reinforcing wires woven into the mesh for that purpose. Staple or nail (nail halfway in, then bend the nail over the wire and hammer it down) the reinforcing wire to the post. If there is any risk of predator invasion by tunneling—and to prevent birds from slipping out through holes created by dusting pits right next to the fence—bury about 6 inches of board all around the bottom of the fence and staple the wire to the top edge of the board. Or dig a trench all around when you are building the fence and bury a foot of the chicken wire. If the chickens have a larger pasture—say a whole orchard to run in—don't worry: it could probably be less painstakingly fenced.

How High a Fence? The rule is this: The smaller the chickens, the higher the fence you'll need. In general, heavy chickens need a 4-foot fence, light breeds need a 5-foot fence, and a 6-foot one may or may not hold bantams. If you are troubled with birds that fly out over the top of your fence, make the fence higher by adding more chicken wire—another foot or two at the top as needed. (Or "clip the wings" of the flyers. You do that on one wing, the outer row of feathers only. Those will be large primary wing feathers. Cut with a sharp scissors. That ruins their aviation balance. But feathers will grow back and have to be cut again after the next molt.) Or fasten chicken wire over the top of the run, and that settles the problem forever. If your chicken run has a covered top it need not be higher than 2 or 3 feet. Then you also never have to worry about birds of prey snatching a bird, or wild birds robbing chicken feed and bringing disease or parasite problems—like pigeons that may carry avian cholera, deadly to a chicken flock.

CLEANING YOUR CHICKEN HOUSE: It's a good idea to clean your chicken house at least once a year, in the spring when the heat-producing litter is no longer needed and will become more of a problem than a help. Or you can do it twice a year: in the early spring and 6 months later in the fall. Or time your cleaning to occur after 1 group of chickens has gone to the freezer and a new batch, now outgrowing your brooder facilities, is about to arrive. Incidentally, this between-flock cleaning policy helps keep your birds healthy, if you're troubled with disease or parasite problems. Clean a chicken house that you've just bought before you move your own chickens into it. Infectious agents—disease or parasite—can live months in the dirt of a chicken house, in the soil around it, in nearby fields—anywhere the infected poultry roamed.

Chicken-House Cleaning Day. You need a warm, dry day to do this job. If you are cleaning a house that is not vacant you'll have to get the job completely done between dawn and dusk, because the chickens will want very much to go home and sleep when the sun goes down. This tends to be a day to remember. There are 4 steps possible in your cleaning process. Do any or all as your individual preferences and situation suggest, but in the following order:

1. Give your birds their insect (external body parasites) or worm (internal parasites) medication, if such treatment is on your agenda. But don't treat for both internal and external parasites the same day—kills the chickens. Then turn them out or move them from the quarters to be cleaned.
2. This step has to be accomplished: Shovel all manure and litter off the floor. Scrape manure off the roosts. Clean old litter out of the nest boxes. Most chicken diseases and internal parasites are transmitted through the feces.
3. This step can be skipped, or done to any degree you think appropriate: Hose down, soak, and scrub the walls and floor with a high-pressure hose, steam cleaner, or elbow grease and basic soap or a disinfectant solution. An ideal disinfectant is a lye-water mixture: 1 oz. lye/1 gal. water. This is most effective if applied hot but is also effective

when applied cold. Lye water is effective against parasite eggs and disease germs, but only if the litter and droppings have first been thoroughly swept away; litter and droppings neutralize the lye, and then it can't work against bugs. Bleach can also be used for this purpose, as can a special-purpose disinfectant available at most feed stores. Some disinfectants are sprayed on. Read and follow disinfectant directions exactly. Some poultry-owners prefer liming the house out once a year by mixing a paste of lime with water and brushing or spraying that on. Make sure you clean the roosts, in cracks and crevices, and under loose boards with a bristle-coated brush or broom. Then let it dry out.

4. This step can be skipped: Paint the lower walls, dropping boards, pits, roosts, nests, and where the roosts and nests touch the wall, with a mite-killing solution. Follow directions carefully.
5. Let dry. Put fresh litter on the floor. Move in the old or new tenants.

Chicken Injuries, Diseases, Parasites

The Chicken Health Handbook (1994) by Gail Damerow will help. Also, download “Sustainable Poultry: Production Overview” from www.attra.ncat.org/attra-pub/poultryoverview.html.

INJURIES THAT CAN BE FIXED: A bird with any of these problems is injured but not diseased, and is fine to eat. So you could choose not to bother with the following remedies and send the animal straight to the deep freeze. But they often can recover, if given the chance.

Broken Leg. A chick’s leg can be splinted with Popsicle sticks and masking tape. A larger bird’s leg can be splinted in the same manner with heavier-duty materials.

Egg-Bound. The chicken squats, strains, maybe spends all day in the nest looking constipated. Treatment: Pour warmed olive oil into her vent. Feed her castor oil. Then gently try to maneuver the jammed egg out.

Prolapsed Vent. This is most likely to happen to pullets who began to lay before they were fully grown. A mass of tissue will hang from the vent. It can be fixed more easily than it looks. Wash the protruding mass with warm water and a gentle antiseptic. Lubricate it with medicated Vaseline or mastitis ointment. Then push the prolapsed mass very gently back into the vent. In cold weather, dry the wet feathers with a hair dryer or some such. Isolate the recovering hen from the rest of the flock (which might be tempted toward cannibalism). Feed her drastically reduced rations for a week to slow up the egg laying. But supply plenty of greens and fresh water. Clean her vent area each day and apply ointment. By the end of the week she will probably be fine again and able to return to the flock. Later she will begin to lay normally. If, however, she prolapses repeatedly, turn her into stew.

Impacted Crop (Crop-Bound). Birds of any age that have eaten too much litter; or long, very dry, once-green feed; or other unfortunate things (like a burlap bag), can get their crop packed with it in such a way that it can’t go down, and it blocks them from eating anything else. The bird will have a distended, doughy-feeling crop and convulsive movements of the neck. The treatment is to pour a teaspoonful of olive oil down the bird’s throat and then gently massage the crop, gradually working its contents up and out of the bird’s mouth. Fortunately, unlike humans (who are adapted for speech), a bird has its windpipe and esophagus completely separated, so you don’t have to worry about them not getting air while you’re doing this job. When you have the crop emptied give the bird water, but not food, for 24 hours. It should return to normal after that. However, sometimes the muscles of the crop have been injured, and the condition frequently repeats. In that case you give up and send the bird to the dinner table.

THE DISEASED BIRD: Most families growing only enough poultry for their own needs don’t experience the variety and scale of poultry health problems that intensive growers with large numbers of the same breed and age in a small area do. So this section attempts to compromise between saying nothing and telling it all. To prevent disease and parasites, don’t let your poultry go where infested bird manure from past years is located, such as in your compost pile or your garden.

If You Have a Sick Bird. Isolate it in smaller quarters to prevent it being literally picked on. Keep it warm (the Number 1 priority!) and provide dietary TLC with special bug and greens offerings. If the bird dies, burn or dispose of it in such a way as to avoid spreading the disease. Don't eat such a bird.

Disposing of Dead, Diseased Birds. Dead poultry, especially baby chicks, can be completely burned in a burn barrel. Make sure you destroy all the remains. A heavy grate on the top of the barrel can ensure that pets or predators don't drag them away. That's better than burying the carcass of a sick animal because of the possibility of it being dug up and/or of the disease organisms remaining in or spreading through ground water.

State Poultry Veterinary Lab. If you have several sick birds and they seem to have the same problem, consult your local agricultural extension agent or agricultural university extension poultry specialist. That person may refer you to your state poultry veterinary diagnostic laboratory. Every state has at least one, and many states have more than one. Call the lab to find out if they prefer you to send a couple live sick birds or one or more dead ones and what they suggest to be the method of delivery. If they will be studying a dead bird, they probably will want you to chill and freeze it as soon as possible after death. If you do have a communicable poultry disease problem, you need a prompt diagnosis, treatment for the rest of your flock, and advice on how to prevent the problem in the future.

Giving a Pill to a Bird. Open the bird's mouth, put the medicine on the back of its tongue, close its mouth, hold it closed, and wait for it to swallow.

Vaccinations. For small home poultry flocks, vaccination isn't usually necessary. Poultry diseases are much more likely to be a problem in big, commercial farms with many birds confined in a small space. Vaccines are available from poultry suppliers for a number of different bird diseases, including fowl cholera, erysipelas, Newcastle disease, laryngotracheitis, fowl pox, and Marek's disease. If you do vaccinate, give the vaccines that are recommended for your geographical area. You can buy them and the necessary equipment to inject, spray, etc., and do your own bird doctoring. To give a shot or eye-and nose-drop vaccines, hold the bird between your legs. Some of these vaccines—such as that for infectious bronchitis—use a live virus, which is given in the birds' drinking water. Be careful when giving any vaccine, especially a live one. The vaccine used for Marek's disease—a live turkey herpes virus—must be given at age 1 day to be effective. Some people are allergic to vaccines.

Pullorum Testing. That same state veterinary laboratory will test your breeders free-of-charge for pullorum and typhoid. All reputable hatcheries can advertise that their breeders have been tested and are pullorum-free. At one time pullorum disease was widespread in both chicken and turkey flocks. An infected hen lays pullorum-infected eggs that hatch

pullorum-infected chicks or poult. The infected young birds spread the disease to others near them and many of them die. Some recover and will carry the bacteria that cause this disease on to the next generation. In order to break that infection cycle, responsible growers began to blood-test all their breeding stock. Infected birds were butchered. (Their meat was all right to eat.) Only uninfected stock was kept for breeding. There is no medical treatment for pullorum disease. Prevention is the only way to go.

SOME POULTRY DISEASES

Blackhead. (See also “Blackhead Disease” under “Turkeys”). Blackhead disease, which is the most widespread and destructive problem of turkey growers, is caused by a protozoan that spends part of its life cycle in the cecal worm. This is why raising chickens and turkeys together can be a problem. If your chickens don’t have cecal worms—or if their cecal worms don’t carry the blackhead organism—you’re okay. Blackhead seldom makes chickens sick, even the ones that are hosting it.

Coccidiosis. About nine different species of *Coccidia*, a host-specific protozoan parasite, afflict chickens, of which three cause the problems. About six afflict turkeys, of which only two make the birds visibly sick. Most likely to be a problem for brooder chicks.

Fowl Typhoid. It’s caused by a bacterium and affects many species of birds including chickens and turkeys. Because prevention and control against fowl typhoid are about the same as for pullorum, buy pullorum-typhoid-clean birds.

Paratyphoid. As with pullorum infection, there is no treatment for this. The birds start dying very young, and half to three-fourths of an afflicted flock may die. It is not possible to separate out infected birds as it is with pullorum. If this disease shows up in a flock, all the breeding birds must be disposed of and a new start made with completely healthy replacements. Paratyphoid is also called “Salmonellosis” and can be a public health problem because humans (as well as reptiles and all other animals) are also susceptible to these bacteria. Humans usually encounter them as salmonella food-poisoning. Chicks suffer with them as a blood-poisoning disease. This organism can be spread by just about anything it gets on, animate or inanimate.

Infectious Bronchitis. This is a viral chicken disease that is highly infectious. When it afflicts young birds it damages the reproductive organs, and they will not lay normal eggs, either by exterior or interior qualities. There is no treatment, but it can be vaccinated against. The vaccine can be administered individually by nasal or eye drops, or to poultry groups in drinking water, or by dust or spray. This vaccine is frequently administered together with the Newcastle vaccine.

Newcastle Disease. This is a widespread, serious, very contagious viral respiratory disease that afflicts almost all species of poultry, especially chickens and turkeys. It could come into your poultry by wild birds or by tracking, bird purchases, equipment, feed, etc. from other poultry farms. There is no effective treatment. It is easy to vaccinate birds against Newcastle disease. The vaccine can be given in drinking water or dusted or sprayed. If you are concerned, ask your extension agent if vaccination is advised in your part of the country.

Bugs on Birds: There are chemical remedies to all these problems, which I have described with reluctance. I don’t like poisonous chemicals. Parasite treatments done during molting can interfere with the bird’s healthy feather development. Never treat for internal parasites and external parasites simultaneously. It will kill your birds. Wait at least 5 days between such treatments. I don’t like environmental pollution. But when my kids got head lice I went straight down to the drugstore, bought some head-lice-killing stuff and used it

on them (following directions carefully). Nobody likes parasites. These are hard decisions. You could burn down the chicken house, wait 3 years, and start over. You can tell me what you did that worked that didn't pollute the world, and I'll gladly add it to these methods.

Bedbugs. This brown or yellow-red insect hides by day under roosts and in nooks and crannies of the chicken house. It comes out at night to feed on the birds. Its bites cause such itching that the birds pull out feathers trying to relieve it. Use Sevin or Co-Ral.

Chiggers. These critters afflict bird and human alike. Chiggers tend to cluster on a bird's skin on its neck and back and under the wings. Too many can even kill a bird. It helps if grass and weeds are kept short.

Fowl Tick (Blue Bug). Night blood suckers like the red mite, these flat, reddish-brown, egg-shaped insects look like ticks, and like ticks, they cause loss of blood, carry diseases, and may cause paralysis. The chemical remedy is malathion spray in the chicken house.

Lice. There are 7 basic varieties of lice: the body louse, which lives on the bird's skin; shaft louse that eats its feather shafts; large chicken louse; brown chicken louse that lives on feathers and prefers southern climates; head louse on the bird's head and neck; wing louse on its wing feathers; and fluff louse in its fluff.

These parasites are common, especially the body louse. These insects are either chewers or biters, and they spend their entire life-cycle right on the bird; off a bird, they die within a few hours. They lay eggs on the feathers and stick them there with a sort of glue. Depending on the variety of louse, the eggs (nits)—which are laid on the breast, the back, and under the wings—will hatch in a few days to 2 weeks. Lice eat skin scales and feathers. Chickens acquire them from being exposed to a bird or rodent, wild or tame, that has them. Lice increase faster in warm weather, but are there in the cold season, also. Too many lice can cause a decline in egg production and in the hatch ability of the eggs.

Birds that are completely confined are far less likely to get them than birds that run loose. You can help your chickens in their fight by maintaining good hygiene according to the chicken-house cleaning directions. Dig in their chicken yard enough to get them started in a new, clean, dust-bathing place occasionally (see "Dust Baths"). Dust clogs louse pores. Crumbling a handful of tobacco leaves in each nest and in bird dusting sites will help. Rotenone and sulfur (from plant nurseries) in the dusting site will also help. Since roosters don't like to dust as much as hens, they may have a worse problem with lice. To dust a bird with rotenone powder hold her by the legs with head downward. This way her feathers will open and you can easily sprinkle in the dust. Don't get it in the bird's eyes.

Lane Morgan told me, "I dust my birds with diatomaceous earth and also put some in their feed. It isn't perfect, but it helps." Another friend told me she dusts her birds with wood ashes and that controls their lice.

Insecticide powder in the feathers of a mother hen will kill her chicks when they huddle under her, so don't dust a mother. If you're going to dust her, do it well before the hatching dates. The tender skin and feathers of a chick are especially vulnerable to louse predations, and large infestations can quickly kill chicks and young chickens. Insecticide treatment will kill the lice but not their eggs, so you have to apply it again in 10 days to kill the newly hatched lice. Time the chemical treatment to match the timing of your cleaning and disinfecting the chicken house. Stronger chemicals used to treat lice are carbaryl, malathion, coumaphous (brand name: Co-Ral). Follow the directions carefully. All this effort may or may not actually succeed in eradicating a louse population.

Mites, Depluming. A severely infested bird may be nearly naked because it pulls out

feathers trying to relieve the itching caused by this mite that characteristically burrows into the skin at the base of a feather. Control it by dipping the bird into 2 oz. of sulfur and 1 oz. soap dissolved per gallon of water. Be sure and get the solution down to skin-level of the bird. Repeat in 3–4 weeks if the first dip doesn't solve the problem.

Mites, Northern Fowl. This one is reddish to dark brown and is found around tail, vent, and breast. Like lice, these mites live their entire life-cycle on the bird. They suck blood and can reduce a bird's productivity and general good health. Sevin or Co-Ral can kill them.

Mites, Red. To check your hen house for these mites, look for little creatures moving in the cracks and crevices of the chicken house walls, perches, etc. You're also looking for small "salt and pepper" deposits that make a "trail" under the roost perches. If the mites are there, they hide in those cracks by day and come out at night and crawl up chickens' legs while they're sleeping to feed on them. Knowledgeable chickens will avoid sleeping on such perches, preferring uninfected places. To find out for sure, pluck a bird off the roost at night, and examine between the feathers of its legs and elsewhere. If the mites are there, you'll see them. And if one bird has them, they all do. When you leave the chicken house you're going to feel like a shower. Take one. And put your clothes in the washer. Treatment for Red Mites is Sevin or Co-Ral unless you want to use an old-time remedy:

The old-time remedy, an effective one, was to brush or dab used crankcase oil, perhaps diluted 50 percent with kerosene, on the crevices and roosts of the hen house. Start after daybreak by chasing the birds out of the house and shutting the door. Smear the stuff with a paint brush or a rag tied to the end of a stick all over the perch, especially underneath where the mites hide all day. Don't let the birds back in until as late in the day as possible. Give the treatment again in 2 weeks, and again in 6 months. Penny Anderson of Aitkin, MN, wrote me, "A few years ago when it got really cold here, I ended up with a lot of sparrows in the barn, and they brought red mites. My great-aunt Marie told me to provide a pan of wood ashes to let the chickens dust in. That and coating the roosts and bottoms of the nest boxes (under the straw) with old oil cleared them up in no time."

Mites, Scaly Leg. These are another common type of mite spread by wild birds. They cause scales on the chickens' shanks (the bare-looking "ankle" to "knee") which protrude and may flake off. You can't see these because they are microscopic in size and burrow into the leg skin, under the scales. Sometimes they also get into the comb and wattles. Severe infestations cause an abnormal gait. You kill these by dipping each bird's feet into a mixture of two-thirds oil and one-third kerosene. It helps if you clean the chicken house together with the treatment. Two weeks after the first treatment, dip again. Some people dip a third time, 2 weeks later. An alternative treatment is to wash the shanks and rub with Vaseline. Yet another treatment is to dip the bird's legs in salad oil or baby oil, up to the shanks weekly for 6 weeks.

Tropical Chicken Flea. These beasties can cause blindness and even death simply by their clustering on the comb, wattles, earlobes, and around the bird's eyes. The chemical remedy is carbaryl (Sevin) in dust or spray.

WORMS: To some extent worms are routine in poultry and can be tolerated, though they lower the flock's general disease resistance. Chicken growers in southern states have the worst problem with worms. If wild birds that have them get in to share your chickens' food, they leave droppings in the chicken pen. Chickens that pick at those droppings then acquire their parasites. Or the dropping of wild birds may be eaten by insects. If your chickens eat those particular insects, they acquire that worm variety. It helps to keep confined poultry well supplied with grit or gravel so they're less likely to peck at

droppings to acquire new grit. If worms do get started in your flock the problem will spread. The worst off birds may have diarrhea and emaciation, be weak, and lay less.

Testing for Worms. You test for worms by having an expert examine the bird's manure. Some owners do this twice a year—in January and in July. Some owners combine the feces of several chickens to send in as a sample—on the theory that if one has them, they all will soon anyway. To send a fecal sample to a distant laboratory, put it on a piece of aluminum foil and fold the foil carefully over it. Put that into a small jar or metal container and close the lid. If the examining veterinarian identifies a parasite, he'll suggest what to do. Or you can worm the birds yourself ...

Worming. Garlic, in any form, fed to the flock may help suppress worms. Some growers routinely add garlic to the flock's drinking water. Other growers feed diatomaceous earth in the same way: 2–3 T. D.E. per 1 lb. (0.45 kg) of bird feed, or about 2 c. per 50 lb. (22.7 kg) of feed, and for the same purpose. D.E. is available from Glyn Miller: 318-793-4950; 1008 Hwy 465, Sieper, LA 71472-9774; glynmiller@aol.com. Steam-cleaning a chicken house at a high temperature can help kill worm eggs. Pharmaceutical worming preparations are available. Some growers believe in regular de-worming, every 6 months. Some fancy-and pet-bird owners advise feces tests, followed by worming if advised. That's expensive. Some growers are against giving chemical treatment unless the birds are definitely appearing unhealthy. Or you can hang in there with "organic" methods. If you want to use chemical treatment, you really would be best off with expert advice about which one, or combination, to use. Follow directions carefully. Overdosing with worm treatment will kill your birds. Withhold all food the night before your morning chicken-worming event.

Here are some common poultry worms:

Roundworms. The worms are 1 ½–3 inches long and live in the bird's intestine. A light infestation doesn't seem to be a problem, but too many is not good. Piperazine preparations are effective against roundworms. They can be given to the bird in water, feed, or in a capsule form. To prevent or limit roundworms, avoid using a dirt-floor chicken house and properly clean out and disinfect the chicken house floor. It can also help to manage poultry so that they are let loose on a particular range only once in 3 years. This is the most common chicken internal parasite.

Cecal Worms. These are also known as "small roundworms." They are very small and are not considered a problem themselves. Their problem is that they are the carriers for the Blackhead organism. (See "Blackhead Disease" under "Turkeys.")

Tapeworm. Actually there are a variety of different tapeworm species. The smallest are microscopic; the largest can be 7 inches long. These flat, white, segmented worms live in the bird's small intestine and can be quite a drain on its (and your) resources. Tapeworm eggs can live in the ground for more than a year. Infestation can be controlled by rotating poultry ranges, using an area only once every 4 years. The tapeworm uses intermediate hosts—snails, beetles, worms—in which to complete its life cycle. Poultry acquire the tapeworms by eating the infected insects.

Others. There are also capillaria worms, acquired by eating infested earthworms, and gizzard worms, acquired by eating the grasshoppers, beetles, weevils, and other insects serving as intermediate hosts. Neither parasite is treatable once acquired.

Roosters

At 3–8 weeks of age, you can distinguish the young cockerel chicks by their slightly larger combs—that red decoration on top of the head—and wattles, the one that hangs under

the chin. Roosters grow their decorations and get color in them first. Roosters are usually larger than pullets. When they have grown, you eat most of them and save a few for breeding; you don't need to keep very many roosters back from the butchering process to have fertile eggs. Three could take care of a flock of 50 chickens very nicely; figure 1 rooster per 15 hens. The extra roosters should be culled from the layers by the time the pullets are 20 weeks old if you want the best egg-laying and breeding performance. Extra roosters may hassle the pullets excessively.

CROWING: Roosters crow very early in the morning, in the night if they get disturbed, and at other times when the impulse takes them. In some places there are zoning laws against crowing. You can't stop a rooster from crowing; you can only stop having a rooster.

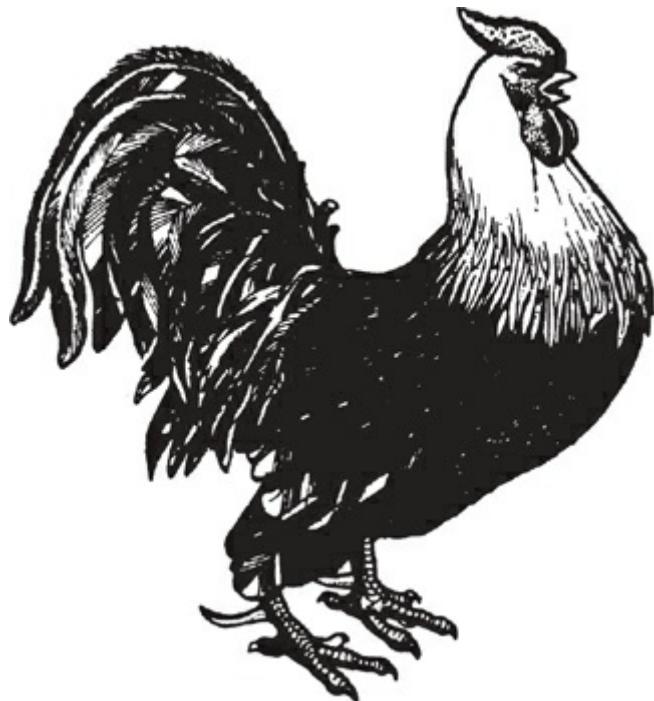

FIGHTING: Young males who are growing up together may look fierce but generally there are no injuries from their combats. These are ranking fights and once the issue is resolved there will be peace. Even fighting game breeds are peaceable if they have grown up together. The serious fighting happens when strange males are brought together at adult ages. Serious injury or death can be the result. The best book on the language and sociology of chickens is *Bantams* by Helga Fritzsche.

NOTE: *Roosters are aggressive and may chase and peck small children in the eyes.*

Many a time I've run out of the house because I heard a small child screaming in the yard, and there was a rooster flying up toward the child's face. I wondered if somehow it was my private nightmare until I received the following letter from another mother, Becky Jacobson of Felton, DE: "Dear Carla, We had a small rooster who would fly at people once in a while, but we never thought much about it. Our few chickens are usually kept penned up in the chicken yard. One afternoon they were out, and my 20-month-old daughter was playing and following her father around. She walked past the rooster and must have stopped in front of him. Before we knew what happened he flew up and spurred her in the eye. She is now blind in her left eye and the eyeball is disfigured. It's cost us thousands of dollars and much heartache to learn this lesson."

Roosters won't bother a larger child; it's your toddler or 2-year-old they would go after. Roosters raised to be fryers, that are butchered as soon as they achieve sufficient weight, don't get old enough to be a problem in this regard. And you don't need roosters to have eggs. Hens will lay eggs even if there isn't a rooster at all on the farm. The eggs won't be fertile, but they're fine to eat, just as good as fertile eggs. If you have a rooster that acts like he might be a danger, have him for dinner, and consider cutting off the spurs of your roosters. Or make capons.

MAKING CAPONS: Roosters can be castrated. It's called caponizing them. Here's a letter I received: "Dear Carla, How do you make capons from roosters? It seems to be a lost art. Seems such a waste to kill them small, when I understand somewhere under the right wing you cut ... and remove something and they grow as big as a turkey if you desire. If you have this information, whatever cost, please let me know." Well, in case you, too, are that vague about it, and also want to know the details as much, here's the caponizing nitty-gritty.

This is indeed an old-time art; it was invented in ancient Greece. You can get a caponizing outfit, including complete directions for using it, from mail-order poultry ranch suppliers. The things you're removing are the male sex glands that are located in a young cockerel's abdomen. Caponizing will solve the pecking and aggressiveness problem, and the roosters will grow sometimes as much as 50 percent heavier than they would otherwise—maybe to 10 pounds. Generally, the birds have no ill effects from the operation. Caponizing is in the process of going out of fashion. It involves virtually major surgery on the bird, which may go awry. The operation results in a heavier bird, but a significant proportion of that weight is fat. The capon market is now being displaced by the new "giants," which are large without the nuisance of the operation, and whose weight is proportionately more meat than fat.

Caponizing can be done by hand instruments or an electronic gadget. You operate when the birds are 8–10 weeks old. Operate in bright light and with the bird firmly held down onto a board or table with straps, its left side down, right side up. Pull enough feathers out to expose the lower rib area. The incision is made between the 2 last ribs from the bird's head end. With traditional hand tools, you need a knife to make the incision, a spreader to hold open the cut, a hook to tear the membrane covering the intestines, a blunt instrument to press the innards back out of the operator's way, and a forceps-style extractor to remove the 2 testicles, which will be located, one somewhat above the other, just in front of the kidney and near the backbone. The testicles are white and oval-shaped. A large artery runs between the two, which mustn't be punctured.

On to a more pleasant subject: your laying flock!

Laying Hens

OF BUYING GROWN BIRDS FOR LAYING: It's best if you buy pullets from 3 to 6 months old, so that their full egg-laying career is ahead of them. There's many a horror story of what happened when a novice bought somebody's worn-out cull hens. Growers don't let go of their best chickens—unless it's your mother, and maybe not even then. Be very careful and gentle whenever you are handling birds that may have eggs inside them. If they are birds that have already begun to lay, moving is quite likely to throw them into a molt and stop their egg-laying for the time being, because chickens are strongly creatures of habit.

They'll go into that molt whether they were just starting a laying season and at full production, or whether they were near the end of it anyway. That's why it's so much better if you buy pullets that have not yet begun to lay—or chicks.

Egg Records: To calculate if you're making or losing money, keep track of the values. In total, the original cost of your laying flock, plus their feed and any other expenses incurred on their behalf, is subtracted from the value of the eggs laid and the meat value of the stewing hens. Small growers generally find that if they use commercial feeds they enjoy their homegrown eggs but lose money on them. If they use homegrown foods and/or foraging, they come out ahead. Exactly how many eggs your layers will produce for you is extremely variable, depending on what breed they are, how well you feed (the more they eat, the more they lay), how much protein is in their feed, how you house them, what time of year it is, and how old they are. Commercial breeds in the 1940s averaged around 180 eggs a year. Now if a bird is laying about 20 eggs per month in her first 10 months of egg-laying, she's doing average; 300 eggs the first year is excellent. The urge to lay is fragile and can be thrown off by moving, changing feed, weather change, broodiness, or molting. And there are other factors to be considered besides pushing for egg production: feeding economy and electricity conservation.

Egg-Laying Anatomy: When you butcher an egg-laying chicken, you'll see the eggs-in-making inside of her. There will be tiny little yellow ones, no bigger than grains of sand, clustered together with small pebble-like ones, graduating on up to larger and larger yolks. (She builds the yolk first.) When the yolk-of-the-day is ready, it enters a long passageway where it is fertilized (if she has had the company of a rooster) and gets the white wrapped around it. Further down the assembly line, her egg gets 2 membranes added to the outside of it that hold the yolk and albumen in place. Then it goes to her shell-building station where the outermost layer is added. When she has finished building the shell, the egg moves on out to where her oviduct meets her digestive tract, just inside her vent (or cloaca). She then lays the egg, which she has spent approximately 24 hours building. When an egg is laid, its passage out is eased by a slimy, wet coating—the “bloom.” When she decides to lay an egg, it generally doesn't take her long. As soon as the egg is laid, the bloom commences to dry into a thin, invisible membrane that protects the outside of the eggshell, and she cackles with the joy of accomplishment.

Of Laying and Aging: You can guess a bird's age by looking at its shanks: young chickens have smooth ones; older birds have larger, rougher ones. A pullet normally starts laying when she is 20–24 weeks old. She starts out making very small eggs occasionally and gradually increases egg size and frequency of laying until she is in full production. It takes her about 7 weeks to work up to full production. She's called a “pullet” until she has her first adult molt that will follow her first season of laying. After that she's called a “hen.” Hens average about 20 percent fewer eggs their second season of laying, but the eggs tend to be larger, and the hen will have put about an extra half pound of weight on herself. Plan for enough replacement pullet chicks to keep the number of your eggs averaging up where you want it. A flock that is 75 percent pullets and 25 percent yearlings and older will operate at peak efficiency. On the other hand, if absolute money-efficiency isn't such a big issue for you and your hens are as much friends and pets as financial investments, you can expect them to live as long as 14 years, and to lay tolerably for maybe 7–10 of those years. The hen's lifestyle can make a big difference. If on a natural schedule and not pushed to lay, she doesn't suffer “egg burnout”—and produces somewhat less but somewhat longer.

LAYING AND BLEACHING: As a hen lays she loses her yellow coloration. If all her yellow is there, she hasn't started laying at all. After a few weeks of laying the yellow will be faded around her vent, eye, and ear lobe. After producing for a couple months her beak's yellow will be faded also. After 6 months of egg production her feet, toes, nails, and shanks will also be faded. When hens quit laying, the color will come back—in the same order in which it left. A parasite infestation can also cause bleaching.

"SEASONS" OF LAYING. A hen that laid 240 eggs her first season will thus lay about 190 in her second season and about 150 in her third, although her feed consumption remains the same all 3 years. For peak laying efficiency, the longest you'd keep a hen is 3 laying seasons. Then you stew her. How do you define a "season" or "year" of laying? Under natural conditions, the first egg-laying season begins (depending on when the pullet hatched) between August and March. That first season will end with a molt in September or October. Her second season starts when she begins laying again after that molt, sometime between November and January. She'll lay until her second molt begins the following September or October. Some growers cull all layers at the end of their second season. Some let them have 3 seasons. Some give them longer yet.

DUST BATHS: Roosters don't care much for dust-bathing, but hens love to dig into warm, loose, clean dirt and take a dust bath when the weather is warm enough so they won't get chilled by doing so. They look for a fairly new place that hasn't yet acquired a flea population. They scratch there until the dirt is fine. They'll find gizzard grit at the same time. They then roll in it with their eyes closed until the feathers are full of the dirt right down to the skin. Then they shake it all out and feel purified. Instinct or experience somehow informs them that dust clogs the breathing pores of the tiny parasites that tend to afflict poultry and is therefore a perfect, natural (nonpolluting) insecticide. You can provide hens that are totally confined with dust bath facilities by furnishing a deep pan or tray with loose dirt or hardwood ashes in it. Or you can build them a "sand box" using 1-inch-thick boards, about 6 inches wide and 20 inches long. Put such an artificial dusting spot where it won't get rained on in summer and where it will be in the warmest place they have as the season cools off. They'll appreciate that. A good dust-bathing material is half fine dirt and half dry sand. Such a human-made dust bath needs to have the droppings cleaned out of it periodically and the contents changed every few weeks. You don't give chickens water baths. If you want them super-clean, supply a dusting place with pure sand in it. They'll do the rest.

DISCOURAGING A BROODY BIRD: You could try taking away all her eggs. But a hen really in the grip of instinctive broodiness may stay on her nest even if there are no eggs in it. If you let her sit there 3 weeks, then separate the hen from the nest, she'll adjust in a day or two. Or you could let her set just 3 or 4 days and then give her the treatment. Or you could act the moment you notice her acting broody. Put her in a pen where there is no soft, suitable nesting place and no straw or litter of any kind with which to try to make a nest. Don't put the cage on a litter floor or she'll obtain litter and that will make her nest-minded again. Put the cage in a brightly lit area. Supply her with plenty of food and water. If you put a rooster in there with her, he'll hassle her and that will help get her mind off brooding. Modern hens will generally pull out of it in only a few days, and will soon be acting normal again. Production-minded poultry growers object to setting because a hen that sets has stopped laying and will not lay again for about 10–12 weeks unless her broody mood is "broken up." Even if the setting is broken up she'll probably be out 2–4 weeks from when it started.

My mother used to dump buckets of cold water on such a broody hen to try to get her to quit it and lay again. Another modern method is to put her in a swinging cage suspended from the chicken house ceiling—a tiny box that has wire sides so she'll get lots of light. It has a slatted bottom that she won't like to set on. A broody hen that won't quit no matter what may be a problem to you but might really be appreciated by another family.

MOLTING: Hens from typically very good egg-laying lines generally molt late and fast, beginning between September and October, lasting 2–3 months. Or not at all. For many chicken generations now, growers have been culling birds who slack off on their laying to molt as determinedly as they've been getting rid of ones that choose to turn broody, and the results are new genetic lines of egg-producing breeds that will lay right through the molting period. So the following discussion will be more relevant to chicken varieties of the old-fashioned sort. With them, your strongest egg-production will typically be from early spring when the days start to get long until molting time.

Chickens molt once a year. Your chickens will molt in late summer, fall, or early winter. Molting is important to chicken-raisers because when the hen molts she quits laying. When a rooster molts, he quits breeding. For chickens on a totally natural cycle, springtime brings a rush of egg-laying, followed by broodiness—when she quits laying—motherhood, repeat of egg laying, broodiness, motherhood—maybe for a total of as many as 4 families a season. And then the molt. With the onset of her molt, such an ancient-rooted bird would stop laying for the year, then lose its old feathers and grow new ones for winter warmth.

The modern hen, if she is of a commercial egg-laying breed, begins to lay eggs when she's 5–7 months old. She skips the broody period, skips the molt, and lays more or less continuously for 12–15 months. Then she finally does stop or slow up for a major molt. She may stop for 3 or 4 months. At this point most commercial or very cost-conscious operations would cull her out for stewing chicken. The average chicken reaches that point at about a year and a half of age. That's why some people simply send the older crop of layers off to the freezer as soon as they molt. There's a middle ground to that. This hen begins to lay when the days lengthen in late winter (January, February) and gradually increases her laying to a peak in April and May. Then she gradually reduces productivity again through July and August. Around September the shortening days stimulate her to cease laying and use the extra nourishment thus available to grow her winter feathers. After 6–10 weeks spent in her molt, she may start laying again in October or November, or she may stay out until January or February. This is a more typical pattern.

The Molting Sequence. Molting occurs first on the head, then neck, then breast, then body, then wings, and, finally, the tail. The new feathers push the old ones out, just like children getting grown-up teeth. It takes a hen 6 weeks to grow one of those big, primary feathers. If she loses and replaces only one such feather at a time, she'll be a long time finishing the molt and returning to lay. Under natural conditions, a very gradual molt helped survival. A chicken that lost large wing feathers only very slowly kept its ability to fly during the molt. Hens that lost several primaries at a time got it over with fastest. While the hen is molting her comb becomes less bright-colored and full-shaped. Then, when the molt is over and she's ready to lay again, the fullness and color return to her comb.

Hens that molt the latter part of July, or the early part of August, are considered good candidates for culling, because they will probably wait until December or January to start laying again, whereas birds who wait to molt until September or later, also begin lay again in December or January (when days start to lengthen). Feeding your hens lots of

good green stuff may help hurry them through their molt and get them back to laying within a couple months. If you have young pullets hatched in early spring, they'll be starting to lay at this fall molting time and that will compensate in your egg production. Then they may go into a molt in early winter. It all depends on a combination of the particular heredity of your hen, her age, and stress factors.

Stress-Triggered Molting. If you want all your hens to go into a molt at the same time, you can easily cause that. Just shut them up in the chicken house in the dark, especially when they've been used to running loose, and for 3 days give them water, but no feed at all. Then provide a poor-quality feed. That will do it. You won't have to worry about eggs for a while. Most often owners accidentally throw their birds into a molt by creating some of these conditions. But some owners prefer force-molting. Natural stresses can cause molting, too. After a serious disease, the recovery phase of a bird is typically characterized by molting.

OF TEMPERATURE, LIGHT, AND LAYING: Although different breeds of chickens can be quite different about when, or if, they lay, in general, the light breeds shut down at freezing temperatures. So if you have Leghorns and you want them to do their best, set your thermostat-controlled heater in the chicken house for at least 40°F. They'll also need 14 or more hours of daylight to start laying and stay at peak productivity. Incidentally, chickens can see most colors, but not true blue; so you can use a blue light for their night warmth without disturbing their rest in the least, or to create light for night inspections.

Daylight Hours. Chickens go to roost and go to sleep when the sun goes down—as early as 5pm in winter at my latitude (see “Hours of Daylight by Month” table). Chickens have a built-in system to measure hours of daylight and lay best when days are long—14–16 hours. The long days stimulate a pituitary hormone. In a local university experiment they were fed that hormone generously, and they not only laid all winter—they laid 2 eggs a day! If a pullet becomes sexually mature while the days are lengthening, she will begin laying eggs even before she has finished growing. If a pullet becomes mature enough to lay eggs when the days are shortening, she may not begin to lay eggs until the days lengthen again the following spring. If you choose to go natural and give your chickens a winter vacation with no more light than what nature supplies, they'll definitely lay fewer eggs in winter—like 2 eggs per week per hen. Then spring will come and they'll all start to lay maximum at once—like 5 eggs per week per hen. Suddenly you'll be up to your ears in eggs.

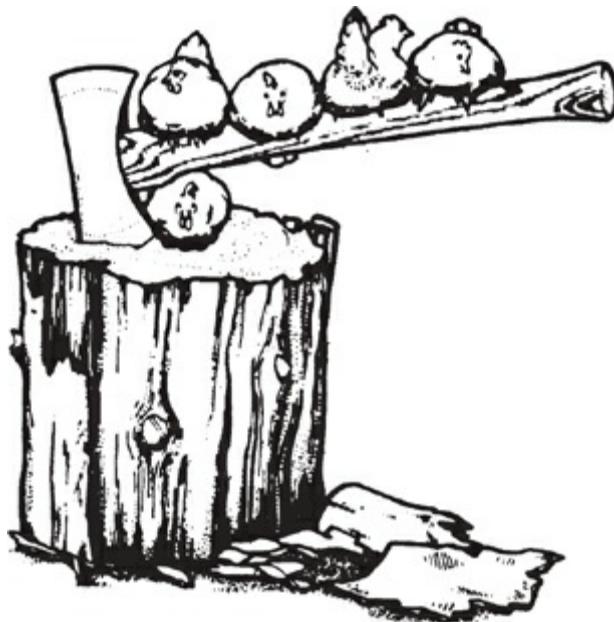

Light-Stimulated Laying. It may not be a good idea for you to put electricity in the hen house or use it if it's already there. Lights will increase egg production but they also raise your electric bill, raise your feed bill (because laying chickens are eating more), and invite egg-laying burnout in your chickens. (Once again, I'm trying to give you all sides of the argument, and all requisite data to make your own decision and proceed on it.) In the northern United States, days are too short for maximum egg-laying during many of the fall and winter months. If you want to buy electricity for egg-making, exactly when you begin supplementing light and how many extra daylight hours you will need to provide depend on your latitude. At an average northern U.S. location, you would start supplementing about August 15. During November, December, and January, the months when days are shortest, you'd need to supply about 5 extra hours of light. You can add the hours to their day at sunset, or you can turn their light on a sufficient number of hours before daybreak and achieve the same result. You can leave the light on all night and still get the benefit to egg-laying, if turning it off is a nuisance to you. Modern timer devices that take care of turning it on and off for you simplify that problem and save electricity. If

you supplement light, it's important that you do it regularly. A lighting period that is irregular, or stops, will promptly result in irregular or reduced laying, reduced rooster fertility, and hen broodiness. And it's important that you continue it until your artificial lighting neatly phases into the days of naturally increasing light.

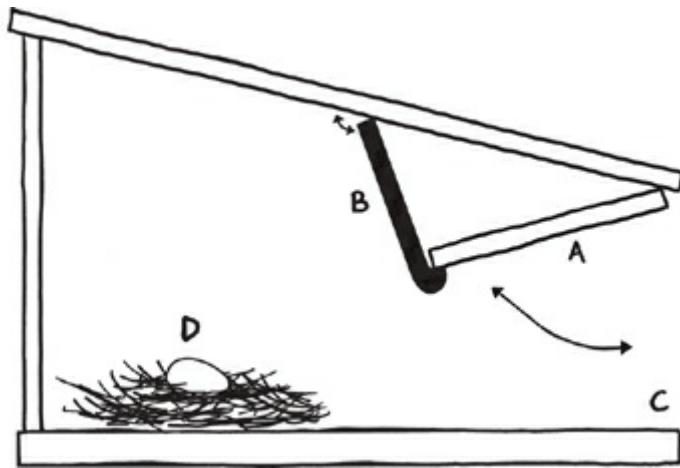

HOURS OF DAYLIGHT BY MONTH				
Month	45°N Lat.	40°N Lat.	35°N Lat.	30°N Lat.
January	9hr, 09min	9hr, 39min	10hr, 04min	10hr, 25min
February	10hr, 26min	10hr, 41min	10hr, 56min	11hr, 09min
March	11hr, 53min	11hr, 54min	11hr, 57min	11hr, 58min
April	13hr, 29min	13hr, 15min	13hr, 04min	12hr, 53min
May	14hr, 51min	14hr, 23min	13hr, 59min	13hr, 39min
June	15hr, 35min	15hr, 00min	14hr, 30min	14hr, 04min
July	15hr, 07min	14hr, 34min	14hr, 07min	13hr, 44min
August	14hr, 06min	13hr, 46min	13hr, 29min	13hr, 14min
September	12hr, 33min	12hr, 30min	12hr, 26min	12hr, 22min
October	11hr, 01min	11hr, 12min	11hr, 20min	11hr, 28min
November	9hr, 34min	9hr, 59min	10hr, 21min	10hr, 41min
December	8hr, 48min	9hr, 22min	9hr, 50min	10hr, 13min

Use a 40–60 watt bulb with a reflector to enhance the wattage. Brighter light isn't necessary to get the effect. If you have a sizable chicken house, one such bulb with a reflector every 10 feet will do. An Alaskan reader wrote me that she hangs a kerosene lantern in her hen house just about dusk during the winter. She leaves only enough oil in the base to burn the needed number of hours to supply 14 hours of daylight. Some growers, with a more sophisticated system, use a small transition light to resemble dusk. That allows the chickens to go to their roosts for the night in a natural kind of way. Bright light, suddenly shut off and leaving the chickens in pitch darkness, can create a problem as chickens may have trouble finding their roosts and steering well enough to fly up and get on them.

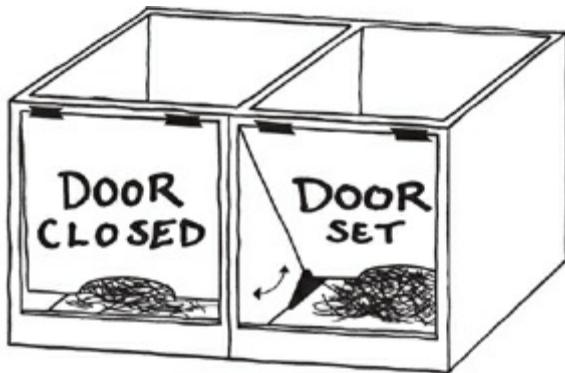

HENS TO CULL: Cull non-layers and maybe also the early molters. A pullet who has never yet laid an egg has a very yellow beak and feet. As she commences laying the yellow gradually bleaches out of beak and feet. So your first culling will be of hens who for some reason do not lay eggs at all.

Trap Nests: One way to be sure who's laying and who isn't is to use a trap nest. A trap nest enables you to keep the good layers and send only the loafers to the table. To make a trap nest, build a box about two feet long and a foot and a half wide. The back should be higher than the front. In the front, put a door hinged from the roof. Cut a lot in the roof and hang a wooden hook through it, so that when the door is raised it can be hooked loosely on that wooden hook. If the whole door is set low enough, when the chicken enters it she will brush up against the door, so knock it loose from the hook, and the door will drop down and imprison her. "A" is the door, "B" the hook, "C" the doorway, and "D" the nest. Block access to all the usual nests. Check the trap nest often so that some layers won't get desperate and get in the habit of doing what needs to be done on the henhouse floor.

Here is a picture of another type of trap nest. Whichever type you use, a good culling system is to partition your henhouse into two separate sections, both of which have nesting boxes, but only one of which has trap nests with the trap set. Every night you move the captured hens that you found in the trap nests over to the other side of the hen house. That way you soon know for sure who was laying and who wasn't, and you have them separated. After you are done culling, remove the partition and go back to normal.

Early Molters. Some people think the first birds to molt should be culled, because they are often the last to return to laying. You can check your flock for culls whenever you want a chicken dinner, or periodically every few months. A pullet or hen with feathers missing from the top of her head is not molting. A bald head and bare back are the result of too many attempts at mating by one or more roosters. (The rooster grabs the top of her head with his beak in order to steady and balance himself and places his feet on her back to hold her down.) To catch early molter culls, check during July and August. Hens that are laying lots of eggs have bright eyes, a warm, fully developed, bright red comb and wattles, and a comparatively large, moist rectum. You can fit 2 knuckles to 2 to 3 fingers between the pubic bones on each side of her rectum. (The easiest time to catch and handle chickens to do this test is at night when they are on the roost.) That's the good girl and you spare the chicken that fits that description. The chicken to be culled has dull eyes, a cold, dull-colored, shriveled comb, a small, round, dry vent, and you can only get one finger between her pelvic bones. That chicken is either a simple non-layer, or she is a layer that is in molt. You can't judge them by the feathers. A good layer may well have ragged, worn plumage because she's putting so much of her energy into egg-laying, whereas a low producer may have better looking feathers.

But that was then. This is now. Genetic lines have been selected for hens that can get through their molt without a break in laying.

Avoiding Culling. Put all your flock on the same in-and-out schedule, not bothering to check for non-layers, and butcher them all and replace with a fresh crop you've raised—say at the end of their third laying season.

Water and Food for Chickens (and Other Adult Fowl)

WATER: You must have a constant supply of clean drinking water available. Even a short period of water shortage can slow growth or egg production, and chickens can take a distressingly long while to come out of such a slump. Grown chickens need twice as much water as they do food. Chicks need even more. In very hot weather, chickens pant to cool themselves (water evaporates from their lungs). That form of air-conditioning may double their previous level of water consumption. Chickens can be left for a weekend alone, but not unless you've made arrangements for an adequate supply of water while you're gone. They can do without food a lot better than without water. In winter time, frozen water can be a problem. My mother used to go out in freezing weather several times a day carrying hot water for her chickens. They'd start to drink as soon as it got reasonably cool and it would be long enough before it froze for them to drink their fill (this was in an unheated, uninsulated chicken house).

You can water adult birds in any sort of container, but something they can't tip over is best. Figure a 1-gal. capacity waterer for every 12–15 hens, filled at least once per day. You can make a homemade waterer out of the bottom of a plastic jug, and then cover that

with a wooden-sided box that has a chicken-wire top. The birds can drink through the chicken wire, but they can't tip the plastic over. If the water freezes in the jug, one sharp rap gets it out and replacements, if needed, are cheap.

Food: Poultry have no teeth and swallow their food whole. They have 2 stomachs. The topmost one is their crop, which stores food. The second, lower one is their heavily muscled gizzard, which "chews" the food by grinding it against small stones the bird has swallowed for that purpose.

Train your fowl of any variety to come when called by rewarding them with their food. Use a characteristic sound, whistle, hand clap, whatever. That way you can gather them when wanted and lure them into their pen when needed.

Food Containers. You can buy fancy food containers. The ones that hang from the ceiling are to prevent the chickens from scratching litter into their food or food out of the container. Or you can make a food container, like a wooden trough, for them. Or you can throw the food on their litter or on the ground and let them get exercise hunting for it. Or some combination of the preceding. Thoroughly clean and sterilize food and water containers once a week for chicks, once a month for adult birds—more often if the containers get visibly disgusting. To do this remove any clinging manure with a scrub brush, then wash the container in a sink or tub that holds 2 ½ c. regular liquid bleach per 5 gal. water along with some laundry soap. Let them drip dry. Refill and serve. Don't pour fresh feed of any sort on top of uneaten older feed ever. Rotate your feed containers so that one is picked clean before you refill it. Don't feed your poultry moldy food.

Of Food and Egg Production. The better your layers are fed, the more eggs they'll produce. To make a laying flock pay, feed them to the hilt. For every 12 percent you cut back on their food, they'll slack off on laying 25 percent. And they must have a balanced diet to grow well or lay well: carbohydrates, protein, calcium and phosphorus, trace elements, and vitamins. Old-timers say the time of day you feed them matters, too: that for best production you should feed them amply twice per day, once before they go to bed, and again have food and water waiting for them when they rise in the morning. (Since chickens are such early risers, you'd probably want to set that food out the night before, after they've gone to sleep.)

Commercial Feed. It's available in differently formulated offerings for baby chicks, growing fryers, growing pullets, layers, and breeders. There are also all-purpose feeds available: for young birds (up to 5 months) and for the older flock. An adult chicken eats 85-110 pounds of feed per year. If you're wondering how much food is enough simply take note of how much they're eating. If there is no food at all left over at night or in the morning, give them more. If they are not eating up all their food, decrease it. That same principle works with home-devised diet.

Commercial vs. HomeGrown Feed. The notion that you must have modern, commercially prepared, or mixed-by-formula chicken feed to own chickens is an insult to the intelligence and honor of thousands of years of chicken farmers who domesticated the animals and kept the genetic lines going right up to the time-line doorstep of our present era. That notion is, however, good business for commercial feed sellers. And it is certainly true that their feeds are carefully researched, carefully prepared, and more foolproof than your own. It is also true that, using commercially prepared feeds, you can grow your meat-bird to the desired weight faster and on less pounds of feed than you can on home-devised or foraging diets. And it is also true that commercial feed is much more expensive than whole grain you purchase directly from a farmer you know, and far more expensive than the grain and other foods you can raise yourself on a small plot of ground. Using

commercial feeds is a luxury that risks bankrupting your operation. On less concentrated, cheaper, home-devised diets, poultry will ultimately achieve their target weight, albeit slower and with perhaps less fat, which you don't need anyway. Layers may not lay the absolute most of which they're capable, but they may not burn out as fast to become culls either. I'd hate to see society come to some kind of crisis and not have the know-how to keep their livestock going without centralized poultry-feed processing and packaging plants.

Feeding Table Scraps. Chickens will eat all your peelings, sour or sweet milk, pickles, meat scraps, and rancid lard. They love all sorts of overripe or damaged vegetables, cull fruit, pea pods and vines, thinnings from the garden, general table scraps, and refrigerator throw-outs. They're not so keen on onions, green peppers, cabbage, or citrus fruits. And don't feed them moldy food. (Feed those to pigs or compost.) Marilou Heath of Rialto, CA, wrote me: "We were out to dinner today. The waitress looked odd when we asked for a doggie bag—all we had left was banana peels, melon rinds, and French fries, nothing that any self-respecting dog would eat. Had to explain it was actually for the chickens. And the bunny loves banana peels."

Grain. A chicken's gizzard is ideal for grinding grain—as long as the bird can get grit. So you don't need to grind it (or have it ground) for them. An exception to that might be for small bantams who sometimes have trouble eating very large grains and prefer them to be ground. Young chicks also need it broken up. A mixture of grain is better than a single grain. Coarser grinds are better than flour or mash grinds, which may stick to the beak or get wasted. Corn is probably the easiest to grow at home. A traditional feed called "scratch" consists of a rather flexible mixture of grains—such as field corn, buckwheat, and sorghum heads. Or corn/oats/barley. Or corn/oats. Or corn/wheat. Or corn/oats/wheat. Or corn/wheat/sorghum. Or your own formula. But corn can be a peril as well as a blessing. Birds love corn, but it's a high-fat, low-protein food. Fat roosters don't breed as well. Fat hens don't lay as well. To a real extent, what you feed them will be reflected in what you get out of them. If you want protein out of them, you have to put protein into them.

Contrary to popular impression, a chicken does not have to have grain to live, though grain is a rich food that certainly encourages them to grow well and lay generously. The most essential time of year to feed grain is winter, when chickens need extra nourishment to keep themselves warm. The best time of day to feed it is just before they go to bed. That encourages them to come home to roost, and to lay an egg at home in the morning. An old-time way of fixing the quantity of grain to feed was to feed only the amount of grain the chickens would clean up in about 30 minutes. In winter they made that 30 minutes in the morning and then another 30 minutes at night. The grain can be fed in a trough or scattered in the litter or on the ground. Hopper feeding keeps confined birds out of their droppings. On the other hand, tossing the grain into the floor litter gives confined birds something interesting to do and reduces the tendency to pick at each other, satisfies their instinct to scratch, and provides them more exercise.

Feeding Chickens in Winter. You can't get something for nothing. When there are no or few natural foods for the chickens outside, or the weather is too bad for them to get out, they need commercial feed, plus grain, water, and grit. Or, if their menu is to be home-devised, feed them protein, grain, and greens. In winter they'll enjoy vegetable peelings; cooked cheap bulky vegetables like squash and mangel (stock) beets; warm, cooked cull potatoes; and sprouted grain. They'll also benefit from a source of calcium. They'll eat some good alfalfa hay and get all the grass and weed seeds mixed in there. If they aren't

on commercial feed, make sure they can get some sunshine or Vitamin D. Chickens that are allowed to be out all winter, freely ranging, don't lay as many eggs as confined (deep-litter or battery-style) chickens. Still, such a hen, if she's of a good-laying breed, may still lay 200 eggs or so, which is not shabby. The lower the temperature, the more food your poultry need to consume just to be okay. Each degree of temperature drop in their environment forces chickens to eat proportionately more food to maintain themselves. In a below-freezing environment 100 heavy breed layers would require an extra 375 pounds of feed per month. For the same cost you could insulate the chicken house better and you'd get more eggs, as well as saving some feed expense.

SUNSHINE: In the dead of winter my mother used to feed both me and her chickens cod-liver oil, which contains Vitamin D. Modern research has explained what old-timers knew from trial and error: chickens, like people, make Vitamin D from sunshine. If they can't get out to have sun shining on them, they'll have to be given cod-liver oil (or some other D supplement) or commercial chicken feed. If chickens are low on D, they won't thrive and they won't lay, or they may lay thin-shelled eggs. Young ones may grow with weak bones that result in leg deformities. The easiest solution is to provide them with an outdoor run since sun shining through glass panes doesn't do the job. But if you live in northern Alaska and in winter being outdoors is not an option, then give the vitamin.

FREE-ROAMING vs. CONFINED CHICKENS: Most chicken growers don't have room enough for roaming chickens, dogs, goats, or anything else. Such are these modern, crowded, times. Chickens that roam, at least some of the time, look the happiest and healthiest. Farm-raised chickens that were mothered by real chicken mothers are most knowledgeable about foraging. Bantie breeds tend to take to it naturally, but most chickens can learn to do some. In summer my chickens range all over the farm, looking for weed seeds and insects. Chickens don't understand about property lines. If you have close neighbors, perhaps you can compromise by just letting the chickens out the last few hours before sundown, so they won't have time enough to get too far from home. No matter how good at foraging your poultry are, don't leave them completely on their own. Chickens can get into insect baits and rodent poisons, and they should not feed near where crops or orchards have recently been sprayed. Give them some food in the chicken house to remind them where they are supposed to lay their eggs and where home is. The best food supplement to freeranging chickens' diets, besides table scraps, is plain old grain, offered morning and night.

Of Roaming Chickens in a Garden. They'll take a toll by pecking tomatoes and strawberries. You have to decide for yourself if the bug patrolling is worth the price you pay in sharing your produce. You'll definitely want to keep chickens out of the garden just after planting corn, beans, peas and beets, until the young plants are well started and no longer have the remnant of a seed at their roots. Otherwise, chickens will dig up and eat the seeds. Some people let only a select few of their chickens (banties usually) do the garden patrol. It really depends on how many chickens you have, how big a garden you have, what type of produce you're growing there, and how bad your bug problem is. To keep them out, you'll either have to fence the chickens in somewhere else, or fence them out of the garden.

Green Food for Confined Chickens. They love green food of any kind, from plain grass to dandelion greens to even chopped nettles. In summer, feed them from your garden: carrot tops, pea shells, surplus Swiss chard. If you serve confined birds their greens in a wire basket hanging from the ceiling they'll be entertained. It's the green feed in their diet

that makes egg yolks from farm chickens darker than those from commercial chickens (more vitamins make darker color). If chickens have the opportunity, they can and will use greens for 20 percent of their diet. An easier plan any time but the dead of winter, however, may be to pasture them. There is a limit to the good chickens can get from any bulk food with high-fiber and low-nutrient content like greens. If you try to push that type of food in general and limit other types, their health will suffer because a chickens' system is made for eating a significant proportion of protein (grubs, worms under natural conditions) and grain (weed seeds under natural conditions). The goose or cow will do better on greens than the chicken.

Fenced Chicken Pasture. For chickens that must be confined in good weather, you can create a portable chicken coop holding, say, about a dozen hens, with a little night shelter at one end and a wire-enclosed and wire-covered pen and an open bottom so they can graze. Move that about every 2 or 3 days onto fresh grass. Don't leave it in one place until the grass is totally killed. Or you can build sizable, fenced runs that are connected to your chicken house. Three is the perfect number of runs for this system (with a possible fourth enclosed run in which you feed and water them). Plant the 3 green runs to some kind of hay or cultivated grass, and then alternate your poultry from one to another—about every 2 or 3 weeks—so they don't stay long enough to eat down to and kill the plant roots. Swiss chard, chicken kale, and chicken lettuce are other good plants to grow at least a little of in the chicken runs. The general rule is this: the larger and greener your chickens' pasture area, the better it will be for them. If you can fence in an entire orchard for them, or some similar territory, better yet. Geese are natural grass-grazers. Chickens are not. The domestic chicken is derived from an East Asian jungle fowl that scratched in the dry leaves and rotting vegetation of a forest floor looking for insects. You have to work out what will work in your particular circumstances. Milkweed, nightshade plants and berries, and leaves of the black locust tree are poisonous to chickens.

Andy Lee's book *Chicken Tractor: The Permaculture Guide to Happy Hens and Healthy Soil* (1998) is about raising chickens on grass in a movable chicken coop. Just out is his *Day Range Poultry: Every Chicken Owner's Guide to Grazing Gardens and Improving Pastures* (Good Earth Publications: 540-261-8875; goodearthpublications.com/). Joel Salatin's book *Pastured Poultry Profits: Net \$25,000 in Six Months on Twenty Acres* (Chelsea Green) covers raising pasture-grazed chickens from building pens to processing. His books (and seminar schedule!) are available in print or video from Acres, USA's bookstore: 512-892-4400.

FreeRange Poultry (1997) by Katie Thear is a British book with lots of attractive poultry skid housing designs. Alanna Moore wrote the Aussie entry on this subject: *Backyard Poultry Naturally* (1998).

Robert Plamondon is both a tech writer and a freerange poultry grower. His website provides FAQs, a description of his own setup, and reviews of recommended books: robert@plamondon.com; www.plamondon.com. ATTRA's info on pastured poultry is at www.attra.ncat.org/attra-pub/pasturedpoultry.html.

Herman Beck-Chenoweth's *FreeRange Poultry Production and Marketing* (1996; 740-596-4379) presents info on production and direct selling for the producer/processor. His system is 8 × 18 ft. wooden skid houses enclosed with chicken wire and with gabled tarp-covered roofs and litter-covered wood floors (300 birds per house). He opens the house doors every morning and shuts the birds in every night. He uses a strong perimeter fence around the field to contain wanderers, but usually the birds forage close to home and return there at night. He harvests continuously. The system is described in more detail at his website: www.free-rangepoultry.com.

Join the American Pastured Poultry Producers Association (membership \$20/yr; good-quality newsletter, *Grit*); for more info: grit@appa.org; www.appa.org.

You can buy or make movable cage/shelters. Henspa offers a wide choice of backyard-sized chicken-house/yard combos with wheels hidden inside, ice-free water supply, feeders, and nests inside: Henhotel (25 hens); Henhaven (5 hens); Henspa (10 hens). There's also the Henspa Deluxe or a vertical garden and portable poultry/swine paddock-fertilizer generator, the Foodspa: www.henspa.com/. Robert and Cindy Pellet build their Forsham Cottage Arks (dovecotes and chicken dwellings) suitable for a small backyard at 0845-872-0218; Goreside Farm, Great Chart, Ashford, Kent TN26 1JU ENGLAND; www.forshamcottagearks.co.uk/.

Brower sells a PVC pastured poultry hoop pen that rests easily, moves around freely, and lets birds graze yet stay cool on scorching hot days and dry on wet days. Brooder flaps/wind blocks are available at additional cost: 319-469-4402; www.browerequip.com.

PROTEIN: Protein is essential for chickens. Free-running chickens, in suitable weather, gather their own from bugs and worms. Commercial feed supplies it. If you are using a home-devised diet, include milk, meat, or bugs in season for their protein. You can feed chickens butchering scraps, including innards, and they'll appreciate them. If you have plenty of freezer space, you can stretch such meals by freezing meat scraps in reasonably sized packages. You can also get protein supplies for them from a feed merchant—meat, bean meals, sunflower seeds, lupine seed, linseed, coarse ground peas or beans, and alfalfa meal or good-quality alfalfa hay. These vary in the amount and completeness of their protein, so you are safest offering a variety, or choosing an animal-derived protein. I would avoid feeding them fish in any form, because of rampant water pollution these days. Don't feed soybeans unless they have been heat-treated because raw soybeans contain compounds that can be poisonous to chickens. Don't feed them cottonseed meal because it contains gossypol that will poison chickens.

Milk Protein. Chickens love sweet milk, sour milk, or buttermilk. If you're offering milk for protein, make sure you give enough. Chickens on a completely noncommercial diet would love a minimum of 1 gal. milk per day per 30 birds, plus all the grain they'll eat (or other substantial food like baked squash and mangel beets), plus ample access to pasture, or being fed cut greens daily (or good leafy, green hay in wintertime). Powdered milk cannot fully meet this need because it is missing the whey (liquid), which contains a part of the nutrients the chickens need. Don't serve milk in a galvanized container because of its tendency to turn acidic. Serve it in plastic, enameled, glass, ceramic, pottery, or stainless steel feeders.

CALCIUM: Growing chickens, like children, need calcium to make bones. Laying hens need calcium to make strong eggshells. If your layer's diet becomes calcium deficient, she'll quit laying within 2 weeks. You can supply a partial calcium supplement by drying eggshells until they're brittle, breaking them up thoroughly with a rolling pin, and then feeding them back to the chickens. (Lane Morgan told me she bakes them because baking makes them easier to crush and, she figures, changes the taste enough to make the chickens less likely to become barnyard egg-eaters.) But a chicken needs more calcium than what she can get from just her own recycled eggshells. Ground oyster shells or ground limestone are good for the calcium content, too. The chicken partially grinds the oyster shells in its gizzard and absorbs what calcium is released that way. The old-timers met this need by feeding surplus dairy products, which are rich in calcium and phosphorus. There can't be

such a thing as too much calcium in a chicken's diet, so offer oyster shells, milk, etc.

Egg Eaters. Overcrowded chickens, with insufficient space to run and insufficient gravel in their diet, are more likely than others to develop into egg eaters. Make sure there's plenty of calcium in their diet, provide nests that are quite dark inside, and gather eggs frequently, even as often as 3 times a day. A chicken who has learned the habit might learn differently if you plant an egg filled with red pepper to give an experience she won't forget. A drastic treatment if you see a chicken eating an egg, or notice egg yolk on its beak, is to cut off the end of the bird's beak, or butcher it. To try to identify the culprit, you might set an egg out in the open and watch and see what happens. Darken the chicken house windows and reduce the wattage of light bulbs, if you are supplementing light. Penny Anderson of Aitkin, MN, advises, "To cure egg-eaters, get plastic or one of those decorative marble eggs and set them out in the nests. Make sure to collect the good eggs as soon as possible."

OF GRAVEL AND THE GIZZARD: Chickens have to have a chance to pick up pebbles (grit) for their gizzards. A chicken has no teeth. It swallows down into a first stomach, the "crop," at the base of the neck. Then, as needed, the bird swallows on down from there into its chewing stomach, the "gizzard." In that tough gizzard, grain is pushed around amongst those pebbles until it is literally ground to powder. Chickens constantly suffer a certain attrition for their gizzard's gravel supply. Confined chickens can suffer a real digestive crisis if you don't take adequate care of them in this regard. Without fresh tiny little rocks to eat, they'll scratch in the manure, find, and eat the old ones over again, which can be comparatively unhealthy. But they have to have them (unless they're living on mash). So, supply confined chickens with a container of fine gravel, river gravel, or pebbles. Or you can buy and give them commercial "grit." Figure 1 lb. of grit per month per 3 adult chickens. Supply an appropriate size of grit. Very small birds can't eat large grit; large birds can't keep very small grit in their gizzard—it tends to just pass on through. Feed-store grit comes in 3 sizes: start, for chicks; grower, for bigger chicks; layer, for adult birds. Limestone can't be used as grit: It's soluble.

CANNIBALISM: Sociologists have been interested in the pecking order (literally) that chickens create among themselves: who pecks whom signifies who outranks whom. Of more practical concern is the bird at the bottom. If it starts bleeding, dab iodine or pine tar onto the hurt place, and isolate it until it's healed, because chickens are likely to devour an injured bird if it can't get away on its own. For minor problems the iodine alone may do the job, as chickens hate the smell of iodine. Or use the commercial product, "Anti-Pick Lotion," for this purpose. You apply that to the feathers and the picked areas of chickens. It encourages healing of the wound and is so distasteful to chickens that it discourages the other birds from further picking. Put your anti-pick substance on as soon as you spot a problem.

Picking is less likely if the birds' diet is adequate with plenty of protein and salt. Crowding can make it worse, and boredom contributes. The combination of bright lighting and confinement can cause it. That's why freeranging birds are much less likely to cannibalize than closely confined ones. Keeping feed before the chickens helps keep their beaks productively occupied. Giving them opportunities to scratch grain out of their litter may distract them from paying so much attention to each other and keep them occupied. To stop an individual pecker who is worse than most, clip the little sharp end part off the tip of that bird's beak with a fingernail clipper. (See "Debeaking.") Or send it to the stew pot. The best thing is not to let cannibalism get started because, like all chicken habits,

once they learn it, it's hard to stop.

NOTE: Birds can get very sick from consuming even small amounts of gasoline, engine oil, or polish. This sort of thing can float on top of a puddle and be taken in by a bird drinking puddle water. Even a small amount can cause chronic gastrointestinal illness to the bird. Antifreeze, rat poisons, insect poisons, plant poisons—any or all of these could be deadly to your poultry.

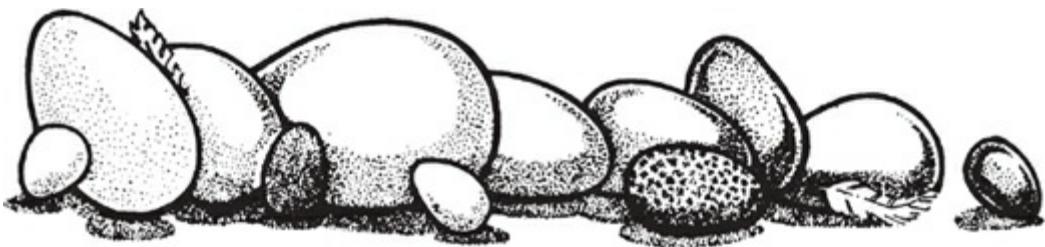

Eggs

Have you ever watched a chicken lay an egg? It's rather a private act, I suppose, but when I was a little girl about 6 or so, I got a great desire to see the egg come out. I patiently waited, every morning that I had the chance, hanging around for days behind a little red hen who laid her eggs in a rather exposed nest. Finally one day it happened: I saw the egg come out! Not as dramatic as watching kittens, puppies, or baby goats come out, but a wonderful moment nonetheless. I was impressed with the serious effort the act required from the hen and her immense relief when it was all over. She jumped up from her nest and walked in a happy and excited way all about, cackling her head off over the joy of it all. So, if you want to meditate on where eggs come from, that's where, and you can rightfully be grateful to the hen because she worked at it.

FINDING EGGS: A basic principle for gathering eggs from any poultry is this: the more you take, the more they lay, and the less they go broody. And you should gather every day to make sure the eggs are fresh. If your birds are confined in a hen house, it's easy to gather regularly and gather often. If not, it can be an adventure. All hens like to lay where there are already eggs. That's helpful. But they'll often pick a new nest spot if you keep emptying it completely of eggs. Then you'll have to discover it all over again. So leave an egg in there marked with a pencil so you won't let it get too old before gathering that one and using a new one. Homestead mail-order suppliers often offer wooden or plastic "eggs," or a smooth white stone can serve the purpose.

The biggest trouble with letting chickens run loose is that sometimes you never do find the eggs—until mama shows up with a family, or you discover a heap of woefully overripe ones. The best way to keep free-running chickens laying in the hen house (besides shutting them up completely, which would probably throw them into a molt and decrease production), is to feed them in there generously last thing in the afternoon when it is about their bedtime (well before true dark), and then shut them up for the night (keeps out night predators, too). They will tend to lay their eggs first thing in the morning. Waiting a few hours after their rising hour to open their door gives you extra security. Then you can let them go on their foraging way. It also helps if you have a roomy, nice chicken house with lots of nesting boxes made the way hens like them, and plenty of clean straw bedding inside.

VARIOUS EGGS: Your homegrown eggs may vary considerably in size, color, and freshness. Pullet eggs are smaller than those the hen will lay later. You can tell when a pullet starts to lay eggs because she gets broad across the behind (same thing happened to me having babies). If you have a small and varied flock you'll learn to recognize each hen's egg—they are a unique combination of size, shape, and color. Then you'll know who's laying and who isn't. (But the heredity will be an undesirable mish-mash.)

BIZARRE EGGS: You may get an egg with 2 yolks. It's fine to eat—just trying to be twins. You may get an egg covered with chicken poop—just wash it off. Your egg yolk may be darker in color and stronger in taste and the egg white thicker and firmer—the whole egg held together more firmly—than store eggs. That would be because your chickens have had access to a richer, more natural diet than commercial layers, which are required to do their most with the least (and the egg shows the difference). Your homegrown egg may have a speck of blood. That's a hereditary characteristic in some chicken lines and doesn't affect the edibility in the least. The egg may have a distinguishable white speck. In that case, it was a fertile egg and, given the right conditions, could have become a chick. Such an egg is also fine to eat. Your egg may have a weirdly shaped shell. It's good to eat, but don't incubate such eggs because you don't want that hereditary trait passed on—besides, they are less hatchable. Your egg may have an egg inside an egg, a curiosity caused when an egg backs up in the oviduct for some reason and thus goes through the last couple production stages twice. The only obviously undesirable egg is one that has a half-developed chick in it or is full of rotten gunk. Otherwise, if you're in doubt, you have to test for freshness.

NOTE: Use cracked eggs only if it's just the outer shell that is cracked and the inner membrane is okay. The membrane is okay if there isn't any egg oozing out the crack. But just to be on the safe side, cook such eggs thoroughly or use them in foods that will be cooked.

FRESH OR ROTTEN? If you discover a nest where some hen(s) hid and laid 25 eggs, then the problem is to distinguish which eggs are still fresh enough to use:

The Bowl Test. The simplest way to determine freshness is to put eggs on the menu. Start by examining the eggs carefully. Usually you can tell a bad egg without even breaking it clear open. It's hard to crack because the membrane inside the shell has become tough. It may smell bad, and if you just start to crack the shell, yucky stuff may come oozing out. Okay, those you toss. Then come the marginal cases. You have to shell them into a bowl to find out for sure. You're bound to get surprised sometimes: an egg that looks dirty and old will turn out to be just fine, and vice versa. If the egg in your bowl doesn't have a funny smell and looks average, I'd say go ahead and use it. So pour it out of the small bowl into your mixing bowl, and go on to the next egg. Incidentally, if the last egg was a rotten one, be sure and rinse your testing bowl well before you pour another egg into it.

Float Testing. If you want to know about the egg without opening it—which, once you've encountered hydrogen sulfide, is understandable—use the float test. Put the eggs in a pan of water. Fresh eggs will lie on their sides on the bottom of the pan. If an egg's a few days old, one end will tip upwards. If stale, an egg will stand on end. If plumb rotten, it will float. This is all because an egg contains an air cell at the large end of it. Eggshells are perforated through by tiny holes that would be needed by the chick for breathing. Thus, with time, a part of the liquid content of the egg evaporates, the white and yolk shrink, and the resulting new space is filled by an enlarged air space. But, like life, this float test is not 100 percent dependable.

Candle Testing. A more sophisticated system is to “candle” the eggs. (See “Candling the

Eggs" for details.) If the contents do not fill the shell, the egg is not perfectly fresh. As with the float test, the larger the airspace (which is now made visible), the older the egg. The yolk should be perfectly clear and round in outline. Another candling sign for freshness is yolk movement: in an older egg the yolk moves about more freely. An egg that has been stored a while will show some shrinkage, however, even if it has been kept chilled and fresh.

SELLING YOUR EGGS: In general, government regulations permit you to sell eggs to friends, neighbors, and at a roadside stand without a license or supervision. If you acquire 3,000 birds or more and sell to licensed outlets like restaurants, bakeries, and grocery stores, then you will need to comply with state and federal laws and should inquire to find out what they are.

NOTE: The USDA, because of increasingly frequent cases of food poisoning from salmonella in some commercial eggs all over the country, now advises against eating raw eggs in any form. I was asked to delete from this book every recipe containing raw or undercooked eggs, and I have done so. But I did it sadly and reluctantly, because egg nogs, egg drop soup, and uncooked eggy ice cream were favorite recipes of mine, and because salmonella in eggs has not been a problem for people with a small family flock and their homegrown eggs. Salmonella poisoning from eggs is most likely to be a problem when 4 conditions are present:

- Commercial eggs are used.
- Many eggs have been combined, as in a scrambled egg mix.
- The eggs are then allowed to sit at room temperature for an hour or more before cooking.
- The eggs are undercooked.

These 4 conditions give one bad egg a chance to contaminate the whole batch—followed by a perfect growing environment for the salmonella bacteria. Poisonings of this sort have occurred, for example, in scrambled eggs prepared ahead for a church breakfast. But for absolute safety, the USDA urges you not to eat uncooked or undercooked eggs in any form, because to kill salmonella, the egg or food with egg in it must be heated to 140°F for at least 3 ½ minutes—no more soft-boiled eggs. How does the salmonella get into the egg? Last I heard, they still weren't sure. The USDA info number about this is (800) 535-4555.

Salmonella: This variety of food poisoning has been a problem in the northeastern United States now for more than 10 years. Recent research has traced it to commercial Grade A eggs. To be precise, a report by the Centers for Disease Control (CDC) states that cases rose sixfold between 1976 and 1986, from 549 to 3,579, and that during the last 2 ½ years prior, 77 percent of the salmonella outbreaks that could be traced to any particular food source were found to have been caused by eggs that had contained salmonella. It used to be thought that the problem was cracked or dirty eggs. The latest CDC study has caused researchers to hypothesize that the bacteria are actually being transmitted to the eggs before the shell is formed. To kill salmonella, the internal temperature of the egg must be raised to 140°F for at least 3 ½ minutes. It is extremely unlikely that your personal flock of birds has this problem.

Eggs as Deer Repellent: Margie Minard of Mt. Vernon, OH, told me eggs help those who have problems with deer in their gardens. Her husband read that one of the huge lumber companies found out that deer hate eggs and had developed an eggy spray for their seedlings. She said "We've just been throwing our used eggshells out here and there in the garden and among the berry bushes and the deer don't come near any more!"

Egg-Using Recipes: When eggs are in season (spring), you can make scrambled eggs, deviled

eggs, pickled eggs, French toast, puddings, crepes suzettes, eggnogs, ice cream, homemade mayonnaise, potato salad, or put plain old hard-boiled eggs into packed lunches. If cholesterol consumption is a worry in your family, feed some or most of the yolks (that's where all the cholesterol is) back to the hens or pigs and shift the recipes to use pure or mostly egg whites. In other words, you could make scrambled eggs for a family using 6 whites and, for example, only 2 yolks. Chicken eggs are 10.5 percent fat. Eggs should be cooked at a low or moderate temperature because a higher temperature makes the egg tough. When eggs are used to thicken liquids, the mixture is generally cooked over hot water kept just below the boiling point to prevent curdling or separation of the liquid.

⇒ **HARD-BOILED EGGS** *Fresh eggs, unlike cold-storage eggs (grocery store), are hard to peel when hard-boiled. That's because they haven't lost any fluid to evaporation—the inside of the egg doesn't have any space between it and the shell—so part of the white layer tends to come off with the peel. The way to avoid this problem is to let the eggs destined for hard boiling get at least 5 days old before they hit the hot water. Then put your eggs into cold water (not more than 2 or 3 dozen in one container), bring to a boil, then simmer, covered tightly, for 10 to 15 minutes. Cool on the stove for half an hour. Put into very cold water and leave for 5 minutes. They should now peel easily. If the egg forms a greenish colored layer around the yolk, the egg has been cooked too long or at too high a temperature. This color can also develop if you store the cooked egg. It is unattractive, but harmless.*

⇒ **SHIRRED EGGS** *Melt 4 T. butter and distribute it among 6 small custard dishes or muffin containers. (There used to be a regular product for this called an "egg shirrer.") Dust the buttered bottoms with dry bread crumbs. Break 2 eggs into each hole. Don't stir. Sprinkle with salt and pepper and set them into a moderate oven until thoroughly set.*

⇒ **EGGY CREPES** *Combine 6 eggs, 1 ½ c. unbleached or whole-wheat flour, ½ c. loosely packed brown sugar or a couple tablespoons honey, and 1 c. milk. Beat until there's air captured in it for lightness. Pour just enough to make a large, thin pancake onto a greased frying pan or griddle over medium low heat, turning when one side is done. Serve flat or rolled up with butter and honey, fruit sauce, syrup, Devonshire cream, or cream cheese inside.*

⇒ **OLD-FASHIONED RICE PUDDING** *Boil 1 c. uncooked rice in 2 c. water (with a pinch of salt) over strong heat until water is absorbed. Then add 5 c. milk and continue cooking over low heat until milk is absorbed, stirring occasionally. Beat 5 eggs, add 1 c. sugar, and 2 t. vanilla. Move rice to an oven casserole dish. Fold in egg mixture. Add 1 c. raisins (optional) at this point. Sprinkle cinnamon on top, and bake at 350°F for 45 minutes.*

⇒ **SCRAMBLED EGGS FOR A CREW** *Beat together 1 dozen eggs, 1 ½ c. milk, 1 t. salt, 1 rounded T. flour, ½ t. pepper, and 4 T. butter. Fry in butter over low to medium heat. Enough for 8 people.*

➲ **DEVILED EGGS** Cut hard-boiled eggs neatly into halves lengthwise. Remove and mash the yolks and season them with salt, pepper, mustard, grated onion, or what you prefer. Roll the mashed, seasoned yolk into balls of the appropriate size and put one ball into each half egg-white. Serve spread out on a platter.

Omelet Secrets. To avoid sticking to the pan, use enough oil to flow around the pan. And use a skillet with flared sides, rather than a straight-sided one.

➲ **VEGGIE OMELET** 4 eggs, pepper, 2 T. butter, chopped vegetables (such as onion, tomato, green pepper, mushrooms, broccoli, shredded sprouts), grated cheddar cheese. Beat eggs. Melt butter in skillet and add egg mixture. Add your choice of vegetables to one side of the omelet and season with pepper. Cook slowly till underside is barely brown, then sprinkle on the cheese and fold the plain side over the vegetables and cheese. When the egg has fully cooked, serve.

Separating Eggs. Separate whites from yolks by cracking the egg over a bowl and gently breaking the shell in two, keeping the yolk in one half of the shell. Let the white drain into the bowl by pouring the yolk from one shell to the other.

Beating Egg Whites. To get the highest peaks, separate the whites and yolks while the eggs are still cold, but wait until they are at room temperature to beat them. (Keep the yolks for other cooking.) Beat the whites with an egg beater at a steady, high speed. They will get frothy and gradually thicken. You can quicken the process by adding a pinch of salt or cream of tartar. The whites are "stiff" when they form peaks that stand by themselves. First you get soft peaks, then harder ones. Homegrown egg whites whip much faster than store-bought ones.

Custard Secrets

1. Custard should come out firm rather than runny.
2. Check for doneness by inserting a thin knife into the center of the custard. If it comes out clean, the custard is done. If any egg clings to the knife, the custard needs more cooking.
3. If it's cooked, but still runny, there weren't enough eggs for the amount of milk. (Most recipes are based on large-size eggs.) Or you used too much sugar, which can also cause the custard not to set up properly. Or the cause of runniness can be that your custard was stirred during baking.

4. If you want a soft custard, stir the mixture from time to time as it cooks. If you want a firm custard, leave it alone. If you want it extra firm, use more eggs.

HOMEMADE EASTER EGG DYES: Wilma Litchfield, my Utah pen pal for years now, wrote me about this. She says safflower (plus 1 t. vinegar) gives pale yellow; orange marigold petals make yellow; turmeric (plus 1 t. vinegar) makes golden yellow; yellow marigold petals make greenish yellow; red onion skins make a rusty red; sandalwood gives a salmon color; cranberries (plus 1 t. vinegar) make a pale gray-purple; blueberries make a bluish purple; raspberries make a pale lavender; walnut hulls cause a nice chocolate brown. Dyeing with red cabbage leaves gets the best color if you add 1 T. alum.

To begin, wipe egg with vinegar, rinse, and pat dry. Put each egg on a cheesecloth square together with the dyestuff you want to use for that egg. Put egg in center of dyestuff. Pull up sides of cloth around egg, tying ends with a rubber band. Put egg packages in a pot of cool water deep enough to cover them completely, heat the water to boiling, and continue cooking at a slow boil for at least 10 more minutes. Take eggs out of water, and cool packages under cool water. (Use white vinegar to avoid adding unwanted color.) (See [Chapter 5](#) for more information.)

No matter what it is, or how unimportant you may think a particular item is, somewhere somebody collects it. And no matter what the subject, somewhere somebody has written a book about it. At least, that's my theory. On this subject a good reference is *Natural Dyes and Home Dyeing* by Rita J. Adrostco (Dover, 1971).

Here are some specific Easter egg recipes.

➲ **ONION SKIN PACKAGES** Wrap eggs in onion skins, then in a cloth, and then tie with string. Onion skins are a natural dye, and the string presses the skin against the egg, making patterns also. Boil these eggs in the cloth package (they can start out uncooked), and then unwrap for lovely surprises. (Can be dyed again with food coloring for further decoration.)

➲ **FOOD COLORING AND VINEGAR** Submerge a hard-boiled egg in a cup of water that has a little vinegar in it. (Vinegar sets the color.) Using a dropper, drop the food color onto the egg. It spreads and makes amazing patterns. Rinse the eggs afterwards to remove excess color. From Carol Kahn, Vernonia, OR.

➲ **PRECOOKED DYES** From Mrs. Linda Crabtree, Kettering, OH: "Natural dye colors turn out much softer looking than commercial egg dyes and often give you a spotty or speckled finish. Dyes should be cooled before using, preferably overnight. Add just a little vinegar to fix the color. (Don't boil vinegar in aluminum.) Examples: 5 red cabbage leaves plus 4 c. water equals aqua color and an egg pattern like tie-dye material. Or boil the outer dry skins of 2 medium onions for an orange dye. Orange peel gives you a light yellow dye. Yellow Delicious apple peelings make lavender with soft rust flakes. Thyme boiled makes a pale graying yellow-orange dye. The possibilities are only limited by your imagination and willingness to give it some effort."

➲ **DANDELION AND PINE NEEDLE EGGS** “First send the children out to gather lots of daffodils, dandelions, needles from fir or pine trees, and big, strong leaves. Then take your uncooked eggs and wrap them with the leaves, pulling in the flowers and needles against the eggshell under the leaf. Cover the egg by wrapping more leaves around the whole thing. Tie string around the leaves to hold them on. Boil until the eggs are hard-cooked. Remove from water, take off the string, and unwrap the leaves. The pine or fir needles will have produced a design on the egg. The green leaves produce yellow. Daffodils and dandelions produce deeper orangish-yellow coloring. For deep dark blues and purples, squash blackberries or blueberries on the egg and then cover with leaves or onion skin. The leaves can be used again and again. Boiling longer produces richer, darker shades. The eggs are beautiful and each is different. We also like to dye the big goose eggs. The geese lay about Easter time and it’s fun to have the big eggs.” All this information is from Nancy Dyer of Corbett, OR.

➲ **FLOWER-PATTERED EGGS** “My great-grandmother taught my mother this. You need brown onion skins, small spring flowers like buttercups, grass flowers, uncooked white-shelled eggs, small squares of soft cloth, and string. Lay flowers next to eggs, petals spread out. Next, position onion skins on top of flowers. Wrap gently in soft cloth and tie with string. Cook in gently simmering water about 25 minutes. Unwrap cloth, peel off onion skin and flowers, and they are truly beautiful.” From Karen Hayes, St. John, WA.

PRESERVING EGGS: Under natural conditions, more hens’ eggs are laid during the months of March, April, May, and June than during the other eight months combined. So you tend to have egg shortages from December to January, and an egg glut in April and May. Preserving eggs evens that cycle out somewhat. The eggs you preserve should be the ones that you are most sure are fresh—not over 4 days old, less if possible. Eggs from hens that have no roosters running with them (infertile) will keep longer than fertile eggs. But you can store fertile eggs, too. There are many storage methods. Choose what suits you best.

About Washing Eggs in the Shell. Don’t wash any egg that is to be stored in the shell unless you’re doing a mineral-oil seal, or unless you follow the instructions below. If the egg is dirty, it’s better to just put it into the daily supply to be used up soon. Not washing helps eggs keep, because an eggshell is naturally covered by a gelatinous him, which washing removes. That him helps seal the shell pores. Without it, the egg is more susceptible to bacteria and evaporation. You can assume that a dirty egg is covered with bacteria. A rotten egg is one that bacteria have gotten into. The washing dilemma exists because it is a fact that bacteria can be more likely to get inside the shells if dirty eggs are washed in the wrong way than if the dirt is simply left on there. That is because adding moisture to the dirt will encourage the bacteria to breed and increase; liquid carrying the

load of surface bacteria, under certain circumstances, can penetrate through the shell pores into the egg; and washing the "bloom" off the egg removes its outermost shell-pore protecting layer.

Safely Washing Eggs for Preserving. Washing eggs in cold water simply causes them to spoil more quickly. You can make it easy for yourself by simply washing dirty eggs in warm water; use within a week and they'll be fine. Or, first scrape off big chunks of dirt with a table knife. Then prepare your water. It must be at least 20°F warmer than the eggs (minimum 90°F; maximum 120°F). Use a cleaning mixture made of 2 T. detergent plus 4 T. chlorine bleach per 1 gal. water. Use a soft cloth to wipe away dirt. Rinse with clear water that is slightly warmer than the wash water was. Do not wipe eggs dry. Let them air dry in the open on a towel or in a rack.

Cold Storage. The commercial method of preserving eggs is to store them at between 35 and 40°F. At that temperature they'll keep fresh for 100 days. A high humidity is helpful. Don't store eggs near smelly things like kerosene or onions because they easily absorb odors through the shell pores. Old-timers did a sort of cold storage by packing eggs in a barrel or crock (nowadays in a plastic can) in sawdust or oatmeal, small end down, and keeping them in a cool place comparable to cold-storage temperature. For you that could be your refrigerator, root cellar, or basement.

For cold storage, it's best to gather the eggs every day or even several times a day and store them right away in your cool place. A chicken's body temperature is about 107°F. To stay fresh, a freshly laid egg needs to cool to around 60°F reasonably soon. The cooling rate will depend on how soon after being laid you collect the egg, what the air temperature was while it was waiting to be collected, and what you did with the egg after it was collected. Eggs put into egg cartons don't cool quickly because the Styrofoam or cardboard is a good insulator. Freshly laid eggs left together in a bucket keep each other warm. In very hot weather you may want to collect eggs at 10am, 1pm, and 5pm. An ideal place to store eggs is a basement or root cellar that is cool and damp and doesn't have much fluctuation in temperature or humidity. Self-defrosting refrigerators are not very good for long-term egg storage because they pull moisture and will gradually dry out fresh eggs. Don't store eggs near where they could pick up strong odors—from onions, chemicals, paints, oil or gas products, and so on. They're most likely to pick up odors if they've been washed. Any poultry eggs can be refrigerated for up to 6 weeks. Always store them in a clean container. Scald it first if there's any doubt. If you seal freshly laid eggs in a plastic bag the eggs can keep in the refrigerator 2 months. When using stored eggs, rotate to use the oldest first.

Pickled Eggs. These come in many varieties. Poking the eggs a few times with a toothpick will help curing (not beet reds—see below). Figure about 7 days to complete curing. These pickled egg formulas all may be doubled, tripled, etc., as needed. For storage, make in larger quantities and keep in the juice, refrigerated. The pickled eggs will keep months that way. Or you may can them.

⇒ **EASY RED PICKLED EGGS** Hard-boil the desired number of eggs. Shell eggs and cover in half pickle juice and half beet juice. Keep in refrigerator 3 to 4 days. Drain and serve with garnish.

⇒ **MUSTARD PICKLED EGGS** Boil the eggs, cool, and remove the shells. Boil together 1 qt. vinegar, 1 t. dry mustard, 1 t. salt, and 1 t. pepper. Pour the cooled brine into your pickling jar and add the eggs. Cover and let them cure at least 10 days before they're ready.

⇒ **SPICED PICKLED EGGS** Hard-boil the eggs, cool, and remove shells. Make a brine of $\frac{1}{2}$ c.

salt to 2 c. water. Soak the eggs in the brine 2 days. Then pour off the brine and make a new brine by heating 1 qt. vinegar, $\frac{1}{4}$ c. pickling spices, 2 cloves garlic, and 1 T. sugar to boiling. Pour it over the eggs.

⇒ **CLOVE PICKLED EGGS** Stick a few cloves in each egg in either recipe above.

⇒ **BEET RED EGGS** Start with 1 c. of strongly colored beet juice, either from canned beets or the homemade equivalent. In a small pan, combine beet juice, 1 c. cider vinegar, $\frac{1}{2}$ c. sugar, and 1 t. salt. Bring to a low boil and hold there for 5 minutes, stirring constantly. Pour over 6 peeled, hard-boiled eggs and refrigerate, tightly covered. Halve to serve. You can add a few slices of cooked whole beet to the mixture.

⇒ **SOY EGGS** Combine $\frac{1}{2}$ c. soy sauce, $\frac{1}{2}$ c. chicken broth (or water), 6 T. sugar, $\frac{1}{2}$ t. sesame seed oil, and 1 T. minced onion in a pan. Bring to the boiling point. Add 4 peeled, hard-boiled eggs, cover the pan, and simmer 10 minutes. Remove from heat. Allow eggs to cool in the mixture for 30 minutes. Turn the eggs during the cooking and cooling to ensure that they are colored evenly. Drain the eggs and cut into quarters lengthwise to serve (may be served either hot or cold). The beet and soy egg recipes are from Eileen Draper, Pullman, WA—belly dancer, artist, writer, mother.

⇒ **DILLY EGGS** In a pan combine 1 $\frac{1}{2}$ c. white vinegar, 1 c. water, 1 t. dill seed, $\frac{1}{2}$ t. white pepper, 3 t. salt, $\frac{1}{2}$ t. mustard seed, $\frac{1}{2}$ t. onion juice, and $\frac{1}{2}$ t. minced garlic. Bring to a slow boil. Boil 5 minutes, stirring frequently. Add peeled, hard-boiled eggs. Cool, cover tightly, and refrigerate.

⇒ **CANNED PICKLED EGGS** Fill a sterilized quart jar with hard-boiled, peeled, cooled eggs. (You can fit about a dozen eggs in per quart.) Add to the eggs in the jar 1 sprig of dill, 1 chopped clove of garlic, 1 dried crushed red hot pepper, and 1 t. peppercorns. In an enamel or other noncorrosive pan combine, for each quart of eggs you are canning, 3 c. white vinegar and 2 T. sugar. Bring the solution to a boil and simmer 5 minutes, then pour hot liquid over eggs and spices to within $\frac{1}{2}$ inch of the jar's top. Put on the lid and seal it. Process in boiling water bath 20 minutes.

Frozen Eggs. The freezer life of an egg is 8 months to a year. Eggs that have been frozen should be well cooked before being eaten. Use only fresh, nest-clean eggs. Don't ever refreeze thawed eggs. Decide how you will use the eggs: whole, as for scrambling, or yolks and whites separated. (Frozen whites don't whip into a stiff mixture.) Or maybe you could use some of each kind. Well, then what percentage of each? Now decide how many of these eggs, whole or separated, you want per package. You have to use your frozen eggs within 12 hours of thawing, so you don't want to pack more than a day's worth per package or they will be wasted. Be sure and label each container as to what's inside: whole eggs, whites, or yolks—and whether the whole eggs and yolks are sweet or salty. Use sweet egg mixtures for baking, salty egg mixtures for other cooking. Be sure and adjust the other ingredients to compensate for the added sweet or salty flavor. Equivalents: 1 $\frac{1}{2}$ T. thawed yolk equals one fresh egg yolk; 2 T. thawed egg white equals one fresh egg white; 3 T. thawed whole egg equals one fresh egg (sort of, because homegrown eggs aren't all that standardized anyway).

Freezing Whole Eggs. Take them out of the shell and pour them into your freezer container, as many as you decide you want in a package. Stir them together, but don't whip in air. For each cup of whole eggs, add 1 T. sugar or $\frac{1}{2}$ t. salt. If you freeze whole eggs in an ice cube grid, each cube is equivalent to half an egg.

Freezing Whites and Yolks Separately. If you are freezing egg whites, don't include

even a speck of yolk and don't add anything else. In the case of the egg yolks, freeze them together with either salt or sweetener, depending on the use you intend for them: 2 t. sugar or corn syrup or 1 t. honey, or $\frac{1}{2}$ t. salt per $\frac{1}{2}$ c. yolks. If you don't add the salt or sweet to the egg yolks, they'll get gummy or lumpy. Baby food jars are good containers for them. Freeze egg yolks promptly. They sour easily. When they are thawed, use within 48 hours or discard.

Brined Eggs. This was an old-time egg preservation method, but the resulting eggs aren't as nice as those from cold storage or freezing. Nevertheless, here's the recipe: Put clean eggs in a crockery, wooden, or plastic container. Cover with a mixture of 3 gal. water, 1 pink quicklime (from lumberyard or drugstore), and 1 c. salt. Put weight enough on top of a plate to hold eggs under the solution. You can add more eggs later, but be careful they don't crack going in. Store in a cool place.

Eggs Made into Noodles. You probably haven't thought of noodle-making in this way before, but it's an excellent way to preserve eggs! Use any egg-noodle recipe from [Chapter 3](#) or your own. Make them, dry them thoroughly, and store them in a dry place. Or else package and store them in your freezer. Or make them into a soup and can them.

Dried Eggs. Dried eggs won't keep more than 3–4 months before the yolk fat goes rancid, but up to that time, they can be useful. Ruth Miller found this recipe for dried eggs in a really old recipe book: "Break perfectly fresh eggs onto large plates—making just a layer on the bottom of each; place in the sun to dry. It will take about 5 days to dry them thoroughly so that they break very easily when touched. Then crumble them finely and leave another day. Then roll with a rolling pin to a fine powder and store in clean, dry tins with airtight lids. A good teaspoonful equals 1 egg. The powder should be soaked in cold water or milk for an hour before use and then be used in scrambled eggs, omelets, puddings, cakes, and so on, with perfect success."

Here's a modern way to dry them: Beat very fresh, whole eggs thoroughly (use an egg beater or the equivalent). Pour beaten eggs to make a very thin layer (maximum $\frac{1}{8}$ inch) on drying surfaces that have been precoated with plastic or foil. In an oven or dryer, dry at about 120°F for 24–36 hours. When the egg layer is dry on top and firm all through, peel away the plastic or foil layer, turn the egg layer upside down and dry that side 12–24 hours more. Then break it up and dry it a few more hours. Then turn your dried egg into a powder using a mortar and pestle or a blender. These eggs work fine in baked goods. Make scrambled eggs by combining the powder with an equal amount of water, such as $\frac{1}{4}$ c. dried egg powder with $\frac{1}{4}$ c. water.

To substitute dried eggs, use 1 $\frac{1}{2}$ T. dried egg plus 3 T. water for each large fresh egg called for in the recipe. Dried Eggs or Dried Egg Whites are available in a 20-oz. can from 970-527-7540; urbanhome@aol.com.

Larded, Salted Eggs. The old-timers used many variations of this method to preserve eggs. The eggs were packed in a crock of lard, or greased with lard or pure butter and then packed in sawdust or oatmeal. They were then stored in the coolest possible place, short of freezing. However, *The Mother Earth News* experimented and learned that eggs in lard will keep several months even when temperatures are 65–70°F. But cold is always better. An Ohio lady, Yolanda Breidenbaugh, wrote me of "a good, cheap way to preserve eggs. It works wonderfully well. Over a year later the eggs still aren't rotted. Here it is: Take freshly laid clean eggs and dip them in melted lard and pack in salt! I put them, not touching each other, in a 5-gal. bucket and set the lid on and put it in a cool cellar. I got 'feed grade' salt at the feed mill. When I want to use one, I just rinse it off with warm water. Even a year later, they're still okay. Certainly good enough to cook with."

Lime/Salt Preserved Eggs. Make a solution containing 16 parts water, 1 part pickling salt, and 2 parts food-grade lime. For example, 1 part could equal 1 cup. Submerge the eggs in that. *The Mother Earth News* tested this one and found it also would preserve eggs several months, even at 65–70°F.

Laws on Home Poultry Processing

Under federal law, there is no inspection if you process fewer than 20,000 chickens (or 5,000 turkeys) per year (Poultry Products Inspection Act, Section 15), so long as the poultry is sold in your state. Local and state regulations may be more restrictive. Here follows a summary of the laws in each state, inspired by and indebted to “Legal Issues for Small-scale Poultry Processors,” compiled by Janie Hipp for Heifer Project International. (It’s free from NCAT/ATTRA: 800-346-9140; www.attra.ncat.org).

Alabama has a state law controlling meat and poultry inspection, administered by the Commissioner of Agriculture and Industries: Meat and Poultry Inspection; 334-240-7255; fax 334-240-7167; 1445 Federal Dr., PO Box 3336, Montgomery, AL 36109-0336; www.agi.alabama.gov.

Alaska’s small-scale poultry processors may need to get a state permit and comply with state laws on food safety and sanitation. For more info: Dept. of Environmental Conservation, Food Safety and Sanitation; 877-233-3663; 555 Cordova St., Anchorage, AK 99501; www.dec.state.ak.us/eh/fss/index.htm.

Arizona law exempts processors of under 20,000 birds if they are processing according to recognized religious dietary laws; or for personal use; or who label the homegrown and home-butchered product with their name and address before sale to individuals or to restaurants, hotels, or boarding houses: Arizona Dept. of Ag, Meat and Poultry Inspection Branch; 602-542-6398; fax 602-542-4290; 1688 W. Adams, Phoenix, AZ 85007; www.azda.gov/ASD/mpi.htm.

Arkansas follows federal guidelines as to exemptions: Arkansas Livestock and Poultry Commission, No. 1 Natural Resources Dr., PO Box 1069, Little Rock, AR 72205; 501-907-2400; www.alpc.arkansas.gov. Or U. of Arkansas, School of Ag, PO Box 490, Pine Bluff, AR 71611.

California law lets persons who process poultry on their farm be exempt from inspection requirements so long as they sell to persons who are not going to resell the birds: Dept. of Ag, Meat & Poultry Inspection Branch; 916-900-5020; fax 916-654-2608; 150 N St., Room A-125, Sacramento, CA 94814; www.cdfa.ca.gov/is/.

Colorado follows federal guidelines in exempting small-scale poultry processors from inspection, but all small-scale processors must have their processing facilities licensed by CDA: Colorado Dept. of Ag; 303-477-4220; fax 303-477-4248; 2331 W. 31st Ave., Denver, CO 80211.

Connecticut’s poultry processing is supervised by the Commissioner of Agriculture: 860-713-2569; 860-713-2514; 785 Asylum Ave., Hartford, CT 06105; www.ct.gov/doag.

Delaware’s Secretary of Agriculture is responsible for poultry inspection. State law is based on the federal guidelines but requires a decision by the Secretary as to any particular exemption: Delaware Dept. of Ag; 302-698-4500; 2320 S. DuPont Hwy., Dover, DE 19901.

Florida’s Animal and Animal Production Inspection and Labeling Act requires that anybody who processes birds for sale must have federal or state permits: Florida Dept. of Ag and Consumer Services, Division of Food Safety; 850-245-5595; fax 850-245-5553; 3125 Conner Blvd., Ste. D, Tallahassee, FL 32399-1650; www.freshfromflorida.com. Or U. of Florida, Meat Processing Center; 352-392-1921; fax 352-392-7652; PO Box 110910,

Gainesville, FL 32611.

Georgia rates as a misdemeanor the offering for sale, or possessing for sale, of any poultry product made, transported, or stored under unsanitary conditions. Their definition of "unsanitary" is very broad. All poultry processing plants must have a license and keep records of all birds slaughtered on site: Georgia Dept. of Ag, Meat Inspection Division; 404-656-3673; fax 404-657-1357; 19 Martin Luther King Jr. Dr., Rm. 108, Atlanta, GA 30334; agr.georgia.gov/meat-inspection.aspx.

Hawaii exempts persons who slaughter poultry for members of their own household and if the product is wholesome and sold at home direct to the consumer (not for resale). Exempt operators must register with the Board of Agriculture and get a permit for exemption (which maybe refused): Hawaii Dept. of Ag; 808-973-9560; PO Box 22159, Honolulu, HI 96823-2159. Or U. of Hawaii at Manoa; 808-956-6564; fax 808-956-8663; 1920 Edmondson Rd., Honolulu, HI 96822.

Idaho follows the federal regulations, including exemptions for small-scale processors, and has no state inspection system for poultry processors: Idaho Dept. of Ag; 208-332-8500; fax 208-334-2170; 2270 Old Penitentiary Rd., Boise, ID 83712. Or U. of Idaho, Dept. of Animal & Veterinary Science; 208-885-6345; fax 208-885-6420; Moscow, ID 83844-2330.

Illinois producers may request, in writing, an on-farm processing exemption. If granted (two years at a time), they must keep records of the number of poultry processed per year (no more than 5,000 to keep the exemption). They must sell only from the farm (no deliveries), and must be sanitary (periodic inspections may occur): Illinois Dept. of Ag; 217-782-2172; fax 217-785-4505; State Fairgrounds, PO Box 19281, Springfield, IL 62794.

Indiana's State Board of Animal Health, under the Indiana Humane Slaughter Act, is required by law to exempt a processor who would be exempt under the federal guidelines: Commissioner of Ag; 317-232-8770; fax 317-232-1362; 140 W. Market St., Ste. 414, Indianapolis, IN 46204. Or Indiana State Board of Animal Health, Division of Meat & Poultry; 317-544-2400; fax 317-542-1415; 805 Beachway Dr., Ste. 50, Indianapolis, IN 46224.

Iowa's poultry inspection is under the Meat and Poultry Inspection Bureau, which exempts processors who handle fewer than 1,000 birds per year and sell all products to the final consumer or use them at home: Iowa Dept. of Ag & Land Stewardship; 515-281-5321; fax 515-281-6236 (or 515-281-5597; fax 515-281-4282); Wallace Bldg., Des Moines, IA 50319; www.iowaagriculture.gov/meatandpoultryinspection.asp.

Kansas exempts poultry producers who slaughter for home use and under certain other conditions: Kansas Dept of Ag, Meat & Poultry Inspection; 785-296-3511; fax 785-296-3556; 901 S. Kansas Ave., 7th Floor, Topeka, KS 66612 www.ksda.gov/meat_poultry.

Kentucky producers must follow rules of the Kentucky Cabinet for Health Services: Kentucky Dept. of Ag; 502-564-4696; fax 502-564-5016; 111 Corporate Dr., Frankfort, KY 40601.

Louisiana's Dept. of Ag and Forestry's Meat and Poultry Division does inspections for operations of fewer than 20,000 birds and grants exemptions upon written request of the processor (quarterly compliance checks on persons with exemptions): Dept. of Ag & Forestry; 225-922-1358; fax 225-237-5908; PO Box 1951, Baton Rouge, LA 70821-1951.

Maine established new guidelines in 2002 that are said to be friendly to small-scale producers and processors: Commissioner of Agriculture, Food and Rural Resources; 207-287-3419; fax 207-287-7548; Deering Bldg (AMHI), State House Station #28, Augusta, ME 04333. Or U. of Maine; 207-581-3406; 5782 Winslow Hall, Rm 2, Orono, ME 04469.

Maryland exempts from inspection any poultry processed for home use, or for sale

from your home if healthy and labeled with your name and address: Maryland Dept. of Ag; 410-841-5700; fax 410-841-5914; 50 Harry S. Truman Parkway, Annapolis, MD 21401. Or U. of Maryland College of Ag; 301-405-2072; fax 301-314-9146; 1296 Symons Hall, College Park, MD 20742-5551.

Massachusetts exempts poultry processors from inspection at the discretion of its Commissioner of the Massachusetts Dept. of Public Health, so long as exemptions fit under federal guidelines. Thus the processor must be selling birds he raised himself. They must be shipped in boxes that bear the grower's name, address, and the word "Exempted." He may sell to households, restaurants, hotels, and boarding houses: Mass. Dept. of Ag; 617-626-1700; fax 617-626-1850; 100 Cambridge St., Boston, MA 02202.

Michigan uses the federal guidelines: Michigan Dept. of Ag; 800-292-3939; fax 517-335-1423 (517-373-8200; fax 517-373-6015); 611 W. Ottawa, PO Box 30017, Lansing, MI 48909.

Minnesota also follows federal guidelines except that direct farm sales are allowed only to households (not to hotels, restaurants, and institutions). To deliver products off farm or sell them at a farmer's market you must get a state license and comply with state inspection rules, no matter how few the birds being processed: Minnesota Dept. of Ag; 651-201-6000; 800-967-2474; TTY 800-627-3529; 625 Robert St. N., St. Paul, MN 55155-2538.

Mississippi follows federal guidelines: Dept. of Ag and Commerce; 601-359-1100; fax 601-354-6290; 121 N. Jefferson St., Jackson, MS 39201. Or Meat Inspection Division; 601-359-1191; fax 601-359-1175; PO Box 1609, Jackson, MS 39215.

Missouri must exempt from inspection laws any facility that would be exempt under federal guidelines, but persons with such exemptions are subject to regular reviews. The Director of the Missouri Dept. of Ag is allowed, after giving notice, to withdraw any exemption if conditions have changed under which it was granted: Missouri Dept. of Ag; 573-751-4211; fax 573-751-1784; PO Box 630, Jefferson City, MO 65102.

Montana's Board of Livestock (under Montana's Dept. of Livestock) does poultry inspection. Persons slaughtering for home use are exempt. Custom butchers are exempt so long as the meat is kept separate from meat prepared for sale, is plainly marked "Not for Sale," and is handled in a sanitary way: Montana Dept. of Ag; 406-444-3144; fax 406-444-5409; PO Box 200201, Helena, MT 59620. Or Meat, Milk & Eggs Inspection Division; 406-444-9761; fax 406-444-1929; PO Box 2021001, Helena, MT 59620.

Nebraska follows the federal guidelines: Bureau of Dairies & Foods; 402-471-2341; fax 402-471-6876; PO Box 95064, Lincoln, NE 68509.

Nevada's State Board of Health does not permit the sale of uninspected poultry products. Federal exemptions don't apply here. Anybody who wants to process and sell poultry must have a state permit. The permitting process requires inspection of your place by the state Board of Health and that there be an inspector present when birds are processed. However, owner/operators may be tested and certified as inspector at their own place: Nevada State Board of Health; 775-684-4200; fax 775-687-4211; 4150 Technology Way, Ste. 300, Carson City, NV 89706. Or Nevada Dept of Ag; 775-353-3600; fax 775-353-3638; 405 South 21st St., Sparks, NV 89431.

New Hampshire's policy follows the federal guidelines: New Hampshire Dept. of Ag, Markets and Food; 603-271-3551; fax 603-271-1109; PO Box 2042, Concord, NH 03302-2042. Or U. of New Hampshire, Cooperative Ext. Toll Free Helpline: 877-398-4769; UNH Cooperative Extension, 200 Bedford St. (Mill #3), Manchester, NH 03101.

New Jersey allows uninspected processing of homegrown birds for home use: NJ Dept. of Ag; 609-292-3976; fax 609-292-3978; PO Box 330, John Fitch Plaza, Trenton, NJ

08625. Or the Division of Animal Health: 609-292-3965. Or Rutgers U., Dept of Food Science; 732-932-9611; fax 732-932-6776; 65 Dudley Rd, New Brunswick, NJ 08901.

New Mexico does not allow any exemption from inspection for poultry slaughtered on the farm: New Mexico Livestock Board; 505-841-6161; fax 505-841-6160; 300 San Mateo NE, Ste. 1000, Albuquerque, NM 87018.

New York exempts by federal rules up to 1,000 birds per year: NY Dept. of Ag and Markets; 800-554-4501; 10B Airline Dr., Albany, NY 12235. Or Cornell U., Dept. of Food Science; 607-255-7616; fax 607-254-4868; 11 Stocking Hall, Ithaca, NY 14853.

North Carolina's Dept. of Ag and Consumer Services inspects poultry products. Exemptions are given for processors of less than 1,000 birds or 250 turkeys; or those operating according to religious dietary laws; or if the birds are home grown for home eating; or custom slaughter of birds intended for the customer's home use. Small growers may process and sell their homegrown healthy poultry if packaged under a label identifying the name and address of the producer. They may sell to households or distribute to restaurants, hotels, and boarding houses: Dept. of Ag and Consumer Services; 919-707-3000; fax 919-733-1141; PO Box 27647, Raleigh, NC 27611. Or Meat and Poultry Division; 919-733-4136; fax 919-715-0246.

North Dakota's Health Dept. gives no exemptions from inspection requirements for farm-slaughtered poultry: ND Dept of Health; 701-328-2372; fax 701-328-4727; 600 East Blvd., Bismarck, ND 58505-0020. Or ND State U. College of Agriculture, Food Systems, and Natural Resources; 701-231-8790; fax 701-231-8520; 315 Morrill Hall, Fargo, ND 58105.

Ohio exempts growers processing for family use, and grower/processors of fewer than 1,000 birds per year who sell to other household consumers (no resale expected). You are still subject to laws on licensing, sanitation, labeling, etc.: Ohio Dept. of Ag; 614-728-6201; fax 614-466-6310; 8995 E. Mam St., Reynoldsburg, OH 43068-3399. Or Division of Meat Inspection; 614-728-6260; fax 614-728-6434.

Oklahoma allows certain exceptions for small producers or religious processing, etc.: OK Dept. of Ag; 405-521-3864; fax 405-522-4912; 2800 N. Lincoln, Oklahoma City, OK 73105. Or Meat Inspection Program; 405-522-6114; fax 405-522-0756.

Oregon follows federal guidelines. Inspection is also not applied to fryers that are sold to ultimate customers at the farm where they were produced: Oregon Dept. of Agriculture; 503-986-4550; fax 503-986-4550; 635 Capitol St. NE, Salem, OR 97310-0110. Or Oregon State U.; 541-737-2211; fax 541-737-2256; 137 Strand Agriculture Hall, Corvallis, OR 97331.

Pennsylvania's Dept. of Ag and various municipal departments can enact and enforce regulations: Dept. of Ag; 717-787-4737; fax 717-772-2780; 2301 N. Cameron St., Harrisburg, PA 17110-9408. Or Bureau of Food Safety & Lab Services; 717-787-4315; fax 717-787-1873; 2301 N. Cameron St., Harrisburg, PA 17110.

Rhode Island poultry growers who do their own processing for either home use or sale must register each year with the Director of the Department of Health during the month of January. Slaughter premises must be approved by the Department, and the Director of the Department can make rules about those premises and can inspect them as he wishes: RI Dept. of Ag; 401-222-2781; fax 401-222-6047; 235 Promenade St., Room 370, Providence, RI 02908-5767.

South Carolina allows exemptions from getting a permit to persons who butcher according to religious dietary laws; persons processing homegrown poultry for home use or doing custom slaughter on somebody's homegrown birds for home use; persons selling to households, restaurants, hotels, or boarding houses homegrown poultry that have been raised healthy and are labeled with the grower's name and address (up to 20,000 birds or

5,000 turkeys): SC Dept. of Ag; 803-734-2210; PO Box 11280, Columbia, SC 29211. Or Clemson U., Meat & Poultry Inspection: 864-656-3311.

South Dakota's Livestock Sanitary Board runs their inspection program and allows no exemptions from inspection: SD Dept. of Ag; 605-773-5425; fax 605-773-5926; 523 E. Capitol, Pierre, SD 57501-3182. Or SD Animal Industry Board; 605-773-3321; fax 605-773-5459; 411 S. Fort St, Pierre, SD 57501.

Tennessee's Meat and Poultry Inspection Act is administered by their Dept. of Ag. Growers report that the rules are confusing, unevenly applied, and not always administered according to the written law: TN Dept of Ag, Ellington Ag Center; 615-837-5103; fax 615-837-5333; PO Box 40627, Melrose Station, Nashville, TN 37204.

Texas accepts the federal guidelines and exempts small-scale processors from inspection. However, low-volume livestock processing establishments must register with the Texas Dept. of Health (TDH) and must develop a Sanitary Operations Procedures Plan that you keep on file for government review in case anybody gets sick from your animals. If anybody does get sick, they may shut you down: TX Dept. of Ag; 512-463-7476; fax 888-223-8861; PO Box 12847, Capitol Station, Austin, TX 78711. Or Meat Safety Assurance Division, Bureau of Food and Drug Safety; 512-834-6760; fax 512-834-6763; 1100 W. 49th St., Austin, TX 78756.

Utah follows federal guidelines: UT Dept. of Ag and Food; 801-538-7100; fax 801-538-7126; 350 N. Redwood Rd, PO Box 146500, Salt Lake City, UT 84114-6500. Or UT Dept of Ag; 801-538-7117; fax 801-538-7169; PO Box 146500, Salt Lake City, UT 84114-6500.

Vermont's Commissioner of the Dept. of Ag, Food and Markets may exempt from inspection any person who could be exempted under the federal guidelines. But Vermont's rules are more strict than federal ones, applying only to processors of up to 1,000 birds. Any meat served in hotels, restaurants, or institutions must be from a state or federally inspected source: VT Dept of Ag, Food and Markets; 802-828-2430; fax 802-828-2361; Drawer 20, 116 State St., Montpelier, VT 05620-2901.

Virginia law follows the federal guidelines, but the state does require producers who want to operate under exemption to get a state permit: VA Dept. of Ag and Consumer Services; 804-692-0601; 102 Governor St., Richmond, VA 23219.

Washington's Dept. of Agriculture is in charge of inspections. Slaughter of birds by religious dietary laws or for home use is exempted. Inspection is unnecessary for poultry growers if they are under 250 turkeys or 1,000 birds of smaller species per year. But some city and county agencies have additional rules and do not recognize these exemptions (King County/Seattle area requires all poultry sold therein to be processed and stored in a state-licensed facility); WA Dept. of Ag; 360-902-1800; fax 360-902-2092; PO Box 42560, Olympia, WA 98504-2560. Or WSU; 509-335-6967; fax 509-335-1082; PO Box 646242, Pullman, WA 99164.

West Virginia exempts producer/processors of up to 1,000 homegrown, home-slaughtered birds per year, but has no application process to get the exemption: WV Dept of Ag, Meat and Poultry Inspection; 304-558-2206; fax 304-558-1882; State Capitol, 1900 Kanawha Blvd. E., Charleston, WV 25305.

Wisconsin exempts poultry processed on the owner's farm, up to 1,000 birds per year. Birds must be labeled and tagged with name/address of the grower and marked "NOT INSPECTED"; WI Dept. of Ag, Trade and Consumer Protection; 608-224-5012; fax 608-224-5045 (or 608-224-4725; fax 603-224-4710); PO Box 8911, Madison, WI 53708.

Wyoming has no exemptions from inspection. The Ag Dept. does inspections: 307-777-7321; fax 307-777-6593; 2219 Carey Ave., Cheyenne, WY 82002.

Butchering Chickens

Once you know what you're doing and have your system worked out, 2 people can kill, pick, and cut up about a half dozen chickens an hour—or even more.

OF AGE AND STAGE: Homegrown chicken to eat comes from 2 basic sources: the broilers or cockerels you raise to butchering age and then put in the freezer, and the hens whose egg production is declining or stopped, that you cull out of your flock. The broilers or cockerels are your young, tender birds. At 8–12 weeks of age, they'll weigh from 2 to 8 (or 12 or even 15) pounds, depending on the breed. They can be cooked as a "broiler," or a fryer. From 14 weeks to 6 months of age, and from 4 pounds and up, the bird will make a fine roaster. If you want to know exactly when your bird is at the desired weight, put it inside a sack. That will keep it still long enough for you to get an accurate measure on a scale. A bird 6–9 months old is a judgment call. Older than that they are stew birds for sure. Culled laying hens have lived long enough to get really tough, so they are your classic "stew hens." You can tell relative age by feel. A young chicken has soft cartilage at the end of the breastbone and pinfeathers. An older, stewing-type chicken has a rigid breastbone and long hairs on its skin.

DARK MEAT, LIGHT MEAT: The color of muscle meat is a result of the exercise that muscle has experienced. Homegrown chickens tend to have relatively darker meat because they lead more active lives. A bird that flies will even have dark breast meat.

CATCHING A CHICKEN AT NIGHT: Enter the chicken's sleeping quarters well after dark, equipped with twine or a burlap bag. Carry a flashlight. Quietly grasp the bird you want by its 2 skinny legs (make sure the 2 legs are from the same chicken), and tie twine firmly around them. Or put it in the bag and tie the mouth of that. Or haul it out with a firm grip around those 2 ankles and leave it for the night in an empty rabbit hutch, where you'll be able to easily reach in and grab it in the morning. Actually, holding a bird by its legs can be a bit of a struggle because they're not crazy about being upside down and will flap their wings and try to get righted. Avoid that wing flapping. Better yet, carry it the polite and friendly way, which is to hold the wings down and put it under your arm with one hand on a leg or two, just in case.

CATCHING A CHICKEN IN THE DAYTIME: If the chicken can't be walked up to when you feed it (or cornered in the chicken house), make a chicken hook out of a length of wire. Unwinding a clothes hanger gives you a good length. Or use a 4-foot piece of heavy wire. Make it single rod except for a miniature shepherd's crook at the chicken-catching end—narrower than a chicken's foot, wider than its skinny lower leg, which is the part you hook it by. Or loop around the other end to make a better handle. Then you set out to pursue your quarry with the wire in hand. Pour a heap of grain on the ground. The chickens will all gather, heads down, backsides to the outside of their little crowd.

When you get within reach of the one you want with the wire, suddenly stretch it out and hook the chicken's leg in the crook. Pull the chicken toward you and transfer the leg from the crook to your hand and get the other one, too. That works, but it's so much easier to catch a chicken while it is sleeping that I always do that. And if you can isolate the chicken the night before you butcher it, by leaving it in the gunny sack or, better yet, in a wire-bottomed rabbit cage or something similar, you won't have to contend with such a full crop when cleaning it.

MEAT CHICKENS TO SELL: Joel Salatin's 1993 book, *Pastured Poultry Profit*, is the classic in this

field. Herman Beck-Chenoweth's *FreeRange Poultry Production and Marketing* (1996) shows a set-up to process 200 broilers per hour (cost about \$15,000).

New poultry processing equipment is available from Stromberg's (800-720-1134) or Pickwick (800-397-9797; www.pickwickmfg.com), or Brower's Pastured Poultry Division, which advertises a 150 birds/hr system for under \$4,000 with rotary kill line, scalding, spin picker, evisceration table, chill tank, aprons, knives, etc. (800-553-1791). You can buy used equipment from Tom Neuberger's South Dakota Poultry Headquarters: 605-296-3314; Rt. 1, Box 303, Canistota, SD 57012. Contact ATTRA for info on homemade scalders and pluckers: 800-346-9140. Kenneth King of Jako, Inc., builds a low-cost batch dunker/scalder, and plucker. He travels to help other area producers on slaughter day with a mobile processor mounted on a trailer (killing cones, scalder, plucker, eviscerating table, etc.), which he also builds and markets: 620-663-1470; 877-525-6462; 6003 E. Eales Rd., Hutchinson, KS 67501; kenking@jakoinc.com; www.jakoinc.com/.

Some producers have built their own state-or federally approved processing plants. (See Patrick Slattery's "Small-scale Processing Offers Large-scale Profits" in *Acres, USA*, Sept. 1995; or Keith Richards' article on "Adding Value to Chickens on the Farm," in *Southern Sustainable Farming*, March 1996.) ATTRA's info on this topic, "Processing & Marketing Chicken Products: Meat & Eggs," can be downloaded at www.attra.ncat.org/attra-pub/poultry/processing.html or www.attra.ncat.org/attra-pub/poultry/marketing.html.

KILLING A CHICKEN: When I was a little girl, chopping chicken heads off for my mama, I used to say a prayer for the chicken before I raised my axe. I would pray that if God had a place in Heaven for the souls of chickens, He should please take this one. In the animal graveyard beside our garden, where beloved, departed cats, dogs, and mice lay planted, brother Dick and I also buried not a few chicken heads with full honors. There was a certain fascination to staging a really good funeral.

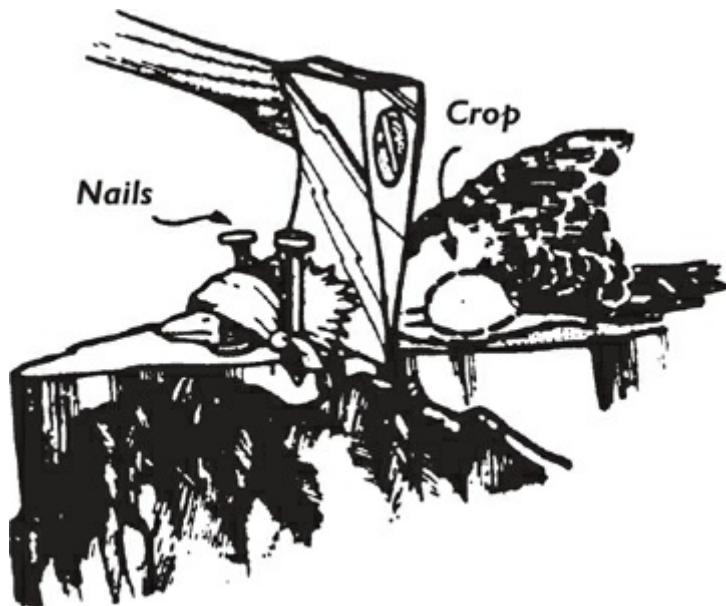

By then the feast would be ready, and Mama would call us to dinner. Oh, Mother's fresh fried chicken! With mashed potatoes and lots of gravy made with milk! Dick and I would eat and eat, the pile of bird bones beside each plate heaping steadily. The wishbones were saved and dried on top of the topside cupboard of Mother's wood cook stove for a week or two, until they'd become properly brittle. Then Dick and I each took hold of a side, got our wish in mind (you couldn't say out loud what it was or the magic wouldn't work), and pulled at the count of three. The one who ended up with the longest piece of wishbone would get his or her wish—or so we claimed.

"Chop and run" is how I killed chickens for Mama and how I did it when I was writing the first edition of this book, but it's not the best way because it's messy. These following methods are approximately in order from worst to best because that's the order in which I heard about them as I accumulated material for this book. To avoid gory details you could just skip to the end of the list. But first read this next paragraph.

Blood. However you get the unfortunate task accomplished, be sure and let the bird bleed out thoroughly, since this will improve its eating and keeping quality. Wear old clothes, have a container ready—a bucket or some such—and don't let go of the chicken's legs and wing tips after the head is severed. Then get the chicken neck down into that container as soon as possible to minimize the mess. If you just drop the bleeding body and run, it will flop around, scattering blood from the severed neck over an amazingly large area.

A Chopping Block Demise. You grasp the bird firmly by the ankles and both wing tips with the left hand (assuming you're right-handed), and place its body on the chopping block so that the neck is stretched out across the block. (A chopping block is a large flat-

topped and flat-bottomed piece of tree, with the grain running perpendicular to the ground.) A heavy-headed ax is better than a hatchet for the job, I think.

Getting the chicken to lie still with its neck stretched out across the top of the block while you aim the blade may require a bit of maneuvering. The chicken may retract its head just when you're all set. [Note: Since I wrote that, I've gotten some interesting advice from readers on how to make that chicken hold still while you're trying to chop its head off. One writer told me that she "hypnotizes" the chicken by putting the chicken's head under its wing, then swinging it around, and only then chopping its head off. Betty Lawrence, White Swan, WA, wrote me that she hammers 2 nails about one inch apart on the surface of her chopping block. She leaves part of the nails sticking up. She lays the chicken's neck between the nails and pulls back gently until the head is next to the nails. If you use this system, you'll have to be careful not to hit those nails—hitting nails is very bad for ax blades—as well as not to hit the crop.]

Anyway, have a sharpened ax or hatchet ready in your right hand for that moment when the bird is in the right position, and then, quick before it moves, with one hard blow bring the blade down and sever the head from the neck. Hit the chicken's neck clear across so you don't cut off just half of it with the first blow. (I've had to try twice to finish the job more times than I'd care to admit.) Cut it off as near the head and as far from the body as you can in order to save the neck for cooking, and to avoid cutting the crop, which is located at the base of the neck.

Wringing the Chicken's Neck. Some people prefer this method. It may be done by grasping the chicken firmly by the upper part of the neck or head. Then get the body swinging rapidly as you would twirl a heavy object on the end of a string. You swing once, swing twice, swing thrice, and then *snap*—like you're doing "Crack the Whip" with the chicken's body. Then the body separates from the head you're holding. It will.

Death by Shooting. A BB gun won't do it. A .22 will.

By "Hanging." Mrs. George Huckabee, Athens, TN, doesn't like dead chickens flopping around on the ground. "Find a low-hanging tree branch; loop a twine string around it firmly. Place loop around the legs of the chicken. It will be hanging head down. Now grasp the head firmly and with a sharp knife, cut the chicken's head off just at the top of the neck." This way the chicken doesn't go flopping around, leaving a trail of blood on your property, and you can control the bleeding mess by having a container ready to put

the bird in and making sure it gets in there and stays in there. Lane Morgan uses this system too.

By Severance. This popular professional method is to pierce the brain with a knife turn through the roof of the mouth, then sever the blood vessels, which are in the neck behind the earlobe. With this method, the bird doesn't flop about either, but it takes some know-how and experience to get it right.

Killing Cone. You can mail-order a commercially produced killing cone from a poultry supplier or from a local farm-supply store or make your own. To make a homemade killing cone, cut off the bottom of a 1-gal. plastic bottle. Cut about 2 inches from the top and handle. Nail the bottle to a wall or tree—or hang it by a rope or hook upside down. To use the killing cone, grab your bird by the ankles and put it, head downward, into the killing cone. Make sure the head and neck extend through the smaller end that you cut. Now proceed with either the “hanging” method or the “severance” method, or by grasping the head with one hand and pulling just firmly enough to create a small amount of tension on the neck, then cut into the neck on the left underside, just back of head and beak—which will sever the jugular. When you do it the latter way the head stays on; you just cut the throat. Have something ready in which to catch the blood, and this is the most manageable and least messy way. Commercially manufactured killing cones are not expensive and come in 3 sizes: one for broilers, pheasants, and fryers; one for roosters, ducks, and guineas; and the largest for turkeys.

Hiring Out. Lane Morgan wrote me that “lots of communities have backyard chicken butchering entrepreneurs. You bring them live birds in the evening and pick up dressed, bagged, chilled chicken the next morning. Or sometimes they'll come to your place. Or you can rent their equipment and have a butchering bee with friends. When both partners work off the farm, which is more and more likely, it isn't easy to find a solid stretch of time to butcher 50 chickens with less-than-efficient equipment.”

PICKING THE CHICKEN: There are those who just skin the bird. In that case there's no scalding, no plucking, no disagreeable wet feather smell, no singeing. If you have no use for the feathers and remove the skin anyway to keep the fat low, this may be your best choice. Otherwise, following tradition...

You need to choose between dry picking and scalding before plucking out the feathers. Dry picking is more difficult than picking after scalding, because the feathers are harder to pull out. I think it's crazy to dry pick when you could scald. So skip to the next paragraph. But then again, maybe you want the feathers. But you can use the feathers plucked from a scalded bird, too. But connoisseurs say they prefer feathers that have been dry-picked rather than scalded and then picked.

Dry Picking. If you're going to save the feathers, have bags ready. Start immediately after killing—even before the bird stops bleeding—before the flesh has a chance to become cold, which will set the feathers in tightly. Pick up the breast and up the side. Then do the wings, back, and finally the pinfeathers, which can be removed with tweezers or with a knife blade (you catch the pinfeathers between the blade and your thumb and pull). You'll clean the feathers later and make them into nice things. Right now you need to get on with the butchering. Go to “Singeing.”

Scalding and Plucking. Put water in a metal bucket or a big pan (like a canner or roaster) on to boil before you go out to kill the bird. While the chicken is flopping and bleeding, adjust the water temperature to about 130-180°F. Better to start out with your water too hot than too cool. Too hot will loosen the feathers plus cook the skin a little. Too

cool won't accomplish anything. And your water will be cooling all the time, especially as you do a series of birds in it. If it gets too cool, stop and resupply with hot enough water. (Rebecca Coufel wrote me that she and her husband do 70 or 80 chickens at a time by pre-wetting the dead birds with a hose or bucket of cold water before scalding. She believes the hot water gets under their feathers better for the presoaking.) Spread out newspapers on which to do the picking. You can roll them up afterwards with the feathers inside to keep them from flying all over your yard.

Now, grasping your bird by the ankles (the unfeathered legs and feet don't need to be scalded), immerse it in the hot water. If you are using a flatter-styled pan, like a roasting kettle, you soak the breast of the bird in the hot water, then turn it over and hold the backside in. Try to manage in such a way that every feathered part of it has nearly equal time in the hot water. Make sure you get the legs that you're holding in far enough to scald the feathered "knees." Make sure the wing and tail feathers get a good scalding, because they are the toughest to pull out. Overscalding any part of the bird will cause the outer surface of the skin to rub off—which doesn't hurt the meat any. Less than 30 seconds should do it. Hotter water does the job quicker; with cooler water you'll have to keep the bird in there a bit longer.

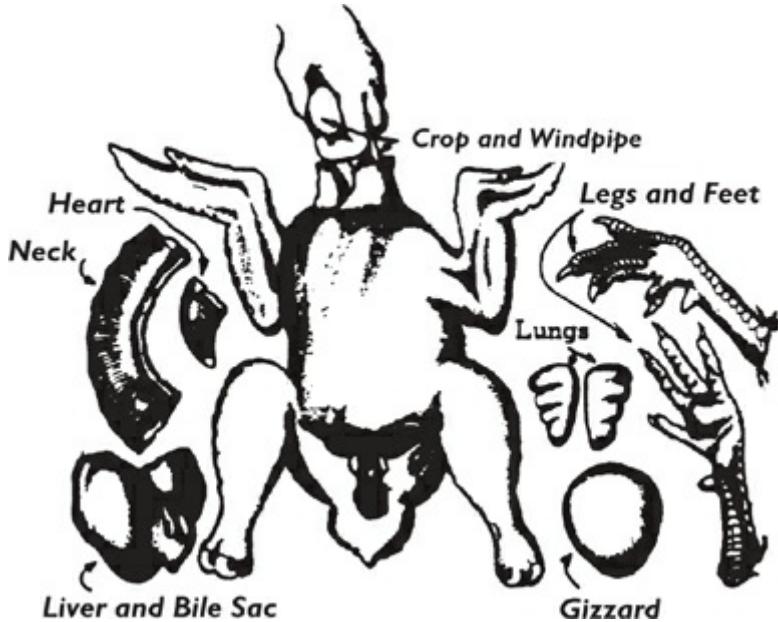

How long you need to scald also depends a good bit on the size of the bird. Little birds like pigeons and quail need less scalding time. Bigger birds need more. A turkey requires the most of all. Older birds will take a higher temperature and a longer time than younger birds. You can scald several birds, one after the other, in the same water, so long as it doesn't cool below about 130°F. If your water gets too cool, add hotter water to bring it up. If the first dip doesn't loosen the feathers enough, you can give the bird another pass in the water. You have to have the bird in there long enough and with enough motion to get the hot water penetrated clear to the skin.

Then take the bird out, let it drain just long enough so you can get your hands on the biggest feathers and start yanking. Have newspapers or some such spread out to pick the bird on so that cleaning up will be easy—but don't let the bird's body actually contact the newspaper because you don't want lead in your diet (causes brain damage). It can help with the requirement to do the picking while the bird is still as hot as possible, if one person scalds and another picks. Commence picking immediately after pulling the fully soaked bird out of the hot water, starting with the wing and tail feathers. Then do the body feathers, and finally the pinfeathers. Purists insist that feathers must be pulled out in the direction in which they are growing. That's certainly true of the biggest ones. I pull short ones any way I can get them.

Singeing. After the pinfeathers have been removed, you will still have down and very fine long hairs, especially on an older bird. These are burned off by singeing. Do it someplace where you won't set anything else on fire. Hold your bird by the ankles over a flame. If you don't have a gas stove, you can use a candle, propane torch, small alcohol burner, or a rolled cone of newspaper or other paper (not with color)—rolled tight at one end (to be the handle), and wide enough at the other to flame readily. A burning paper bag won't blacken the bird as much as a newspaper, but a newspaper cone is probably actually the worst way—probably gives them a lead content or some such and it certainly risks setting something else on fire. Don't touch the paper to the bird in this process, since that would dirty it with ashes. With practice you can do several chickens with one paper cone. Have all the chickens you plan to singe right there at hand when you light the paper. That's the way my mother and I used to singe them. Constantly change the bird's position over the flame, holding the bird with one hand and the cone with the other, until all parts having these hairs have been exposed enough to singe them completely. It won't

take long to singe the whole chicken.

CLEANING THE CHICKEN: Now your chicken is ready to be cleaned or “drawn.” That means you’ll remove the head, feet, and innards. First, put the bird into very cold water in order to cool the entire body quickly. Get ready a bowl of clean, cold water to rinse pieces in (or you can rinse them under the faucet), a very sharp knife, and an empty container to hold the cut-up pieces. Have ready a wooden cutting board to cut up the chicken on. Don’t cut the chicken on newspaper because the ink could get on the meat. Have something ready to hold the disposables, like a wax-paper-lined box, or a bucket.

You can dispose of innards by burning, composting (but not where varmints will scatter the compost pile), or feeding them to the pigs. Your chickens would be delighted to recycle the chicken butchering scraps—if you have no fear of parasite or disease transmission. Do not feed these raw chicken scraps or any other poultry innards to your dogs and cats, lest they become tempted to obtain more of the same by killing a few birds for themselves.

Poultry Tuberculosis (TB). Incidentally, there is a variety of TB that chickens can get. The older the bird, the more likely it is to have this—or any other problem. On the other hand, I’ve never had TB in a flock and most family flocks never do. But if you did, the bird would feel very light, wasted, and the innards would look weird, would have abscesses on them (bird TB attacks the digestive tract and their intestines get abscesses on them). If you suspect TB, don’t eat the bird.

Head, Feet, and Oil Sac. You need a small, but very sharp knife to do the next steps. If the head is still attached, cut it off and discard. If the head was chopped off and the chicken flopped on the ground and got dirt on the stump, cut the dirty part off and discard. Carefully feel for the knee joint right at the top of where scaly leg meets feathered knee. Bend the knee and cut across each joint until the foot is off. Some authors tell you to cut off the small oil sac at the end of the chicken’s back on the “north end going south.” That isn’t necessary. Its presence doesn’t affect the taste. It is necessary with certain other birds (goose and duck and game birds).

Outing the Innards. Place the chicken on its back with its hind end closest to you. Carefully cut across the abdomen from thigh to thigh (or from below the breastbone to just above the anus—it doesn’t matter which), making sure you do not cut into any of the intestines in the cavity. Reach inside carefully between the intestines and the breastbone

until you reach heart level. Loosen the membranes between the innards and the body wall and gently pull out the entrails in one mass. The gizzard, heart, and liver will come out with it. Be especially careful of the gallbladder, a greenish sac embedded in the undersurface of the right lobe of the liver. If it should break, the bile that it contains will make bitter and undesirable any part of the chicken that it touches. You'll probably have to make a special effort to scoop out with your fingers the light pink lungs, which adhere inside the ribs.

To finish extricating the innards, cut carefully around the outside of the excretory vent, allowing plenty of room so as not to cut into it or the attached intestine, so that it can now be discarded along with the intestines. The kidneys in the back cavity adhere closely and should now be at least partly removed. Just scoop out what you can with your fingers of the soft, brown kidney tissue. It's impossible to get all the kidney out. Don't worry about what's left. It will be cooked along with the rest of the bird. Now, finish up the front end of the chicken: cut the skin the length of the back of the bird's neck. The crop tears very easily. The crop is a thin-skinned round pouch off the bird's esophagus that serves as a first stomach. You must gently pull it apart from the skin next to it. Then carefully pull crop, esophagus, and windpipe out of the bird and discard them.

Removing Giblets. "Giblets" means heart, liver, and gizzard—usually the neck, also. To get the liver, cut off the part of it that contains the gallbladder—allow plenty of leeway (better safe than sorry), and discard the gallbladder along with its attached liver section. Rinse the remaining liver and put it into your giblets bowl. Cut the gizzard open along its narrow edge. Continue the cut to three-quarters of the way around. Inside the gizzard there will be food and grit. Empty that out onto your newspaper. Carefully peel off and discard the yellowish inner lining of the gizzard. If you can get that lining separated from the gizzard proper at some point along your cut edge, the rest of the lining should strip out, easily connected to it. If it tears and does not all come out the first time, you'll have to work it loose at some other point, then pull again. When the lining is all pulled off, discard it. Rinse and save the gizzard. Cut the heart away from its attached arteries, rinse, and put in your gibblet bowl. Cut the neck off at the base and add it to your loose pieces in the bowl.

Outing the Innards: Poultry Shears Method. An alternative system popular with owners who must butcher many small birds (like game birds), duck owners, and efficiency lovers in general, is to cut off the oil-gland on the bird's tail, then carefully cut around the vent until the anus and attached intestine are separated from the rest of the bird, and then use the poultry shears to cut all the way up the back on one side of the backbone. The bird is then opened out from that cut and the innards will basically just drop out. Sort out and deal with heart, liver, gizzard, and neck as above. (Poultry shears are wonderful. You can also use them to simply halve and quarter the bird and be done with the cutting up process, too!)

Dealing with the Garbage. At this point you have feathers and innards. You can make use of the small feathers (see "Cleaning and Using Feathers"). Or you can bury the whole works in your compost bin. Make sure no creatures can dig it up again.

Washing the Bird? June Scherer, Eastman, WI, wrote me that she washes and scrubs the chicken's skin with dish soap at this point. "It's surprising how dirty they are, and the soap leaves no taste. Just rinse good."

Marketing Your Poultry. You could go into the poultry business. Lane Morgan wrote me, "People (at least city people) will pay a lot for humanely raised, nonmedicated poultry." She's right. I have a cousin who does well taking orders for broilers. She merely

grows them and then contracts out the butchering. Takes only prepaid orders. She charges \$8 per bird [1992]. Many families order their year's supply of chicken from her and then store it in their deep freeze to eat year-round. It's true that there is an amazing, clearly discernible difference in the taste of "real" chicken like hers and factory-produced supermarket chicken. And she, as Lane Morgan suggests, can indeed guarantee her customers that her chickens' lives, though short, are pleasant, and that they bear no antibiotic or other chemical residue. She never has advertised. She got started because people asked her to and her business has grown by word of mouth.

A reader in Missoula, MT, became a serious chicken rancher in a similar way: "I sell 100 chickens every 7 weeks. There is a large population of Hmong [Vietnamese] people in Missoula. One day this teacher friend called to ask if I had any chickens to sell. At the time, my husband and I annually raised fifty chickens for ourselves and fifty to sell. Joan asked me if she could tell her Hmong friends about my chickens and I willingly agreed. I remember Joan saying, 'You may have a lot of people coming out.' That turned out to be the supreme understatement.

"The next morning we started getting calls at 8am. It didn't stop all day. Whole families came out. Usually only one person in the group had English. It was wild. When all the chickens were sold, except for ours, the people still came. They insisted that we had too many chickens. 'Please, sell only 3 more!'... In the end we had only 25 for ourselves. Still more Hmong people came. They pointed to my chicken house where my laying flock lives. When I told them that I had no more chickens to sell, they said, 'Yes, you have many chickens. You sell me some!' I'd say, 'No, those are my layers.' They'd say, 'You sell me 3 layers!' Then a young man came who had excellent English. I explained the situation to him, and we came to an agreement. My husband built a brooder house in which I can raise chicks all year. The Hmong would buy even more than what I have now, but one hundred at a time is all I care to manage."

Killing, plucking, cleaning, and singeing is not an issue at all for the above writer. She told me that one of the big reasons the Hmong were so eager to buy live chickens from her is because it's a matter of conviction with them to do their own butchering! But if you're willing to butcher as well as grow the birds, there are exemptions for small producers in the Poultry Products Inspection Act. Check with your state Department of Agriculture for more information.

MAKING USE OF UNUSUAL CHICKEN PARTS

Cooking Giblets. If your bird is a roaster, you can use the giblets (except for the liver) in the stuffing or gravy. (Precook and dice them, then mix them in.) If your bird is to be a fryer, fry the giblets right along with the rest of the pieces. If it's a stew bird, use the giblets (except the liver) right with the rest. Another way to use giblets is to grind them up for taco and pizza meat. When chicken is canned, the hearts and gizzards are canned separately, and the livers are not canned at all.

⇒ **FRIED LIVERS AND HEARTS** *Sift together 1 c. flour, ½ t. salt, and ½ t. baking powder. Add enough water so you have a thin batter. Dip the separate hearts and livers one by one into it. Then fry them in hot (350°F), deep fat until the batter changes color to a golden brown. Remove from fat, drain off excess fat, and serve.*

About Bird Livers and Pâté. The liver gets left out of most recipes because its flavor is just too distinctive to blend successfully. From extra livers you can make the gourmet delicacy called pâté. The livers of about 5 or 6 average-sized chickens will give you ½ lb. of chicken livers. If you just do in a couple every Saturday for Sunday dinner, you could

add the fresh livers to your supply in the freezer until you have enough to make pâté. You can make pâté out of any bird livers; recipes are by weight of liver, and variety of bird doesn't matter. If you have a food processor or blender, that helps to get the pâté perfectly smooth. After the pâté is made, it's stored in a small crock or bowl in the refrigerator. Old-timers kept the vulnerable pâté from contact with air by smoothing the top and pouring clarified butter over it until it was completely covered. Nowadays you can cover it with plastic wrap pressed close over the top of the mixture.

Make pâté in small amounts because it doesn't freeze successfully and needs to be eaten up within a few days to a week at most. Pâté is good with a taste of mustard or tart jelly—red currant or crab apple—or with chutney. It's good served cold with sliced apples, crackers, toast fingers, or melba toast, or to make fancy sandwiches.

⇒ **PLAIN PÂTÉ** Cook $\frac{1}{2}$ lb. livers slowly in 2 T. butter with 2 chopped onions until the onion is soft and the pink in the liver has disappeared. Remove the liver, mash with a fork, and force it through a sieve, or blend until smooth. To the sieved liver, add $\frac{1}{2}$ c. sour cream. Salt and pepper to taste.

⇒ **GOURMET SEASONED PÂTÉ** Sauté 1 large onion, chopped, and 2 minced cloves of garlic in $\frac{1}{3}$ c. butter until vegetables are limp. Add 1 lb. chicken livers and sauté until pink has thoroughly disappeared. Add tarragon (1 T. if fresh or 1 t. if dried), 1 t. salt, $\frac{1}{2}$ t. freshly cracked black pepper, 1 t. dried thyme, $\frac{1}{2}$ t. cayenne pepper, $\frac{1}{2}$ t. cloves, and $\frac{1}{2}$ t. allspice. Process mixture until smooth. Add 3 T. dry sherry, and blend again until smooth. Pour into bowl, cover, and refrigerate overnight before serving.

Unfinished Eggs. When butchering cull hens, eventually you're going to encounter one with a cluster of eggs of all sizes—from the size of grains of sand to soybeans size to almost-regular-egg size. They look like little egg yolks. That's what they are, for the addition of an egg white and a shell are the last 2 steps on a hen's ovarian conveyer belt. The sight will give you awful pangs of guilt, as you will have obviously goofed in your culling and butchered a hard-working egg layer. At least you can avoid wasting the unborn eggs. Carefully remove them, rinse, and save. Use fairly soon. They are good food. You can cook them in the chicken broth for soups, scramble them together with regular eggs, or stir into any rice-vegetable mixture that you want to turn into a fried rice.

⇒ **CHICKEN-FOOT SOUP** Scald feet with boiling water until the skin and claw cases will peel off. Then place cleaned feet in cold salted water and cook slowly with stew-type veggies and seasonings to taste.

⇒ **BARBECUED CHICKEN WINGS** You'll need 20 chicken wings, $\frac{1}{4}$ c. soy sauce, $\frac{1}{4}$ c. honey, 1 T. vinegar, and $\frac{1}{2}$ t. ginger. Mix all the ingredients and marinate the chicken wings overnight. Bake at 400°F for $\frac{1}{2}$ hour, turning chicken occasionally while baking.

SERVING THE BIRD WHOLE

About Trussing. A roasting bird is “trussed” by drawing the thighs and wings close up against the body and fastening them securely with skewers or tying them with a string. Trussing keeps those appendages from drying up while the thicker parts of the bird are still baking.

Roasting a Bird (Chicken, Duck, etc.). Roast 2–2 $\frac{1}{2}$ -lb. chickens at 400°F for 1–1 $\frac{1}{2}$ hours, and they will brown well. Roast 2 $\frac{1}{2}$ –4-lb. chickens at 400°F for 1 $\frac{1}{2}$ to 2 $\frac{1}{2}$ hours. (If cooked at a lower temperature they will require a longer time to cook and won't be as brown.) Roast 4–8-lb. chickens at 325°F for 3–5 hours. If your bird is stuffed with a dressing, allow 15–20 minutes additional cooking time. (See “Cooking a Turkey” under

"Turkeys" for instructions on larger birds.)

About Stuffing. The bird may be stuffed through both the opening you made to remove the crop and in the abdominal cavity. Stuff sufficiently to fill it, but loosely, since stuffing expands when cooking. When the body is full of stuffing, sew up the skin or close with a combination of skewers and thread. If the sides are very slack, skewers alone could do the job. The loose skin of the neck is drawn over the stuffing in that neck cavity and sewn or skewered. A bird for roasting may be frozen with the stuffing in it for up to 2 months. Make the stuffing ahead and prechill so it is thoroughly cold before you stuff and freeze the bird. (See [Chapter 3](#) for stuffing recipes.)

➲ **BARBECUED BIRD** You'll need 1 whole (4–5 lb.) chicken or duck, salt, and pepper. Have plenty of hot coals ready. Season inside cavity. Fasten bird securely to rotisserie rod (or a pole over an open pit). Salt and pepper the outside of the bird. Position bird 6–12 inches from the coals. Enjoy the aroma as the bird sizzles for 2 ½–3 hours. When it's done, serve it piping hot.

CUTTING UP THE BIRD

A Halved Broiler. Traditionally, you start with a bird in the 1 to 1 ½-lb. range. Split the bird into 2 halves, down one side of the backbone and along the breastbone. If you want, you can also cut it along the other side of the backbone and remove the bone completely. To freeze the broiler, place 2 pieces of freezer paper between the halves to make it easy to separate them, then wrap well in a plastic bag or freezer paper. Label with date of freezing and "broiler."

Quartered Bird. You just cut each half in half again so that you end up with 2 breast-wing pieces and 2 thigh-drumstick pieces.

Making Old-Time Frying Pieces. I cut off both the legs and wings before opening the abdomen to remove the entrails. But a person can cut them off afterwards, too. You may leave the drumstick connected to the thigh and serve the resulting larger piece as one, or you can find the joint by wiggling it with one hand and feeling for it with the other and then cut them apart. To get the thigh off the body, place the chicken on its back. Pull the thigh away from the body. Cut through the skin that is thus exposed, between the thigh and the abdomen. Now bend the thigh sharply away from the body cavity until the ball of the thighbone pops from the hip socket. Cut between ball and socket and finish separating the thigh from the body. Do the other leg the same way.

Next comes the wing-joint cut to make a big piece. You press the top bone of one wing against the body. Feel for the shoulder ball-and-socket joint. Cut through the joint, pull wing outward from body, and cut it from body. By this technique a portion of breast meat will come away with the wing. (It makes the wing piece more significant than it is otherwise.) If you prefer just wing and no breast meat with it, pull one wing upward to expose the joint connecting the outer wing to the body and cut through that joint. Do the other wing the same way.

The last step is cutting up the body. Insert knife blade into the cavity of the bird. Cut parallel to the backbone, slicing through the ribs at approximately the halfway point. Do the same thing on the other side. Pull apart the breast and back. You'll see the meat-covered shoulder blades that unite them. Slice down through these bones to separate the breast section completely from the back. Cut across the backbone where the chicken's rib cage ends to divide the back into 2 pieces. To finish, place the breast skin-side up and cut down the length of the breastbone to divide it into 2 equal pieces. If this were a very large bird, like a turkey or goose, you could cut across extra times to get more breast pieces.

FREEZING, CANNING, OR DRYING POULTRY AND OTHER SMALL STOCK MEAT

Freezing a Roaster. Trim away and discard the excess fat. Cool bird in the refrigerator or soak it in ice water until it is well cooled. This may take 6–8 hours. Then drain thoroughly, for 20 minutes (the drier it is when it goes into the freezer, the better it will keep). Wrap the giblets in freezer paper. Put the giblets into the bird's empty cavity, then slip the bird containing giblets into a plastic bag. Lower the bird in bag into a pan of lukewarm water. Be careful not to let any water get inside the bag. The water will press the plastic against the bird and expel all air. Twist tightly the part of the bag remaining out of the water. Then loop the tag end of plastic double and fasten with a wire twist or a strong rubber band.

Freezing Cut-Up Chicken. Chicken in pieces is more compact than a roaster, and so takes up less freezer space. The freezer life of a chicken is about 6 or 7 months. If you freeze cooked chicken, it will stay prime only 2 or 3 months.

Canning Poultry, Small Game, or Rabbits. Use cut-up pieces. Remove as much bone as possible so it will pack more compactly. You can include the neck, but do something else with the gizzard, heart, and liver. You could can the gizzards and hearts separately. Or make broth with them and the wings and use it to cover your canned meaty pieces. Or, instead of canning the wings, which are bony and don't have much meat, use them for old-hen recipes, soups, or dog biscuits. Boil chicken pieces 1 hour to precook. You can bone them and can the meat pieces for creamed chicken, sandwiches, or chicken a la king. Or can on the bone.

⇒ **HOT PACKING, ON THE BONE** Precook until no pink color is left, even at the center of the pieces. Add 1 t. salt per quart jar. Pack clean quart jars loosely with precooked, hot pieces. Pour hot chicken broth over the meat. (You'll need $\frac{1}{2}$ – $\frac{3}{4}$ c. per quart.) Leave 1 inch of headspace. Put on lids and process in pressure canner at 10 lb. for 65 minutes for pints, 75 minutes for quarts. Take jars out of canner and complete the sealing.

⇒ **CANNING GIBLETS.** Precook in pan until cooked through. Add $\frac{1}{2}$ t. salt per pint. Pack hot. Add broth to cover giblets, leaving 1 inch headspace. Process in a pressure canner at 10 lb. for 75 minutes (for pints).

⇒ **HOT PACK, NO BONE** Precook. Remove bones. Fill jars immediately, leaving 1 inch head room. Process in pressure canner at 10 lb. pressure for 75 minutes for pints, 90 minutes for quarts.

⇒ **RAW PACKING ON THE BONE, NO LIQUID** Wash pint or quart jars in hot soapy water, then rinse. Pack raw chicken pieces into jar, drumsticks and thighs against the outer glass, breasts in the center. Add 1 t. salt per quart sprinkled over chicken, no liquid. Wipe jar rim dry. Put on lid. Process in pressure canner at 10 lb. pressure, 80 minutes for quarts.

Drying Chicken. Start with freshly butchered chicken. (Or turkey, but not fat poultry such as duck or goose; fat poultry meat doesn't dry well.) First precook. Cool, remove skin, bones, and all fat. Cut all remaining meat into equal-sized cubes no more than $\frac{1}{4}$ – $\frac{1}{2}$ -inch square. Distribute these cubes across your drying surface in a very thin layer. Dry in oven or dehydrator 4 hours at 140°F, then continue at 130°F until drying is finished. It helps to stir once in a while and turn trays occasionally. If sun drying, it will take 2 or 3 days. You're done when the meat cubes are dry all the way to the center and so hard they can't easily be cut with a knife.

CHICKEN RECIPES

⇒ **OVEN-BARBECUED CHICKEN.** Lay your chicken pieces, skin side up, in an oven pan. Sprinkle seasonings (salt, pepper) over. Lay raw slices of onion on top of the meat. Pour a

little water into the bottom of the pan. Bake for a half hour at 375°F. Pour your favorite barbecue sauce generously on top of the chicken. Bake another half hour.

⇒ **OVEN-FRIED CHICKEN** Combine $\frac{1}{2}$ c. flour, 1 t. salt, and $\frac{1}{4}$ t. pepper in a plastic or paper bag. Dip your chicken pieces into melted butter. Then shake a few pieces at a time in the bag of flour and seasonings. Put the floured pieces skin side up in a baking pan. Bake at 375°F for an hour or until done. Variation: Instead of coating in flour, coat in crushed cereal. Or crushed barbecue potato chips. Or crumbs. Or crushed taco chips.

⇒ **CURRIED CHICKEN** Boil chicken until tender. Fry 1 minced clove of garlic and 1 or 2 chopped onions in butter until onions are transparent. Add 1 T. curry powder, $\frac{1}{4}$ t. ginger, pinch of salt and one of pepper. Stir until well mixed. Put the cooked chicken pieces into this curry mixture (hold back the chicken broth for some other purpose). Pour a cup of buttermilk over the top. Simmer over low heat for 1 hour.

⇒ **HUNGARIAN PAPRIKA CHICKEN** In a plastic or paper bag, mix together $\frac{1}{2}$ c. flour, 2 t. salt, and $\frac{1}{4}$ t. pepper. Shake a few chicken pieces at a time in the bag until they are well coated with the seasoning mixture. Brown the coated pieces in a little oil in a frying pan. Add a chopped onion and 1 c. hot water. Cover and cook on low heat until chicken has become tender. In the meantime cook noodles until tender. Place the drained noodles in the bottom of a big frying pan. Lay the fried chicken on top of that. Keep warm in the oven while you make the paprika sauce. Combine $\frac{1}{4}$ c. flour, 2 t. paprika, $\frac{1}{2}$ t. salt, and $\frac{1}{8}$ t. pepper with 2 c. buttermilk. Heat, stirring constantly, until the sauce thickens and begins to boil. Pour it over the chicken and noodles and serve.

⇒ **CHINESE SWEET AND SOUR CHICKEN** Combine $\frac{1}{2}$ c. honey, 2 T. lemon juice, $\frac{1}{2}$ t. salt, 1 t. Worcestershire sauce, and 2 T. mustard. Pour the mixture over the chicken. Marinate chicken in the mixture for 2 hours, refrigerated, turning chicken in the sauce regularly. Then roast or broil the chicken, turning and basting once in a while. If the chicken is in the oven, set heat at 400°F.

GOOD RECIPES FOR OLD HENS! You can use these recipes for other small, tough old creatures (like rabbit) simply by substituting “creature” for “chicken.”

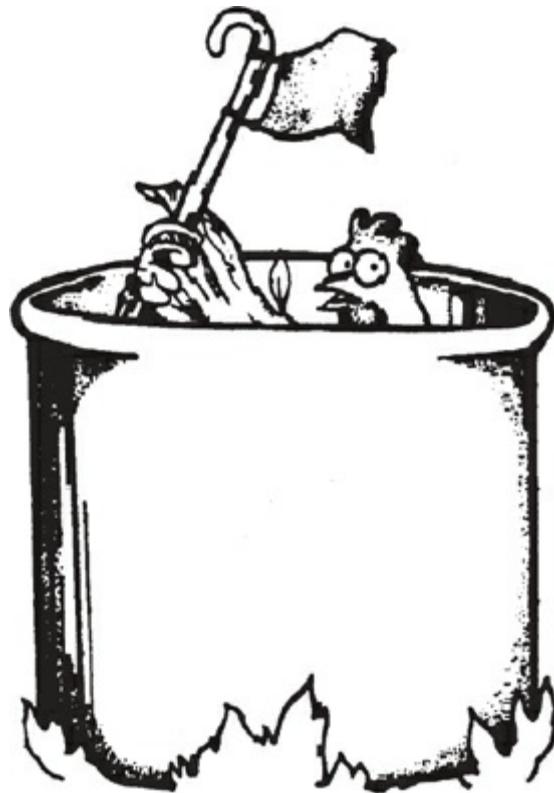

⇒ **CHICKEN AND NOODLES** This recipe is delicious and warms up well. Put your stewing hen in a deep pan. Add all giblets except liver. Cover with water and add $\frac{1}{2}$ t. salt for each pound of chicken. Add 1 carrot, 1 small onion, 1 clove, and 3 peppercorns. Bring to a boil, reduce heat, and simmer until the meat will come off the bones and is very tender. That will require at least several hours or more, depending on how tough your old bird is. Cool it down enough to work with. Take the chicken off the bones and discard bones, skin, and cartilage. Return the meat to the broth. Mash the vegetables in the broth. When you’re almost ready to serve this, heat it to boiling. Pour in noodles and cook, frequently stirring to make sure nothing is sticking, until the noodles are done. Serve. I always make this with homemade egg noodles.

⇒ **CHICKEN STEW** Prepare the chicken as for “Chicken and Noodles” (above), but instead of adding noodles, add potatoes, more carrots and onions, and peas (or any other vegetables you have and enjoy in stew). Cook until tender.

⇒ **“CREAM” OF CHICKEN SOUP** Prepare the chicken as for “Chicken and Noodles” (above), but instead of adding noodles, puree vegetables and add them to the chicken and broth.

⇒ **CHICKEN POT PIE** Make “Chicken Stew” (above) or use leftover chicken stew to make this. Brown 7 T. flour in a frying pan with 4 T. butter. Gradually add enough chicken broth to

make a good gravy (about 2 ½ c.). Butter a baking dish. Put the vegetables and meat from your chicken stew into the dish. (Hold back any excess broth to use in another recipe.) Pour the gravy over it. Make a dumpling dough by your favorite recipe (see recipes in [Chapter 3](#)). Drop the dumpling dough by marbles or teaspoonfuls (depending on how you like to make it) on top of the meat and gravy. Bake at 350°F until the dumplings are done.

⇒ **CHICKEN AND DRESSING** Cook the chicken and giblets (except liver) until you can easily separate the meat from the bones. Let cool and remove bones and cartilage. Then grind the chicken skin and giblets and add to the meat. The chicken meat is nicest sliced thin. Make a bread dressing base from (preferably homemade) bread plus egg, seasonings, and chicken broth and milk (see recipes in [Chapter 3](#)). In an oven pan put a layer of dressing, then a layer of chicken, a layer of dressing again, and so on. Bake, covered, for 40 minutes at 350°F.

⇒ **IVY'S CHICKEN LOAF** Ivy Issacson is a beautiful person, a real old-timer. Her husband, Dick, has experience driving oxen and knows how to make an ox yoke, starting with the right sized tree. Here's her recipe: First, boil your old hen by the "Chicken Noodle" recipe (minus the salt), until it is so tender you can pick out the bones and discard them. Keep the chicken meat and broth. Mix 1 small loaf bread torn in to pieces with 4 c. corn bread and add enough of the chicken broth to moisten the breads thoroughly. Now add ½—1 c. chopped celery, ½—1 c. chopped onion, salt, pepper, and sage to taste. Place mixture in a buttered 12 × 15-inch pan. Cover with the chicken meat. Mix ½ c. melted butter with ¾ c. flour. Add 2 c. milk. Cook same as any white sauce until thickened. Cool. Add 6 eggs, beaten. Pour over chicken. Sprinkle with buttered bread crumbs. Bake at 350°F for 1 hour. This will give you 15 to 20 servings. Good to take to a potluck!

⇒ **GERTRUDE JOHNSON'S CHICKEN SPREAD** Cut a stewing chicken of at least 2 lb. into pieces, and place it in casserole that has a tight-fitting lid. Dot with 4 T. butter. Add 1 onion, peeled and quartered; 2 carrots, halved; 2 ribs celery, halved; and 4 peppercorns. Lay 3 lemon slices on top. Cover casserole tightly and bake for 3 hours at 325°F or until chicken is very tender. You might want to just serve the chicken for supper right at this point in the recipe!

Otherwise, remove chicken and cool. Discard the vegetables, spices, bones, and skin. Run meat through a meat grinder 2 or 3 times, or whirl it in a food processor until smooth. Put chicken in a mixing bowl and blend in 4–8 T. of softened butter. Stir in ½ t. Worcestershire sauce, salt, and pepper to taste. Press your chicken spread into small jars. Pour a ½-inch layer of clarified butter over the spread in each jar. Cover tightly and refrigerate until wanted to make sandwiches.

» **DOG BISCUITS** You can use the excess broth from any old hen recipe to make this, or you could cook the chicken specially to get broth, use the meat in another recipe, and use the broth for dog biscuits. (Actually you can make this recipe with other types of meat broth, too.) This recipe will yield 60 medium-sized dog biscuits which your pet will consider a great treat. Mix together 3 ½ c. unbleached flour, 2 c. whole wheat flour, 1 c. rye flour, 2 c. cracked wheat, 1 c. cornmeal, and ½ c. skim milk powder. On the side, dissolve 1 T. (or 1 pkg.) yeast in 3 ½ c. lukewarm chicken broth. The richer this broth is, the more your dog will like the biscuits. Let yeast-broth mixture sit 10 minutes, then stir in the flour mixture. Roll resulting dough out ½ inch thick. Cut dog biscuit shapes from dough. Brush biscuits with egg wash. Bake on greased cookie sheets at 300°F for 45 minutes. Then turn oven off and leave biscuits in there overnight to finish hardening.

Cleaning and Using Feathers

Now that you've taken care of the meat, you can get back to the feathers. You can make and sell jewelry, art objects, and trout lures from feathers. Or clothing. Or a quilt. But first you have to clean them.

CLEANING FEATHERS

Cleaning Nice Feathers. Wash them in warm water with a little detergent in it, then wash them again in a fresh tub of water with detergent (or washing soda or borax). Then rinse them, and place them into a clean cheesecloth bag or gunny sack and slowly dry. Fluff the feathers several times a day. If you hang them out on the line, dry them in the shade because the sun will bake the life out of them. Or you can dry the feathers by putting them into a slow oven for about half an hour, then removing them, then putting them back into the oven 2 or 3 times. The oven must not be too hot. Or you can suspend the bags from the ceiling of a warm kitchen, or some similarly very warm place.

Cleaning Not-So-Nice Feathers. Ducks and geese are not generally subject to the kind of feather parasites that afflict chickens. You could just throw away the feathers and resolve to trade in your dirty-feathered poultry variety for waterfowl. Or you can struggle on. You won't get good results from what are called "dead" feathers. Those are the ones that the chickens lose in their regular molting process and your children find in the yard or on the chicken-house floor. They will be hard to clean and not as lively and nice as freshly plucked ones.

Pat Woods, Sedro-Woolley, WA, wrote me that a neighboring chicken farmer just presented her with 6 great big sacks of feathers in this condition, and what should she do? Personally, I wouldn't bring home a batch of feathers that had critters, because next thing you'll know they'll be all over your own farm. Just tell your well-intentioned neighbors to keep their feathers. So I'm writing to her and writing up her situation for the book at the same time. (I'm always glad to get questions from people. It tells me what people are needing to know and helps me make this book a more useful one for its readers.)

If somebody gives you a mess of feathers that are not in good shape (and that's the way you'll usually get them)—I mean, containing lice and other creepy-crawlers along with the

dirt, droppings, and so on—and you want to keep them, here is what you do.

You'll have to pick out rocks, straw, sticks, and major globs of flop by hand. If there are no bugs, go ahead and strip the wing and other large feathers to get those big quills out of the way. It takes a long time to strip feathers. And cut off the sharp tips on the shorter feathers. If there are bugs, you'll want to give it all a very antiseptic laundering first. Sew or tie the feathers into a bag. If you've got something like old scrim curtains, the kind you can look through, that's perfect, because they let the dirt out. But any loosely woven cloth will do. Then you put the whole thing in the washing machine, and wash it repeatedly until you're satisfied. Or wash the bag by hand, squeezing it and letting it fill, again and again. You can use a soap suitable for wool, even some bleach, and warm, but not boiling hot, water unless the bug problem is bad. In that case, a dose of boiling water in a pan on the stove may be the only answer for your "presoak" cycle.

So if you've got questions too, do write me—don't feel embarrassed about it. If I don't know, I'll just tell you so, or maybe I can find out, and then we'll both learn something. If you have a question, suggestion, or need another copy of this book, or want to know about other books I've written, or the latest edition, find me at www.carlaemery.com.

Drying Feathers. If you have a dryer, put your washed sack of feathers inside a pillowcase for extra coverage, then just go ahead and dry them on a very low heat setting. If not, hang the feathers inside a very loosely woven bag in the shade on your clothesline or some place where it can get lots of air. Give the bag an occasional shake. Or you can

spread them on screens placed above the floor, or even on the floor itself, if you make sure to turn them over often enough for thorough drying. The main thing is to get them dry as quickly as possible without exposing them to direct sunshine. If the feathers don't dry quickly enough, they will start to deteriorate in quality, becoming fibrous and, ultimately, decomposing.

USING FEATHERS: Whatever feathers you use to stuff, they must be absolutely dry. The higher your percentage of the more down-type feathers, the better. Don't use the quills (wing and tail feathers) at all, unless you strip the fluffy part off the quill base and use it without the quill. You can sell well-washed waterfowl down. It takes about 5 ducks to make a pound of down. Or you can make something of your own with it. Make pillows. Or a quilt.

Making a Feather Quilt. Lay the feathers, still in their cheesecloth bags, upon the bottom layer of the quilt as it is stretched out on your quilting frame. Then put your quilt cover on, tack it down, and sew or tie it. Or the feathers could be placed directly between layers of cheesecloth, and then the quilt made over that. If this method is to be used, stitch over the entire cheesecloth and feather layer (and quilt, too, if you wish) to create an effect of "diamonds" or "squares." This will keep the feathers from shifting out of place and bunching. Another technique is to sew 2 layers of cloth together around 3 edges leaving the top open, and then sewing from the head to the toe of the quilt, creating long pockets into which you stuff the feathers and down, then sewing the top edge closed. Such quilts can be washed very occasionally if care is used, but it is preferable to have removable covers, and thus protect the feathers from washing as much as possible. To make pillows and ticks, use commercial ticking and fill them as slack or full as you like. But the first time, make them fuller than you think you want, because they will gradually pack. Use a ratio of about $\frac{1}{4}$ small body feathers to $\frac{3}{4}$ down to get a resilient pillow. Sew double-stitched seams to keep the feathers in. Make sure you have the feathers in a special inside layer, because you don't want to have to pull a needle through the feather section as you quilt the top. It will pull feathers out with it every time.

Making a Feather Bed. Use regular twill ticking to contain the feathers. Sew double seams so you won't have feathers creeping out. Leave one end open. Pour in 10 to 20 lb. of dry, clean feathers and sew it up. Feather quilts go on top of you; feather mattresses beneath you. With feathers above and below in that manner, you can sleep warm, even in temperatures 50°F below zero, and I kid you not. That's what the settlers in places like Vermont—where they had no heat in their homes at night—used for bedding.

Feather-Stuffed Clothing. Items such as down jackets can be made by creating 2–3-inch channels in the garment to keep the feathers evenly distributed. For clothing use a higher percentage of down, up to 90 percent. Use a down-proof lining, and sew double seams everywhere.

Making Old-Time Quill Pens. The second, third, and fourth quills of the wing are the best for this. If you want them to be clear, put the feather into boiling alum water for 5–10 minutes, then scrape its outer "skin" off. After this, dry the quills in hot sand on a stove, or before the fire.

There exist strange, believe-it-or-not life paradoxes: you get by giving; risk can provide safety; and great, breakthrough understandings that change a person's life and set them back on the right road can come in lulls between episodes of fierce struggle, born of action. I have a theory that you can't go and contemplate dandelions and have anything important happen in your head—unless you are first bone tired from doing something you think is important. But, on the other hand, I don't think you can get along on pure

action either. So spend some time with the dandelions. Or in the garden. Or with the milk cow. Or watching your chickens. In those lovely, quiet times your head gets a chance to tell you a few things you were needing to be told. Your own head can be your best friend, if you listen.

TURKEYS

Don't buy just 1 turkey. Turkeys don't like being alone, and a solitary one may refuse to eat and, consequently, die of starvation. Or the lonely bird may adopt a human. Margie Minard of Mt. Vernon, OH, wrote me: "We have a pair of bronze turkeys. I love them! Their names are Ben Franklin and Betsy Ross. Betsy has been sitting a nest for nearly 3 weeks. Ben has been lonesome since Betsy has been so busy and has become my buddy. He goes to sleep every night on his perch in the barnyard, but every morning he's waiting for me to get up and go out on the porch and have my coffee with him. I talk to him, he peeps back, and we share an apple. Our pair of turkeys seems to be very sweet and very gentle creatures." (A word of caution, here: I wouldn't recommend getting to be that good friends with any farm animals unless you're planning to keep them for breeding.)

Dynah Geisel of Missoula, MT, reported: "I used to keep adult turkeys in the hope of raising my own babies. However, the females wanted to be pets, following me everywhere, trying to come into the house, wanting to sit in my lap outside, etc. The males at around 1 year of age became so mean that they terrified grown men and were a real danger to little children." Indeed, these big turkey toms (a tom is a male) can be very aggressive and dangerous. Once I had a band of gobblers that sneaked up and attacked my husband, Mike, when they were freeranging. (They didn't stay freeranging!) Yet I've also had freeranging turkeys that got along fine with everybody.

Turkeys, like the other poultry, come in different kinds and sizes, but even the small ones are sizable birds. If you're going to raise turkeys, you'll need to invest in a large deep freeze and, even so, be cautious that you don't raise more than you can use. Turkeys have received a lot of bad press about being hard to raise. They are a little slow to learn how to drink and eat, and a little more vulnerable to disease than other poultry, if kept in large numbers. (Crowded birds in general are more vulnerable to disease and parasites.) Other important issues are the initial high-cost of poult, the large amounts they will need to eat (expensive if they are on all-commercial diet), and the large amount of turkey meat you will end up with. Most families would want to raise 6-12 turkeys per year for family use. For commercial growing, 1 acre of land supports between 100 and 150 turkeys.

All turkeys have brightly colored, bizarre-looking folds of skin hanging down from their heads called "wattles." Somebody asked me what wattles are for. I don't know. A full-grown gobbler is an amazingly ugly creature, or handsome, depending on your point of view. Mature toms gobble noisily when strangers approach.

TURKEY BOOKS AND SUPPLIES *Starting Right with Turkeys* by G. T. Klein is a classic on the subject, first written in 1946 and updated in 1972. For a more modern treatment of the turkey subject, see *Raising Your Own Turkeys* by Leonard S. Mercia. Or *Turkeys: A Guide to Management*, available for \$22.95 from David Bland, 800-423-4525 or Stromberg's, 800-720-1134.

For my summary of the most important things about growing turkeys (that aren't already covered under "Chickens"), here goes.

Turkey Breeds

THE BROAD-BREASTEDS: The biggest of the turkey breeds (also known as the “heavies”) are the broad-breasteds, either the traditional Broad-Breasted Bronze or the newer Broad-Breasted White. The Broad-Breasted Bronze is the brown-or black-feathered turkey, but since dark-feathered birds end up looking “dirty” when plucked, the white varieties are becoming the commercial choice.

Broad-Breasted Whites grow large, even larger than Bronzes. These birds grow very fast, have exceptionally large, meaty breasts and may ultimately dress out to 25 lb. (hens) or even 45 lb. (toms). (Other poultry breeds don’t have such a striking difference in ultimate weights between the sexes.) You can reasonably send one of these to roast any time from 12 lb. on up. Both Bronzes and Whites make good large roasters at 24–28 weeks. As turkeys (and other poultry) get larger, their feed conversion efficiency and rate of gain decreases. The usual goal is to grow an 18-lb. tom (12-lb. hen), in about 5 months, or a 25-lb. tom in 6 months. Hens can be butchered at only 13 weeks as fryer-roasters or at 20 weeks to make medium roasters (about 14 lb.). If left to full maturity, they get heavier yet. Toms can weigh 50 to 60 lb. at maturity, but by then the meat is toughening. Because the Broad-Breasteds can put on more flesh weight than the others they should be started a month earlier than a medium or light breed.

Many formerly abundant turkey breeds are now extinct or very near extinct due to the extent to which the market has become dominated by the 2 broad-breasted breeds. But some still exist.

NOT BROAD-BREASTEDS: If you want a turkey variety that can be fertilized without human assistance, and has good setting and mothering instincts, it keeps getting harder as more and more genetic lines are losing that ability. You can get small-sized Beltsville Whites that will reproduce naturally. And you can get naturally mating Bronze turkeys from Wish Poultry, Box 862, Prairie City, OR 97869, spring hatch only. The Bronze is a large bird that does relatively well either in confinement or on range.

Beltsville Whites. These are smaller turkeys; they make good broilers at 15–16 weeks and good medium-size roasters at 24 weeks. Beltsvilles do not convert feed as efficiently as the Broad-Breasted varieties, but they are usually cheaper to buy as poult.

Bourbon Reds, Royal Palms. The reds and palms are both medium-sized turkeys. The Royal Palm is the only major turkey breed whose hens are dependable brooders.

Others. Some sources sell Wild Turkeys. These are hardy, good flyers, and smaller than the commercial breeds—a “light” variety. Because they are being raised in order for the bird to make a comeback in the wild, check with your state game regulatory agency before ordering any. You may need a permit. The Wild Turkey breed needs a high-protein feed, like gamebird starter. Other turkey breeds are Black Spanish, Narragansetts, Blue Slates, and a rare Guatemalan turkey, also called the “ocellated turkey.”

Turkey Reproduction

Most people start by mail-ordering turkey poult just as is done with chicks, but you can breed your own. Keeping turkey breeders over winter is expensive because of their sizable food consumption. A broad-breasted tom can eat as much as 250 lb. of feed per year. Letting a bird hatch its own eggs is an iffy method of building a flock because sometimes hatchability is not good. On the other hand, it’s nice to know that at least some of the domestic turkey species could survive without artificial insemination and electricity. Growing the better part of your turkey food keeps the expense down. And if you are well-informed about what you’re doing, you can avoid the pitfalls.

A good time to buy poult being reared to be breeders is 8 months before you’ll want the eggs. Use only the birds that best represent the characteristics you want to breed for. For light-breed turkeys, 1 tom per 20 hens can do the job. Medium-heavy breed turkeys need 1 tom per 18 hens. Heavy-breed turkeys need 1 tom per 16 hens. But you should have at least 2 toms to ensure fertility and performance since one may die or just not have the right stuff. Commercial breeders get the birds started early by stimulating the toms with extended light hours 4 weeks before mating, and hens 3 weeks before egg production with 13–14 hours of at least 50-watt lighting or sunlight.

TURKEY SEX: When hens begin to lay, they begin to mate. The toms strut and court them. The hen chooses the tom she prefers, squats near him, and with luck, he responds and mounts her. If he doesn’t respond she loses interest in males for a while. (I can relate to that.) Males that have been “pre-lighted” tend to respond more effectively. Sperm then stored inside her will fertilize her eggs for somewhere between a few days and a few weeks.

Artificial Insemination, or AI. The breeds that are not heavy-breasted and are old genetic lines can usually reproduce naturally. The commercial, heavy-breasted breeds of turkey are not as fertile because that body type selected for by growers, with its very large breast, has some technical difficulties in achieving fertilization naturally because that big meaty breast is too much in the way. So heavy-turkey growers either inseminate artificially completely or attempt to raise the fertility rate by supplementing nature with AI. Inseminating turkeys is not as hard as it sounds.

Milking the Tom. First you capture the tom and the lady and have them close by because turkey semen must be used within 30 minutes of collection. The ideal AI schedule is to inseminate once, wait 4 days, and inseminate once more; after that, do it once every 2–3 weeks while the egg-laying season is on. Toms can donate 2–3 times/week. You need at least 2 people to do the job. You “milk” the tom by flipping him on his back (or you can

have him upright and work on him with his legs spread a little from his backside) and stroking his abdomen and pushing his tail up and toward his head. His organ enlarges, protrudes a little bit and then someone must grab it high up and stroke downward just like you're milking a cow. That's it. Have something ready in which to collect the semen. You'll get only a half cubic centimeter or less of it—less than $\frac{1}{8}$ teaspoon.

How to AI the Hen. Get her into position by flipping the hen on her back, flipping up her tail, and evertting the cloaca. Now pour the tom's semen into it. But for best results, it's not that simple. Ideally, you will expose the opening of the oviduct and use a glass or plastic straw or a small needless syringe to place the semen about $1\frac{1}{2}$ inches into that oviduct. If you can't find the oviduct you may have a hen that's not in lay, in which case it's all a waste of time anyway.

Egg Production: Have available nests that are 24 inches high by 18 inches wide by 24 inches deep with comfy litter in them in a dimly lit area before laying will start—1 nest for every 4 or 5 hens. For a lot of hens you could supply a 3×6 -foot community nest. One of those can accommodate about 20 hens. Supply litter generously and gather eggs frequently during the laying season because turkeys like to lay together and tend to step on and break each other's eggs. Heavy hens may lay 50 eggs, medium hens 50–70 eggs, light turkey varieties 85–100 per bird. Turkey eggs are good to eat, but are generally too valuable as the progenitor of another turkey to waste in an omelet. As with chickens, turkey egg production is best the first year and then each succeeding year decreases about 20 percent. Like chickens, egg size increases the second year.

Natural Brooding: Broodiness is common among turkeys, but full-fledged mothering ability is not. At least, among the most modern breeds, the turkey hens simply don't have the best sense about the care of poultts. Ideally, your turkey would lay 15–20 eggs, then stop and brood them. At least take the eggs until you have a reasonably sized clutch for the hen to sit on. Or let chickens, ducks, or geese brood the eggs. A medium-size chicken can cover 6–7 turkey eggs. The incubation period will be 28 days.

I think the retention of breeds that have the requisite instincts and experience to reproduce on their own is important, and the people who raise these are doing the homestead market a valuable service. If you have a mothering turkey, provide a turkey-sized A-frame inside the pen, 1 for each hen, with straw inside to make into a nest. The nest can be about 14 by 24 inches, on the ground. She'll lay eggs in there and brood them. Some growers slaughter the breeders as soon as the poultts are independent of them so as not to have to feed them over winter. Old breeders can be cooked like any other turkey—only longer.

Incubating Turkey Eggs: If you're planning to incubate, broodiness is a problem and you'll want to chase broodys off the nest and treat them like you do a chicken with unwanted broodiness (see "Discouraging a Broody Bird" under "Chickens"). The growers who incubate eggs feel that it makes more economic sense to keep those hen turkeys laying and they will, of course, stop immediately if allowed to stay broody. Incubate turkey eggs for 28 days at 102°F in a still-air incubator or 99.5°F in a circulated-air incubator. Relative humidity during the first 25 days should be about 62 percent (dry bulb reading 99.5°F ; wet bulb reading 87.5°F). During the last 3 days it should be about 70 percent (dry bulb 99.5° /wet bulb 90°F). Which brings you to the directions for raising poultts.

Brooding Poultts

A "poult" is a just-hatched turkey.

MAIL-ORDER POULTS: Order your poults to arrive after the weather has turned warm. Or you may be able to buy them at your local feed store. They cost \$3 to \$5 each, depending on the breed. To mail-order turkey poults you need to get your order in early, by midwinter. Check on delivery schedules since they are hatched during only a few months of the year—about March to July. Poult delivered to you in late May or early June will have just the right amount of time to reach finished weights before Thanksgiving. If you begin your brooding after warm weather has arrived it will be easier and cheaper.

SANITATION: Do make sure you clean the brooding area, disinfect it, then let it stand empty for a month before the turkey poults move in—if it has previously held chickens. This precaution is because turkeys are susceptible to coccidiosis and blackhead disease, both of which are carried in chicken droppings. Still, the most severe turkey disease problems occur in large commercial flocks. Small numbers of turkeys raised and then put into the deep freeze seldom have communicable disease problems.

BROODING: See “Brooding Chicks” under “Chickens” for further information, because the basics are the same. You can brood in a cardboard box with an electric light or a shed-room or in a penned-off space in a barn. If you are using a thermostat-controlled brooder, brood Broad-Breasted Whites at 100°F the first week and Broad-Breasted Bronzes at 95°F the first week, and then reduce 5 degrees a week just as with other young poultry. Depending on your climate and the time of year you start them, they may need supplementary heat as little as a few days or as much as the full 8 weeks. If poults get wet and chilled, they must have heat to recover. As with other poultry, most of the work and worry with turkeys comes in the first 8 weeks. It’s important to check on poults frequently and observe them closely, even after the first few days, to see if there is some problem.

Teaching Poult to Drink and Eat. You can use chicken feeding and watering equipment for turkeys. As soon as your mail-order poults arrive, take them one by one out of the shipping container, dip their beaks into their proper drinking container (which should be filled with lukewarm water). Then dip their beaks into their proper feed trough (which should be filled to the brim). Do this same thing morning, noon, and night for each poult for the first few days, or until they learn how to eat and drink and can do it on their own. Some people put a few chicks in with the poults to show them how; chicks are quicker learners than poults.

But don’t count on that technique working. There are reports of poults having died of starvation while standing on their food. (Anyway, it’s unhealthy for them to eat food that has been spread on the floor or ground and gets mixed with feces.) Unlike chickens, turkeys seldom scratch to find food. Instead they peck at something that catches their attention. So an additional good teaching technique is to put strips of aluminum foil or some brightly colored marbles both in their feeders and waterers to catch their attention and encourage them to start picking at it. Or you can lay their food out on clean sheets of white paper towel. Or put it in low-sided box tops like oatmeal carton lids. Another technique to help them find that feed and water is to supply intense light, such as 150 watts, 24 hours a day for the first 3 days.

After those first 3 days or so, you can take away the chicks so they won’t get trampled. Move the feed from paper towels or box tops into the regular metal feeder, and fill the trough only $\frac{3}{4}$ full.

Commercial Turkey Food. Most local feed stores don’t carry turkey starter mash, although that is a very suitable food for the poults. So, the poults can be fed chick-starter rations with plenty of water. In either case the feed will contain a coccidiostat (antibiotic

to prevent coccidiosis). They'll eat the starter ration for their first 8 weeks. Then gradually shift them to a grower's ration. At about 16 weeks of age they are gradually shifted to a finishing ration. Growing and finishing rations are not usually medicated. Supply grit. If you are using any medicated feeds for older birds, be sure and stop offering them at least a week before slaughter and preferably longer.

About Antibiotic Withdrawal. Food writer Lane Morgan, who reviewed this book, complained that in the chicken section it says to withhold medication for 5 days, and here it says a week. Actually, never medicating them is best. Or, lacking that, stopping as long before slaughter as possible. Or 7 days. Or 5. How desperately hungry are you? Starvation is worse than a little antibiotic in your protein. These things are judgment calls, not absolutes. The basic principle here is that the less antibiotic you feed your animals, the better—for them and for you. Routine antibiotic-feeding results in an animal whose own immune system is under-developed and under-functional. That's true whether it's livestock or your children. Antibiotics are a quick fix for which we pay a long-term price in the development of antibiotic-resistant varieties of whatever we were fighting in the first place. Livestock diseases often transfer over and become human illnesses too, and this can also happen with antibiotic-resistant varieties of livestock illness. Simply speaking, the more you use antibiotics (or pesticide, herbicide, fungicide, etc.), the sooner they won't work any more. Basically, if you have fed your animals antibiotics, the longer between that feeding and your consumption of the meat, the better.

Home-Devised Poult Diet (or Diet Supplement). It helps to supplement the chick starter at first with scrambled eggs or chopped hard-boiled eggs because the fast-growing poult need a lot of protein at first and, like broiler chicks, can develop leg problems without it. Or you can start them on home-grown food using the same rations as for geese (see "Feeding Goslings" under "The Waterfowl"), only leaving out the water poured over the food. They like crumbled cornbread, too, and can make good use of fresh whole or skim milk served from their first week on. Other good foods for them are eggs scrambled with milk and mixed with any kind of flour or fine grain—ground or rolled oats, barley, or corn, etc. They love bugs, especially maggots. They'll eat boiled meats, including butchering leftovers. A liquid mixed with any fine grain makes a home-grown mash for them.

Birds on a home-devised diet need to be able to get out and forage when weather permits. Later they can handle more coarsely cracked corn and wheat if they have grit. Large-scale growers may plant special crops of soybeans, alfalfa, rape, or kale for them. For just a few birds you can let them find their own food so long as it's not something forbidden. They can benefit from greens like Swiss chard, rape, alfalfa, cabbage, lettuce, and so on for about a quarter of their diet. Gradually add a combination of cracked corn, wheat, oats and greens. (See the chicken section for more on useful home-devised diet options.) Or you can supplement commercial rations with such combinations. The birds must have insoluble grit to be able to make use of whole grains and other fibrous foods.

Of Turkey Housing and Yards

TURKEY SPACE: Until they're 8 weeks old, the poult can get along on a square foot of space per bird. But they'll grow fast and need more square footage per bird before butchering time. A peculiarity of turkeys is the great difference in size between toms and hens. In an all-tom flock, you'd eventually need 5 square feet of floor space per bird. An all-hen flock could manage with 3 square feet per bird. Another consideration is that some turkey breeds are considerably smaller than others. Those smaller breeds could grow in even less

space. Breeders require more space than birds simply being grown for slaughter: 6–8 square feet per bird. In general, the more space you can provide, the better your poultry will do.

TURKEY YARDS: You can raise turkeys in complete confinement, but providing their house with an attached fenced yard would be nicer. The yard should be well-drained ground with no puddles, or pavement, or gravel, or fenced pasture, or rotated pastures. Their shelter house has its uses, too. Confining young turkeys during rainy weather will keep them out of wet grass. Wet poult can easily get chilled, weaken, and die. Or they can be raised in an off-the-ground sunporch for exercise and sunshine. You don't walk into a sunporch pen. You build it so that you can feed and water from outside the cage. That way you don't carry in any blackhead disease on your shoe soles. The sunporch is the ideal way to raise turkeys in areas where they are very likely to catch diseases.

Blackhead Disease. This is very serious for turkeys. Chickens very seldom get blackhead though they may act as a carrier for the cecal worm that hosts the blackhead protozoan. Blackhead is the most common and destructive disease afflicting turkeys, and it can strike them at any age if they happen to pick up cecal worm eggs that contain the organism. Blackhead-afflicted turkeys are droopy and their droppings are brownish-colored and foamy. Their heads may look dark. The liver of a blackhead-affected turkey may have ulcers, and inflammation of the intestine may be present. If you live in a blackhead-afflicted area you'll want to be careful to keep your turkeys completely away from places where chickens go. If your birds have the disease, they can be treated with drugs. It also helps to keep them on a sunporch.

Sunporch. A typical turkey sunporch arrangement is a pen $5 \times 12 \times 2$ feet high, entirely supported 2–3 feet above the ground on legs, with half of it roofed over and 2 sides covered or next to another building. You can keep 1 turkey for every 5 square feet in such a sunporch. The floor can be a problem. The smaller varieties and those that will be butchered by 12–16 weeks can manage the wire floors. Large turkey varieties that are destined to be heavy roasters need a wood slat floor, or some other firm arrangement to avoid developing leg problems. Wire or slat floors do solve the sanitation problem nicely. The droppings fall through, and the birds don't pick up any parasites and are safe from predators. However, turkeys in a sunporch do suffer the usual confinement-associated problems of feather-pulling and cannibalism. To prevent this behavior avoid overcrowding the birds, and keep them busy with food and water, roosts, fibrous foods like oats, and greens or a cabbage hung by a string for them to peck at.

Range Arrangements. Or you can let older birds out completely in the daytime and pen them in only at night. If shade is provided for the yard—even a row of sunflowers or corn—the birds grow faster and feather better. It will help prevent parasitic infections if this

ground has not had poultry running on it for a year—or more. Like geese, turkeys can be very hard on your garden if they are not confined. Turkeys are good foragers and can find a good part of their diet if they are allowed to hunt for greens. In reasonable weather turkeys that are well feathered-out over the hips and back (about 8 weeks old) can sleep out in the open on the ground, and you can plan to have them in the deep freeze before the cold weather sets in. Adult turkeys being kept for breeders don't need as much warmth as chickens and are quite hardy against cold weather. I once had a tom whose nose decoration froze off, but the rest of him survived a bitter winter fine.

A good design for a turkey pen is a long run with posts set into the corners to hold up high wire sides. Ground-running turkeys can be fenced in with 4–6-foot hog wire or heavy-gauge poultry wire with reinforcing barbed wire at the bottom outside of the fence. Or you can use temporary fencing moved once a week or so to keep them on clean, dry ground.

Moving Turkeys to Yard or Range. If you are planning to range your turkeys, be careful with the transition. Turkeys are slow learners, and if they have been previously kept in complete confinement and are suddenly set loose in the open, they will not know the use of shade to protect them from sunlight or of shelter to protect them from rain and storms. They are likely to pile in a corner and smother or not know to eat out of their new feeding arrangement. Poult in a new environment are as vulnerable as when they are a day old and must be watched as carefully and helped as carefully to learn the necessities in their new environment. Make sure they do have shade available. Make the move on the morning of a good day. Move their feeder and waterer as needed to avoid the creation of a muddy spot that could harbor disease and organisms.

Gapeworm. This parasite can dwell in turkeys' bronchi and trachea. An infestation can result in a sort of pneumonia, shortage of breath, or suffocation. Birds acquire gapeworm by eating infected earthworms. The gapeworm is "6"-shaped, red-colored, and you can sometimes see them simply by opening an afflicted turkey's mouth and looking down its windpipe. If your turkeys have 'em, check with your vet. There is a treatment.

POULT AND TURKEY FLOORING: Poult don't do well on a dirt floor. Cover litter the first week to keep them from eating it. And don't put them on newspapers because they'll slip and develop bad legs. Distribute the litter very evenly and then put some sort of rough paper on top of it. Turkeys produce an exceptionally wet, copious manure. Remove wet or dirty litter daily, and add dry, clean litter. You can expect to gain about 100 lb. compost from them before the season is over.

Turkeys That Sleep on the Floor; Piling. Turkeys have a problem with "piling." That happens when something frightens them, like sudden light, unexpected noise, or strange animals. Fireworks and sonic booms can cause piling. They are most likely to pile when frightened at night. Then they tend to all run and pile up in the nearest corner of their building or fence. If you see them piling you need to unpile them as soon as possible to prevent injuries and smothering of the innermost ones. A low-wattage night-light is said to help prevent piling.

Turkeys can get along permanently without roosts. If they don't have them, like broilers, they will just sleep in the floor litter. In that case, keep the litter relatively clean and dry to prevent breast blisters and dirty feathers.

Turkey Roosts. Supplying roosts of either the step-ladder sort or just flat frames with perches helps avoid night piling. Flat roosts can be 1 ½ feet off the floor with 9–12 linear inches of roost space for each bird. Turkeys will begin to use roosts when they are about 4–5 weeks old. Older turkeys that are being raised out of confinement, with a pasture to

roam in and a minimal shelter to sleep in, can benefit from roosts made of 2-inch poles or 2 × 4s laid flat. These are good when spaced about 2 feet apart and built 1 ½–2 ½ feet up off the ground, allowing at least a foot of perch space per bird.

Butchering

By 12–16 weeks of age turkeys can become “broilers” or “fryer roasters”; by 22–26 weeks of age they should weigh enough to be heavy roasters. If you’re not sure if the turkey is heavy enough for butchering, weigh it. Broiler-fryers are considered ready at around 4 lb. If it’s a tom and weighs 18 lb. or more, that’s good enough. (Those numbers are for Broad-Breasted Whites—lighter breeds could be considered ready to roast at lighter weights.) If your turkey is not yet up to the weight you desire, turn it loose and continue feeding it another couple of weeks, then weigh it again. If you keep turkeys longer than 6 ½ months, the hens may start to lay. Both toms and hens tend just to acquire fat after that age rather than to grow. And soon they’ll go into their first molt, which means many more pinfeathers to fight with. Turkeys are quieter than chickens to have around while they are young, but once the toms reach maturity (at 5 or 6 months) they will start to gobble noticeably. If you send your turkeys out to be butchered, Lane Morgan suggests scheduling will be easier if you don’t do it around Thanksgiving. Beat the rush.

KILLING A TURKEY: First, catch the bird and tie its legs. (If you can first herd the turkey into a confined area, especially a small, dark room, it helps.) Then grab its legs and tie them together. The butchering process with a turkey is basically the same as that with a chicken except that your bird is approximately 5 times bigger. It will take you about half an hour to kill and pick 1 bird, and another half hour to finish it up freezer-ready. The turkey may then be beheaded with an ax (a 2-person job, one to hold the turkey and one to chop). Another method is to suspend a cord or wire from a beam, so that the lower end comes even to about your shoulder. Hang the bird from this by its legs—head downward. Give it a sharp blow on the back of its head to stun it, then reach a sharp knife through its mouth and cut crosswise to sever the arteries in the throat. Or use a turkey-sized killing cone. And/or cut the throat just back of the jaws. Allow the bird to bleed out thoroughly.

PICKING: To dry-pick, begin doing it immediately, while the bird’s still warm. Be careful not to tear the flesh. Pull the wing feathers and the main tail feathers by yanking them straight out. Remove the breast feathers next because the skin of the breast is tender and likely to tear if it’s cold. Jerk them straight outward from the bird as it hangs, a few at a time. After plucking the breast, move up over the body and then to the back. Finish on the neck.

Scalding is easier than dry-picking, once you’ve figured out how to manage the logistics. A metal garbage can is an easy answer. Scald the bird at 140–180°F for 30–60 seconds. (See “Scalding” under “Chickens.”) Turkey pinfeathers are probably easiest to remove under running water with pressure and a rubbing motion, or with a dull knife by applying pressure between knife and thumb, the way teenagers squeeze pimples. Then singe and eviscerate, same as chicken. Remove the oil sac on the tail as for waterfowl.

Cooking a Turkey

➲ **TURKEY BROILER** Prepare, quarter, and barbecue the same as a chicken broiler. Turn frequently and baste with a good sauce each time you turn a piece.

➲ **PAN-FRIED TURKEY** Start with a 4–9-lb. turkey that has been cut up according to the directions for chicken frying pieces (see “Cutting Up the Bird” under “Chickens”) or as you

prefer. In a bowl toss together $\frac{3}{4}$ c. flour, 1 t. paprika, $\frac{1}{2}$ t. oregano, and 1 t. salt. When the flour and spices are well mixed, pour them into a bag and shake the turkey pieces in there, 2 or 3 at a time, until each is well-coated. Fry the turkey pieces just like you would chicken, first browning them well, then cooking them covered on top of the stove or in the oven until all meat is tender and cooked through (about 1–1 $\frac{1}{2}$ hours). Remove lid and continue cooking until pieces are crispy again. Remove them. Make gravy in the drippings with the leftover flour/spices mixture, and serve.

⇒ **TURKEY BURGER** If you have a lot of turkey meat, you can vary the menu by making burger out of some of it. Grind it and add flavoring ingredients such as ketchup, onion flakes, lemon juice, Worcestershire sauce, paprika, salt, pepper, etc. Shape patties and cook in your preferred manner until the meat is completely done.

⇒ **TURKEY SAUSAGE** 1 lb. ground turkey, $\frac{1}{4}$ c. seasoned bread crumbs, 2 T. chicken broth, 2 T. minced onion, 1 T. minced fresh parsley, 1 t. vegetable oil, $\frac{1}{4}$ t. ground sage, $\frac{1}{4}$ t. ground thyme, $\frac{1}{8}$ t. ground black pepper, 1 egg white. Combine and blend well all ingredients, except egg white. Beat egg with a fork and add. Shape patties and place on nonstick or oiled cookie sheet. Broil 3–4 inches from heat 4–5 minutes (until light brown). Turn and broil other side 2–3 minutes (or until cooked through).

⇒ **BOILED TURKEY** You'll need 12 c. water, 2 large carrots, 3 stalks celery, 1 quartered onion, $\frac{1}{2}$ c. coarsely chopped parsley, 4 t. salt, 1 t. dried thyme ($\frac{1}{2}$ t. if you use powdered), $\frac{1}{2}$ t. peppercorns, and $\frac{1}{2}$ t. whole cloves for this recipe. You also need a very large kettle with a rack in the bottom, so the turkey won't stick. For a 12–14-lb. turkey use a kettle that will hold at least 12 qt water. A canning kettle will work, although the metal it is made of does not heat particularly evenly. Cutting the bird in half lengthwise through the breast bone will allow you to cook it in 2 smaller kettles by dividing the other ingredients. Put the turkey and the giblets (except the liver) into the kettle and add the water. Add all the vegetables and spices. Cover and bring to a boil. Reduce the heat and simmer about 15 minutes per 1 lb. turkey. Cool the turkey in the broth for 30 minutes then cover and place in the refrigerator overnight.

The next day, take the turkey from the broth, and remove the skin. Remove the meat from the bones, starting with the large pieces of breast meat. Wrap the meat well and either refrigerate or freeze. A whole breast will slice beautifully, and the other meat can go into casseroles, sandwiches, soups, etc. You could return all of the bones and skin to the stockpot and simmer for 4–6 hours to get additional broth. Chilling will allow the fat to rise to the top of the broth; remove it before storing broth in refrigerator or freezer.

⇒ **ROASTED TURKEY** You must first figure out how you're going to get it into the oven, if you let it grow to a humongous size. Then rub the outside with oil or butter, stuff it if you want, and truss. It will cook faster if you don't put the stuffing into the bird, but bake it separately. But a problem with roasting turkey is keeping it from drying out. So it helps—and is delicious! —to have a nice moist dressing inside it, and gravy to pour over when you serve it. For dressing, gilet gravy, and seasoning, proceed as you would for chicken, except everything is on a larger scale.

Set the bird on anything that will hold it, fit into your oven, and won't burn—like a cookie sheet. Set it down on top of a couple slices of buttered bread to keep it from sticking to the pan. Some cooks roast them breast down, but I prefer breast up. Some cooks, especially for a very large bird, bake it for an hour and a half, take the bird out, turn it over, and continue baking with the other side up. But I think that's unnecessary extra struggle.

Roasting Temperatures and Times. The following baking times tend toward the maximum rather than the minimum. It's hard to be precise because you may have started

with the bird more or less chilled from the thawing, and ovens vary in their true temperatures, and stuffings vary in their density and temperature. So your bird is quite likely to be done an hour or so sooner. That's okay. It's easy to keep a roasted turkey warm in the oven before dinner. It's impossible to hurry one up while your hungry would-be diners are waiting for it to finish baking. Note also that fresh turkeys take a little longer to roast than ones that have been frozen—about 5 or 10 minutes longer per pound.

Roast at 425°F for half an hour, then finish at 325°F. Continue roasting until it has turned a nice shade of brown. The larger the turkey, the more baking time. With stuffing, figure on cooking a 6-lb. turkey, 3–3 ½ hours at 325°F; an 8-pounder, 3 ½–4 hours; a 12-pounder, 4 ½–5 ours; a 16-pounder 5 ½–6 hours; a 20-pounder, 6–7 hours; and a 24-pounder, 7 ½ hours.

Eating Up a Whole Turkey. This can be a real challenge for a small family. This is not a one-time happening, so you might well do some advance planning. Figure on roast turkey for its first appearance at the table. Serve it with baked or mashed potatoes, stuffing, and maybe a green vegetable, hot gilet gravy, homemade bread, and dessert. A real feast. Now it's not so simple. For the second appearance you could offer turkey a la king with a "white" sauce that substitutes chicken broth for the milk. Add pieces of turkey, pimento, and peas and serve over toast. Next time have turkey sandwiches with mayonnaise, salt, pepper, lettuce or whatever. Or turkey (taco) salad. Or turkey pizza. (Marinating leftover turkey in olive oil and rosemary prevents drying.) Or turkey and rice. The last time serve Turkey Bone Soup.

➲ **LEFTOVER TURKEY AND RICE** Spread out 4 c. cooked, chunked turkey meat in a large skillet or shallow baking pan. Mix together salt and pepper to taste, ½ c. honey, ½ c. prepared mustard, 1 t. curry powder, and 1 T. turkey drippings from the roasting. Pour the sauce onto the turkey meat and mix it all together. Heat thoroughly on top of the stove, stirring as needed, or bake until hot (about 30 minutes at 350°F), stirring once or twice during that time. Let your family spoon this over cooked rice. A sprinkle of chives over all adds more color and flavor.

➲ **TURKEY BONE SOUP** Break up leftover cooked turkey when you're seeing more bony skeleton than meat on the carcass. Put bones, meat, and your leftover stuffing along with carrot chunks and some onion and maybe celery into a kettle with plenty of water. Add a few peppercorns, salt, and a bay leaf. Cook an hour or until you can get the remaining meat easily off the bones. Then sort out and discard the bones. Now add about ½ c. rice or barley, and cook on low heat until the grain is ready.

➲ **CANNING TURKEY—OR RABBIT, OTHER SMALL GAME, OR OTHER POULTRY** Cut the bird up enough to be able to precook it in a big pan or pressure cooker. Cook until you can easily remove all the bones, then discard them. Place the hot meat pieces into quart jars. Add 1 t. salt per jar, put on lids, and process at 240°F (10-lb. pressure) in a pressure canner for an hour and a half. When the cooker is opened, remove jars and fully tighten lids.

➲ **CANNED TURKEY SOUP STOCK** The water that you precooked the turkey meat in is a good basic soup stock. Cool and skim to remove the fat. Pour stock into pint jars. Add 1 T. barley, rice, or other soup-grains to each jar, plus small pieces of the gizzard and heart and marginal bits of meat scavenged from the bones pile. Do not add liver. Fill to within ½ inch of the top. Put on lids, process for 35 minutes at 240°F (10-lb. pressure). Tighten lids.

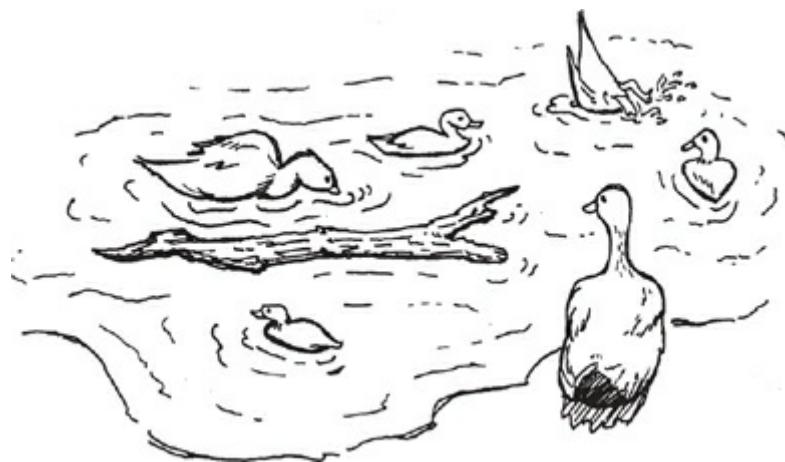

Turkeys never have to ponder the mysteries of life and love. Reality can be harsh and hard, full of pain you can't escape—but it can also be joyful and marvelous, like falling in

love. You can love your plants and animals and feel in control. When you fall in love with another human being, you must trust them to care for you. You're no longer in total control (although I've seen some people manage to come darn near it—loving and being in control of their own life and now their partner's also: a stressful lifestyle). There is a time to love, when it's very hard not to love. Yet you could resist. Would it be better to say no this time and hope for a better match next time? There will be another chance.

THE WATERFOWL: DUCKS AND GEESE

Many of the principles of waterfowl care are the same as those for chickens and are covered in that section. This section covers cases in which duck and goose care are the same for each other but different from that for chickens. Following this combined section, there are individual duck and goose sections.

In general, ducks are small waterfowl, and geese are big. (The Muscovy is a bird that fits into both categories. I've seen it grouped with the geese, but it's more often categorized with the ducks, and that's what I've done, too.) Ducks and geese often form strong attachments to their owners. On the average, ducks are noisier than geese, especially White Pekin females. Muscovy ducks don't quack, but they do hiss like a goose. The waterfowl are actually harder in resistance to poultry diseases than chickens and seldom suffer disease when kept in small flocks. However, when waterfowl are raised in very large numbers in a small area, they, like all animals under those conditions, are more likely to be affected by disease. Egg-specialist duck breeds lay as many eggs as egg-specialist chicken breeds. Duck and goose eggs are 14.5 percent fat, as compared with chicken eggs, which are 10.5 percent fat; in both cases the fat is located in the yolk. Some shade and shelter are preferable, and fencing will keep birds in and predators out.

FURTHER DUCK AND GOOSE INFORMATION: For more info, read Dave Holderread's *Raising Ducks* and the *Book of Geese: Successful Duck and Goose Raising* by Darrel Sheraw (Stromberg Publishing: 800-720-1134; www.strombergschickens.com) ; *Ducks and Geese in Your Backyard* by Rick and Gail Luttmann (1978); *Waterfowl: A Guide to Management and Propagation* by Simon Tarsnane; and *Modern Waterfowl Management and Breeding Guide* by Oscar Grow.

To join the American Pheasant and Waterfowl Society (\$25 annual dues and you get the *APWS Magazine* with classified ads, breeders directory, annual convention, lending library, free "wanted" ads, etc.), check out its website at www.apwsbirds.com for current phone numbers and email addresses. Another good waterfowl website is www.poultryconnection.com/quackers.

WATERFOWL BREEDERS: Also see “Places to Buy or Order Poultry” under “Chickens” in this chapter for other waterfowl addresses, because most chick hatcheries offer some waterfowl.

Clearview Hatchery offers a free catalog: 717-365-3234; Gratz, PA 17030.

Johnson’s Waterfowl offers 21 breeds of ducks and 12 of geese: 218-222-3556; 36882 160th Ave. NE, Middle River, MN 56737; www.johnsonswaterfowl.com.

Metzer Farms sells ducklings, goslings, guineas, pheasants, wild turkeys; 35 breeds in all; also equipment. Free catalog: 800-424-7755; 831-679-2355; metzinfo@metzefarms.com; 26000 Old Stage Rd., Gonzales, CA 93926; metzefarms.com.

Phinney Hatchery offers ducklings, goslings, etc. Free price list: 509-525-2602; 1331 Dell Ave., Walla Walla, WA 99362.

Windchime Lakes: Dan Bishop is a swan specialist. Contact 402-359-4444; 4820 Dodge St., Omaha, NE 68132; swan@swan.net.

Toe-PUNCHING: Because they have webbed feet, and because their feet have no nerves, ducklings and goslings are sometimes marked to record sex, breed, genetic category, etc., with small holes punched in the web between the claws, or with a certain number or location of notches cut into the edge of the web between toes: for example—1 hole for a goose, 2 for a gander.

Of Water and Waterfowl

For best health, these birds need at least to be able to get their heads and feet wet. You don’t need a pond to raise waterfowl, but they do like at least a small tub in which to splash. Frequently changed swimming water for them in something like a shallow hog pan or a child’s swimming pool can be sufficient. Adults can be kept in a pen with just a bucket or tub of water that is refilled a couple times a day. A water container with a float valve works well—sunk into the ground so that the edge is level with the ground, it is perfect. Or you can make a cement pool, maybe 3 feet across and 12–18 inches deep. Put gravel around the edge of the swimming pool to keep the area from being muddy and help keep the water clean.

Once started, ducks require little commercial feed if they have enough foraging space, eating a combination of grain, green stuff, worms, and bugs in season—grasshoppers, caterpillars, crickets, and slugs. Geese can live on grass, but you may not want them in any lawn area since their droppings are very messy (not a treat for children’s bare feet). Both ducks and geese are among the most efficient animals at converting feed to meat, and they tend to get fat if overfed. Ducks are ready for the deep freeze faster than geese: 8 weeks of feeding yields 7 lb. of duckling; 13 weeks of feeding yields an average 12 lb. of young goose (live weight). These are the healthiest of the fowl (with geese being even harder than ducks) and are rarely afflicted with diseases or parasites, and they require little or no shelter, even in winter.

OF WATER AND MATING: In such a pool as described above, the waterfowl that can’t mate effectively on land can accomplish what must be done. The heavy duck and goose breeds—Giant Toulouse, Aylesbury, Rouen—need swimming water in order to mate successfully. Wild ducks and geese mate on the water. Domesticated birds closely related to the wild also need water to mate: Mandarins, Wood Ducks, and Canada geese. Ducks or geese that are sitting on a nest always need access to water; a shallow pan of it can suffice. The birds

must dampen their feathers daily to add required humidity to the eggs' environment.

POND LIFE: If you have a pond, about 25 ducks and 6 geese is the maximum population per acre of water surface that you'd want to carry. You wouldn't want them swimming in a place you use for people swimming because they poop copiously into the water—which is good fish food—and on the banks of it. They like to eat water lilies and small frogs. A reasonable-sized flock of ducks will clean up a pond full of green filamentous algae because their droppings encourage microscopic pond life that hold back the algae. Those droppings can also be food for certain species of fish. Ducks eat water weed roots and will clear the shore of a pond, widen and open up streams. Waterfowl do not effectively control tropical water plants such as water lettuce and water hyacinth. An overpopulation of ducks will muddy water and cause bank erosion as they dig up the edge looking for worms and roots. It's always best to look for balance in an ecosystem.

DUCK PLAGUE: Ducks and geese in commercial flocks in the eastern United States have a problem with acquiring duck virus enteritis (duck plague) from migratory waterfowl that stop over on their ponds. Birds without such attractive open water avoid the disease.

PREDATORS: You may lose ducklings and goslings to underwater predators, snapping turtles, pike, otter, or some other aquatic creatures.

STICKY EYES: Their water should be at least 8 inches deep so the waterfowl can get their heads in there, yet shallow enough (or with a ramp supplied) so they can easily go in and out for swimming. (Exhausted waterfowl have been known to drown, especially ducklings and goslings that are not fully feathered.) Clean the water container thoroughly at least once a week to prevent mud sludge and bacteria build-up. Waterfowl that haven't been able to dip their entire head into water to rinse it off sometimes develop sore or sticky eyes, an infection that may cause permanent blindness. Grossly dirty water can also cause sticky eyes in your waterfowl. Treatment for sticky eyes is astringent eye ointment.

WATERFOWL ON SALTWATER: Ducks thrive in saltwater too. But if your wetlands are salty, be sure you supply adequate amounts of fresh water for drinking.

RAISING YOUNG WATERFOWL: It would be wise to start with only about a half dozen birds, at least until you better understand what you're doing and how the fowl are going to fit in with your environment and lifestyle. Don't overcrowd your waterfowl. Consider that you need about 13 square feet of housing and about 40 square feet of run area for 1 goose or 2 ducks. You can mail-order ducklings and goslings, but these larger birds are not cheap. Ducklings cost about \$3 each. The care of young ducklings and goslings is distinctly different from that of chicks in some important ways, although the basic principles are the same. Or, if you have breeder birds, you could let them raise the babies.

Incubating Waterfowl Eggs. Use all the guidelines for chicken eggs-in-waiting, plus: In the incubator you'll want holders suitable for eggs larger than chicken eggs. Serious waterfowl hatcheries use incubators that are specially adapted for hatching these eggs. Set the temperature control for 99–100°F for a forced-air style incubator, 101–102°F for a still-air incubator.

Incubator Moisture. Waterfowl keep their eggs very moist. In a dry climate, even in an incubator, high humidity is not good enough. There are several ways to supply this extra humidity: Give a light spraying of lukewarm water to the eggs once a day. Or, do as a friend of mine does and remove duck and goose eggs from the incubator twice per day and dunk them in warm water. The way the parent bird keeps them wet enough is to get

off the nest, get her breast feathers all wet, and then return to the nest. Finally, you might enhance the water pan's evaporation ability by resting a piece of sponge in it that rises a couple inches out of the water, and each time you turn the eggs, spray them gently with warm water.

The Hatching. On the 25th day quit turning the eggs, but keep on dunking or spraying the water until the ducklings pip their eggs. The pipping should take 28 days after incubation began for most ducks, but Muscovy eggs require 35 days. Give 1 last spraying and/or dunking when the pipping occurs. Then you hope for the best. Day-old ducklings can be vent-sexed in a manner similar to chicks.

BROODER SHELTER: Although they are hardier than chicks or poult, ducklings and goslings must also be kept from chilling for the first month. Their shelter can be simple, but it should be dry and not drafty. The flooring of your brooding space can be wood, concrete, or dirt. An 8 × 10-foot southeast corner of a barn would make a fine spot in which to start ducklings. If you are using a brooder setup that was designed for chicks, you can expect that it can handle half as many ducklings as it could chicks, or a third as many goslings. Plan for about 1–1 ½ square feet of floor space for each duckling or gosling, increasing the space to 2 ½ square feet for each bird at 7 weeks. Waterfowl grow faster and develop warm feathers earlier than baby chicks. Some people use unheated boxes insulated with 2–4 inches of rags, straw, sawdust, or grass, covered with burlap, with a small entry hole in the side. The young ducklings' body heat can keep them warm in this close environment. Although this is less expensive than a heated brooder, you have to be careful that the babies don't suffocate.

Brooder Heat. If you are using infrared brooders, every 25 goslings or 30 ducklings should have their own 250-watt heat lamp. You'll want to raise the heat source a few inches higher than what you use for chicks for these larger babies. Having enough separate heat sources for the number of young birds eliminates overcrowding around the heat source, which could result in smothering. Leaving the light on all night can also discourage crowding. Try for a starting temperature of around 90°F at the edge of the heat circle. Each subsequent week, reduce the heat 5 degrees until you get to 70°F. Brooder temperatures that are chronically too high cause the birds to grow and feather out more slowly than normal. Panting birds are a good indication also that the heat is too high. Huddling birds are not warm enough. After 4 to 6 weeks you can turn the heat off, unless your outside temperatures are outrageously low. By 4 weeks of age ducklings have begun to grow a covering of heavier feathers for their backs and can go outside in the daytime in good weather. As early as 10 days, goslings are ready to abandon the brooder.

Duck-Raised Ducklings: For those ducks that make good mothers, the ideal circumstance is to let the mother duck manage her own ducklings. Duck-raised ducklings learn faster to forage for themselves and how to swim. There are, however, some cautions. Ducks with broods should be separated from the rest of the adult flock and confined at night until the ducklings are 6–8 weeks old. Even 2 hens with broods should be kept separate, as they often react with hostility toward any but their own ducklings. If you are planning on hatching more eggs than you have brooding mothers, you can incubate.

Waterfowl Mothering Chicks. If you give a duck chicken eggs to sit on, she'll do a good job, but once the chicks hatch out, it can be a very risky business. Most owners take duck-hatched chicks away and brood them separately, because the duck mother may lead her chicks to the deep water, and the chicks are likely to get wet or drown as she goes about her necessarily sloppy way of drinking. You can have chickens or turkeys set on duck eggs, but if you do, be sure to confine the foster mothers for the first 2 weeks so they won't

desert their charges. If you set duck eggs under a chicken hen, keep the number down to 8–9. Unless a chicken has set and hatched ducklings, don't trust ducklings to her care.

Of Ducklings and Goslings, Food and Water

Strangely enough, you have to be just as careful to keep these babies dry as you do baby chicks, at least for the first 2 weeks. Chilling after becoming wet is the most frequent cause of duckling deaths. Waterfowl raised by their parents learn to swim early, but hatchery goslings and ducklings can't swim until they feather out at about 6 weeks. Even after they can swim, young birds can tire easily and drown, so be sure they can easily get out of water containers and ponds by providing a ramp or gently sloped banks.

DRINKING WATER: Always keep drinking water available, and in generous quantities. When mail-order babies first arrive, dip their bills, one by one, in lukewarm water several times. Then dip each bill in the feed trough.

NOTE: Make sure they drink before they eat, or they can choke on the dry stuff. Be sure the water you supply at all times is deep enough for them to get their entire head into. They need more water than chickens in order to clean the dry feed out of their breathing holes, located in the upper bill near the head.

Drinking Containers. A suitable water container for young waterfowl could be a narrow trough about 2 inches deep by 1 inch wide. They would be able to submerge their heads in that. (Young Call ducks have a tendency to chill, soak, or even drown themselves in their water containers and need special supervision.) Ducks can be extremely messy with their feed and water. Use a watering device that they can't get into and splash from because you want to keep your brooder house floor dry. A piece of clean burlap bag spread over the floor surface would be a good beginning flooring. Or, if they're on a cold floor, cover it with a litter layer—about 4 inches of shavings, ground corn cobs, peanut hulls, peat moss, or almost any other sort of organic dry litter. If places on their flooring do get wet, shovel them away and add dry material. Or move the water pan frequently and stir the litter as needed to keep the top reasonably dry.

NOTE: Do not put newspapers down for water-slopping babies. Newspapers become a slippery

surface, which can cause the birds to become spraddle-legged and crippled.

STARTER FOOD: For goslings and ducklings, food should be ready when they arrive. Keep food in front of them all the time. But fill their feeder only half full to prevent waste. They'll also need very small gravel for their gizzards. Because of the shape of their mouths, you can't use chick feeders for these birds. To start with, offer food in small box tops scattered near the heat lamp until they learn to eat. Later you can supply food on rough paper, like the bottom of open grocery store bags. Don't feed them on smooth paper; they can slide around on it and get hurt. Older birds can be fed from pans or troughs or from self-feeders that hold pellets and have small openings.

HOME-GROWN STARTER FOOD: Commercial chick feed is not good for young waterfowl. The protein content is too high, and some of the medication in such feeds can harm them. I worked up the following system to start goslings on home-grown food, and they liked it. I suppose this sounds bizarre to people who are used to feed that comes from the store in sacks. All I can say in my defense is this: they thrived. I fed them 3 times a day, all they would eat of the following: For breakfast, cooked oatmeal covered with a little water. Lunch: scrambled eggs covered with a little water. Supper: homemade whole wheat bread covered with a little water or milk.

I supplied greens at all 3 meals—not grass or tough stems at the beginning—but very tender green leaves. They enjoy finely chopped onion greens and dandelion greens and practically any others that are fresh. Ducks thrive on watermint and cresses. I cut the greens up for them with a knife or scissors. If you are supplying water in a trough, sprinkle the green bits in the water. After the first week, I offered more and more greens. Young waterfowl won't pick each other to death, but, if short of green foods, they may pull and eat each other's feathers, which isn't very good for either the eater or the eaten.

I gradually shifted from cooked food to grain. Their bills were stronger and they could manage weeds better. In good weather they went outside to pasture with my daughter as goose girl. Grass is a very important part of a gosling's diet. Protein is the eggs-and-milk part of their diet. Feed about 20 percent protein. At 2 weeks on a home-devised diet, supply or allow them to get some grit. They're well fed if they have 2 or 3 feedings a day of all they can consume in 5–10 minutes.

COMMERCIAL STARTERS: If you can't get a duck-starter ration or goose-starter (either one would be fine for either species), you can use *unmedicated* chick, turkey poult, or gamebird starter for the first week or two (then switch to grower feed) if the feed is also recommended for ducklings and goslings. That's because some types of chick starter and growing feeds contain drugs for coccidiosis control that can cause lameness or even death if fed to the water birds. Yet some folks have fed medicated starter and layer feeds to waterfowl and gotten away with it; maybe they were feeding starter medicated at a low level. Crumbles are the best consistency. Fine mash feeds are more likely to cause the birds to choke.

After 2 weeks for ducklings, or 4 weeks for goslings, gradually shift to a pelleted grower ration. Ducklings and goslings being raised for the commercial market are usually given turkey finishing rations or some similar food their last couple weeks. By using genetically fast growers like the White Pekin, placing high-protein commercial rations constantly before them, and ensuring the inactivity of confinement, you can have freezer-ready ducks at 7 lb. in 7 weeks. Goslings for the commercial meat market are usually finished in the fall months when they're 24–30 weeks old.

HOME-GROWN FOOD FOR ADULT WATERFOWL: They can make it on mixed grains and greens. Aim for variety and some ranging if possible. You can get ducks and geese accustomed to eating whole corn off ears that you've broken in two—that helps them get started. Feeding them ear corn is easier for you—if you have it—and prevents more aggressive birds from hogging the food supply. If you're going to feed them oats, feed it before the corn, or instead of it. Wheat is probably the best single grain for waterfowl. Oats and wheat are a good combination. They can eat nonmedicated rabbit pellets. Feed round, firm fruits and vegetables (apples, beets, turnips, potatoes) by crushing them first, as under a board, because the broad-billed waterfowl can't peck like chickens and need some help getting started with them. Waterfowl on a home-devised diet may produce about half as many eggs as those on a commercial laying mash—so the laying-mash people say. But those birds can give you residue-free meat and eggs!

Housing for Post-Brooder Geese and Ducks

If you have just a few adult waterfowl, you may be able to keep them with your chickens. Unlike chickens, ducks and geese don't roost but like to sleep on the ground or floor. On the other hand, chickens may peck at ducklings and goslings, so provide them with some small pen within the coop that the chickens can't get into.

There are 3 distinct schools of thought on the subject of shelter for waterfowl. One is no shelter at all, or only a windbreak of bales of straw. A second concept is shed-sheltering, allowing them a place with 3 sides and a roof, but an open front. The third concept is a complete building—which may be a small, possibly portable, mini-dwelling—with or without attached pen or yard, in which they can be confined just at night or all the time.

No SHELTER: Waterfowl always need access to shade, but once they are 6 weeks old they can do without other shelter (unless there is a long spell of chilling rain or stormy weather). By 8 weeks of age they can pretty well take care of themselves. Adult waterfowl seldom require shelter. This is because their outer coat of closely packed feathers has been waterproofed. Ducks in the wild build their nests near water on the ground. A flock of ducks can do well and lay without formal houses or nest boxes.

Nevertheless, some fancy breeds are less hardy or less disposable than others, and some climates have worse winters than others. Ducks, who do not roost but sleep on the ground, have been known to become frozen to the ground by their own moist droppings. (Ducks that have access to open water may spend the night there.) Unconfined ducks (especially the breeds with poor mothering instincts) are likely to lay eggs all over the place—on the ground, even in the water. If you have foraging, unsheltered waterfowl, be vigilant against predators, keep them in the territory where you want them, and consider shelter at least from severe storms. If baby ducks are being raised by you or their mothers near any body of water that is halfway natural, you may take some hard losses. Bullfrogs and other critters like to eat baby ducks. You might do better bringing the young ones into the house to raise until they've attained a good size.

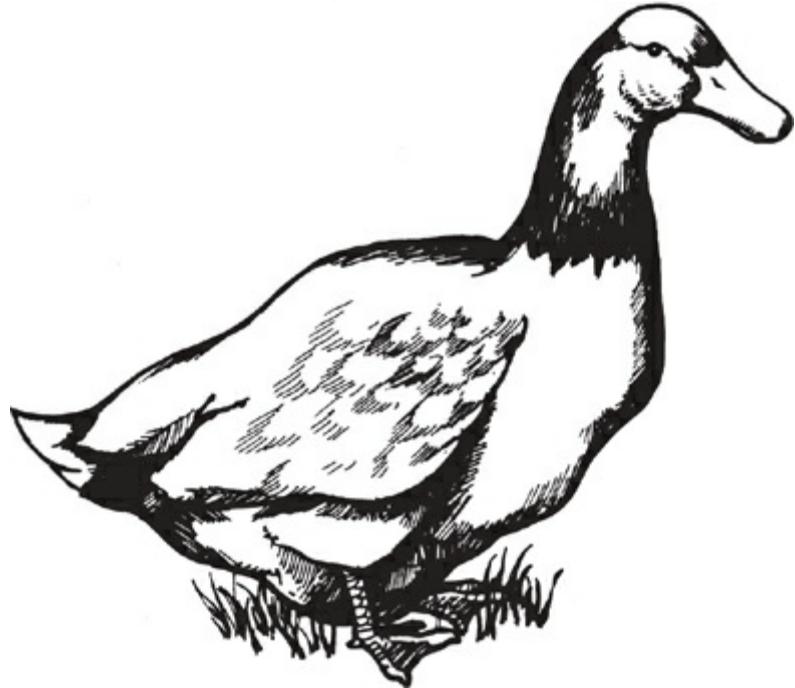

A 3-SIDED SHELTER: Some waterfowl raisers prefer this system that protects the flock from wind and rain but otherwise allows them freedom. Waterfowl dislike wind, and such a shelter (built broadside against the prevailing wind direction) can at least protect them from wind and precipitation. Waterfowl like fresh air and dislike poorly ventilated quarters. They are nervous and like to be able to see what is going on about them at night. And if crowded into a small house they may startle and pile in a corner. There's no need to make the 3-sided (with a roof) shelter any taller than the birds it is designed to

protect (which saves on lumber). Waterfowl confined indoors a lot may not be as healthy as those allowed to live outdoors. Like Chinese geese, African geese are susceptible to frozen or frostbitten knobs (on their beaks) in winter and would be better off with at least this minimal shed-type shelter. If it will be below 20°F, these knobbed fowl need even more shelter to protect their knobs. If, however, the knobs do freeze, it merely results in a discoloration of the bill and knob, which will return to normal by the following fall.

TOTAL SHELTER: Waterfowl can be housed just at night or all the time. Ducks adapt well to housing at night only because their egg-laying habits are so precise (almost all lay their eggs before 8am, 9am for sure), and because their habits are so regular (they can be trained to return home to be fed and be confined at a precise time). Duck and goose owners in areas where night predators such as rats, raccoons, skunks, weasels, and ferrets are active prefer to confine their birds at night—or even all the time—in a building similar to a chicken house. Call, Mandarins, and Wood Ducks are not as hardy as the others and do need winter shelter, though they can go outside and get in the water at 40°F and warmer. African, Chinese, and Egyptian geese benefit from winter shelter (in temperatures below 20°F). Ducks will start laying earlier in the year if housed; it does not make any difference to geese. If you do confine ducks at night, be aware that they are nervous creatures and can damage themselves by panicking and running in circles. If you leave on a low-wattage night light, you will minimize this danger.

Waterfowl housing can be small and portable and frequently moved to keep the ground underneath tolerable. Such housing may be set into sizable, well-drained, well-shaded fenced runs that (ideally) have access to clean, running water. Small ducks such as Calls, Indias, and Mallards can be raised sunporch-style. A graveled duck yard that can be cleaned when hosed daily at high-pressure and is sloped somehow to drain, can help keep clean the quarters of a large spring flock being raised for butchering. Without gravel or concrete, you risk a sea of mud.

TOTALLY CONFINED WATERFOWL: Allow 4 square feet of floor space per duck for ducks that are let out during the day. If ducks are kept confined at all times they'll need 6–8 feet of floor space per bird. If you limit the total number of fowl and have a loose, deep (1-foot) litter layer, you can keep them confined and it can be manageable. Large (15 inches square), shallow nesting boxes located on the floor in the corners of their housing will attract the egg-layers. Confined ducks need excellent ventilation in hot weather and plenty of water, always. Shutting them up together with chickens can be a problem if there are too many birds for the space, because ducks have such exceptionally copious and liquid droppings. If the waterfowl housing is to be permanent, the ground underneath should slope to one side for drainage and the floor should be made of pea gravel, which can be hosed and drained, or concrete with a center floor drain. Waterfowl kept completely on hard, dry ground, however, can sometimes develop bumblefoot, which is a warty local infection of the foot that causes limping. Isolate such a bird in a place with a soft straw flooring. Treat the foot with antibacterial ointment. After the skin has softened some, lance and drain if appropriate. The birds don't get bumblefoot on grass pasture.

OF FLYING AND WATERFOWL: The flyers are Muscovies, Indies, Calls, Mallards, Canadas, and Egyptians. To keep these at home you'll have to clip the long feathers on 1 wing side with heavy scissors when the feathers first develop and after each molt, if you keep the birds that long. Or you can "pinion" them—which means to amputate the tip of the wing (the part below and outward from the "claw" extension just beyond the last wing joint) on 1 side. The pinioning operation is done when the duckling or gosling is a week old. The cutting is done with a sharp knife, razor blade, or debeaking machine. And use 4-foot-high fencing.

About Feathers

The feathers and down from geese and ducks can be used to make pillows, comforters, insulated jackets, and other outdoor clothing, and you don't always have to kill the birds to get their feathers. In the spring, geese grow lots of lovely little feathers and then pull them out themselves and use them to create wonderful downy nests. These goose feathers are very soft and warm. Duck feathers have the problem of an odor which is difficult to remove completely. Nevertheless, either duck or goose feathers are softer, fluffier, and more moisture-proof (so they don't absorb sweat) than chicken feathers. A general rule is that the feathers from 3 geese or 5 ducks will amount to 1 lb. of feathers. You can sell goose feathers if you have enough to make it worthwhile. Mature ducks have more down than young ones and also more down in the fall when cold weather has set in. So what human beings might try to do is share in the feather crop that's going to come off anyway.

LIVE PLUCKING: In Colonial days, goose feathers were obtained 2 (spring time and harvest time), 3, or 4 times a year, by stripping them from the live birds—except for the quills, which were used for pens and were never pulled but once from a goose. The first time is when the geese are between 9 and 11 weeks old—when they start molting. After that they are plucked about every 8 or 9 weeks. The best feathers of all, however, are said to come from geese that are fully grown, from October on for spring-hatched geese. In Europe and in some areas of Canada such live plucking is still done. But times aren't so grim now, and I don't know anybody who plucks their geese until after they've been butchered and scalded.

Live-plucking causes momentary discomfort and stress to the bird and does reduce egg

productivity. But if you must try this, wear old clothes and tie a cover over your hair, because the down flies everywhere. Have paper or cheesecloth bags and string ready before you start. Pull a stocking over the bird's head to keep it from biting. Pluck the down and short body feathers in a season the birds would normally be shedding them, at which time the feathers release a little easier than at other times. Pull the feathers the "wrong way"—against the grain, firmly and quickly. In small pinches, pull the feathers from the underside of the bird, removing not more than half the feathers from any area. Don't leave bare patches and keep the plucked birds from swimming for a couple weeks so they can regrow sufficient feathers to stay waterproof. They say the birds get used to it, but it seems to me that the small gain in feather quality is not worth either the stress to your birds or the extra work for you.

A good further source is "Producing Your Own Down" by Ken Bernsohn, in *Organic Gardening and Farming*, Vol. 25, No. 3 (March 1978), p. 114.

DRY-PICKING A DEAD BIRD: If you're planning to save the feathers, have bags ready before killing the birds. Pull in the direction they grow. Working over a large garbage bag or in a confined area will keep the down and small feathers from floating away. Be careful to free the feathers of any skin or flesh that adheres, or they will be tainted. Pull the large flight feathers first, then the outer layer of feathers second, and finally pull the soft under-layer of down. If you want to get some stuffing from the feathers over 2 inches long (especially the large wing and tail feathers), cut with a scissors, or strip off and discard the quill. But most people don't bother with that. After the feathers are taken off the bird, remove the down by brushing the body with your hand moistened in water. The bags full of feathers can be closed at the top with string or staples or folded tightly. The next step is to clean and dry the feathers. (See "Cleaning and Using Feathers" under "Chickens.")

CHICKEN-STYLE SCALDING AND PICKING: This, of course, you do to a dead bird. In a large container, heat water—enough to cover your bird completely—to 140°F or higher. Add a little detergent (or shampoo) to the water and stir it in—this is so the hot water can get past the bird's preening oil. Holding the bird by its feet, submerge it completely and swish it forcefully around for about 1 ½ minutes (much longer than for a chicken)—until the hot water has penetrated the bird's skin and done its job of relaxing the feather follicles. Older birds may need more time. Then, right away pull out the feathers, big ones first. If you have trouble getting them out, your water wasn't hot enough and/or the bird wasn't in there long enough. (Try it again.)

WAXING METHODS: The disadvantages of these methods are that you need to buy and melt the wax, it ruins the feathers, and it takes a lot of wax to do the job—especially on a goose. Nonetheless, some growers think it's easier this way. Use paraffin, a combination of half paraffin and half beeswax, or a commercial mixture that you get from a poultry supplier. The wax takes out the feathers easiest immediately after butchering. The wax should be heated to between 160 and 200°F in a double boiler. Higher-temperature wax penetrates better but doesn't adhere in as thick a coat. A wax coat that's overly thick may not cool and harden as well.

NOTE: Do not heat the wax by itself. Do not let the double boiler run out of water.

Hold long-necked birds by the head in one hand and the feet in the other to dip them. The dryer the birds when dipped into the wax, the better the wax will cling to the feathers you're trying to remove. You can keep dipping and stripping until you're satisfied. Commercial growers scald and pick first, then dip and strip to get whatever's left over. The wax can be recovered by heating (in water) to melt it and then straining or screening

out the feathers, etc. It can be reused for this purpose again and again.

HOT WATER/HOT WAX/COLD WATER: For this technique you need 3 pots, 2 hot and 1 cold. You dip the dead bird first in hot water and do a full chicken-style scale, then dip the bird in hot, melted wax. Then dip the bird into cold water to solidify the wax. Then you can strip wax, feathers, and pinfeathers all together from the bird.

COMBINED HOT WATER/HOT WAX-HEAT: Save your scalding water. Add paraffin to the hot water, which will melt and form a thick floating layer on the top of it. Put the bird into the hot water and swish to scald the feathers loose. Then pull it out very slowly so that a layer of the wax will cling to all the feathers. Allow the paraffin to solidify and then pull wax and feathers away.

Once the feathers are off, singe off the filoplumes (the remaining long, hair-like feathers) over an open flame of alcohol, and cut off head and feet at the first joint. Some people like to skin the carcass to remove all signs of feathers, but this can cause the meat to be dry and less flavorful when it's cooked.

Cleaning Ducks and Geese

Remove the oil sac on the tip of "the north end going south," including all the yellow oil-producing area around it. That's where birds get oil to preen themselves, and that of water birds is strong tasting enough that it would be a problem to leave it on. Clean as you would a chicken. The esophagus and windpipe of ducks may require some force to remove.

Of Ducks in Particular

DUCK FEATURES: When the duck preens, it spreads the oil from an oil gland at the base of its tail, over its feathers. A layer of insulating down under larger contour feathers that are lubricated with this oil enables the duck to swim in near-freezing water. Even the webbed feet are made to withstand cold because there are neither nerves nor blood in them. Most domestic breeds are earthbound, but Muscovies, Calls, East Indies, and Mallards can still fly to some degree. Ducks can live up to 30 years; however, few make it to that age because their ability to produce eggs drops off after 3 or 4 years. If you are buying adults for breeding stock, choose birds 6–7 months old with evenly colored bills and legs, and make sure they are healthy. The male duck is called a "drake." The female is called the "duck" (which, of course, also means the species in general) or "hen."

DUCK TEMPERAMENT: Of all the varieties of poultry, ducks—male and female alike—are the gentlest and least likely to act aggressive. Drakes seldom fight unless females are present. (This might be an incentive for you to choose them if you have small children.) Ducks are notoriously nervous and noisy at night and will make a commotion over the slightest deviation in their environment's characteristics, benign or dangerous. Because ducks are so nervous, announce yourself when you are coming to them, move slowly, and talk to the birds to calm them. If a duck does display aggressive activity, it is best to remain calm and ignore the behavior.

Ducks tend to be either good egg layers or good meat producers. Meat producers are calmer, easier to confine, and grow faster and bigger. The feed conversion ratio for ducks is about 3:1, which makes them a good economical choice whether you pick a breed for meat or eggs. You may also want to consider the noise level, coloration as a defense against predators, and expense and difficulty of obtaining the birds. And then there are

the eggs-meat combination breeds to consider.

DUCKS IN PRINT: *Raising the Home Duck Flock* by D. Holderread (1978) is a helpful book. *The New Duck Handbook: Ornamental and Domestic Ducks* by Raethel Heinz-Sigurd, translated from the German (1989), has everything about housing, care, feeding, disease, and healing, with a special chapter on commercial uses of ducks.

DUCKS FOR EGGS: Don't buy ducks for eggs until you try eating duck eggs. Duck eggs have a ducky flavor, all the more so if the birds do a lot of scavenging in the bottom of a muddy pond. Also keep in mind the pollution problems of various bodies of water. So if you're going to let your ducks feed in water, be sure it's not polluted water. You can hide duck eggs in an omelet with chicken eggs and use them in baking. If you have trouble eating duck eggs straight because of the unfamiliar "strongness," make bread and custards out of them. Or, like the people in countries where duck eggs are a staple, you could get used to the taste and learn how to cook with them.

Becky Coleman of Charlo, MT, wrote me: "I kept Khaki Campbells for eggs once and found that, except for a certain toughness, they couldn't be told from chicken eggs. They had the run of the yard and a pond, but were mainly fed a chicken layer crumble. I wonder if the strong flavors people talk about come from what the ducks have been eating, rather than being intrinsic to duck eggs." Thank you, Becky! I haven't personally kept ducks for eggs, and there are real perils for me in passing on lore I've read and never experienced, so I appreciate it when somebody straightens me out. (The trouble with trying to cover everything in a book is that it's not possible for me to try it all myself.)

Duck eggs do not fry nicely by chicken-egg techniques—best to use a different process. (See "Frying a Duck Egg.") Incidentally, duck hens often lay more copiously if they haven't mated with drakes, and nonfertile eggs keep better than fertile ones. So if you need eggs in quantity, consider segregating your layers from your breeders.

Of Duck Laying and Setting. Light-breed ducks (egg breeds) will begin to lay at about 6 months of age. Heavy-breed ducks are mature and will begin to lay eggs at about 7 months. An egg-laying duck's commercially useful laying period is considered to be 3 seasons. Actually though, they will lay longer than that. Most ducks lay their eggs at night, so it's a good practice to confine them then. Ducks begin to lay in the spring, in the morning. It's customary to let them out after 10am, by which time they will be done laying. You can maximize egg production by providing at least 14 hours of light (use a 40–60 watt bulb) daily. Some people leave the lights on all night, as it also keeps the ducks calmer. If you want a duck to go broody, leave her eggs and let them fill up a nest. Freeranging ducks will build nests of twigs, leaves, grass, and their own down, on the ground. Muscovies, Indies, Calls, and Cayugas are likely to be good brooders. Cayugas are good at incubating goose eggs. Among the Blue Swedish, Aylesbury, and Rouen breeds, some individuals may be good brooders.

EGG BREEDS

Indian Runner. There are many varieties of Indian Runner ducks of which the White Penciled, Fawn, and White are said to be the best egg producers (225–325 eggs per year). The Indian Runner originated in Asia (as did the rarer Bali to which it is related). Runners are a nervous, light breed (drakes are 4 lb. at butchering age, ducks are 3 ½ lb.) that stand quite erect, nearly perpendicular to the ground. They can move quickly, which helps protect them against predators. Their feed-consumption-to-egg-production ratio is very good, and they lay equally as well as the other best duck layers—the Khaki-Campbell. And their eggs are larger. They are exceptionally good foragers but make poor mothers.

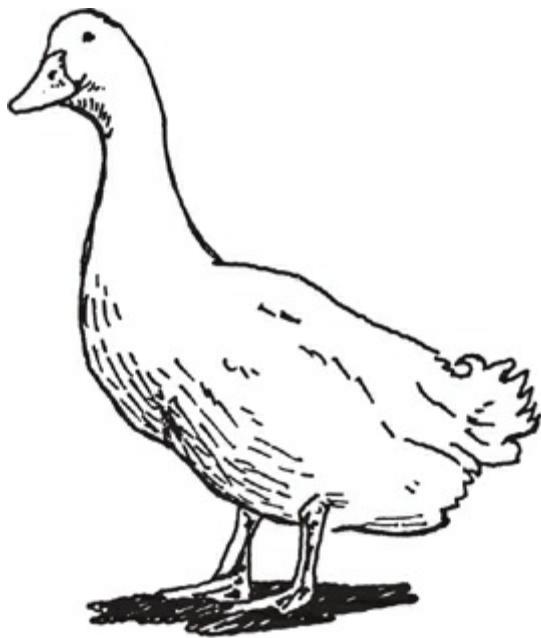

Khaki-Campbell. This duck is a quiet, healthy, good foraging, hardy breed that will continue laying in cold weather—as many as 300–325 eggs a year. The Khaki-Campbell duck is khaki with bronze highlights, has a green bill, and weighs only about 4 ½ lb. They don’t go broody, and they are the least interested duck when it comes to swimming. Their eggs are creamy white and large, considering that this is one of the smaller breeds of duck—smaller than Pekins or Rouen. Khaki-Campbells were developed by an Englishwoman (Mrs. Campbell) out of Mallards, Indian Runners, and Rouen ducks. Crossbreeding has diluted many strains. To get a good egg-laying bird, be sure you get a Khaki-Campbell selected for high egg production. Authentic Khaki-Campbells are said to lay well 3–4 years and do well in winter, as long as they’re sheltered from extreme cold. Butcher young Khaki-Campbells at 4 lb. to get a meat that is lower in fat than most ducks.

Welsh Harlequin. These ducks are said to have laid as many as 300 eggs annually. Duck egg production of these egg-specialist breeds is right up there with the best chicken layers. It’s interesting to note that, like the egg-specialist chicken breeds, the egg-specialist ducks are also lighter in weight, more high-strung in temperament, slower growing, and non-brooding.

MEAT BREEDS

Aylesbury. These ducks are a British strain considered by the English to be the prime meat breed of duck. They are noted for being less nervous than Pekins and exceptionally friendly toward humans. They are also less hardy. They have white feathers and skin and light orange legs and feet. Aylesburys eat grass quite well and will be ready for slaughter at 7 lb. at around 8 weeks. The males will grow to 9 lb., the females to 8. For breeding, use a single drake to 2 ducks and provide water for a mating surface. Aylesbury ducks are not the best egg-layers. You may get anywhere from 35 to 125 eggs a year. In pre-incubator England, broody hens were used to raise the Aylesbury young.

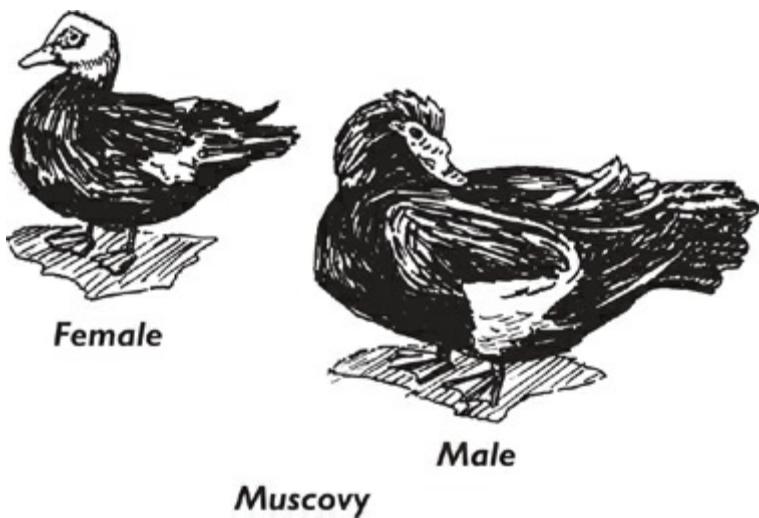

Chinese White Pekin. This is the most popular meat duck. The White Pekin is a blocky, extra-heavy duck, disease-and stress-resistant. The Pekin is probably the best bird to raise if your main interests are efficient meat production for home or market and white pin feathers. They are an extra large duck and grow very fast with an efficient growth-per-pound-of-food ratio (2 ½ lb. of feed required per pound of gain). The White Pekin can be ready to eat at only 7 weeks of age, weighing 6 ½–7 lb. The bird is then perfect for roasting (although fairly high in fat content) and is technically called a “duckling.” Adult Pekin drakes weigh 10 lb., hens, 9. The Pekins come in numerous different genetic strains, as developed by different competing breeders. In general, Pekin drakes are very fertile; the Pekins’ large, white eggs are quite hatchable; and 1 Pekin drake can handle 3–5 ducks.

White Pekin

Although they are high-strung and poor setters, freeranging pairs have been known to raise up to 20 ducklings a year. Don't mate a younger drake to older ducks. Pekins are a poor choice for a foraging duck, and the females are noisy. The Pekin is considered a good layer—between 125 to 175 eggs per year, if they are well-managed, and so could be used as a meat-eggs breed. When Pekin ducklings are being raised on a commercial scale for meat (and not being kept for breeders), they are referred to as "green ducklings." Green ducklings are kept confined to limit their exercise and kept under continuous light because that stimulates growth. Feed-conversion efficiency drops off after 7 weeks, and green ducklings are butchered shortly after, when their wing feathers develop. That's pure agribusiness for you.

Muscovy. This is a large white or colored (depending on the variety) lean duck with well-muscled breasts. They often have a darkening, like a mask, around the eyes. The Muscovy duck is the only domestic breed not of Mallard derivation. They originated in South America, come in White or Colored, are slower growing than Pekins or Rouens, but are a first-class forager. Muscovies are also different from other ducks in the nature of their feathers, which are not as downy, are harder, and don't oil as well as those of other ducks. They can actually drown, if unable to get out of the water for too long—especially heavy, long-winged males. The good news about Muscovy feathers is that they're easier to pick than those of other ducks. An adult male can weigh 16 lb., but is more likely to be around 12. The much smaller females weigh 7 lb. Their meat is best if they are slaughtered before 17 weeks. The big ones can get quite fat if confined and overfed.

The Muscovy is said to be resistant to diseases that the Pekin and the Runner (when kept in large numbers) are subject to. It is noiseless, which your neighbors might appreciate, but hens fly quite well when fully grown. Unlike the other ducks, the Muscovy roosts at night like a chicken, preferring a fence or tree so they're safer from predators. But the flying can be a problem; for example, they might get into your orchard—or your neighbor's. But if you put Muscovies in your deep freeze shortly before full adulthood, the flying problem won't come up. Or you can clip 1 wing.

Muscovies have sharper claws on their feet than other ducks, and the big drakes can become temperamental, so be cautious when handling them. The Muscovy hen may lay as many as 100 eggs a year. It is probably the best for reproducing itself, as the hens are excellent layers and brooders, with excellent fertility and hatchability. The hen will lay 20–25 eggs and then brood them. She may produce and care admirably for 2 broods each season. She'll even face and drive off dogs and foxes. The ducklings are hardy, but they take a month more than other ducks to grow full feathers. Most duck eggs hatch at 28 days, but Muscovy eggs require 35 days.

Rouen. This duck breed is large, like the White Pekins, which makes it a good roaster, and colored as prettily as the wild mallard from which it was adapted several centuries ago. Fly-tyers say that Rouen feathers make good trout flies and streamers. The Rouen doesn't fly, and it has a quiet, friendly nature, which is nice if you have small children. They lay 35–150 eggs a year, some blue-green as Easter eggs, some creamy white. Rouens are slower growing than Pekins. They can be butchered anywhere between 2 ½ and 6 months. Rouens tend to stay very near home. Genetic Rouen lines vary in egg-laying powers—some are excellent, some poor. A reasonably light drake can take care of 4 or 5 ducks. Look for the trait of continuing to produce fertile hatching eggs past 3 laying years. Rouens do well on farm ponds and near wooded areas where a rugged duck with good survival instincts is required. A 3-foot-high fence will keep Rouens (and most other non-flying ducks) in.

DUAL-PURPOSE DUCK VARIETIES

Blue and Black Swedish. This duck is rare in the United States (but more popular in Europe). It's a good insect-eater, lays 100–150 bluish to grayish white eggs a year, and has been said to be less prone to predator attacks because of its protective coloration. Crested drakes weigh around 7 lb., the ducks, 6 lb. They make good mothers and forage well.

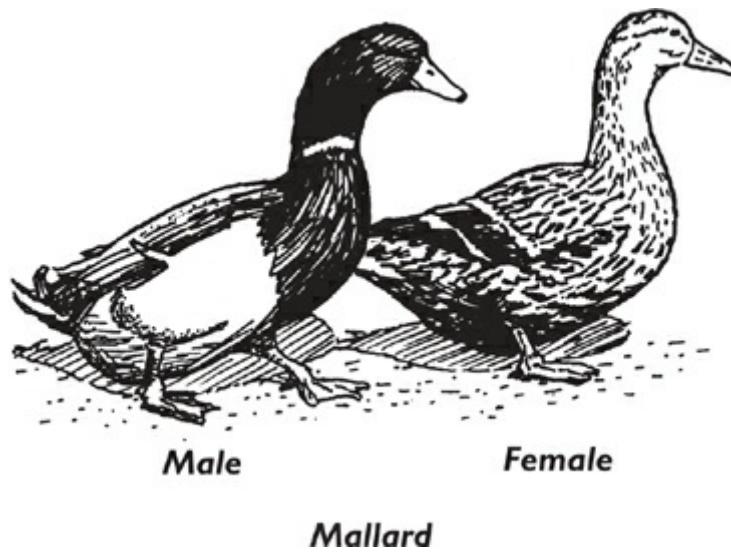

Buff Orpington. These ducks are another rare dual-purpose (eggs and meat) breed. Drakes weigh 8 lb., hens 7. They may lay up to 250 eggs a year.

Cayuga. In the same weight class as the Swedish, Cayugas are a rare, rugged black American duck that can stand extreme cold very well, are good foragers, and lay 100–175 eggs a year. They are very quiet, but to avoid an unattractive carcass, it's necessary to remove the skin and pinfeathers.

BANTAM DUCK BREEDS: There are also the bantam duck breeds—the Call, the Australian Spotted, and the East Indie, all of which are excellent foragers and brooders. Most people keep them as novelties, as they do not produce eggs in great quantities (not more than 125 a year) and are comparatively small (usually under 2 ½ lb.) for a good meat source. But their meat is of very fine quality, and they do lay well in the spring, if the eggs are gathered daily.

Call. These are the best-known of the bantams. They are noisy little birds, either gray or white, favored as live decoys in England, where they originated. You'll need some patience to raise Call ducklings. They may do well on a diet of rolled oats and ground greens mixed in with their water. You can buy them from Shane Risner at Prickeree Pines Gamebird Farm: 616-897-1080; 2849 Gulliford, Lowell, MI 49331; X95risner@email.com.

Mallard. These are relatively small (male, 2.8 lb.; female, 2.4 lb.) ducks that can fly. They prefer living where there's water to fly from and alight on, and they frequently dive and swim underwater. They are a wild species (believed to be the progenitors of many domestic ducks), are perhaps the best duck foragers, and are natural mothers. The Mallard does not fatten as well or ship as well as the Pekin, and they have gamey-tasting meat. The drake has dramatic feathers, while the female is a demure brown. Check with your state game regulatory agency before ordering Mallards—you might need a permit.

DUCK FOOD: By the time they're a month old you can have your ducklings on a diet of grain, household scraps, and food from foraging. Liquid milk, mixed into their dry food at feeding time, and hard-boiled eggs can promote egg production and add shine to plumage. Adult breeder ducks being fed over winter can make it on a home-devised diet suitable for chickens. Ducks, like chickens, need calcium from some source for eggshell making and grit for their gizzards. Like chickens, they should not eat decaying vegetation or spoiled feed because they can get botulism poisoning from that. Most grains, including millet and rice, are popular with ducks.

The Duck-Foraging Option. Because of their foraging ability, ducks can be a bargain to raise, plus they help control bugs and slugs. At 4 weeks of age, your ducks can go on

range. Foraging birds grow more slowly and are leaner at butchering time but will ultimately (in as many as 12 weeks perhaps) reach the same target weight. They are naturally good foragers and will hunt for and consume tender grass, clover, and green leafy plants in general—as well as insects, slugs, snails, and all their ilk. The most natural foraging territory for ducks is wet, low marshland. But a year-round large flock can make excellent use of a pond plus plenty of foraging space on shore. If given the opportunity, they'll eat weeds, berries, and seeds; will glean for fallen grain and fruit; do bug patrol in alfalfa fields and under rabbit hutches; and will clean out algae from ponds. Ducks enjoy Japanese beetle larvae. When liver flukes are a problem to cattle, ducks sent into their pasture will devour the snails that host those parasites and make the land safe for the cows again.

Ducks are not as good grazers as geese. Unlike geese, ducks must have young grass, so it helps them if you mow their foraging area to encourage new growth, or put some geese in with them. Some duck growers help by locating 1 or more electric lights near ground level, turning them on only at night. The ducks can then feed on the insects attracted to the lights. Foraging ducklings need adequate space for the number of them. Confined too closely they'll simply end up killing all vegetation in their space and creating a foodless mud hole. If you have wandering ducks and live near a road there may be a problem. Ducks travel together, they are fearless, and they don't move fast. Ducklings raised by a mother duck learn to find their own food very young.

By allowing your birds to forage you can cut back on the amount of their commercial ration or even completely do without it if you regularly supplement with such grain as cracked corn, wheat, milo, oats, etc., during seasons when they can't forage as well, or year-round if their foraging territory is limited.

Commercial Food. Ducklings do better on crumbles than mash, which they are very wasteful of. Ducklings need more niacin than chicks; lack of it stunts their growth and causes weak legs. So if your ducklings are not on a duck starter you could add a soluble vitamin from the feed store to their water. Their crumbles should be sprinkled occasionally with fine gizzard grit. Don't feed cracked or whole grains until the ducks are at least 4 weeks old. Once they get big, feed only once a day except in the dead of winter. Feed in the evening—about what they'll clean up in a quarter hour. Confined birds will need more feed, more often than foragers, such as twice a day. Confined ducks in winter can get along on cheap grains supplemented with greens or quality hay. Don't throw grain for ducks on the ground; offer it in a trough. Confined birds will enjoy greens or vegetable throwaway parts cut into small pieces and put into their water. Add ground eggshells to their food for calcium. Even if you're feeding all commercial duck formula, it's good to supplement with fresh greens.

DUCK REPRODUCTION: Ducks are sexually mature in 5–7 months. A drake in his first year is called a “drakelet,” and a duck in her first laying season is called a “ducklet,” corresponding to a pullet. Don't raise male ducks or geese without the company of females. This can result in birds that bond to other males and will never mate with females.

Telling Drake and Duck Apart. With ducks it can be difficult to figure out which sex is which when you want to slaughter or sell some of your fowl and keep others for breeding. The Rouens can be distinguished by color, but most other domestic ducks cannot be sexed by color. You can sex ducks that are old enough for slaughter by voice. By then females will have developed a raucous, raspy-sounding call, whereas the male is comparatively hoarse and quiet. That doesn't work with the Muscovies, but adult Muscovy males are

considerably larger than females, so you can tell that way. Another way to sex mature ducks of all the Mallard-derived breeds (doesn't work with Muscovies) is by tail feathers. Males have about 4 curly feathers on the upper side of the tail that form a loop back toward the bird's head. Those are called "sex curls." Females don't have them. Duck hens with yellow or orange bills may develop dark spots on their bills when they begin to lay. An experienced person can identify the sex of a duckling by 2–3 weeks of age, by examining the duckling's vent, but this requires care as ducks injure easily. To do it, you'll need good strong lighting since the sex organs inside the vent are very small.

Duck Mating. Under natural circumstances, ducks mate on the water. The smaller breeds can also accomplish this on land as can smaller pairs of the bigger breeds. So pondless duck breeders select small drakes and large ducks. In general, heavy breeds should have 1 male to every 3–6 females. Light-breed drakes can service 4–7 duck hens. It's smart to have an extra 1 or 2 avian studs for backup. If you are raising several duck breeds, keep them separated to assure the ducklings are of purebred status. Provide each breeder bird with 5–6 square feet of floor space inside and 40 square feet outside. Commercial breeders feed a breeder developer ration, about $\frac{1}{4}$ lb. morning and evening, until about 1 month before egg production, at which point they switch to a breeder ration—as much as the birds want to eat.

Hatchability. Fertility is greatest when egg production is highest. Hatchability declines after the first few settings. It's uncertain how long your drake breeder will remain fertile. One Runner drake is on record for having fertilized eggs 20 years, but most duck growers don't take a chance and retire drakes after 8–10 years of age.

BUTCHERING A DUCK

When. If you're not sure if a duck has hit the 7-lb. slaughter weight yet, weigh it. But some breeds never get near that weight, no matter how much food and time they have. If you're planning to butcher a duck, it's best to do it at 8–12 weeks, before 5 months for sure. After that the meat is tougher. In addition, ducks in molt are unsuitable for butchering. Pin feathers from the coming plumage make the plucking a formidable task. They molt at about 10 weeks of age, so butcher either before that or well after it. Or skin the duck.

Catching a Duck. First try to corral it in a small pen or fence corner so you won't end up chasing it. With one hand right under the head, grasp it by the neck, and with your other hand, bring its body close to you, wrapping your arms around its wings so it can't flap them. Ducks are easily hurt, especially their legs and wings, so you have to capture them without a big fight. Once you have hold of the bird like this, you can carry it with one hand under its body and the other holding its wings down. You can carry it with the head pointing to the back of you or to the front. Keep the bird away from your face and take special care with Muscovy claws.

Killing a Duck. Chop off its head. Or stun it with a sharp blow on the head and then stick it through the throat or just behind the eye with a narrow-bladed knife. Or hang it by both its legs and cut the throat back of its bill. Or use any of the same directions as found under "Chickens" in this chapter. Bleed the bird thoroughly. For picking directions, see "About Feathers." A 7-lb. duckling will dress out to about 5 lb. of meat. For fried duckling some people prefer to peel off the skin and fat from the body and legs (the wings will be hard to do). If the duck is to be cut up (rather than roasted whole), any of the chicken methods can be used. Chill the carcass to 34–40°F as soon as possible.

DUCK RECIPES

Frying a Duck Egg. You can't fry a duck egg the familiar, chicken-egg way and expect it

to be tender. So lightly grease and heat a frying pan that has a lid. Break your eggs into it as for frying chicken eggs. Pour a little hot water about the edges of the eggs. Put the lid on the skillet and cook like that until the egg-white is firm (a few minutes). Serve promptly.

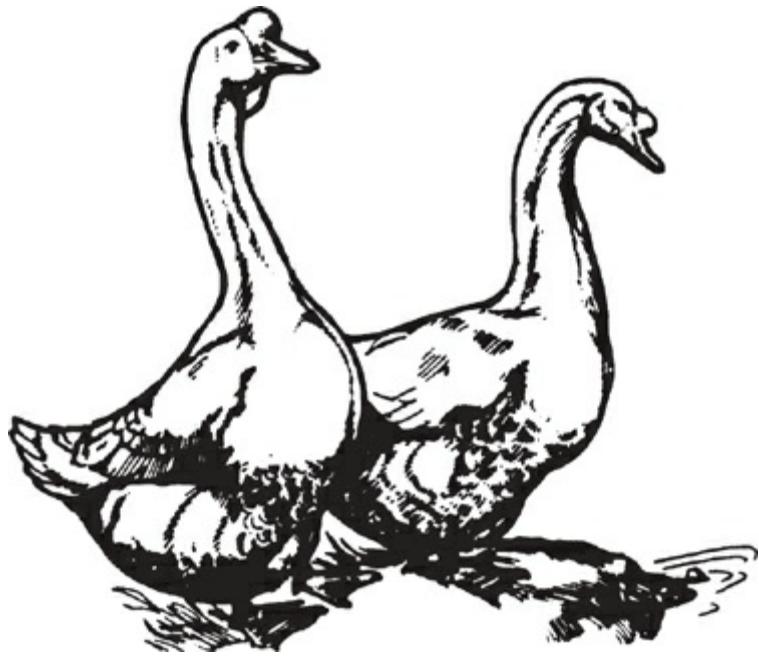

⇒ **ROAST DUCK WITH ORANGE JUICE** Rub the duck inside and out with salt and pepper. Put a whole onion and some chopped celery inside the duck or stuff it with a bread stuffing. Rub the outside skin with cooking oil or butter. Pierce the skin of a fat duckling in multiple places to allow the fat to render out. A duckling can be roasted at 450°F for 15 minutes, then at 350°F until done. A full-grown duck should be roasted at 350°F for about 25 minutes per pound, uncovered. When the skin is turning brown, begin to baste the bird once in a while with freshly squeezed orange juice or with the pan drippings. Optional: When the duck is done roasting, make a sauce by adding 2 T. flour to the drippings in the pan. If you burnt the bottom, pour the drippings into a frying pan and add the flour there. Add a cup each of water and orange juice. Don't let it boil. Pour the sauce over the duck and garnish with orange sections.

⇒ **FRIED DUCK** Cook the gizzard, heart, neck, and rib bones the same as to make Seasoned Giblet Gravy (see recipe under "My Favorite Goose Recipes"). Or fry the first 3 along with the other pieces. If you saved the skin and fat from the body and legs when you were cleaning the bird, cut them into small pieces and render out the duck grease. Remove the cracklings. Beat 1 egg with a fork and add 3 T. milk and salt and pepper. (You may need more dipping batter than this.) Dip each piece of duck into the batter, then roll it in fine, dry bread crumbs. Brown the duck pieces in the rendered duck fat. When browned, pour off most of the fat, add 2 T. water, cover and bake at 350°F for 45 minutes in a Dutch oven. Remove cover during the last 10 minutes.

Doris' Duck Tip. If your duck has a fishy or wild flavor, put the whole duck in salt water and add onions. Bring just to a boil and drain off water. Then prepare the duck as usual. Another lady told me her system was to stuff the duck with an apple and an onion, each chopped, and seasonings.

Geese

Although their primary value is as a meat bird—a good roast and *paté de foie gras* (goose liver spread)—many people keep a couple of geese on their farms as pets. They act as "watchdogs," honking loudly whenever a strange person or animal approaches. Although some geese lay fairly well, none will lay as well as the best duck and chicken breeds. On the other hand, some duck breeds are practically burnt out on laying after 3 years, and some commercial chicken breeds have a similar decline. Your goose is healthy, long-lived, and intelligent. They can thrive on no more than grass, can be a cash crop, and will lay eggs for an amazing number of years. (This perhaps can be an example to us on the benefits of plain living and moderation.) Most goose owners brood the eggs to maximize meat production and get table eggs from ducks or chickens.

Your geese will appreciate a grassy field; they need grass in their diets. In fact, except in winter, geese fare quite well with very little care. It's not unusual to see them foraging through snow. They are extremely resistant to disease and parasites, and they need only a little shade in summer and a bit of shelter against extreme cold. Young geese are relatively quiet animals, which may be a factor if you have irritable neighbors. The "goose" is the female, "gander" the male. A group of them is called a "gaggle."

NOTE: Be careful when handling big geese, even docile ones. Their wings may be longer than your arms and they have clawed feet. Their strong wings can break an arm and they have serrated bills that can tear flesh. An adult goose's charge, complete with loud hissing and flapping wings, can frighten anyone, especially a small child. However, if you are raising goslings just to freezer size, they won't get mature enough to become that aggressive.

Sylvia Nelson, Hillsdale, WY, wrote me, "Our first batch of geese, gray Toulouse, imprinted on me and just worship me. We also have a few white Embdens and 2 cross-breeds, hatched out last season, our first successful hatching. Toulouse and Embdens are supposed to be gentle, but a couple of years ago we learned how fierce they can be. My husband woke up one night, with a terrible ruckus going on in the duck and goose yard. He looked out, and saw a fox in the yard. We had seven geese at the time, and each one had a mouthful of fox, and were each pulling in a different direction. The next morning we found a couple of scratches on the geese, no missing geese or ducks, and chunks of fox fur all over the yard, plus a 1-inch-square piece of hide. The fox never returned!"

A gander will be particularly aggressive during the reproductive cycle. Dynah Geissel of Missoula, MT, wrote me, "The female geese are not mean but will bite if you mess around with their nests. There is always a dominant male who is ferocious during breeding season. He will even bite me at that time—even when I'm feeding him. The rest of the year he's not exactly friendly, but he keeps his distance, except if I approach a nest. Sometimes if there's not a goose in sight, I'll check to see how many eggs are in a nest. The geese seem to have a sixth sense, for out of nowhere one will come running to bite me."

GESE IN PRINT: You'd benefit from reading *The Book of Geese* by D. Holderread. See also the section earlier in this chapter, "Further Duck and Goose Information."

GOOSE BREEDS: There are about 15 breeds of domesticated geese. Basically, the goose is raised for meat. Personally, I like goose meat much better than turkey. Whatever breed of goose you prefer, you'll probably want to separate breeds or choose only one, because purebred geese are more marketable than those that are crossbred. An exception is the cross between the White Chinese gander and an Embden goose, a match that produces a goose that matures quickly to market weight.

Chinese. The closest thing to an eggs-and-meat goose breed is the White Chinese, which is almost as lovely on the water as a swan, gives noisy warning like a watchdog, and is a good forager and weeder. But they are less hardy than some geese in winter. The Chinese need shelter at below-freezing temperatures and heat at 20°F or lower. You'll at least need to provide them a south-facing lean-to with a straw-covered floor. They are about half the size of the larger breeds—10–12 lb.—but still big enough for a Thanksgiving dinner, though connoisseurs complain that the Chinese's carcass configuration is not as good as that of the larger breeds. But, the Chinese has a naturally leaner meat. The Chinese is the smallest bird and the best egg-layer among the goose breeds with quite good fertility. They produce from 40 to 65 eggs per year. Their eggs are large, white, and—like any other bird egg—just fine for cooking and baking. Some strains of Chinese have lost much of their broody urge; others still have it.

Pilgrim. This is an interesting, more recently developed breed (developed before the Second World War). The adult male is white with blue eyes. The adult female is gray and white with hazel eyes, which makes it easy to distinguish it from the male. Even day-old goslings are sex-linked to white and gray. The Pilgrim ganders are said to be friendly to humans and diligent in helping rear their goslings. Pilgrims are cold-weather hardy, being able to do without shelter even in sub-zero weather. Pilgrims are smaller than Embdens, rating as a medium-sized goose, and weighing 14 lb. (goose) to 16 lb. (gander).

Toulouse. These geese have broad bodies of dark gray with white abdomens. They have reddish-orange legs and toes and orange bills. They are hardy in winter and are basically meat birds that grow fast—a pound or more a week for the first 12–14 weeks—and end up quite large. Toulouse are meat specialists. A Toulouse will have fall weights from 20 to

25 lb. Some Toulouse males grow quite large, up to 26 lb., if allowed to grow to maturity—which requires a full year. Toulouse geese have another advantage: they are the best goose for reproducing themselves, though the White Chinese and Embden geese also go broody very well. Although the female will lay about 25 eggs over a month, let her set on only 15. Giant Toulouse geese are an extra-heavy variant of the Toulouse that has the reputation of being a quiet breed, which may be kept unfenced because they won't wander far. Giant Toulouse geese will lay about 60 eggs per season, but hatchability runs only a little over 50 percent. The Giant Toulouse is said to be a relatively poor brooder and mother.

Embden. These geese are pure white, have very nice feathers, and are also hardy in winter. Like the Toulouse, they grow fast, although they are slightly smaller. The White Embden is the commercial grower's favorite. A gosling can go from 4 oz. at hatching to 11 lb. in 10 weeks. At the end of 12–14 weeks you can put 10–12-lb. birds in your freezer. Or let them grow longer. An Embden will have fall weights of 18–20 lb. Embden geese go broody very well and will lay between 35 and 40 eggs a year.

African. The African goose is not as heavy as the Toulouse or White Embden, but it matures earlier. It is light brown with dark brown accents and a black knob on its head. The dressed carcass is on the lean side, with an abundance of pin feathers. The African goose is a heavier relative of the Chinese, weighing 14 lb. (goose) to 16 lb. (gander) at butchering stage, a couple pounds heavier as a breeder. It also is a relatively good layer. African geese are significantly noisier than other breeds.

Royal Chinese. This rare breed is the largest goose in captivity. They can exceed the adult weight of most other breeds when they are only 10 weeks old.

Buff and Sebastopol Geese. Both are unsuitable for meat and egg production. The Sebastopol does have beautiful curly feathers, making it fine for showing or to keep for a pet.

Canada or Wild Geese. These are best left wild. Although you can keep one from flying off by penning it or clipping its wings, they give you neither plentiful eggs nor good meat and you need a permit to keep one.

CARE AND FEEDING OF GEESE

Care of Goslings. A good time to get mail-order goslings is when you have really warm weather. Order from the supplier who can get them to you quickest, and make arrangements to pick them up immediately upon arrival. Goslings will be about \$5 apiece. An average family could eat 5 or 6 a year. (Plan to have that many disposable goslings a year once your flock gets going.) It's important to get your order in well before early spring, or the mail-order sources will be sold out. That's because a lot of these birds lay only in the spring, and if you don't get your babies then, you won't. For more detailed information on raising goslings, see chick-raising information under "Chickens" and the waterfowl section.

Feeding Goslings. Provide green grass to goslings as soon as they will eat. Although you can feed goslings the same diet as ducklings, you can also offer them bread or corn bread moistened with milk. Provide a fine grit. For the first week, feed them all they can eat in 15 minutes, 4 times a day. You can gradually reduce the number of feedings until the fourth week. By then they should be surviving well at pasture, supplemented with a little grain.

PASTURE FOR GEESE: When you are raising goslings, plan to provide them with green stuff,

starting in the first week. Lawn clippings are fine for them so long as the grass hasn't had any chemical treatment. If the weather is mild, and you make sure they don't get either chilled or overheated, you can literally let them out to graze, from a few days of age on. This saves you a lot of money on other feed. The best kind of grass for them is tender and green, not long, dried up, and coarse. Same for weeds—they can't eat high, coarse weeds until they are older. Don't let them get rained on or be in wet grass until they are at least a month old, especially when the weather is cool. And if there is no natural shade for them, they'll need to be able to find shade under trees, or under a shelter—maybe a sheet of plywood nailed a few feet up on top of 4 corner posts.

At 5 or 6 weeks of age your goslings can survive entirely on pasture if they can get enough of it, although it's helpful to their diet if you continue the supplemental grain and/or pellet feeding until they're completely feathered. For serious, large-scale goose raising, goslings enjoy fields of ladino clover, other white clovers, alfalfa, and almost any grass such as bluegrass, orchard grass, timothy, and brome-grass. They can eat grocery store culls of lettuce, cabbage, endive, and celery leaves. They also like barley, wheat, and rye, especially for fall pasture. For best results, plan on 1 acre of prime pasture for each 20–40 geese. The larger the goose, the more grass it will eat. The poorer the quality of the pasture, the more space will be needed per bird. You can compensate for poor pasture by feeding supplemental grain. It will help keep your pasture in good shape if you rotate the birds from section to section, so they don't have a chance to eat any of it down so far it can't grow back quickly. In winter, your geese will try to forage and may be able to discover some dried grass and weed seeds, but they'll also need some good (*not moldy!*) alfalfa hay, corn fodder, grain (they like cracked wheat and rolled barley), or whatever you're feeding your chickens. Geese enjoy warm, cooked cull potatoes and can thrive on them. Feed any poultry such warm food toward evening. Then they will face the night's chill full of inner warmth. You can train them to enter shelter at night or during the winter in response to that feed.

Geese as “Weeders.” Geese love green stuff. It's their natural food. Grown geese can thrive on grass and weeds alone, if the plants are tender (they don't get good nutrients from tall, tough, stems). Feeding geese grass gives them cheap nourishment and keeps them healthy. They love to eat dandelions, morning glory, pigweed, thistles, and burr weeds, which can be a blessing. Unfortunately, however, their favorite foods in my experience seem to be lettuce, chard, young peas, beans, and corn. They'll even eat onions. If they get into the garden very often they can wipe you out, so you either have to fence your garden away from the goslings and geese, or fence the goslings and geese away from your garden. If you put them into a corn field after the corn is grown up tall and the ears are almost ready to pick, they'll get the weeds and leave the corn. But if you put them in there with the young corn plants, the geese will wipe them out. They are the same in a field of sunflowers. And beware of small trees in your orchard. Geese have been known to strip tender bark.

Before herbicides came into standard usage there was a goose-glorious period of agricultural history, when commercial growers rented young geese by the truckload in spring as weeders—12 geese considered equivalent to 1 person with a hoe. If you are buying geese to function as weeders in cotton fields, orchards, vineyards, berry patches, etc., figure 7 geese per acre. The geese should be at least 6–8 weeks old, and the weeds can't be so far ahead of them as to be high and coarse. Water and shade placement control the movement of the weeders. Geese can survive and thrive on clover, alfalfa, grasses, and weeds alone, but if their greens diet is limited in quantity or quality, some supplemental feeding in the evening is a good idea. Geese aren't so reliable in commercial

fields of strawberries. If weeds are scarce, they'll eat the berry plants, and they like strawberries both green and ripe. Unlike chickens, geese don't scratch off the mulch looking for worms.

CONTROLLING GEESE

Fencing for Geese. As with 4-legged herbivores, you can turn the geese into a fenced pasture to graze. Goose-fencing keeps them in and it keeps them safe. Geese are quite vulnerable to large predators. My last summer's batch went down to the creek, and something got every one of them. Unfenced geese tend to wander away down a creek into the woods and will most likely be gone by the next day. Skunks, raccoons, or weasels will do the job, although I have heard of a case in which the geese killed a skunk. Two-inch poultry wire netting works fine for younger birds, and it need be only 18–24 inches high, since these birds don't usually fly. For birds 4–6 weeks or older, regular woven-wire fencing will work—3 feet high is good. Or even single-strand electric fencing. They'll stay in pretty well behind minimal fencing, except a henless gander may occasionally fly over and need to be caught and returned. The latest thing in goose-fencing is an electrified net, powered by an optional solar/battery system. I've talked to a grower who had such a system, and he was very enthusiastic about it. (Your hardware dealer could tell you more.) If you want to manage your geese without fencing, the best alternative is to make one of your children into a goose-herder to take care of them, as geese actually herd pretty well.

Controlling an Aviator Goose. Take the tips off the wing feathers 5 inches on one side. Just cut with scissors. It off-balances the goose. If you were to cut off both sides, he could still fly because he would be balanced. Be careful not to cut the wing, and if the bird is molting, just cut the tips of the feathers. (During molting, a thick sheath of blood vessels nurtures growing feathers. If you cut through that, your goose could bleed to death.)

OF GOOSE AND GANDER: It's easier to tell a young goose from an old one than to tell a female from a male. A young goose has soft, yellow down on its legs, an older one does not. But determining sex is difficult. Domestic geese are all to some extent polygamous, so it's efficient to eat the surplus males. But adults all look alike except in size—except for the color-differentiated Pilgrims. There usually isn't much difference in size either, yet with sharp attention perhaps you can discern the ganders, which not only are larger, but also have a broader head, longer neck, and more upright carriage. And ganders are more aggressive. If a strange dog comes along, the ganders will be the ones to take it on. A gander also has a somewhat louder and shriller voice than a goose. If any mounting is going on, that tells you. The one on top is male. Otherwise, if you're determined to know, you have to do a rabbit-style close anatomical observation.

Sexing Adult Geese. Get somebody to help you. Pick the goose up, turn it upside down and start hunting around. There isn't much to see, but with practice you can learn the difference. Lubricate a finger. Stick it in the cloaca about half an inch and rotate gently several times. Now press around the outside of the vent gently to squeeze out the sex organ. It's difficult to get the penis visible, so if you get a round hole with a twisted nubbin sticking out, you know you have a male, but if you don't see a nubbin you may or may not have a female. If you can get a friend who has done it before to help you the first time, it's easier. See *Sexing* (Stromberg Publishing: 800-720-1134; strombergschickens.com) for more details.

The easiest way to differentiate the sexes is to wait until spring. You may not know, but the geese sure do. The one who ends up laying eggs and sitting on the nest is the female.

Breeder Ages. Geese do not mate well if the goose is older than the gander. A goose

produces eggs for many years, the most between ages 2 and 5. However, if she eats too much and gets obese, she won't lay as many eggs, and those she does lay aren't as fertile as they would be after a diet. The gander ain't what he used to be after about 10 breeding seasons but is still good for some offspring. Geese will breed even up to 40 years of age. (101 is claimed to be the record.) If your geese don't breed their first year, don't panic: Geese sometimes don't start until their second year. Frequently, that first family may not be as numerous or hardy as later hatches. But after their trial run, most geese, left on their own, will brood and raise about 15 goslings a year.

Gander-Maturing Ages. The age of maturation varies. In some breeds, ganders are not mature enough to mate effectively until they are 2 years old—3 if they are of the Egyptian or Canada breeds. Slower breeds may be pushed into becoming productive earlier if exposed to increased artificial light.

Possible Breeding Ratios. These vary with the breed. The Canada and Egyptian geese mate only in pairs. Ganders of other breeds may pair exclusively with one female, but polygamous groupings are common. Embden, Toulouse, and African geese can suitably be grouped 1 gander to 2 or 3 geese. The Pilgrim, Buff, and Sebastopol ganders can each handle a harem of 3 or 4 geese. The smaller White Chinese gander can manage a harem of as many as 6 geese. For breeds that are capable of polygamy there should be at least 2 or 3 geese per gander for best tranquillity in the gaggle. However, there have been cases in which, as individual ganders grew older, they became monogamous and grew indifferent to all but one mate. But Chinese ganders not only accept a larger harem than any other variety, they also will not revert to monogamy.

Goose Conservatism. Geese generally choose partners in the fall. Once the groupings are established, it is difficult to add more geese. Geese do not mate on first encounter like so many other animals. If your proposed partners are new to each other, you'll have to allow them time to get acquainted. Many ganders do not change partners easily. Previous companions have to be completely absent for as long as a month before such a gander will accept one or more new ones. How did "goose" ever become synonymous with "stupid"?

LAYING AND NESTING

Breeder Foods. Geese lay best when they're getting grass, even in winter. If you are serving feed-store food, begin feeding them 15–25 percent breeder feed or mash and some good-quality hay in January, a month before egg production. A calcium supplement will assure eggshell hardness. It would also help to feed breeder geese a chicken-laying mash, if you're giving commercial feed. Whatever's in that, it does indeed push females to lay.

Egg Laying. Don't let overeager birds go broody in January, because none of the eggs will hatch. The way you prevent that is by taking the eggs every day, leaving just one (not the same one). Unlike the duck (which dependably lays early each morning), the goose will lay her egg any old time of day. Goose eggs are used the same way you would use a chicken egg. They taste just the same to me, but are much bigger. One goose egg will make an omelet; fry one and it fills the pan. Goose eggs are also prized in decorative eggshell arts. Becky Coleman of Charlo, MT, wrote: "My pair of Embden geese were 'mature' when 1 year old. They hatched 8 goslings out of 9 eggs. That pair was hatched one spring and started breeding the following spring. I took away the first couple dozen eggs and then let the goose set with results as stated. The one egg that didn't hatch was cracked."

Goose Nest. Freeranging geese will lay their eggs on the damp ground. If you have

predators in the area, it is best to restrict your laying geese, but they will still prefer to nest outside. A good nest for a goose is an old tire with straw or hay in the center of it or, better yet, an old doghouse or something similar with clean straw inside of it. Smaller breeds prefer a smaller "house"—a box or barrel. Keep a little distance between nests to discourage squabbles. When the goose starts laying, remove all but 2 eggs until you have accumulated a nest full. The eggs can be stored in a cool place up to 2 weeks. (Wild goose eggs should not be gathered.) When you feel the weather has improved enough for her to raise a family, leave the eggs. When she has filled up her nest with a dozen or so eggs, she'll begin to set. A broody goose, in proper season, can raise up to 20 goslings.

Wherever she nests she'll lay her eggs there and brood them, and then both parents will help raise the family. Once the young are hatched the mother will provide the needed warmth for them, but it will be helpful if you provide food and water in appropriately sized containers for the young ones.

Chicken-Brooded Goose Eggs. If you have a breed that will lay more eggs and you wish to hatch them all, you can put fertile goose eggs of a non-broody layer under a setting hen and let her raise them. Take the excess goose eggs away before you let the goose accumulate her nest. Choose foster hens that are completely free of lice and ticks. A hen can cover 6 goose eggs, but they're too big for her to turn. You'll need to mark them and turn them yourself every day. Sprinkle them with water daily, too. Expect a hatch in 28–35 days. Or you can put orphan birds from a mail-order source under a hen who has a new family (see instructions at "Inter-Species Brooding and Mothering" under "Chickens"). When the goslings hatch, you may be able to slip them into the goose nest, but watch carefully. If the goose rejects them, the chicken hen may raise them.

Incubating Goose Eggs. Like duck eggs, goose eggs need a high humidity to incubate. While the eggs are waiting to go in the incubator, use all directions listed in "Eggs-in-Waiting" under "Chickens" with the addition of a light spraying of lukewarm water every time you turn the eggs and a once-a-day dunking. (See "Incubating Waterfowl Eggs.") Large-breed geese hatch in 30 days, Chinas in about 28, Canadian and Egyptians in 35.

BUTCHERING: If you have an old goose, I'd let it die with its dignity intact rather than trying to eat it. I wouldn't eat one over 3 years old. They get tough as shoe leather.

Catching a Goose. A good time is very early in the morning. When he comes hissing at you, bend toward him, reach out, and grab his neck behind the head. Then you can hold his head away from you with that hand, so he can't bite, and with the other arm, just scoop up his body, pinning the wings by tucking him under your arm and pressing him to your side. Hold him backward—with the head under your arm and coming out behind you and the bird's rear end on your front side. Otherwise the bird can stretch out that long neck and bite you in the face. That way—holding his neck in one hand and his body with wings pinned under your other arm—you can carry him safely where you need to go. The usual goose-slaughtering time is in the fall, when they are 5–6 months old, although you can kill heavily fed birds at 12 weeks if you don't mind dealing with more pinfeathers. At 5–6 months, they'll weigh 10–15 lb. and pinfeathers won't be a problem. Over age 10 months, their meat becomes tough.

Killing a Goose. You can hang it by the feet, stun it, cut the throat, and bleed it out thoroughly. Or ... some friends have been continuing my education about geese. They say they shoot a goose in the head with a .22, and then skin it out rather than pick it. Well, meat's meat.

Scalding and Picking a Goose. Heat the water to 155°F—you'll need a *big* pot of it for a

20-lb. goose. You can heat water in a big canner to boiling and then pour it into the bottom of a metal garbage can and repeat as needed until you have enough accumulated to get the bird entirely under water somehow. Follow directions under "About Feathers." Soak the goose as long as 4 minutes (in 140°F water with lots of agitating), depending on its size—long enough to get the feathers loose. The bigger a bird is, the longer you have to soak it to loosen the feathers. Follow directions under "Butchering a Duck" to cut up the bird. You can save the blood as well as the entrails for other stock.

SOME OF MY FAVORITE GOOSE RECIPES

⇒ **BRAISED GOSLING** This is a delicious way to prepare a bird that has just reached roasting size. Use a roaster with a rack at the bottom of it. Put a chunked carrot, an onion, a turnip, a pared and cored apple, and a stalk of celery on the grating. Lay the bird on that. Rub salt, pepper, and a little sage on it. Pour some boiling water in the side. Cover and roast at 350°F, 15 minutes to the pound. Baste with butter.

To make the gravy, remove the gosling when done, and mash the vegetables by pouring them and the cooking liquid through a sieve into a bowl. Skim away as much of the grease as possible after it has set a moment. Chop the cooked giblets (except the liver, which you discard), and add them to the broth. Put about 3 T. of the goose grease into a frying pan. Thicken with flour, then add the broth gradually, stirring the lumps out before adding more liquid, until it has all been added. Season your gravy to taste. Serve the bird on a platter, the gravy in a bowl. Have mashed potatoes ready to pour the gravy over. Applesauce, and green peas or lima beans will complete a wonderful meal.

⇒ **SEASONED GIBLET GRAVY** This is a variation of the above. You roast your goose without the vegetables in the roaster. Precook the neck, gizzard, and heart (again discard the liver, or do something different with it—like make paté de foie gras, for which I don't know the recipe, only that it's made out of goose livers) by boiling them until the gizzard is fork-tender. Allow enough time, because it often takes just as long to cook that gizzard tender as it does to roast the entire rest of the bird. (If you wanted to use the giblets as part of your bird's stuffing, instead of in the gravy, you'd cook them the night before.) Season the giblet water with 1 t. salt, 2 peppercorns, 1 clove, a bit of bay leaf, a sectioned carrot, a sectioned celery stalk, and an onion.

After the giblets are cooked, cool them. Remove the neck bones, and cut the meat into very small pieces. By now your roast goose should be done. Make a gravy as in the recipe above, using grease from your goose roast, flour, and the broth the giblets were cooked in along with the mashed vegetables from it and the minced gilet meat. Make lots of the gravy. For your second (and third?) meal from this food reheat your leftover gravy, adding sufficient water to get it the right consistency again since it thickens some while stored. Add sliced leftover goose meat to the gravy and serve over slices of bread or with potatoes.

⇒ **GOOSE STUFFED WITH SAUERKRAUT** This is a good fall dish, when the geese and the sauerkraut are both at their prime. Fill the goose with homemade sauerkraut. Sew up, tie into shape, and place in a large kettle. Cover with about 2 qt. more of sauerkraut and add boiling water. Simmer gently for 3 hours. At the end of this time, take your goose out of the pan and put it in your roaster. Rub the skin with butter. Bake in a 400°F oven about 1 hour, or until nicely browned. Serve the boiled kraut seasoned to taste with salt, pepper, or butter, since the boiling weakens the flavor.

Life is a river. Lived right, it's a quick, clear river rushing over and around the rocks in a long straight path down to the sea. But I sometimes see someone allowing his or her

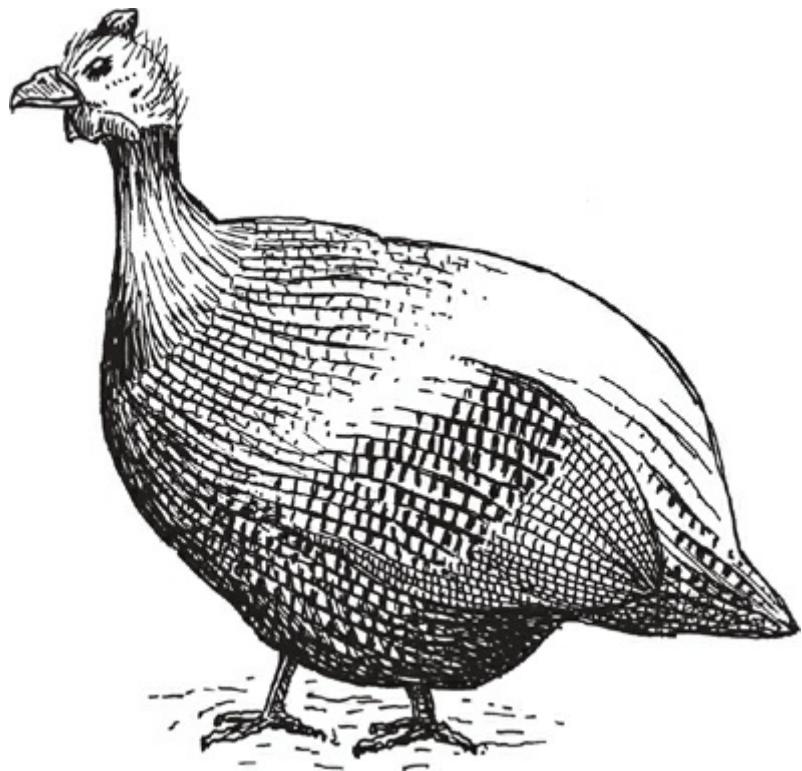

beautiful river to turn into a sluggish, muddy swamp with a multitude of mosquitoes growing on top. Getting out of the swamp requires change. There's a basic rigidity of life: that it's hard (or impossible) to change him, or her, or it, or that. The place where you've got room to maneuver, to manage a healing of the swamp, is to change you. That's something always within your power to do.

But first you have to get the vivid and important realization that you are in a swamp—and you want to get out!

Ain't that something. For umpteen pages I give instruction, then I preach. It's a good thing I have teenagers to keep me humble. In this new edition I've tried to reduce the burbling and stay with the subject better than I used to. But then wonderful readers write me and say they loved thus and such in my book—and it's frequently a burble rather than a how-to they're talking about, though it's also surprising how many people have written to thank me for prosaic things such as chicken-butcherering directions. So I don't really know which is most important. Guess I'll just keep doing like I'm doing.

GUINEAS

What is not considered a game bird but acts a lot like one, comes from Africa, and roosts in a tree if you don't keep it penned up? It's a guinea, called the African chicken, although it is more closely related to the pheasant. They're noisy, quarrelsome with other poultry, and probably not practical to own unless you're going to keep them penned up (because unconfined guineas hide their eggs, lose their babies, and are difficult to catch) or unless you have a major insect problem and lots of room for them to roam. But they are hardy, do have a tasty meat, and lay rich eggs.

Dynah Geissel, Missoula, MT, wrote me about guineas, "I wouldn't say that guineas are useless. They announce the arrival of a hawk by screaming and standing their ground while the chickens run for cover. They also broadcast the arrival of other visitors. They are excellent and persistent setters, but they lay their eggs in the fields where they become easy prey to predators such as skunks. They are terrible mothers who will lead their 12–15

keets through puddles, wet grass or anything else in their way. The best bet is to take the eggs and let a hen hatch them. If a guinea does manage to hatch her clutch, take all but two and raise them yourself. Turn them loose when they're 8 weeks old. Butcher them in the fall (shooting them out of the tree where they roost is your best bet). Be sure you shoot the babies and not the adults. This partly for the sake of tenderness, but also because a guinea dramatically mourns the loss of its mate. The meat is wonderful—like pheasant."

You can get more information on guineas in the handbook *Guinea Fowl*, available from Inman Hatcheries (see "Poultry Supplies" under "Chickens" in this chapter).

Guinea Attributes

SELF-RELIANCE: Guineas have been companions to human beings since the ancient Greeks, yet they can never be called more than "semi-domesticated." Guinea fowl will be less dependent on you for care than perhaps any other type of animal you raise. They are able to search out their own food—except in winter—and as a result they are one of the less expensive birds to raise. They are both hot-weather and cold-weather hardy, being adapted from northern Canada to the torrid south, but will need some protection during extremely cold weather. They are less prone to disease than any other poultry, clean in habits, and are not associated with the familiar "poultry" smell.

INSECT-EATING: If allowed to roam, guineas will consume more insects than other fowl. Unlike the grain-loving fowl and unlike the plant-eating fowl, guineas are insect eaters. And they will work hard to get bugs. Guineas eat ants and will wipe out ant hills. They eat potato bugs and Japanese beetles. They do not scratch and will not harm garden or flowers; they go there looking only for insects. They chase flies, and catch them. They will ride on larger animals, picking insects and catching flies. The guinea is naturally an open-range feeder, but no matter how far it travels in daytime bug searches, it always returns home by evening.

GUINEA PATROL: Like geese and watchdogs, guineas make a loud frightened shriek when they notice strangers coming around—human or animal. They have been known to chase away wild birds like robins and waxwings from berry bushes and fruit orchards with their noise, flying into the trees and darting at the other birds. The guineas themselves are not fruit eaters and will not pick at fruit even if it falls on the ground. Guineas are on guard at night, too, and their noise can be a real problem to you and your neighbors. One of the flock, by turns, stays alert all night, ready to give the alarm. But owners have complained that they simply make noise all the time, rather than making useful noise, and they may be eaten by the very creatures they're supposed to give the alarm about. This new generation of guineas, hatched in incubators and raised in a brooder, doesn't live up to the reputation of its more naturally brought-up ancestors. When you eliminate old-time mothering and the survival lore that is thus passed from parent to offspring, you forsake education, and raise a helplessly ignorant species.

GUINEAS FOR MEAT AND MARKET: Guineas produce excellent meat. The guinea usually weighs 2–3 lb. at 16 weeks. Birds for market are butchered at 2 ½–3 ½ lb. The weight is mostly meat because of their small, flying-bird bones, a little smaller than a roasting chicken. The best time to butcher is at 4–6 months of age. The meat is all dark and tastes like a game bird's, so there is a market selling guinea meat to elite restaurants. As with other birds, young guineas are tender, while old ones are best as stew birds. You may substitute guinea in any recipe calling for grouse, partridge, or pheasant. You can also substitute guinea in

any recipe for chicken, keeping in mind that the bird is the size of a light-breed chicken and is typically leaner than chicken and thus benefits from ingredients that add fat or moistness.

Low-Cholesterol Eggs: Guinea eggs are brown-shelled and are the lowest in cholesterol of all poultry—or so I've heard. They have a flavor all their own. The exceptionally light yolks are excellent for souffles, mayonnaise-making, and baking. Their eggs are small, banty size. If you're making angel food cake, 16 guinea whites equal 11 hen whites. Guinea eggs keep well because of an unusually heavy shell. However, since they're such poor layers and hide what they do lay, you're lucky if you get very many of those wonderful eggs.

Getting Started

There are several varieties of guineas, but the main difference between them is color of feathers. Basically, a guinea is always a guinea. The 2 most commonly available varieties in the United States are the Pearl and the White African. Pearl Gray guineas have lovely feathers. The Whites, with their lighter skin, are sometimes preferred by restaurants, where they may be served in pheasant dishes. They're said to be not quite as loud as the Pearls, and you can see them better to follow to a hidden cache of eggs. Thomas G. Horan, RR 4, Box 417, Tamaqua, PA 18252, 570-467-3683 (evenings best), is a guinea specialist. He offers nine varieties: pearl, white, lavender, dun dotte, coral blue, royal purple, buff, opaline, or porcelain. Ralph Winter, 21357 White Pine Lane, New Vienna, IA 52065-9728, 563-853-4195, www.guineafarm.com, offers 20 colors of guineas to choose from (also 10 varieties of peafowl and blackneck swans).

Start your flock with day-old chicks from eggs set under chickens, or mail-order keets, because adult birds, when moved, are likely to wander, even if they've been penned for as much as several weeks. Your keets can be adopted and raised by your hen, or in a brooder.

GUINEA FEED: Besides insects, the freeranging guinea will pick up seeds of grasses, weeds, and grains. A dense patch of blackberries or such undergrowth is heaven to a guinea. If you want them to stay close to home, you can let them out only in the late afternoon to range. Completely fenced-in birds kept in a rotation setup need to be shifted every 3 weeks, but fenced range won't work for unfed guineas unless it's large enough. They need enough territory for adequate insect-hunting, since that is their primary diet. When guineas are close-penned, or cannot range because of weather or snow cover, you can feed them high-protein turkey or gamebird feed, chicken or turkey laying mash, or a home-devised chicken diet. If using a home-devised diet, they need less grain than other birds, and more protein—corn, wheat, oats, milk curd, and meat scraps. They appreciate oyster shells and limestone grit.

GUINEA SHELTER: Adult guineas are certainly happy roosting in an orchard, all year round. But some owners prefer to teach them to roost in a poultry shed. This solves the problem of having to shoo them inside in extremely bad weather (guineas intensely dislike snow). They don't need a heated or insulated shelter. To teach a guinea to sleep indoors, you start when they're about 2 months old and getting the urge to roost somewhere high. Each night, drive them into the place where you want them to roost. They can be taught the habit. Or you can let them roost outdoors in the summer. Then each evening of the fall feed them nearer the place you want them to roost, so that by the time really cold weather comes it won't be so difficult to get them to sleep in there. But for easiest and best management they should be confined in bird runs. (See "Pheasant Housing" under "The

Game Birds.”)

GUINEA PENS: At least 1 cock and 3 or 4 hens should be penned together. The pen size should be a minimum of 6×10 feet for this group. Sides 5 feet high on a pen that small will prevent the birds from flying out. If they are to be penned during laying season, place the pen in such a way that at least 1 corner contains brush or tree limbs, deep grass, or hay. Guineas do not like nesting boxes. The hens will lay their eggs on the ground where they feel securely hidden. Make a special egg-door in the fence by the nesting place, so you can gather eggs without coming into the pen. Another good argument for letting the birds roam, at least once a day, is to help you gather the eggs unseen. What guineas see, they remember, and they don’t make a mistake more than twice.

WORMS: The primary health problem a guinea can suffer from is worms, round and tape. It is possible, but risky, to worm them.

Guinea Reproduction

MALE AND FEMALE: It’s difficult to tell the sexes apart. Baby guineas cannot be vent-sexed. After the keets are 12 weeks old, a cock’s comb is just a little larger than the female’s. The adult cock’s comb and wattles are just a little more developed than the female’s, and the white on his neck extends farther down. The cock’s call is one-syllabic, while the hen’s is either a 1-or a 2-syllable call, variously rendered as “put-rock,” “buck-wheat,” or “good-luck.” If one bird is separated from the others, you can tell by its call what sex it is. Males are the ones that rush about with wings lifted a little, an expression of avian courtship. Under natural circumstances guineas are monogamous. But they will accept harem life. You can maintain egg fertility with as few as 1 cock to every 4–6 females. The social grouping so formed will be permanent. The cock always remains protectively near his hens. If the hens have 1 wing clipped and are kept in a pen, an unclipped cock won’t fly away and leave them. Guineas can mate with chickens. The resulting offspring, like the mules that result from horse–donkey matings, will be sterile.

NESTS: Since guineas are known for laying in out-of-the-way places, it’s a good idea to confine them each day until they’ve laid (until 3pm if you’ve got a number of hens). If your guineas are free-roaming, you will have trouble finding their eggs. Guineas are seasonal egg-layers, and they hide their nests. There’s an art to finding those nests. When the laying season begins (late March to mid-May, depending on your climate), watch to see where they go. The flock will go together to lay between about 11am and 1pm. A guinea nest will be a shallow hole scratched in the ground. All the hens may lay in the same nest, even at the same time. The cock stands nearby to guard them. You must see without being seen. Guineas are easily upset and may quit laying, or move the nest. So don’t ever come near while they’re laying. Just mark the spot visually, and then, after they’ve gone on their way, go find it. The laying season will be over sometime between August and October.

When you take out eggs, leave from 1 to 5 (opinions vary) marked ones. Never let them see you take the eggs. A guinea hen will set when she gets an accumulation of 12–24 eggs. So, you’ll get a greater total of eggs from which to hatch keets (under a hen or in an incubator) or for eating, if you mark and leave those 1–5 eggs in her nest and take the others to put under setting hens. Rotate the ones you’re leaving, and don’t worry about their freshness—remember that guinea eggs are the best keepers. With you taking more of the eggs, the guinea won’t get broody until late summer. If you want to break her from the

notion to set, just take all the eggs. Guinea broodiness breaks up easily.

INCUBATING GUINEA EGGS: Guineas lay far fewer eggs than commercial chicken and duck breeds. A hen will lay maybe 45–55 eggs a year, in the period from May to September. The good news is that guineas live a long time, and, like geese, lay as many eggs when they're relatively old as they did their first year, and their eggs remain as fertile.

HATCHING GUINEAS: You may return 12–15 eggs to a guinea hen for setting, set 20–28 guinea eggs under a brooding chicken hen, or incubate the eggs. The eggs take 28 days to hatch. Brooding guinea hens have been known to give up on the rest of their eggs once 2 or 3 keets have hatched. The remaining eggs can be saved if you move them to an incubator or chicken hen. Forced-air incubator setting should be 100°F; during the last 3 days of incubation it should be 99°F. Still-air temperature would be 101–103°F. Humidity: 83–85. Do not turn eggs after 25 days. Humidity is essential because of the hard shell. Humidity during the last 3 days should be 90–94. For eggs incubated under a hen in a dry climate, or in dry weather, it will help the keets hatch out of their thick-shelled eggs if you occasionally sprinkle them with warm water. If you're hatching only part of the eggs, choose the larger ones, because larger eggs tend to hatch out larger birds. Because of keet susceptibility to lice, if you plan to hatch guinea eggs under a hen, she needs to be louse-free, and sitting in a clean nest. The last week before hatching, give her an anti-louse treatment, and put her on fresh sod for nesting material. A little pinch of fine-cut tobacco mixed in the nest litter helps. Banty hens are better for the job than a heavy-breed hen, because they're less likely to cause heavy-footed harm to the fragile-boned guinea keets after they hatch.

KEETS: The guinea chicks, or “keets,” are tiny and vulnerable. They are available from hatcheries from about April through August for about \$1.50 each. For the first few weeks, you'll want to keep them penned up and feed them frequently. Start with 6 meals a day for the first month. Then give them 4 meals a day for 2 weeks. After an additional 6 weeks of 3 meals a day, you can feed guineas much like turkeys. They'll grow twice as well on turkey starter feed than on chicken starter, but they can make it on (nonmedicated!) chick starter. If their feed is to be home-devised, it should be high in protein, with chopped hard-boiled eggs, crumbled cornbread, and cottage cheese or clabbered milk, as well as bread crumbs, oatmeal, and a few greens, with fine grit. Keets cannot eat a coarse feed.

They need a 95°F brooder warmth and to be in groups no larger than 25. They can get through 1-inch holes and fly by the end of 2 weeks. They can drown in chick-size waterers. During the first 2 weeks water them from very small, shallow containers with marbles or rocks in them, devised so they cannot possibly get wet. The keets will stand on the rocks and drink the water. Lice will kill them. Make sure your brooder area is clean in this regard. Wood shavings are a good litter for keets. If you bring up the young keets with chickens of the same age, they learn to come in at night, with no work on your part.

GUINEA MOTHERS: Guinea hens are not the best mothers for their young, so it's really preferable to raise them with a chicken or in a brooder. Modern guinea mothers don't have good judgment about how far a keet has the strength to go, or under what conditions. Keets mothered by a chicken tend to be less wild and more manageable. Guinea keets that are to be mothered by a hen should be penned for the first few days with the hen, until they learn to recognize her “come-here” call. For the first 2 weeks they mustn't roam in wet grass or get caught in the rain. Use a portable coop and move it every day to fresh range. By the time guineas are 4–6 weeks old, when they begin to

develop adult feathering, hen and chicks should be completely free to wander. Keets raised in a brooder can be shifted to range and range shelters when 6–7 weeks old. Once on free range the keets need no more supplemental feeding. Guineas are herd creatures, and keets raised with a hen will stay with her until they are fully grown, which may deeply upset a banty hen who wants to go off by herself and set privately on a new clutch of eggs. But the guineas will want to stand guard, guinea-style, while she lays her eggs, and roost with her at night.

Catching a Guinea

My helper, Pam (a treasure: a grown woman with a husband and a beautiful baby, who volunteers her time for the cause of making this a better book; God bless her!), at first kept trying to upgrade my language. She wanted me to say “Administering a Pill to a Bird” rather than “Giving a Bird a Pill” and “Guinea Capture” rather than “Catching a Guinea.” I’ve been fighting for the right to use Plain English on the printed page for 25 years. So I had a talk with her. I asked, “Why must we have a 2-or 3-syllable word when a 1-syllable word can do the job? Why must we make the reader of a how-to book feel like the writer is so-damn-smart and been-to-college?” I explained that my big worry is how to manage to get that reader, you, to truly believe that you—whether amateur, city-raised, Ph.D. or only 6th-grade graduate—can do all this stuff, too. Doctors “administer” medicine. You and I give pills! Right?

Plain language empowers plain people. That’s the whole idea: that you, too, could do any or all of the stuff in this book. And it’s okay—it’s great!—whatever you choose to try. When you give knowledge to people, you empower them. So many times some beautiful person has come up to me and said something like, “I love your book because I can understand what you’re saying! You write like people talk!” I do that on purpose. I wish I did it better, and more. Using Plain English in a book doesn’t mean the writer is dumb. My IQ is awesome. If I wanted to write more obscurely, more formally and distantly, in the usage of the literati, I could. But I don’t want to. Talked Pam into my point of view, too! Like I said, she’s a neat lady. And well on the way to recovering from that college degree!

So, to catch (or “capture”) a free guinea … you can make anything work once or twice: shine a spotlight in her eyes, teach her to feed in an open coop and then sneak up and shut the door, or run her into netting supported by stakes. Using a net on the end of a long handle is a good technique. Be careful when handling guineas, though—their bones are fine and their legs easily broken. It’s helpful if they’ve been taught to sleep indoors. And shooting them in the head always works, if your aim is good!

THE GAME BIRDS

Pheasants, partridge, quail, grouse, and peafowl—the “game birds”—vary a lot, but in general they all are fragile, they typically do not reproduce efficiently or at all in confinement, their eggs must be incubated, they are raised in total confinement (either in runs or cages), and they are chronically nervous. The main argument for keeping them is the extraordinary beauty of some varieties (the pheasants in particular), the small size of some (particularly the quail) that make “garage ranching” possible, and their market value as specialties. Game birds are usually fed commercial gamebird starter/grower/finishing/breeding rations. Whether you can make them pay or not depends on your knowledgeability and skill as a handler and the quality of your facilities—as well as the current state of the market and your ability to network with it. For highest egg-laying rates, many growers send older birds continually on to market, replacing them

with their offspring as breeders. That way they're assured of having young, vigorous breeders all the time.

GAME-BIRD BOOKS AND SUPPLIES: There are lots of books on raising game birds in general and on each specific game bird, too. Inman Hatcheries (see "Poultry Supplies" under "Chickens") offers gamebird books: *Raising Game Birds*, *Game Bird Propagation*, *Pheasant Breeding and Care*, and *Partridges—Their Breeding and Management* by G. E. S. Robbins. Other useful gamebird references are *Pheasants—Their Breeding and Management* by K. C. R. Howman (helpful to newcomers) and *Raising Game Birds*.

Join the North American Game Bird Association, run by and for gamebird breeders, for \$45 (\$55 Canada) per year. You get a directory of members, listing in a hunting preserve directory, and *Wildlife Harvest*, a news magazine covering new and proposed regulations, meetings, courses, and ads for birds and equipment: 201 N. Main St., Eureka, KS 67045; www.naga.org. Or subscribe to the *Game Bird Gazette* (\$23.95/yr). It covers breeding, hatching, brooding, feeding, and housing of game birds such as quail, pheasants, guineas, partridges, doves, ducks, and swans. There's a large classified ad section in every issue: 801-575-1111; PO Box 171227, Salt Lake City, UT 84117-1227; www.gamebird.com.

SOURCES

B & D Game Bird Farm is where Bert and Dianne Tumey offer bobwhite, Tibetan, and Pharoah quail, ringneck pheasant, chukar junglefowl, guineas, books, videos, supplies, and a free brochure: 405-964-5235; Rt. 1, Box 812, Harrah, OK 73045; info@bdfarm.com; www.bdfarm.com.

Bayou Bird Farm offers many varieties of pheasants, junglefowl, and peafowl: 318-949-2294; 846 Elsie Dr., Princeton, LA 71067.

Cutler's Pheasant Supply: 810-633-9450; 1940 Old 51, Applegate, MI 48401; cutlers@greatlakes.net; www.cutlersupply.com. Free 56-pg. catalog lists incubators, brooders, feeders, waterers, ringers, netting, catching nets, coated wire, books, medicine, blinders, and much more.

Cottonwood Grove Bird Sanctuary offers quail, pheasants, partridge, junglefowl, and peafowl. Contact David Bauer: 308-893-2707; 5480 W. 85th St., Kearney, NE davidbauer@frontiernet.com.

George Irons offers many kinds of pheasants (also peafowl and ducks): 508-252-3148; fax 508-252-3992; 117 Hillside Ave., Rehoboth, MA 02769; tragopan9@yahoo.com.

Oakwood Game Farm hatches 50,000 ringneck pheasants and chukar partridge weekly. Established in 1966. Free price list: 800-328-6647; fax 763-389-2077; PO Box 274, Princeton, MN 55371; oakwood@sherbtel.net; www.oakwoodgamefarm.com.

Reston Gamebird Farm ships eggs and adults: 14 pheasant varieties, three of quail, three of partridge. Contact: 3621 Reston Rd., Roseburg, OR 97470.

GameBird Housing

GAME BIRDS AND STRESS: Because of their natural wildness, game birds are easily stressed by life in captivity. Stress makes them more susceptible to disease. Crowding, poor nutrition, changes in their diet, changes in their housing, and handling of any sort tend to be stressful to them and must be managed as carefully as possible.

PENS FOR SMALL GAME BIRDS: It's best if you separate birds by species and age. The smaller game birds, such as quail, are usually raised in tiered metal battery-style pens or in

homemade off-the-ground pens that have a wood frame with poultry-netting sides and small-mesh flooring. A basic homemade pen uses 2×4 s for the frame and 4 legs, which support a $2 \times 2 \times 4$ -foot cage. The floor of the cage is made of hardware cloth (a rugged galvanized screening). The wire floor allows droppings to fall through to below the pen where they can be gathered up for the compost pit. The sides are of chicken wire. The top can be made of chicken wire if the pen is inside, wood or metal if it is outside. Such pens can be on tall legs with a back-sloped roof and can be fixed on posts or portable.

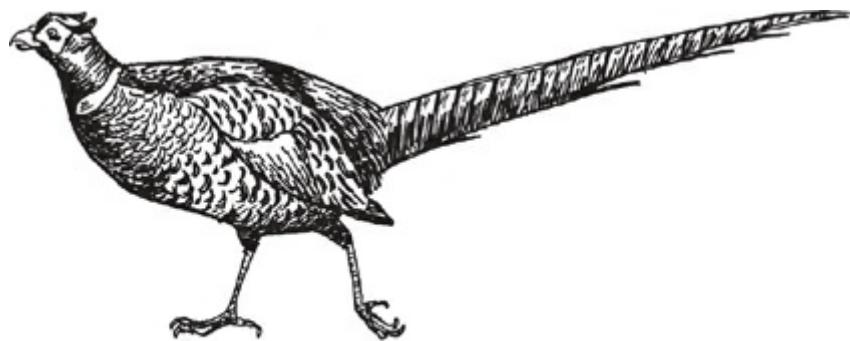

HOUSING FOR LARGER GAME BIRDS: Pheasants, for example, are usually kept in sizable cages that have a chicken-wire top and sides. Such a cage could be partitioned off inside an existing building—about 6×12 feet—or built outside. Outside ground pens can be built to include brush, one or more trees, and shrubs; that provides a more comfortable and natural environment for the birds. Dimensions can be adjusted according to the variety of bird, number of birds, and the space you have. Height should be 6 feet. Outside ground pens need a south-facing shelter to protect the birds from sun and storm. If your climate is cold, the shelter needs to be a little house with a bird-size door to get into it. The ground in a pen needs to be kept clean, either by spreading a heavy litter, such as that of tree leaves, which are regularly stirred and occasionally changed, or by regularly raking and removing bird droppings. Game birds, like chickens, can become afflicted with external parasites such as mites and lice.

GAME-BIRD BREEDING: Separate your breeders in the correct ratios of males to females for your particular species about 4–5 weeks before you will begin gathering eggs. Both males and females will be stimulated to produce if you supply 17 hours of light a day and maintain a temperature of at least 60°F.

Here is information on the specific gamebird varieties: first pheasants, then partridge, then quail.

Pheasants

Pheasants are large, colorful relatives of the other game birds—partridge, quail, and grouse. The males are the most colorful as well as the largest. Pheasants are not good egg producers, but they are, in many cases, beautifully feathered birds. They aren't the most practical for home food production, but they might make money for you.

Ringneck Pheasant

PHEASANTS FOR HUNTING: Some pheasants are raised for hunting. Raising sports-variety pheasants is under the control of your state game commission. In the states I know of, you must have a permit to raise them in captivity. In Idaho there are unannounced visits by an inspector making sure that certain requirements with regard to their housing and so on are met. So talk to your state game commission and find out the rules before you order a

game variety. They don't regulate the "show" pheasants—the goldens and silvers, for example.

PHEASANT HOUSING: Pheasants are the most timid domesticated bird there is. Free-running Chinese Pheasants will mate with chickens, resulting in an impractical hybrid. Pheasants will absolutely suffer in crowded quarters with lots of commotion. They need to be in a big, long pen where they can get away from you. It has to have a roofed top to prevent them from flying away. If they get out after belonging to you awhile, they may hang around, roosting on a board fence or some such until hunting season. Then they will disappear. They can generally take care of themselves in the wild okay, but to harvest them you may need luck and a .22.

DEBEAKING: Not necessary, says Tracy Haan of Sioux Falls, SD. Use a special pheasant lamp, plus mix baby chicks with the baby pheasants: "It works wonderfully." Separate the species when grown. "Adult pheasants won't pick each other if they have ample flying and roosting space (especially roosting space)."

PHEASANT REPRODUCTION: Pheasants are polygamous. For maximum economy, pen 1 cock with 4 or 5 hens. Don't put more than 1 cock in the same pen. Game hens have a tendency to leave the nest after their first few chicks hatch. You can take the abandoned eggs into the house and incubate them to finish up the hatch. Then add the remaining chicks to their mother's family. Or you can collect the eggs and do all the hatching in an incubator.

Incubating Pheasant Eggs. Pheasant eggs will hatch in 23–26 days, varying with the exact variety of bird. Forced-air temperature is 100°F, but the temperature in the last 3 days of incubation should drop to 99°F. Still-air temperature for incubation would be 101.5–102.5°F. Desirable humidity is 86–88. Do not turn eggs after 21 days. Humidity during the last 3 days should be 92–95.

Raising Pheasant Chicks. Chicks are available, May to August, from hatcheries. You can't tell ringneck pheasant chicks apart by sex until 6–8 weeks, when they finally develop distinguishing plumage. For a method of sexing day-old ringneck pheasant chicks, see *Sexing* (Stromberg Publishing; 800-720-1134). Use turkey starter or gamebird starter to feed them. (Or you can feed them a home-devised diet as you would for chickens—heavy on the protein side.) Young pheasants are easily stressed and need calm and routine. They are also highly cannibalistic and often use their very sharp beaks on each other, requiring an ongoing struggle with debeaking and anti-pick lotion on your part. Interesting food that needs a lot of picking at, like crisp fruit and vegetables and grain, also helps divert the birds from picking at each other. Pheasants mature in 26–28 weeks and will dress out at 2 ½–3 ½ lb. They start their own laying career at 7 or 8 months of age, or the next spring. Commercial growers bring them into production earlier using artificial lighting to create a long day.

⇒ **CREAMY PHEASANT** Using poultry shears, cut your pheasant into quarters. Sprinkle with salt and pepper. Saute the pieces in butter together with a bay leaf and a cup of chopped onion until the onions are transparent. Stir in 4 T. flour and continue cooking until mixture browns. Mix in 3 c. cream and simmer until the meat is cooked through.

Partridge

Before ordering partridge, check with the state gamebird regulatory agency in your area that controls wildlife management. You may need a permit. Chukar partridge come from India, weigh about 1 ½ lb., and are raised for meat. They have a beak that grows so fast,

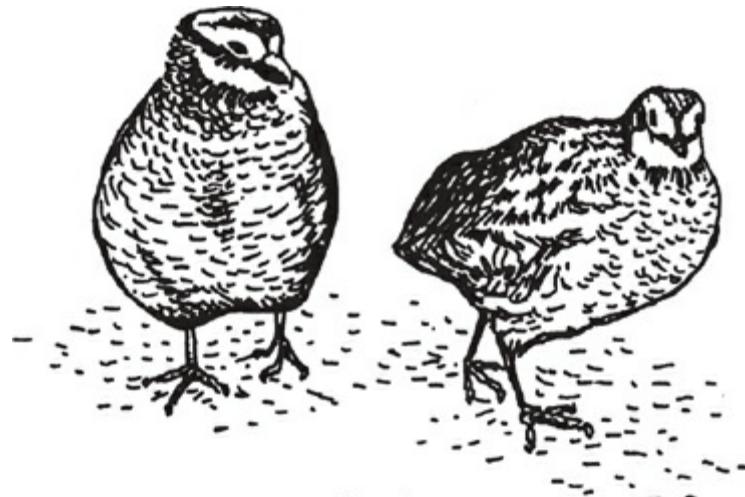

it must be trimmed (debeaked) frequently or it will become difficult for them to pick up feed. Males and females look the same, but the males are a little larger. Adult chukars are sexed on the basis of the leg nubs. The male has short nubs on both legs. Hens may have the nubs, but never as large as the male ones. Vent sexing is the surest way to tell. Chukars are not monogamous. They reach breeding age at 26–28 weeks, but hens will wait to begin laying until the next spring after hatch unless forced with artificial light (17-hour days).

SHELTER AND FOOD: A $2 \times 2 \times 4$ -foot pen could house 15 chukar. One 8 feet long could hold 30–35 chukar. Breeders are usually housed in a colony pen ($2 \times 2 \times 1$ foot) with 1 male to every 3 or 4 females. It's better to house these polygamous birds in separate families to avoid cock fights. Young chukars are easily stressed by rough handling, changing pens, changing their food, or changing their feeding routine. They do best if kept in the same pen from hatching to maturity, after which their nerves get calmer. Chukar do well on a gamebird ration, starter until 3 months old, then grower mash until butchering. For your breeders there's a gamebird breeder mash. After 6 weeks of age, supplement with grain and crisp fruits and vegetables to reduce cannibalism.

INCUBATING CHUKAR EGGS: The incubation period will be 23 or 24 days. Forced-air temperature for incubation is 100°F, dropping the last 3 days of incubation to 99°F. Still-air incubating temperature should be 101–102°F. Humidity is best at 80–82. Do not turn eggs after 21 days. Humidity during the last 3 days should be 90–94. For information on vent-sexing chukar chicks (and other fowl) see *Sexing* (Stromberg Publishing; 800-720-1134; strombergschickens.com).

Quail

These, and pigeons, are the smallest of the domesticated birds. Quail require the least space of any food-producing domesticated animal and can be raised in an apartment. A $2 \times 2 \times 8$ -foot pen could hold 50 quail. Coturnix and Bobwhites are the most commonly raised quails. Bobwhite quail are raised to eat as dressed birds and for shooting preserves. Coturnix are raised for their eggs (says my friend Lee, "Quail eggs are a son of a gun to peel"), as well as for meat. Blue Scale and Gambel quails are some rarer varieties. Bobwhites are the most difficult quail to sex. The vent system has to be used. Quail eggs are small. An incubator that will hold 90 pheasant or chukar eggs can hold 200 quail eggs. If the incubator can hold 300 of the larger eggs, it will hold 800 quail eggs. For more information consult *Albert F. Marsh's Quail Manual* (Garden Grove, CA: Marsh Farms, 1976) or *A Quail in the Family* by William J. Plummer (Henry Regnery Co., 1974).

Quail

COTURNIX QUAIL: After centuries of foreign cultivation, Coturnix quail were imported to the U.S. There are various breeds of Coturnix quail: Pharaoh, Tuxedo, Manchurian, Golden, British Range, English White, Australian Fawn, and Giant Brown. The Giant Brown was developed at Texas A & M Univ. by Dr. Fred Thornberry, Poultry Science Dept. It's a wide-breasted variety that reaches a tasty 10 oz. at 6 weeks. They're available from Bear Bayou Quail Farm, PO Box 514, Channel View, TX 77530; 281-452-5407; bearbayouquail@flash.net; www.bearbayouquail.homestead.com.

SEXING COTURNIX: In 2 varieties, the Pharaoh and the Manchurian Golden, the sexes can be color-distinguished once the chicks are 2 weeks old, at which time they grow new feathers with their distinguishing colors. Males have a reddish breast tint; females have a gray-mottled and more speckled breast. The other breeds are the British Range black quail, the English White, and the Tuxedo breeds, and they can be sexed only after 6 weeks, when they are sexually mature and the hens have started laying. A laying hen will have an enlarged vent of a more bluish color. The sexually active male has a ball-like appendage immediately above its vent. If the ball is squeezed, foam will run out. If the male does not have the ball, he will not breed. Coturnix females grow to be about 20 percent larger than the males. Females may be heavier yet because of the developing eggs in their bodies, so comparative weight can be another way to sex them. They also have different calls. The hen says, "whee-whee-whe." The cock says "grr-rrr-rrr-rrr."

Coturnix are rather sensitive to handle. Some people do very well with them; other people have a hard time getting very many eggs—and the egg is the basic purpose of raising them. They are a small bird with a very small egg, but those eggs are almost identical in flavor and nutrient content to chicken's eggs. And the Coturnix needs far less feed to produce the same weight of eggs. They start laying eggs when they are a little over 7 weeks old. They can be very productive egg-layers with high fertility, hardy, and fine to eat, though the dressed weight of a mature Coturnix is only about 4 oz. The hen quail averages 6 oz., the cock, just a shade less. Males can be eaten at 6–8 weeks. Coturnix quail are characteristic of their gamebird relatives, elusive and alert. If they escape—and it's possible—they will be gone forever. Low cages prevent injury from the quail's tendency to fly straight up. These quail require plenty of water because the egg the hen lays almost every day is 1/5 her body weight, and a good part water. Adult quail can eat turkey laying mash, or home-devised diet for confined guineas. You can experiment with other foods to see what they enjoy.

COTURNIX REPRODUCTION: To select breeders from a batch of chicks, choose at 6 weeks of age

healthy, active birds that have the proper breed characteristics. The ideal sex ratio is considered to be 1 cock per 2 hens, though they can be raised as monogamous pairs or in a ratio of 1 cock to 3 hens. Don't keep a solitary bird; they need a mate or the single may die. The young are mature and in full egg production by 35–50 days and will be fully grown at 10 weeks. The hens will lay 5 or 6 eggs per week, so 20 to 30 hens can lay about 1,250 eggs—which may be hatched or eaten—in 10 weeks. So their potential reproduction rate is phenomenal. Laying birds are fragile (egg inside!) and should not be handled unless absolutely necessary, and then very carefully. The Coturnix quail lays a large egg for its size, and, if not allowed to set, a lot of them—200–300 per year.

INCUBATING COTURNIX EGGS: The eggs should be incubated 16–18 days, 99.5°F (forced-air) or 101–101.5°F (still-air), at 85 percent humidity, turned a minimum of 4 or 5 times per day. Temperature the last 3 days of incubation can drop to 99°F. Do not turn the eggs after 15 days. Humidity during the last 3 days is best at 90–94. Regular incubator trays won't be suitable for the small quail eggs but can be adapted by using an upside-down egg tray in there to hold them. Using an incubator, your quail production, because of their rapid maturation and prolific egg-laying, can be extraordinary. For quail to set their own eggs, supply extra space and nesting material of soft grass. Each hen will produce at least 4 families per year, each of 10–14 young quail.

BOBWHITE QUAIL: These birds are monogamous and usually pair for life. The male has a white eye-stripe and brown throat. Females have a buff line through the eye and a buff throat. They are physically mature at 16–20 weeks and, if mated, will start laying eggs at 24 weeks. The mature birds weigh $\frac{1}{2}$ lb. If dressed out for eating, a Bobwhite will weigh a little less—about 6 oz. Bobwhite normally mate mid-May to mid-August and lay from 50 to 60 eggs (varying with climate and weather conditions). However, if provided 17 hours of light per day and kept in a temperature over 60°F, the bobwhite hens, once they reach the breeding age of 6 months, will lay eggs the year round—200 or more per year. Bobwhite quail will not set their own eggs in captivity. To incubate these quail eggs allow 23–24 days. Forced-air temperature should be 100°F, dropping the last 3 days to 99°F. Still-air temperature should be 101–102°F. Humidity should be 84–86. Do not turn the eggs after 21 days. Humidity during the last 3 days should be 90–94°F (wet bulb). In the brooder the Bobwhite chicks should start at 100°F, gradually reducing to 70°F when they are nearly grown.

QUAIL CHICKS: These are so tiny that if you use a regular poultry waterer, you must put rocks or marbles in the waterer to keep them from drowning. There is specially designed chick and adult equipment marketed for quail raisers. G.Q.F. Mfg. Co., P.O. 1552, Savannah, GA 31498, and Rocky Top General Store (see "Poultry Supplies" under "Chickens") are among those. Raise Coturnix quail chicks by "Chickens" directions with "Guineas" refinements. Or they can be fed gamebird starter to 6 weeks, grower to adulthood, and breeder ration for breeders. The chicks will die of dehydration before they'll drink dirty, stale water.

QUAIL HOUSING: A $2 \times 2 \times 8$ -foot pen could comfortably house 20–25 quail. If such a pen is divided into eight 1-foot-wide compartments, you could keep them in individual colonies; a pair of Bobwhite; a trio of Coturnix. When birds are housed in smaller groups it's easier to identify less productive and/or disruptive ones. A water trough in the back and a feed trough in the front is considered ideal. A wire floor allows droppings to fall through. If the floor is slightly tilted to one side, it allows the eggs to roll gently out of the pen to an

outside gathering place—which keeps them clean and makes them easy to get.

USING QUAIL MEAT AND EGGS: The young birds are fine eating, either roasted whole (for ½ hour), halved and broiled, or substituted in any squab (young pigeon) recipe. The eggs are a delicacy in the pickled form. Butcher at 6–14 weeks of age. (See “Pigeons and Doves” for directions on the slaughter of small birds.) Coturnix eggs are said to be “rich, mellow and usually served fried, poached, boiled, or pickled, are delightful decoratives in salad dishes, and make interesting appetizers and hors d’oeuvres.” That information was from Fred Frey, Missoula, MT. He also wrote, “Their meat is all dark, no white meat on the breast. Recipes include browning in a heavy fry pan followed by 45 minutes of baking. Some include sauces or baking along with a dressing. Very good if not allowed to dry out, which a small bird like this can easily do.”

Peafowl

If you join the United Peafowl Association (US \$25, Canada \$30, others \$35 per year), you’ll get the bimonthly *Peafowl Today*; peafowltoday@yahoo.com; www.peafowl.org. Bill and Monte Haney offer 30+ varieties of peafowl: Box 612, Angelton, TX 77516; 979-848-0407; www.bigtexranch.com. Visitors by appointment only. Roughwood Aviaries offers 17 kinds of peafowl and is “Home of the Purple Peafowl”; PO Box 71, Austin, IN 47102; 812-752-5227; in@scottsburg.com. Bayou Bird Farm has seven varieties: 846 Elsie Dr., Princeton, LA 71067; 318-949-2294. There’s more info in *Keeping Peafowl* by James Blake. D.C. Townsend offers more info on raising peafowl at www.peafowl.org/ARTICLES/1/.

PEACOCKS: Peacocks are not strictly the zoo bird you may think. Some homesteaders keep them and are really enthusiastic about their advantages. Besides those lovely feathers on the male, they are good to eat. The meat is fine-grained, tenderest when they are about 6–8 months old. They are as fine watchdogs as guinea hens. And also beautiful. Like a pheasant, they thrive in the woods, so they don’t need any feed in the summer. Because of that foraging ability, they are cheap to feed—if you have them running loose. (But loose animals can get into trouble.) They resemble a turkey in the diseases they are subject to. In winter, 25 pounds of corn will keep a pair right through.

Peacocks don’t become able to reproduce until 2 years old. The male doesn’t finish developing his beautiful plumage until age 4, or even 5. If you need to keep them caged, they require a big run because they are big birds. The run has to have a wire top because they are strong flyers and love to roost on places like the barn roof. The run’s fence must also be very tight to the ground; otherwise they may squeeze under, even at the cost of injuring themselves. That period of adjustment before they decide to belong to you and your place can be risky. If they escape from you they will be almost impossible to catch. They only lay once a year and not very many eggs. They will brood their own eggs, if given the chance.

PIGEONS AND DOVES

Both pigeons and doves are technically members of the pigeon tribe, but doves are smaller. There are many varieties of pigeons that vary considerably in size, color, and weight. Most pigeons are raised for meat because they grow so fast. In fact, during the 1930s depression, pigeons were the primary source of meat for many families. All of the pigeon and dove varieties are monogamous, raise young called squabs, and feed them “pigeon milk.” Pigeon milk is an interesting substance that is secreted by the lining of the

parents' (both sexes!) crop. The milk is rich in protein and fat and the parents pump it out of their mouths into those of the squabs. Caged pigeons must be confined as permanent pairs, but only a few pairs can produce enough squabs to vary your menu. You can keep them in wire cages or in ground runs.

BREEDS: Pigeons have been domesticated for thousands of years. There are squab recipes dating back to the Romans. There are many types and colors of pigeons to choose from. When you purchase your starting pair, be careful to distinguish between the squabbing breeds and the exhibition breeds—they are very different. The exhibition types don't raise as many squabs, their squabs are not as large, and they have a longer molting season and fewer squabs in the winter. The Runt (a breed unchanged since Roman times), White King, Giant Homer, and Mondaines are the premier squabbing breeds. They are big and healthy, and require only casual attention. Herb Schull offers 19 breeds of pigeons: W8744 Park St., Pembine, WI 54156. James M. Feasel offers several breeds: 419-639-2935; 2373 County Rd. 181, Clyde, OH 43410; jfeasel@glis.cc.

PIGEONS IN PRINT: *Making Pigeons Pay: A Manual of Practical Information on the Management, Selection, Breeding, Feeding and Marketing of Pigeons* by Wendell Mitchell Levi (1946) is a classic on the subject. Also try *Pigeons* by B. Hunt and B. Waldman (Prentice Hall, 1973); *Doves and Dovecotes* by Peter and Jean Hansell (Millstream Books, 1988); *Raising Turkeys, Ducks, Geese, Pigeons and Guineas* by Cynthia Haynes

Feathered World is the U.K. pigeon paper: 0844-556-0470; fax 0844-556-0471; Winckley Publishing, 197 Higher Walton Rd., Walton-le-Dale, Near Preston, PR5 4HS, ENGLAND; feathered.world@winckley.co.uk; www.winckley.co.uk.

PIGEONS GONE WILD: Pigeons bought to be pets or food animals will go wild, if they are neglected—or encouraged to be independent. If a pair move out of your cage, you'll have pigeons in your chicken house, pigeons in your barn loft, pigeons in your garage, pigeons in your machine shed. You can pat yourself on the back because the pigeons are foraging and making it quite well on food they steal from your other animals and neighbors. But if they are roosting over your car, you will have a fresh set of droppings on the hood every morning.

They will turn every building they sleep and nest in into a chicken house full of smelly droppings—"guano." They reproduce really effectively: in a few years your homestead may have more pigeons than are welcome. Cities are famous for their downtown pigeons, which is exactly the same situation, only a public problem rather than a private one.

Dealing with the Independents. If you get pigeons where you don't want them, you'll have to wrestle with the situation until they are all dead or back where they are supposed to be living. The adults can be caught, with effort, in traps. But it's not an easy matter to harvest squabs from the kind of places pigeons choose for their nests. (Best done in the dark with a flashlight and a bag to plop them into. Don't break your neck, leg, etc.) You can always invite your friends in for a shotgun hunt, if you live isolated in the country. Any pigeons are edible, but the old ones, like all old poultry, are only stew birds. Moral of that story: keep them in their cages.

Freeranging Pigeons. These roam to eat, but come home to roost. There are 2 very big arguments for their freedom. One is monetary: free pigeons will find much of their own food, yet come back home to roost, and you can still collect the squabs. (Independent

pigeons will raise only about 5 squabs per year.) The other has to do with time: free pigeons will subsist with only quite casual attention. So free-roaming pigeons are worth considering. When times are tough, it's hard to argue with a proposition like that. With luck, and occasional forceful management, you can insist that your pigeons live where you prefer them to, meaning a place where you can collect the guano, and where it will be wanted (in your pigeon loft) rather than on walks and roofs. Pigeon guano, like all poultry manure, is exceptionally good garden fertilizer.

Feed. To keep roaming pigeons coming back home, you feed them. They are generous about what they will eat and gratefully return home for—whole wheat, alfalfa leaves, or vegetables. They also like corn and peas. Purchase some grit specifically made for pigeons. Such foraging pigeons find insects and gather spilled feed from the pens of other animals. Confined pigeons are not efficient feed-to-meat converters. A breeding pair can consume 100 lb. of grain in the time it takes to produce 10–12 squabs. But if you do keep confined pigeons, feed them twice daily with a commercial pigeon ration or a high-protein diet, heavy on the grain and legumes side, together with grit and salt—and vitamin D (cod liver oil) every 2 weeks if they're getting inadequate sunshine. Temporarily confined pigeons have also done well on a combination of grains and legumes. Be sure all feed is dry and free of mold. Pigeons need plenty of clean water, both to drink and to bathe in.

Shelter. Free-roaming pigeons will appreciate a small home with at least enough room for nesting and eating your offerings. It can be like the shelter for confined pigeons, only with an outside landing perch next to a doorway for them to enter and leave. Their dwelling should be designed so that cats and other predators cannot enter. Build it so you can keep their loft dry and well ventilated. In cold weather your pigeons will need some extra warmth to keep their quarters above freezing, since they will still be incubating eggs or raising squabs. Confined pigeons need more room than you might think—they're not like *Coturnix* quail in this respect. A pair of pigeons will appreciate a dovecote (pigeon house) at least 4 feet square in floor area, about 2 feet high, with a chicken-wire partition to make 2 apartments. Provide a window for the front side of the dovecote, which you should place to get maximum sunlight. If you have the space, a $10 \times 15 \times 7$ -foot flying pen would be an ideal completion of the arrangement. Clean out the guano once a month. Provide a large pan of water for bathing as well as for drinking.

THE NEST: Each pair needs a nest. Use an old-time wooden orange crate sitting on the floor

of their room. Some pairs will maintain 2 nests, 1 with newly laid eggs and 1 with still growing squabs, which is why the dovecote needs 2 apartments. Provide straw, pine needles, or other fibers for nest-building material.

Getting a New Pair Settled In. You'll probably start by buying a pair or two of pigeons from a poultry dealer or a nearby pigeon owner. At least, you hope you have a pair. Pigeons are difficult to sex accurately, even by experts, especially when the birds are young. Be sure they are healthy. Swellings on the necks or near their mouths are probably canker disease. Have their shelter ready before you bring them home. Let them loose in it. Keep them there for 3 weeks. It must be a place where they can see out, if you intend to let them loose eventually and want them coming back. Feed them well. At the end of the 3 weeks, if you want them to be free, open the door to their flight deck, give them a little grain or other food every day, and that's all there is to it.

Domestic Relations. Sexing some breeds of pigeons is very difficult. Males are a trifle larger, act more aggressive, coo more actively at other pigeons, and may at the same time "dance" (strut and turn completely around). Males will fight other males. The male pigeon chooses the nest site, chooses his mate, and nudges her to his nest. Young pigeons first take a mate at 6 months. If you see a bird mounted momentarily on the back of another, you have a pair. At night, pairs roost side by side. Pigeons mate for life, but if widowed or divorced by humans, a pigeon will accept a new mate. The time to mate a pair is during the molting season, between February and July. Place the new cock next to the hen, but divide them in the center with chicken wire. The male will court his lady, billing and cooing in classical dove style. He also proves his practical abilities by feeding her partly digested grain. If she accepts, you can take out the partition and consider them a pair.

On the Nest. About a week after the molt is over, the hen will lay an egg, then another in a day or so. If the female lays more than 2 eggs, remove the extras. Two healthy squabs are all that can be expected at one time from a pigeon family. Once both eggs are laid, the pigeons will incubate them—both parents sitting in shifts on the eggs. Usually the female is sitting on the eggs from about 3pm, through the night, on until about 10am the next morning. Then the male takes over until afternoon when the female is back on. That's one way to sex your pigeons. The one on the nest at noon is probably the male. The one on the nest in the evening is probably the female.

Incubating Pigeon Eggs. To incubate pigeon eggs, allow 17 or 18 days to hatch. Use a forced-air temperature of 99.5°F; the temperature the last 3 days of incubation can be 99°F. Use still-air temperature of 101–101.5°F and wet-bulb humidity of 85. Do not turn the eggs after 15 days, and raise humidity during the last 3 days to 90–94.

Pigeon Parenthood. The eggs will hatch usually within a few hours of each other. The adults will do all the work of caring for the young, but you should make sure they have what they need. When a pair of squabs are about 3 weeks old, a good hen will begin laying more eggs. When the adult birds begin to incubate the new eggs, it is imperative that you remove their fledgling squabs to your table or deep freeze. Squabbing breeds have been developed with this expectation in mind. The squabs are very dependent on and demanding of the parents; it is too difficult for the adult pigeons to try to incubate eggs and care for squabs at the same time. But some, less prolific, pairs will wait 6 weeks to lay more eggs. If you are not rushed by the presence of new eggs, take the squabs when they're feathered out under the wings; they'll be about 4 ½ weeks old. You can slaughter them or feed them out to 6 weeks old and then slaughter. Your breeding pair will live to be about 7 years old, laying all the while.

Lice. Infestations of lice can be dealt with by adding small amounts (not more than 1 T.

per 2 ½ gal. water) of sodium fluoride to the pigeons' bathing water.

How to Kill, Pick, and Clean a Pigeon

Squab size is anywhere from 14 to 28 oz. Most breeds will attain this size in 25–35 days. Break the neck with a sharp, twisting pull. Cut off the head, hang by the feet, and let bleed. Or place the bird on a chopping block and sever its head with a very sharp knife. Now scald and pluck away the feathers (see directions in the "Chickens" section), or skin the bird. To skin a small bird, you tear open the breast skin and then pull skin together with its feathers upward and outward. Pull the skin off over wings, legs and back. To clean the bird, see instructions under "Chickens." The poultry scissors method is easiest with small birds.

COOKING PIGEON: Preparing squab shouldn't be confused with preparing gone-wild pigeons captured in the field, forest, or your barn. Exercise results in dark meat and the gamy flavor of wild things — which is not necessarily distasteful. But squab, since it has never done anything but sit and swallow, has pale meat and a mild taste. It will weigh ¾–1 lb. Squabs can be fried, roasted, or broiled. Older birds can be pot roasted, made into the traditional pie, or stewed.

⇒ **BROILED SQUAB** Split the bird and flatten the resulting pieces. Rub them with butter, and sprinkle on salt and pepper. Place them on the broiler, breast side to heat. Serve each half-bird on a thick slice of buttered, toasted homemade bread with a sauce poured over—either gravy or heated condensed mushroom soup.

⇒ **PIGEONS ROASTED IN GRAPE LEAVES** Brush the birds inside and out with melted butter and dust lightly with salt and pepper. Wrap each bird tightly and thoroughly in grape leaves—2 should do the job. Place the wrapped birds side by side in a baking dish, about 1 bird for each person you are feeding. Bake at 350°F until they are cooked through and tender. To serve, remove and discard the grape leaves. Make a sauce with the pan drippings, 2 T. butter, and the juice of a lemon, mix well, and then pour it over the birds on their serving platter.

⇒ **TRADITIONAL PIGEON POT PIE** Stuff birds (4 serves an average-sized family) with the stuffing of your choice (see recipes in [Chapter 4](#)). Sew the cavity shut with a needle and thread. Brown birds in butter. Place them in some sort of covered baking dish or pan. Add several onions, large carrot chunks, and whole potatoes—as many as your container will comfortably hold and your family can be expected to eat. Add 2 c. hot water, cover tightly, and bake at 325°F until the meat is tender (about 1 ½ hours). Cook giblets (not liver) separately. When giblets are tender, cut into small pieces and add them to the pot pie. When the pot pie is almost ready to serve, take out the meat and vegetables, and thicken the remaining liquid by adding 3 T. flour that has been premixed with ½ c. cold water. When your gravy has thickened, pour it back over the birds and vegetables and serve—or serve the gravy separately.

⇒ **ROAST SQUAB** Stuff the bird's whole cavity with the poultry stuffing of your choice. Rub the outside of the bird with celery salt and pepper. Place in roaster, cover, and bake at 400°F for 45–60 minutes. During roasting, frequently baste the bird with drippings. At the halfway point, turn so that both sides will have a chance to brown.

I've been doing fairs every weekend this fall, sitting behind my card table laden with copies of my book, working hard on this new edition while waiting for customers for the older one. People who don't know me are skeptical, hesitant when they see my hand-lettered, scavenged-cardboard sign, and multicolored, ringbound books with unprinted green cardboard covers.

Couldn't be worth much, they reason, a homemade book.

If they're curious enough to give me eye contact, I hand them the one-sheet brochure. Maybe a person pauses long enough to leaf through a sample copy. Perhaps he or she even buys one and carries it away—the expression on his or her face showing surprise at its weight. I watch the person going and I have to chuckle. Maybe I'll be sitting here years later and we'll meet again.

There's such a big difference between the new readers and the old ones. The old ones notice my table, creep up, and study the situation and me. Maybe they begin, "I have this book ..." talking so because they doubt that the dumpy, aging woman behind the table could possibly be the Carla they had imagined—so rumpled (from sleeping in the car) ... and where are all her little kids? (My kids are too grown-up now for tagging along with me to fairs. They're living with their own families, or off at college, or have their own weekend plans.) Eventually she, or he, hesitantly asks, "Are you ... Could you be ...?"

I say, "Yes, I'm Carla."

Or maybe they are able to recognize the person in the old photos of a younger me, now concealed behind aging flesh. Some people do. They greet me with a shout of acclamation, rushing up eagerly to tell how they got their first copy of the book, and their land, and what they learned to do on it, and what happened then. Often they buy the new edition and ask me to autograph it, or they go home and get their old one for that purpose.

I think of this book's readers as "my people." They're my readers, at least, the people who live my (our) dream in all its tawdry chicken-plucking day-in-and-day-out fine print. They're the people I've worked my writer's lifetime to serve. I want to touch these precious, truly beloved readers—real beside me at last. So we clasp hands across the table. Or, if they look like huggable sorts, I come around the table and put out my arms, and we hug each other with genuine feelings of love. I know that a particular reader is someone who already knows me well and cares about me. She or he's the person I've worked so long and hard to serve, visualized in my mind's eye, talked to as I wrote and wrote and wrote this book over the lonely days, months, and years.

Those meetings with loving readers are always a beautiful experience—my reward! Then I know it's all been worth it. And I'm again astonished, and humbled, to discover that a mere book can mean so much to people. The job of writing is indeed a special one. And the work truly is greater than the workman!

An extraordinary encounter of that kind happened one unforgettable day a couple years ago at the Missoula (Montana) County Fair. That time I did have several children with me, but they were all off watching the pig races. A couple came in the door of the Culinary Arts Building, where I'd just wound up a chicken-butcher demonstration. They were carrying a copy of the book, holding it together, out in front of them. They were both silently crying, unashamed, walking slowly toward me.

The audience for my chicken-butcher lesson had been very small. There'd been an article in the newspaper that I was at the fair, and the demo was in the fair schedule, but it obviously didn't hold nearly the attraction of the pig races. Just as well. It was embarrassing to realize that most of the people I was talking to knew more about chicken butchering than I did. But there were also a few genuine novices there, for whom I was so grateful. They were the ones I'd hoped to help when I put the event on my program. I knew it wouldn't be fun, but I'd been determined to do it. I knew nobody but me would ever have the gall to teach a chicken-butcher class. And that's among the things people tell me they most often have to do for the first time, depending only on what it says in the book.

Before it started, while my audience waited inside, I had to remove the poor “subject” from its wire carrying cage and dispatch it out back of the building with a few of the “students” observing. As I had arrived in what I imagined would be a proper alley, I observed to my horror there were hundreds of dressed-up fair attendees strolling by the site. And the knife I’d been provided turned out to be so dull it was a considerable achievement merely to draw blood, to say nothing of managing an elegant and humane execution of the bird. I was also trying desperately to keep my bird’s head way down in the 5-gallon bucket I had available, so it wouldn’t escape to do a flopping, blood-splattering extravaganza before all those noncomprehending and curious eyes. That achievement by the bird would probably have gained it the sweet revenge of landing me either in jail or in an asylum.

Well, I did finally manage to get the job done and brought my headless bird back into the exhibition hall. There I demonstrated its immersion in scalding water, picked off its feathers, singed away the remaining hairs, and finally demonstrated how to cut it into frying pieces. I felt so relieved when it was all over. I sat chatting with some of the people who’d come to watch, autographing books, answering a few last questions about the fine points of chicken butchering.

That was when I saw the couple come in the door and head straight for me, bringing their beat-up old book for an autograph. They hadn’t bothered dressing up, or maybe they didn’t have any better clothes. They slowly approached, eyes fixed on me. I stepped away from the people I’d been talking to and waited until at last the middle-aged couple stood before me. They were a decade or two younger than I, but still gray and dusty, shabby, holding that frayed green-covered book out toward me as if it were their ticket to enter—as if it were something so precious to them. The tattered book was darkened by years of ... Was it smoke from a wood cookstove in a small, poorly ventilated cabin? Did their lungs look like that inside? I wondered.

I smelled dope. They were both just reeking of marijuana. They were both looking at me, silently crying, tears running furrows of wetness down their dusty cheeks. What to do?

Like me, I thought, they were once so young and handsome, so full of hopeful dreams. Looking at them, I already knew the story: how they’d left a big city together years ago when they were young and moved to some version of the rural outback with such an optimistic, beautiful vision. How they’d struggled, worked, raised food, raised children, been scorned by some of their neighbors and their kids’ teachers—and finally, perhaps, even by their kids. But they never gave up. And they still did have their acres—I hoped—and each other, obviously. And that beat-up, much-used old book.

Well, they were definitely more “my people,” aroma and all, than those who sometimes show up—real-estate agent types, dressed to the nines, beaming at me, able to buy several more books to take with them, tickled pink with my role in their prosperity and, clearly, lifetime straight.

The couple stood crying before me.

I felt a sudden crushing emotion of shame. They’d taken it all literally, I thought. They actually went out and tried to live it—all of it. They stayed with it, never wised up, never went back to town as so many of the others had—others who bought the book and wrote me a Hooray-Carla-we’re-back-to-the-land letter, but later—a year or two, or five—the book was in their garage sale. They were outta there.

I felt so guilty, so sorry for this couple. I started crying too, looking in their eyes and knowing all that, all the suffering they’d gone through because of keeping so loyal to the Dream. Always raising and butchering the dang chickens themselves instead of buying

them ready-to-fry at the supermarket.

Should I be punished for articulating and promoting so hard, so costly, a lifestyle? Maybe I should be horsewhipped, tarred-and-feathered, dragged forever through a field of organic mud behind a stubborn mule in just retribution for setting their feet on that more rural path. How their parents who, years ago, must have planned an easier, more prosperous, more respectable life for them, must have been disappointed. Their parents probably hated me. I felt so guilty.

But I took a step toward them, toward the beauty inside them that radiated from under the shabby cloth, the aging skin, the trappings of poverty, the smell of burnt grass. Then they took the last step forward toward me. We, all three, put our arms around each other, and cried and cried. We cried together with the bittersweet intensity of summing up a life's meaning in a moment: mine as writer, theirs as readers. We were three people made one through the mysterious magic of a stack of printed and bound sheets of paper. We were so close, and it was so beautiful.

After a moment, whatever it was we were doing was done. The tension broke. Our wordless solemnity and tears suddenly turned to easy chatter and laughter, the way people act when they're coming out of church after services. Then they told me their story. Sure enough, it was all just as I had figured—except they didn't want me to feel guilty. They were grateful for the vision and the guidance I'd given them!

Then the woman confided that she wanted to be a writer like me and asked my advice. I gave my blessing and what wisdom I could, for that's another hard path.

I autographed their book. I gave them the latest edition (they couldn't afford to buy it) and was promised some home-grown food in trade (which they later sent to me). Eventually it all wound down, and they left. But I'll never forget that day ... that meeting ... them. They left me a gift of canned jam and a searing emotional memory I'll never forget and never escape. Sometimes it's scary being that involved in people's lives.

Five years later, I see the woman's articles in homestead-genre magazines quite often. It makes me happy and proud for her. She keeps getting better. She'll be doing her own book someday, I reckon.

INTRODUCTION

This chapter is dedicated to the discriminating woman who would rather own ... a cow or a goat!

September 1993. Almost done with the ninth edition. I am amazed at the sophisticated and widespread knowledge that exists these days among home-dairying people. Once, perhaps, I had a lot to offer here. I'm not so sure any more, but I've done my best to catch up on things and to update this section while staying within my time and space limitations. There are so many good books written about this area, so many opportunities for education and self-education, and so many dedicated dairy extension agents with information to offer. This chapter can now be thought of only as a place to begin. (Actually, the same can be said of every chapter in this book.) My hope is that I can still

be of use—by providing a little information on just about everything and leads about where to find more.

Marietta, the shorthorn cow, got mastitis Christmas Eve. So from then until now [April 1974], we had no milking cow. We finally squeezed out enough money—\$350—to buy a Jersey carrying her third calf, due to calve in August. She was number 108. I had a notion I'd go out and milk her for the first time and tell about the experience for the introduction of this chapter. I figured it would really be rapturous and poetical.

Well, that morning I couldn't get out the door without an entourage of Becca, 4, Luke, 2, and Baby Sara, 11 months. And for some reason they were all in bad moods and Sara was crying more on than off. We arrived at the barn accompanied by our dog, Thor, who not only chases chickens but also thinks he must impress milk cows with his importance. A cast of about 30 chickens were with us, too, pursuing the grain can I was holding, figuring on sharing the cow's feed.

Number 108 apparently had never been in the presence of whining children, a barking dog, or cackling, crowing, thieving chickens. She wouldn't move a foot when I tried to chase her, and she turned out to have a solid distaste for stanchions. Fifteen minutes later I was squatting in the middle of the barn holding crying Sara with one arm, trying to milk with the other, and admonishing the children and Thor by turns to be quiet. The chickens were in the manger eating the cow's grain. At that moment Dolly yelled from the house that I was wanted on the telephone, and I thanked God for mercifully giving me a release from my suffering.

When I returned to the barn after the phone call, I was alone because the baby was asleep in her crib and the other children were happily occupied elsewhere. The chickens had their tummies full of the cow's grain, so they were off looking for something more exciting—fat bugs perhaps. And I'd locked the dog in the house. By the time the milking was over, number 108 had developed such an affection for me that she followed me back to the house and walked around it for the next 2 hours, mooing longingly.

The homesteading literature is somewhat slanted toward goats. Goats are small, and they are playful, mischievous, and fun. But I've had experience with both cows and goats and let me tell you—cows may not jump around, but still water runs deep, and they sure enough have an emotional life. This morning I was getting ready to milk number 108, now called Nelly. I've submitted to her disinclination for stanchions and discovered it a blessing. I finally realized that I couldn't drive her anywhere because her notion is to follow me, and if I get behind her she just stands there. There's always a period of

adjustment when a new animal joins your family. A cow has a different mentality from a goat. Cows are very steady animals. Once a cow gets a notion of how things are supposed to be, that's the way she's going to proceed, and it's unreal for any mere human to try convincing her otherwise. But if you learn to yield a little to a milk cow's preferences, she can be really loving and giving in her own way.

So now I gather up the milk bucket. I use a plastic bucket because it's so much quieter—doesn't ping and startle the animals or me out of our reveries. And I fill ajar or pitcher part way with warm water and put a rag in it, for udder-washing and seduction. Then I go directly from the house through the gate into the field. Nelly sees me and comes right away. It's not good for milk cows to run. My father drilled that into me—never, never run a milk cow. Nelly used to run to me when she saw me, but that was when she was new and so nervous. When a 700-lb. cow runs up to you, that's too much love. You'd really rather she walked up—just in case her brakes slip. But now as soon as Nelly sees me she starts coming, following me to wherever I decide to stop. That will be a flat spot inside the barn or in the field, depending on the weather. If I bring grain and the chickens follow, Nelly starts eating the grain along with the chickens. She's used to them now. She has a much bigger mouth than they do, so they don't really get away with that much. I take my bucket and go to the rear and start milking.

It's so nice out in the sunshine. The children may be near, and the dog too, but Nelly is used to them now. Nelly, being a Jersey, isn't very high off the ground. I can even sit on the ground to milk. She's very careful not to move around while I'm milking. Instinct tells her she must be still. Her whole psychology is such a beautiful mixture of inborn wisdom about how she will take care of me (or a calf) and how I will take care of her (she's descended from millennia of "domesticated" human companions) that it's virtually a spiritual experience being near her. Her belly is hanging low because she's full of calf again. I think any animal—whether it be a goat, cow, sheep, reindeer, or yak—that goes through being pregnant, bearing young, and then using her own body to make food, enough food for her baby and mine too, deserves a lot of respect and affection. When I started writing this book I had goats. Now I have cows. They're both wonderful.

Dairying

SELLING DAIRY PRODUCTS: There's a big difference between home-dairying and dairying in order to sell your products. Even in places where milk can be sold raw, licensing is required, and the nannies or cows must be carefully tested and kept free of brucellosis and tuberculosis. Do you have money to invest in a special outbuilding for dairying, or a cheesemaking place? (You could sell stocks for financing.) Can you write a 5-year business plan? Have you studied your state's dairy laws? (In at least 21 states, for example, goat milk when retailed must be pasteurized—requiring an investment in equipment.) Have you talked to your dairy extension agent? That's somebody who's willing to explain everything, shepherd you through all the preparatory steps, guide you through the legal requirements for your building and equipment, and later regularly inspect for cleanliness and test your milk samples to be sure they don't contain bacteria or antibiotics. (Dairy production is the most heavily regulated and supervised food business there is.)

If so, then you're ready to start your dairy business. You could sell milk, cheeses, yogurt, maybe even meat and sausage products. But the more products you sell, the more start-up money you will need to build approved facilities. You'll also need a lot of marketing time and know-how—especially for selling goat's milk. Usually, the hardest part is finding the

money to pay for everything you need for the start-up of a commercial operation. The easiest commercial dairy areas to get started in are cheesemaking in particular, and the special services and specialty products markets in general. (For example, whole milk with cream that rises to the top and that is home-delivered in bottles is coming back in some areas.)

But to sell fresh dairy products (as opposed to processed ones), you must have the highest possible sanitary standards. Milk direct from a cow is 100°F. In a commercial dairy the milk moves through hoses directly from the cow to a plate cooler that in just a few seconds chills the milk to about 38°F. Then it probably goes to a stainless-steel tank, then to a pasteurizing unit where bacteria are killed and enzymes are neutralized. Then it is separated into skim and butterfat. Then a sophisticated system mixes butterfat in again but only in the amount right for the particular product: nonfat, 1 percent, 2 percent, etc. Then the milk is homogenized, a process that breaks big fat globs into ones so tiny they can't get together and float to the top but remain evenly distributed in the milk. Then the milk is piped to a machine and put into containers. Some dairy farms can't afford all that equipment and prefer to be part of a co-op, so they can truck the milk from their holding tanks to a center for the rest of the processing. But, one way or another, most dairies get their milk from the cow to the grocery store within 48 hours.

Dairying, like many kinds of farming, is a hard business to survive in and an easy one in which to lose your shirt. Between 1981 and 1991, the amount of money that farmers in Washington State received for milk decreased by more than 20 percent, even though the retail price of milk at the store increased 27 percent. During that period a lot of the Washington's dairy farmers left the business.

Dairy farming has changed a lot since my grandfather's day, when cows ate grass in meadows and were milked by hand. The basic trend has been to get big or lose out. Washington is one of the top dairy states and one where there are still many medium-sized herds harvesting the rich coastal mainland grasses. Here an average dairy farmer markets \$350,000 worth of milk each year from an average of 210 milking cows. That same farmer also has maybe 200 more calves, to be sold for beef, and heifers not yet come to milking age. Each year, the farmer will buy \$175,000 of feed, especially hay. Washington's dairy farms are small compared to the average California dairy operation, where 1,000-5,000 cows are the industry standard.

So you can see why commercial dairying tends to be a sophisticated big business, and why so many small dairies have gone under. The industry, nationwide, is increasingly dominated by mega-dairies, each with over 1,000 cows—almost always Holsteins—bred for maximum production, fed for maximum production, and living computer-monitored lives designed to wrest every possible ounce of milk out before the cow goes to the hamburger line.

They work hard for a living—the cows and the dairy farmers. And their product, milk, is a wonderful food, a high-protein food that is far, far more pure (as best I can figure it) than almost any captured-in-the-wild food. Milk is the most monitored food in the food chain! And if you have a bit of land with enough room for a couple goats or a small cow, you can have your own organic milk, butter, ice cream, etc., from animals who were fed organic foods. Because what comes out is as pure as what goes in!

DAIRY INFO AND SUPPLIES

Ascott Dairy offers a wide range of home dairying and cheesemaking supplies: Units 21/22, Whitewalls, Easton Grey, Malmesbury, Wiltshire, SN16 0RD, ENGLAND; 0845-130-6285 or 01666-826931; www.ascott-dairy.co.uk.

Caprine Supply offers a huge free goat supply catalog, including cheesemaking supplies: 800-646-7736; fax 913-585-1140; Box Y, 33001 W. 83rd St., DeSoto, KS 66018; info@caprinesupply.com; www.caprinesupply.com.

Cheesemaking Supply Outlet: call/fax 440-968-3770; 9155 Madison Rd., Montville, OH 44064; rmhcso@alltell.net.

CreamLine: This quarterly newsletter for small-scale dairy owners interested in on-farm processing also contains useful info for folks just making dairy products for family use. It's packed with hard-to-find sources for small-scale equipment, facts on pasteurization, cheesemaking, packaging, etc. It profiles successful small dairies and provides recipes for dairy products. While it's no longer published, back issues are available. Contact: Vicki Dunaway; call/fax 877-881-4073; PO Box 186, Willis, VA 24380; mail@smalldairy.com; www.smalldairy.com. Vicki has also published *The Small Dairy Resource Book*, a 56-pg. annotated bibliography of books, periodicals, videos, etc., on farmstead dairy processing: cheese, ice cream, butter—both production and marketing—which is first in providing small dairy info! To order a print copy (\$8), go to agmarketing.extension.edu/Commodity/PDFs/SmallDairyResourceBook.pdf or call 301-504-5411 (to order free publications). Vicki also publishes *Home Dairy News*.

Dairy Center Inc.: PO Box 2564, Ontario, CA 917626690; 909-628-4784; fax 909-627-8781.

Glengarry Cheesemaking & Dairy Supply offers equipment, supplies, etc., for making cheese, including molds, ingredients, and courses: 888-816-0903; fax 613-347-1167; PO Box 190, Lancaster, Ontario K0C 1N0, CANADA; info@glenngarrycheesemaking.on.ca; www.glenngarrycheesemaking.on.ca.

Hoegger Supply Co. offers all a goatkeeper could need, reasonably priced: 800-221-4628; fax 770-461-7334; PO Box 331, 160 Providence Rd., Fayetteville, GA 30215; hoegger@mindspring.com; www.hoeggerfarmyard.com.

Lehman's Hardware sells ready-made or custom goat and cow bells, each with a unique tone; milk pasteurizers; carved butter molds; milk cans; strainers; cream separators; butter churns; cheese presses; milk funnels and strainers; anti-cow kickers; milking stool, etc.: 888438-5346; www.lehmans.com.

NelsonJameson is a “food and dairy supplier”: 800-8268302; www.nelsonjameson.com.

New England Cheesemaking Supply offers equipment and info to make and sell cheeses. Free catalog: 413397-2012; fax 413-397-2014; PO Box 85, Ashfield, MA 01330; www.cheesemaking.com.

United Pharmacal Company carries lamb nipples—they also work for baby goats and pigs. They also carry animal antibiotics, grooming equipment, etc. Free catalog: 800-254-8726; PO Box 969, St. Joseph, MO 64502; www.upco.com.

Milk a Sheep? Cow? Goat?

If you're just getting started, your first big decision is what kind of animal to milk. Around the world not only cows and goats are milked, but also sheep, reindeer, camels, water buffalo, and others. Any dairy animal is a miracle of efficiency. Grass, vegetables, grain, water, and salt go in one end. Milk, baby animals (meat), and manure to build up your garden soil come out from various other locations. There is no waste. She can be purchased reasonably, moved from location to location—and will love you! But what kind to buy?

SHEEP: How about dairy sheep? Yes, you can milk sheep! They have wonderful milk. See [Chapter 11](#) for more on this. Nevertheless, most home dairymen will choose a goat or cow.

GOAT OR COW? Worldwide, goats are milked more than cows. Figured by percentage of body weight, a goat is more efficient and produces much more milk than a cow. On the other hand, cows produce much more meat from their surplus calves and can get along better on a basic pasture/hay feed. Any cow eats much more than a goat does and requires hay in quantity in winter, whereas goats can get along on less hay and quite a bit of vegetable food and brush. Cows give more milk per animal by far, and their cream can be more easily separated to be made into butter, whipping cream, or plain cream. A milk cow can be bred annually to a beef-type bull in order to have a beefy calf for eventual slaughter.

Expenses. You can keep about 5 goats to 1 milk cow as far as the expense of feeding goes. You won't have near the struggle keeping the cow out of the garden as you would with the goat. On the other hand, if 1 goat dies you haven't lost everything. Around here, a home-dairy-type Jersey could sell for \$800. A Holstein would cost much more—\$1,000 for an average dairy-quality Holstein, \$1,800 for a good cow that's bred-back to a good bull. If you get offered a cow for \$500 or less, it's somebody's cull, giving maybe 2 gal. per day. The least expensive cow would be a first-freshening ("to freshen" means to calve and give milk) heifer, but if it's your first time, you might be best off starting with a cow with some experience.

The best cow is one that isn't too old and is already rebred and trained to milk. How much milk should she give? Twenty years ago when I was first writing this book, a cow who gave 6 gal. per day was super. Dairies now have cows that are giving 12 or 13 gal. per day. That's how much dairy cows have been selected upward. But these super Holsteins are more prone to mastitis now than they used to be. And that's a ridiculous amount of milk for a family cow unless you're going to raise other animals on the surplus. Dairies usually sell off a cow as a cull when she gets down to 4 or 5 gal., and that's still a lot of milk for a family. One of the small, old-time home-dairy breeds, like a Jersey, may be more what you want. It's simplest for you if she's bred and in at least her second lactation.

Incidentally, by the time you get a cow or goat home, through the period of adjustment, and allow for exaggerations on the part of the seller, she may turn out to be giving a little more than half what you were promised. Which still can be a lot of milk.

Dairy-type bull calves now sell for \$140–\$185, a beef-type calf for \$185–\$250. If you bought from the dairy itself, you might get one for \$95–\$110. It's hard to find a young heifer calf for sale. People hang on to them. A cow grows up to weigh between 700 and 1,500 lb., depending on the breed. A bull can weigh around 3,000 lb. That's a lot of meat compared to a goat.

The price of goats is much less than that of cows, but is still much more than it was 25 years ago. Back then, a non-purebred milking nanny changed hands for as little as \$5, when you could get somebody to take one. Now a registered show-type milking nanny might sell for \$100–\$150, a grade milker for \$70–\$75, a young grade doe for \$35–\$65. Kids back then were generally given away. Now at the livestock auction, a 2- or 3-month-old buck may sell for meat for \$25, a doe for \$35. A year-old goat for butcher might bring \$75–\$110 from the ethnic meat buyers.

But livestock prices are volatile, responding mercilessly to the laws of supply and demand. I've lived long enough to have seen them take amazing crashes several times. I remember one such time—February 1, 1974—when the bottom dropped out of the beef market, and beef-type bull calves were selling for under \$10, others up to \$35. When

prices are like that, what a great time to invest in some animals for yourself! Milk cow prices hold fairly steady if the cows are in good health and sold privately. But when sold in the livestock auction ring, they are affected by the great fluctuations in beef cow prices and sell for per-pound prices, which can be low.

The Land Factor. Whether you have a cow or a milk goat (or goats) is a very individual matter and depends a lot on what kind of land you have, as well as on how much money you have to get started and your personal preferences. Some people get really hot arguing one against the other. I started out with goats because I started out poverty-stricken on 3 acres and had a chance to get the goats at \$5 a head. I've had as many as 20 at one time.

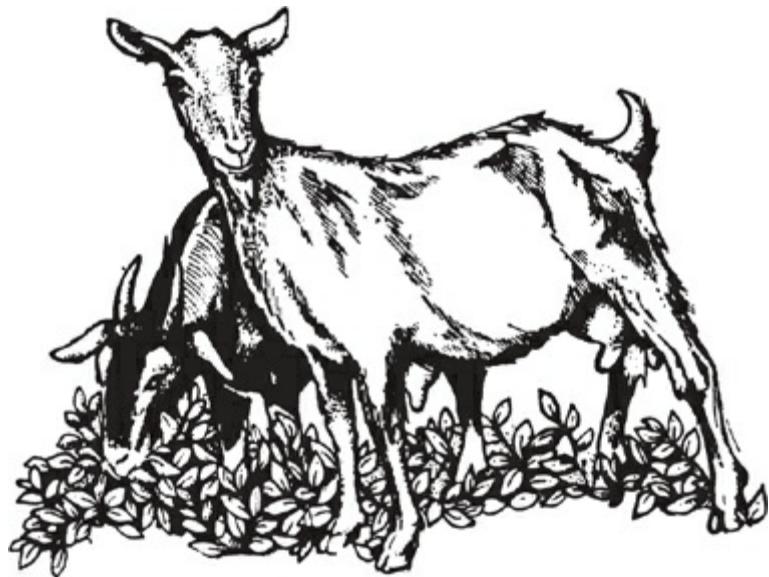

If you have a brushy cliff behind your house and just enough flat land for a vegetable garden, I'd say get a goat—it will thrive. If you are planning to homestead in dense timber where there is no open, grassy meadow, don't buy a cow. You'd have to buy hay year-round for her because you wouldn't have enough grass. Get goats. Their instinctive feeding habits are like those of a deer. By preference they eat twigs instead of grass, so they'll be delighted with a forest and will help make a clearing for you. They like to eat the young tips of trees and bushes—just the way you'd prune—but beware: they don't know when enough is enough and can kill the plant or tree. That's fine if you're afflicted with lots of dense brush. They'll keep it back. But protect your orchard!

If you have a nice alfalfa pasture and plenty of capital and you'd like to raise baby calves and pigs and lots of chickens, a cow would be very sensible. If you get a cow, you raise calves and dine on beef-steak instead of goat-burger. But how much land for a cow? You need at least 1 well-watered, good green acre for her grazing, either all at once or divided for rotation. Another lush acre will grow her winter feed, since an acre can grow almost 2 tons of hay and that's how much winter hay she'll need. With luck you can also graze her on her hay field—maybe the month of March before it seriously gets going, and then after your last hay cutting is off in August and September. A further eighth of an acre of garden will grow lots of winter veggies for her.

Goat's Milk vs. Cow's Milk. Like I said, I think any animal that shares the fruit of its body with us, be it milk or meat, is wonderful. I think it's disrespectful to cows to get too prejudiced toward goats. And by the time you're done reading this dairy section, you'll see that I love goats, too, just as much as any confirmed goat-lover does. The fact is that milk is milk, and it's food, and that's the important thing.

A poor goat in her first lactation may give only a couple of cups a day. A prime milk goat may give as much as 5 quarts a day. A small Jersey cow will give 2–4 gallons a day. Really fresh goat's milk tastes very like cow's milk. It does develop a strong taste more rapidly after that, but there's no need to drink old goat's milk unless you're trying to get cream to rise to the top of it. In that case you need to let it rest a few days. Don't judge fresh goat's milk by canned goat's milk. That stuff is pretty awful.

Goat's milk is prehomogenized like store milk, although given enough time some cream will finally rise to the top. You can skim it off with a dipper and have it on something for a real treat. Cow's milk is fun because the cream rises fast and clearly to the top, so you just skim it off and there's your whipping cream and cream for butter-making and cream to go in a pitcher on the table to pour over the strawberries. Some people struggle to make butter from goat's milk. I did, too, and made it. But I think the most sensible thing, if you're going to use goat's milk, is to just plan the menu around whole milk the same way you would if you were living on reconstituted powdered milk and you couldn't afford to buy cream or butter—only this way is so much better because the cream and butter is there—you're eating it—it's just not separated out so you can see it.

GOATS

You can raise goats for fun, for milk and/or meat, or to make a living. Here are some commercial options for goat keepers:

1. Use nanny goats to raise calves (25 goats can raise their own offspring plus 25 to 35 calves).
2. Sell milk from a goat dairy (you need pasteurization and bottling equipment, a big market reasonably nearby, and a willingness to work hard and constantly). You can get extra income by selling kids for meat at Easter time. There are hundreds of prospering 50–150-doe goat dairies in the United States, even some 500–900-doe dairies.
3. Manufacture goat cheeses: blue, caerphilly, camembert, cheddar, chevre, feta, semi-aged, soft-ripened, shepherd's, tomme, and capriano are all classic goat cheeses.
4. Sell fresh goat's milk curd (used in sauces and for making cheese—in 1988 goat curd sold in New York City for \$6.98/lb.), and goat yogurt (sells for more than regular cow yogurt).
5. Sell goats for meat (to the fancy restaurant trade) and for fine leather. This works well for people with a going grassland operation of sheep and/or cattle because meat (and/or Angora) goats eat some plants that sheep and cattle don't, and the three animals pasture well together.
6. Raise goats for fiber—angora or cashmere. In 1988 mohair sold for \$1.75 to \$7.25/lb. (depending on the quality). That same year, cashmere “down” sold for from \$39.68 to \$77.93/kg. Fiber-goat raising comes under the Wool Act.
7. Train wethers (castrated male sheep) to pull, either alone or in a team. One can pull a small cultivator or a light wagon loaded up to 2 times his weight. He should be taught to lead at 2 months, be halter-broken by 6, harness-broken by 8, pulling loads by 10. Use verbal commands as with oxen. Dairygoat suppliers sell goat harnesses and carts.

GOAT INFO: *Raising Goats for Milk and Meat* by Rosalee Sinn is available from Heifer International: 1 World Ave., Little Rock, AR 72202: 800-422-0474: www.heifer.org. This spiral-bound training manual has been used worldwide to teach goat care. It's suitable for 4-H. You might also read *Practical Goatkeeping* by Jill and John Halliday (1990); and

Raising Milk Goats Successfully by Gail Luttmann (1986). Older classics are *Raising Milk Goats the Modern Way* by Jerry Belanger; *The Goat Owner's Scrap Book* by Dr. C. E. Leach; *Management and Diseases of Dairy Goats* by Samuel Guss, DVM; and *Fundamentals of Improved Dairy Goat Management* by Robert A. Jackson, DVM, updated by Alice G. Hall. *One Day with a Goat Herd* by C.J. Stevens is good for beginners. *Your Goats* is G. Damerow's 172-pg. guide to raising and showing goats, including how to buy, raise, choose a breed and equipment, etc. *The Illustrated Standard of the Dairy Goat* by Nancy Lee Owen covers buying, breeding, showing, and milking.

English books are *All About Goats* by Lois Hetherington (1992) and *Goat Farming* by Alan Mowlem (1992). Mowlem's book covers goat keeping in developing countries and exotic/tropical goat diseases. It's available from The Smallholder Bookshop: 01953-498040; sales@smallholderbookshop.co.uk; www.smallholderbooks.co.uk.

The Pack Goat by John Mionczynski explains the use of goats as pack animals. These bright, cooperative animals are good for rough trail hiking. A goat can carry a load that's 20 to 40 percent of its body weight. *Life in the Goat Lane* by Linda Fink covers shows, breeding, kidding, etc.

The National Goat Handbook is a comprehensive source of information on goat breeds, diseases, dairying, and much more: outlands.tripod.com/farm/national_goa.... Clemson University has a goat behavior page complete with videos: www.clemson.edu/cafls/departments/animal_vet_science/behavior_database/goat.html.

MAGAZINES, NEWSLETTERS, STORES, CLUBS

American Dairy Goat Association offers a wide choice of books and videos on goats, and it's the biggest registry for the six major dairy breeds. It publishes a directory plus info handbooks and has a question-answering service: PO Box 865, Spindale, NC 28160; 828-286-3801; fax 828-287-0476; info@adga.org; www.adga.org.

American Goat Society also registers main dairy and pygmy goat breeds and trains judges: 830-535-4247; fax 830-535-4561; PO Box 63748, Pipe Creek, TX 78063; office@americangoatsociety.com; www.americangoatsociety.com.

Boer Goat and Meat Goat On-Line Magazine is a busy commercial site with announcements, advertisements, a breeder's directory, and articles: www.boergoats.com/. Cornell University's web info at www.ansci.cornell.edu/goats/index.html (click "Resources" and then "Marketing Products") advises on starting a meat goat operation. Additional info is offered at two other Cornell sites. (To access these sites see www.ansci.cornell.edu/4H/goats/index.html and www.sheepgoatmarketing.info.) They also offer an Ethnic Calendar and the Empire State Meat Goat Producers Ass'n: www.esm GPA.org.

"**Cyber Goats**," at www.cybergoat.com/, is a busy website that offers classified ads, breeder's links, auction notices, list of caprine vets, breed lists, online auctions, national breed show announcements, and links to various breed talk lists.

Dairy Goat Journal has served goat owners since 1916: 800-551-5691; fax 715-785-7414; 145 Industrial Dr., Medford, WI 54451; \$21 for 6 issues/yr; \$35 for 2 yrs (12 issues); csymag@tds.net; www.dairygoatjournal.com.

Goat Rancher covers the meat goat scene: 888-562-9529; 225 Hankins Rd., Sarah, MS 38665; www.goatrancher.com.

Institute for Goat Research offers courses and demonstrations: Box 730, Langston, OK

73050; 405-466-3836; www2.luresext.edu/goats/index.htm.

Jack & Anita Mauldin Boer Goats is a website that shares Boer goat info and some general goat info also. Articles on “Goat Birthing from Beginning to End,” “State and Federal Scrapie Requirements Program,” etc.: 260 County Rd. 1286, Ector, TX 75439; 903-961-2050; [jjack@jackmauldin.com](mailto:jack@jackmauldin.com); www.jackmauldin.com.

“**Meat Goat Blog**” is a meat goat blog with excellent information and resources: www.meatgoatblog.com.

Meat Goat Monthly News and/or *Ranch & Rural Living Magazine* (\$25 for 12 issues/yr) covers meat goats, the wool and mohair industry, and goat shows: 325-655-4434; PO Box 2678, San Angelo, TX 76902; info@ranchmagazine.com; www.ranchmagazine.com.

GOAT VET RESOURCES: *Fundamentals of Improved Dairy Goat Management*, by R. A. Jackson, DVM, and Alice Hall, combines the know-how of a goat keeper with the expertise of a vet. *Goat Health Handbook* provides diagnosis/treatment info for goat diseases. Both are available from Winrock International Institute for Agricultural Development, 38 Winrock Dr., Morrilton, AR 72110; 501-280-3000; information@winrock.org, \$8.50; www.winrock.org. *The Goatkeeper’s Veterinary Book* by Peter Dunn, B.V.Sc. (an English book), and *The Management of Diseases of Dairy Goats* by Sam B. Guss, DVM, an older book on this subject, are available from Caprine Supply. You may find *Natural Goat Care*, by Pat Coleby, also helpful; www.amazon.com.

DIETARY SUPPLEMENTS: I deeply appreciate the nutritional supplements I take. Your hard-working dairy animals may benefit from some, too. You can buy herbal supplements, books, vitamins, minerals, colostrum, milk replacers, medications, etc., from Nutritional Research Associates: 800-456-4931; Box 354, South Whitley, IN 46787; and Vita Stress: 1202 13th St. SW, Puyallup, WA 98371; 253-203-8303; www.vitastress.com.

A footnote: I enjoy noting a resemblance between people and their favorite animals. (I've always had Border Collies, or a Collie/Husky cross—strictly working animals for this workaholic woman!) Is that true of the chosen milk animal also? Goat keepers do seem to produce far more books and magazines than cow keepers! Is that because goat keepers, like their inquisitive charges, are a more paper-loving (literary?), or more social and lively group? Are cow keepers, like their bovine milkers, more sedate and reserved, with less appetite for newsprint?

COURSES ON GOAT KEEPING: YOU can study “Dairy Goat Production #225” by correspondence. Write Independent Study, University of Guelph, Guelph, Ontario, Canada N1G 2W1. The course teaches breeding, feeding, housing, herd health, and kidding. Slides and tapes included. Incidentally, this is the best mail-order education I know of on food production skills in general. The program is managed by the Ontario Agricultural College, 519-824-4120 ext. 56211, fax 519-824-9813; www.oac.uoguelph.ca. You can take courses just to learn or for a diploma. There are dozens of possible choices from “Making Maple Syrup” to “Greenhouse Management” to “Livestock Biology and Butchering” to “Marketing for Small Rural Enterprise.” Their program combines manuals, videos, tapes, assignments, and a telephone counselor.

You can also enroll in the Dairy Goats correspondence course from Pennsylvania State University, 307 Agricultural Administration Bldg., University Park, PA 16802, for 9 lessons covering dairygoat origins, characteristics, feeding, care and management, breeding, housing, and equipment. In-person courses and demonstrations are offered by the

Institute for Goat Research, Box 730, Langston, OK 73050, 405-466-3836; www2.luresext.edu/goats/index.htm; the Dairy Goat Research Facility, University of California at Davis, Animal Science Dept., Davis, CA 95616, 530-752-6792; <http://animalscience.ucdavis.edu/facilities/goats>; and also at the International Dairy Goat Research Center, Prairie View A&M University, Box 4079, Prairie View, TX 77446, 936-261-3311.

Barney Harris, Jr., Extension Dairyman at the Florida Cooperative Extension Service, 203 Dairy Science Building, University of Florida, Gainesville, FL 32611, 863-763-6469, dairy.ifas.ufl.edu/index.shtml, is eager to send people goat information. Or you could study there in the Dairy Science Dept., where he is a professor, and get a degree in dairying!

GOAT ASSOCIATIONS: There's the American Dairy Goat Association, Box 865, Spmdale, NC 28160, 828-286-3801; fax 828-287-0476, a registry for the 6 major dairy breeds (the biggest). It also puts out a directory plus informational handbooks and has a question-answering service. Canadians can join the Canadian Goat Society, Box 357, Fergus, Ontario, Canada N1M 3E2; www.goats.ca. If you want to research goats, try the International Dairy Goat Registry, Rt. 1, Box 265-A, Rossville, GA 30741; www.goatidgr.com, which registers all breeds and also offers a library and archive.

GOAT-KEEPERS' SUPPLIES: Hoegger Supply Co. has a \$1 catalog that offers everything the goat keeper could possibly imagine needing. Write P.O. Box 331, Fayetteville, GA 30214, 800-221-GOAT. There's also Caprine Supply, Box Y, DeSoto, KS 66018, 913-585-1191.

GOAT WORDS: I've heard you shouldn't use "billy" and "nanny"—you should use "buck" and "doe" instead. But "nanny" is also commonly used and the goats don't care! I hate to hear a non-pedigreed goat called a "scrub" though. It really puts her down unnecessarily. The word "chevon" means a goat intended for meat, or goat meat itself. A "wether" is a castrated male goat. "To kid" is to give birth, when speaking of a goat.

Getting Started with Goats

HOW MANY GOATS? Let me deal in conservative figures in case your goats turn out to be average or worse. Such a goat gives about 3 qt. milk per day. You'll need 1 qt. per day to feed her kid, and more later, leaving only 1 ½ qt. or so for your family. Yearlings won't give even that much. They aren't as large as full-grown goats and their teats and bags are smaller. At one time I milked 2 mature nans and 2 yearlings. I got only about 1 ½ gal. per day, and that barely supplied the 2 nan kids that I was feeding plus our 4 children, me, and Pa. Now, as I write this section about goats, I'm milking 7 goats and that includes some really good ones. I get about 6 gal. per day. With this supply I always have plenty for the family, for making butter and cheese, and for raising 2 pigs. You really can't have too many does. You can get them to adopt a calf or a bum lamb or let them raise their own kids for meat or market crop if you don't want to bother milking them. If you feed a milk goat really well, including vegetables and grain, she'll give more milk and can be milked for as long as 2 years on one freshening. The basic rule of thumb though is that you need 1 goat per person in your family in order to have all your dairy product needs met.

COMPANIONSHIP: Goats need companionship to be happy. But it doesn't have to be another goat. A sheep, a cow, or your children can serve the purpose. Chickens can't, though. A chicken just does not have it—except to another bird. Dynah Geissal, whom I am honored

to call friend, and who regularly writes for many of the best homesteader magazines, advises: "A goat is a herd animal. If she must live alone, you will become her herd. This can be fun sometimes and maddening the rest of the time. She will get along with other livestock, or even a dog, if there are no other goats, but she is happier being one of a goat herd."

By the way, Dynah generously shared her wisdom for many parts of this section on goats. You'll find that she and I don't always agree on the details, but she may be right and I wrong, and I wanted you to benefit from her experience.

WHAT AGE TO BUY? Says Dynah Geissal: "Buying a kid has some advantages: you learn while she learns, but you'll wait a long time for milk. An older doe who is past her prime, but still in good health, may be a good bet. If a goat owner shows you an older doe who has been a special favorite, a good milker, and a good mother, you may have found a goldmine. You may be inexperienced, but your older doe is not." Let me add that a yearling usually doesn't produce well, but if she has good genes, she probably will. Your goat will give more milk each freshening up to age 6 or 7, with the years 4–6 being usually her highest production time. But with good care she'll keep freshening and milking well right on to age 10 or older.

BREEDS: I won't state a preference among the full-size dairy goat breeds. They're all wonderful. But individuals vary. There are more than 50 goat breeds (more than 200 worldwide). Visit the website at Oklahoma State U. for profiles on each one: www.ansi.okstate.edu/breeds/goats/kinder/index.htm.

MEAT GOATS: Read Sylvia Tomlinson's 1999 book, *The Meat Goats of Caston Creek*, and *Meat Goats: Their History, Management and Diseases* by Stephanie Mitcham (a veterinary pathologist) and Allison Mitcham, a good coverage of diseases and treatments. "Meat Goats Make Money" is an audio from *The Stockman Grass Farmer*: 800-748-9808; PO Box 2300, Ridgeland, MS 39158. You'll find ATTRA's "Sustainable Goat Production: Meat Goats," at www.attra.ncat.org/attra-pub/meatgoat.html.

QUESTIONS TO ASK BEFORE YOU BUY A GOAT

1. What breed or cross is she?
2. How old is she?
3. Is she bred?
4. To what kind of goat?
5. When will she freshen?
6. How many times has she kidded before?
7. How many kids did she have? (Goats can have anywhere from 1 to 4. I had a goat who had 3 every time.)
8. Or, how long has she been milking?
9. What is it like to milk her? (Try it yourself, if possible.)
10. How much milk does she give?

11. How many teats does she have?
12. Does she jump fences?
13. Is she hard to catch?
14. Does she bite or butt other goats?
15. Has she had a distemper shot?
16. Are there tumors or abscesses in her udder?
17. Will she lead?
18. Can you watch her being milked? Examine her milk for signs of mastitis: strings, clots, blood, etc.
19. Have a look at her parents if she's young, at sisters and brothers if she's older, to view her wider gene pool.
20. Ask her owner to show you how to do hoof trimming and where stud service is available.

NOTE: Tuberculosis and brucellosis are rare diseases but are worth taking care about because they can infect humans through the milk. Buy animals that are guaranteed free of these or get them tested yourself before drinking any milk.

Boer. These stocky, muscular, meat-type goats were developed in South Africa in the '30s. They came to the U.S., by way of New Zealand, in 1993. They are most common in the Ozarks, Southwest, and Texas where they clean up brush and are marketed for butcher (best prices near Moslem holidays and in winter). International Boer Goat Ass'n (IBGA) membership info is available from: 903-364-5735; PO Box 1045, Whitewright, TX 75491. Boer Goat Breeders' Ass'n of Australia offers literature and info, registration, etc.: (02) 6773 5177; fax (02) 6772 1943; c/o ABRI, U. of New England, Armidale, NSW Australia 2351,AUSTRALIA; www.australianboergoat.com.au.

You can buy Boers from Sherwood Farms: 417-995-4691 or 417-880-1452; 363 State Hwy. 245, Dadeville, MO 65635. Other Boer goat breeders can be found at www.ranchmagazine.com/breeder.html.

Kiko. This New Zealand meat goat was imported to the U.S. in 1991. Dr. An Peischel has an outstanding herd: 615-963-5539; fax 615-953-1840.

Spanish. This is the goat equivalent of the beef cow, a meat rather than dairy breed. Spanish goats are tough, thrifty, and hardy. They may be kept in flocks of 350 to 400 does if you have lots of pasture and some Pyrenees dogs or equivalent to keep coyotes and wild dogs off. Available from 8-Mile Ranch, Jim Willmgham, PO Box 1828, Uvalde, TX 78802-1828; 830-278-3884.

DAIRY GOATS

Alpine. Alpines come in a variety of colors and patterns. French Alpines were very good milk producers for me. Alpines are Dynah's favorite breed: "They are independent, quiet, hardy, and give large quantities of milk. They are friendly and affectionate, yet go about their business when you are not working with them." Merryl Winstein raises dairy goats: Sunnystimes Dairy Goats, PO Box 19875, St. Louis, MO 63144; 314-968-2596. Or Sheradee Peyton, 4496 N. 172nd, Walkerville, MI 49459; scottpeyton@hotmail.com. Or contact Alpines International: Tina Antes, Alpines International Secretary/Treasurer, 7195 Cty.

Rd. 315, Silt, CO 81652; www.alpinesinternationalclub.com.

La Mancha. No ears and full size means it's a La Mancha, a great milking breed. Saanen, French Alpine, and Toggenburgs have a similar size and milk production, erect ears, and are of Swiss origin.

Nubian. Nubians are the same on size and milk production as LaMancha, but have long, drooping ears. They're from Africa and withstand heat well. They have good dairy temperament.

Oberhasli. This is a relatively new breed of full-size Swiss dairy goat. Try the Oberhasli Breeders of America for a directory of breeders: www.oberhasli.net.

Saanen. These are among the largest and most popular of the Swiss breeds. Mature does weigh 135 lb. or more and stand from 30 in. at the withers. Bucks weigh from 185 lb. and are a little taller. The Saanen's hair is quite short and all white. Saanens are terrific milk producers, and also good-natured, patient, long-suffering, people-loving goats! I had one called "Angel" and it was a fitting name. Contact: National Saanen Breeders Association, www.nationalsaanenbreeders.com; \$15 to join. More info is in *Saanen Roots* by Allan L. Rogers (available from Caprine Supply).

Toggenburg. Toggenburgs are always some shade of brown with white markings on the face and rump. Among the goat breeds that I've had experience with, Toggenburgs far and away impressed me the most. Mine were persnickety aristocrats. It was an old Toggenburg that usually bossed the herd. Toggenburgs had very definite notions as to how I ought to handle them and were more independent than the rest, but, wow, did they ever give milk. They were also in the front line when it came to fighting coyotes. The Toggenburgs always got the most blood on their horns. Visit the National Toggenburg Club website for information about shows, breeders, and membership; www.nationaltoggclub.org.

FIBER GOATS

Angora. Angora goats originated in the Himalayas. At this point I am interrupted by a polite but testy letter from writer-about-Angoras Sue Drummond, who did me the favor of stating: "I have no idea where you got your information on Angora goats, but most of it is way off base. The following is what I would suggest you print about Angoras." So, yours-truly-always-and-humbly-grateful-to-be-corrected cut out all the "off-base" stuff, and here's the word from a true expert instead! Bruised feelings aside, I'm honestly grateful anytime somebody who knows better takes the trouble to straighten me out. Now here's Sue:

"Angora goats originated in the Himalayas and have been kept for their luxurious fiber for centuries. They are white, long-haired goats that produce mohair. Angora goats are not kept for their milk. Their hair grows around one inch a month all year round. They are the most efficient producers of fiber of all animals except for a few breeds of wool sheep. Angora goats are sheared twice a year in the spring and the fall. An adult doe produces from 10 to 16 lbs. per year."

"Mohair is valued for its properties of sheen, loft or fluff, strength, fire resistance, soil resistance, and its ability to take dye brightly. Raw mohair can be processed for handspinning by washing and rinsing it in 140°F water using dish-washing liquid. Care must be taken not to agitate the hair too much during washing and it must not be dried in a dryer. The mohair can be carded and spun and dyed in the yarn or dyed before spinning."

"Texas is the largest producer of mohair in the world after South Africa. Texas is the home of around 2 million Angora goats. Other states such as Oklahoma, Arizona and New

Mexico also have substantial Angora goat populations and Angoras are found in nearly every state in the United States.

For more info on Angoras, contact the American Angora Goat Breeders Association: 830-683-4483; PO Box 195, Rocksprings, TX 78880; www.aagba.org. Ranch Magazine prints articles about Angora goats: PO Box 2678, San Angelo, TX 76902; 325-655-4434. And check out *The Complete Angora Goat* and *The Angora Goat Book & Guard Dogs*, a guide for beginning Angora goat raisers by Jean Ebeling, \$26 (postpaid): 5443 CR 401, Marble Falls, TX 78654. And the East Angora Goat Breeders Ass'n, Bob Ramirez: Keldaby Farm; 413-624-3090; 12 Heath Rd., Colrain, MA 01340; www.keldaby.com. Cerulean Farm offers Saanen dairy goats, Angoras, Anatolian shepherd guard dogs, and spinning equipment: PO Box 100, Harrah, OK 73045; 405-356-2612; bluemohair@earthlink.net.

Cashmere. These goats are another fleece type. They produce "cashmere," which is not the same thing as the mohair that angoras produce. Cashmere is a fine under-down that cashmere goats grow between the longest day in summer and the shortest day in winter. Their body hormones are triggered by shortening day-length to grow it. They shed the cashmere in the spring, unpredictably any time between January and May. You can't comb the down out until it becomes loose. If you leave combing too long, you'll lose it. The finest cashmere goats are said to be in China, but they're also grown in Turkey, Iran, Iraq, New Zealand, and Australia. Some are being imported into the United States.

Cashmere goats are available from Cashmere Goat Registry of America: 22819 Stanton Rd., Lakeville, IN 46536. Or Flying M. Manor, Sarah Mace; 920-836-2769; 3788 W. Breezewood Lane, Oshkosh, WI 54904. For more info, contact Northwest Cashmere: northwestcashmere.blogspot.com. Or International Cashmere Co.: 614-493-2401; 614-493-2595; PO Box 845M, Piketon, OH 45661. There are three cashmere processing plants in the U.S. (eight in the world). More info is in the *Cashmere Goat Manual*, which started as a project for the El Paso County 4-H Club. It's \$10 from Jim Osborn, 3585 Spaatz Rd., Monument, CO 80132; 719-488-8860. And read *Angora Goats the Northern Way* (1988), by Susan Black Drummond; and *Angora Goat and Mohair Production* (1993), by Maurice Shelton. Or contact the Australian Cashmere Growers Association: <http://acga.org.au>.

Nigerian Dwarves. These little spotted or patterned, naturally horned, dairy goats come from West Africa. If milked, they give about $\frac{1}{2}$ gal. per day. They will mate all year round and can be bred every 8–10 months. Kathy Claps wrote me: "This is a small breed, as small as the Pygmy, but has a more refined, dairy-type conformation. They are found in a great variety of colors and milk quite well for their size." The American Nigerian Dwarf Dairy Association is the national breed club: PO Box 96, Monticello, NM 87939; www.andda.org. Or contact Penny J. Tyler: Tupence Nigerian Dwarf Goats, PO Box 799, Allyn, WA 98524; 360-275-4236.

Pygmy. An adult goat that never gets more than 20 inches high is a Pygmy. They can be milked but only give about $\frac{1}{3}$ as much as a full-sized goat.

Or you could have a cross between any 2 or more of the above breeds.

MOVING YOUR NEW GOAT: When you buy a goat, find out how the current owners get her places. Do they lead her with a rope or shake a can of grain in front of her nose? This information immediately becomes very important. It's nicest if she's broken to lead. All my new or naughty goats wear collars with a short rope attached. It makes it easier to grab them and get them started leading. I don't like the grain-can bit because with a big herd and some calves and horses in there too, I'm liable to get trampled. But for just a few goats it's a good technique to train them to follow as you walk along holding the can, occasionally shaking it so they can hear the scrumptious noise. Stop and give them just a

bite before they start or whenever they look like they're losing faith in you and the can. Or you can grab the horns and just drag them along with somebody behind to push—a time and place when horns are useful, but still a desperation measure. Or you can carry them—another desperation measure.

THE BUTTING ORDER: Goats are rough on each other. They occasionally even bite each other. A big goat with big horns will bully a new goat, especially a small one, and keep it away from the food. If you're planning to have just 2 goats and have small quarters for them to live and eat in, it would make sense to get 2 goats that are dehorned or naturally hornless. And make that either 2 yearlings or 2 adults while you're at it. There are exceptions, though. I had a yearling once that was so mean to the big goats I had to sell her. Generally, though, once a herd gets established and used to one other, they all live together fairly peaceably. Given time, any combination of goats will become pals. A boss goat always emerges, too, usually a big, older nanny. She will lead the herd out to feed in the morning and back home at night. But goats aren't necessarily charitable to the weak. If a goat seems hurt or sick, put it in a pen by itself with water, straw or hay bedding, and good food. The other goats probably wouldn't let the sick one get its share of food and might persecute it to boot.

Fencing, Housing, and Food

FENCING FOR GOATS: The biggest problem with any goats, male or female, is controlling them. They can jump over, crawl through, or squeeze between—and they can do terrible damage terribly fast if they get where they don't belong. Wrap the trunks of your fruit trees with chicken wire 6 feet high if you have goats. This keeps the goats from eating the bark. If the goats are sticking their heads through and getting stuff they shouldn't, fence them in with chicken wire. Keep them well fed so the garden won't look so tempting. Even so, they may get out just for the principle of it.

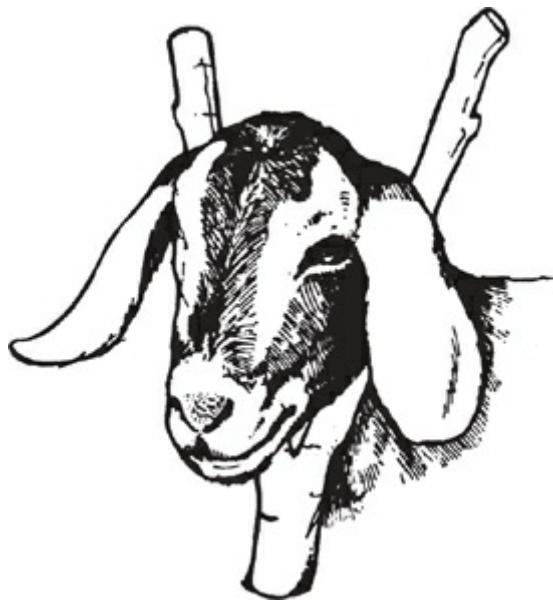

Dynah Geissel wrote me: "Just as you would prepare a place for a new baby, preparing a place for your new livestock will save a lot of anxiety and confusion when you bring them home. First, check your fences. Each goat should have access to $\frac{1}{4}$ acre. The minimum fence height is $4\frac{1}{2}$ feet. A determined goat can clear a 6-foot fence, but if she is properly cared for and has not established bad habits, $4\frac{1}{2}$ feet will generally restrain her. Obviously the fence should not lean out. Also, if the top is wire, there will be no 'step up.' There should be no vertical gap greater than 14 inches and no horizontal gap greater than 8 inches. You'd be surprised what a goat can slip through."

Don Fallick wrote me: "Rail fences for goats don't work well, unless the rails are so close together that a goat just can't get through. Even then, the goats can see through, and may jump right over even an 8-foot fence. But goats (and deer) won't jump a fence they can't see through or over. Many goat breeders have found a solid wood fence 5 feet tall keeps their goats at home. If you decide to build a solid goat fence from slabs, nail the vertical slabs to horizontal stringers, with the bark side away from the goats. Goats love to chew on bark and can loosen up even the hardest driven nail just to get at the tiny piece of bark under it. If you intend to fence goat kids, make the top panel inward-sloping, or make it of chicken wire, to prevent them from caroming off the corners and flying out."

"Goat fences need gates that hook shut with spring-lock hooks. Besides being able to jump unbelievably high, goats have prehensile tongues, and can unlock most standard latches, even including spring hook latches. Goats have prehensile lips and can reach and unlock latches that many people have trouble with. I once rigged such a latch so the hook was inside a coffee can, which made it difficult for me to let myself out of the pen when I

was working inside it. After I got it finished, I tested it by going inside, unlocking the latch and letting myself out. The goats watched in fascination. Then I went out, locked the hook, shook it to make sure it was latched—and got less than 3 paces from the gate before a goat nudged me. That's how quick they figured out how to unlock it! So if all else fails, use a chain and padlock!"

Curing a Fence Tester. If a young goat starts going through (or over) fences, Mike finds a forked tree branch shaped like a "Y." The goat's neck goes into the "V" and the ends of the stick are tied above its neck with leather or something. It can't squeeze through fence holes anymore, and jumping isn't convenient either. If a goat grows up thinking it can't do those things, it will give up trying. After 6 weeks you can take off the yoke and there won't be a problem again. If the goat does jump again, just put the yoke back on as a reminder. That's how to raise goats that don't test your fences.

Picketing a Goat. If a goat knows it can and wants to, it can jump over a 5-foot, or even a 6-foot fence. If I get a goat that has a bad jumping habit, I sell it to somebody who has the kind of situation where they have to picket a goat anyway. To picket the goat put on a collar or halter and attach a light-link chain. The chain is attached to a metal stake that you can drive into the ground with a mallet where you want her to browse. Or use a "stay." That's an old tire or a heavy piece of iron instead of a stake. You can move the stay around occasionally without the trouble of pounding in the stake. None of my goats have to be picketed because we have plenty of room here.

Catching a Goat. How do you deal with a goat that jumped the fence and is happily eating your neighbor's roses and doesn't want to be caught?

1. Try the grain-shaken-in-a-can bit. Turn the grain so he can see it.
2. If he's leery, walk past him carrying the grain but completely ignoring him. Go pick up some curious object beyond him and examine it. Then put down the object and walk back past the goat, still carrying the grain, and still carefully ignoring it. Whistle if you can. The goat will be overcome with curiosity and follow you. Slow down. At a point of closest approach dive for legs or horns, whichever you think you have the better chance of grabbing. I love horned goats because in desperation I can usually catch them by those handles. Then yell for help.
3. If that didn't work, rope him, and put him up for sale.
4. If you can't rope him, shoot him and make goat sausage.

GOAT SHELTER: Goats don't need fancy quarters. Just a good dry place to get in out of the rain or snow. An indoor home with an open door to pasture is perfect. Goats or cows both have plenty of sense to know when to go in and are happiest choosing that for themselves. But Dynah Geissal, who lives in Montana, pointed out 2 important exceptions: "... kidding and extreme cold. Goats can tolerate very cold weather if their shelter is dry and draft free. When the temperature drops to around 20 degrees below however, there may be problems. Newborn kids are especially at risk, as are unprotected udders. At this temperature I add extra bedding, close the barn door to maintain as much warmth as possible, leave a light on to encourage movement even at night, and feed extra hay."

Goat Shed. A quick and easy shelter from rain and sun can be made by putting 4 posts in the ground, adding a sheet of tin for roofing, and wrapping some tin around 3 sides.

Dynah Geissal wrote me: "There should be deep bedding, which is changed once or twice a year, fresh air but no drafts, and at least 6 x 6 feet per goat. Never allow ammonia to form. One door may be left open without creating a draft. Bedding should be dry at all times. In case you're wondering—no heat. If your barn is heated, your livestock will not be acclimated to the outdoors. Keep them dry and draft free, and they will be fine. You will also need a keyhole feeder for hay and a method for giving them fresh, clean water. A milking platform or stanchion is also required."

Don Fallick: "Goats love to push on anything handy, so I've learned that goat barn walls must be sturdy. To build a goat shelter, I have the wall boards nailed onto the walls from the inside of the barn, not the outside. I frame 2 opposite walls and slide them from the inside, then scab studs to the corners and frame the other 2 walls. Also, since goats in the wild do not live in caves, they'll never be comfortable in a barn that has no windows, and you'll want light to see by when examining kids, or milking. But windows can be a problem, as goats, and especially kids, jump around so much. There is real danger of them breaking the glass unless it is protected with expanded metal mesh, if you can get it, or 2-inch mesh welded wire fence (not woven wire—it's not strong enough)."

Goat Hutches. This is ready-made, portable goat-sized housing. You can buy molded plastic huts for kids from the Pet Castle Co.; 915-643-2517; 800-351-1363; PO Box 1059, Brownwood, TX 76801. VIC offers fiberglass hutches, both small and large: 507-498-5577; 800-537-7145; 111 Maple Dr., Spring Grove, MN 55974.

However, Don warns: "It's tempting to make a goat barn no taller than goat height, to conserve materials and heat in winter. This is false economy. You will eventually need to get into the barn to remove composted manure. Goat manure, with a little bedding thrown in, composts into an extremely dry, tough layer of felt-like substance that must be cut before it can be shoveled. If you don't have room to swing a pick or a mattock, you'll wish you did!"

Sleeping Platforms. Says Dynah Geissal: "A nice addition is one sleeping platform for each goat. Some use them; some don't, but the ones that do will really appreciate them. Each platform should be 12 inches wide, 2 feet off the ground, and 4 feet long."

GOAT FOOD AND WATER

Water. Like other animals (and you), your goats need fresh, clean water available all the time. Freely available water helps goats have good health and do their best milk-giving.

Food. I've just read a book that said goats could starve on grass. True, but it's not that simple. Goats need some brush in their diet, but they can get along on brush plus grass and a wide variety of weeds (herbs) and/or vegetables just fine. The vegetables can take the place of brush. They don't do as well just on grain and grass—say, oats and hay. They need some veggies, too. Goats can eat grain, stock beets, corn fodder, carrot tops, lettuce,

nice second-cutting alfalfa (they don't care for the coarse stuff), melon rinds—anything from the garden. They like brush, rose bushes, and apple branches, so if you have fruit trees, roses, and berry bushes, you'll have to protect them. Chicken layers' mash will kill goats. Grain or alfalfa will bloat them if they aren't used to it. (If you live near somebody's alfalfa field, install especially good fencing.) In fact, any major sudden change of diet can be rough on your goats.

NOTE: Some plants are poisonous to goats, such as azaleas, laurel, milkweed, and wild cherry. Ask your extension agent about problem plants in your area.

Wintering Goats. I know that in a pinch you can winter goats purely on hay because I've done it. But to keep milk production up and to keep them happiest they need some vegetables, a grain ration, and access to brush. Just what quantity it takes to winter goats depends on the quality of your feed and the method you use to feed. A good winter ration in an average winter around here—which is not a real rough winter—is 6–9 bales of good hay (second-cutting alfalfa) for the whole winter. You ration it out to them—plus a handful of chopped grain apiece per day. They like squash, mangel beets, and carrots, too. That's a good liberal diet for a milking doe. Goats that aren't being milked don't need any grain at all.

Feeding System. Feeding in a manger does go farther than throwing feed on the ground. Dynah says a "keyhole feeder" is best of all. And have your hay stored so they can't get in and walk around on top of it because they've no judgment, and will get it in such foul condition that they won't want to eat it.

Goat-Feeding Myths. I read recently in a very popular book that goats are "wasteful" eaters. That same book instructed its readers to give them what seemed to me an amazing quantity of grain per day. Well, if you gave any goat that much grain, of course it would "waste it," because they can't eat that much. It also described goats as "finicky" eaters. They can be. Goats are a lot like cats and dogs. Everyone has heard of Aunt Minnie's tiger tomcat that won't touch anything but chopped liver and she has to buy it fresh every day for him—or some such. You can do that to a goat if you work at it.

But not everybody has a large range area with a large variety of plants, which is the way goats would naturally meet all their nutritional needs. Consider Dynah's feed-store-based system.

Dynah's System. Dynah Geissal has published "20 or 30 articles" on food-growing subjects. I am so grateful she shared her experience in this goat section. This longtime goatkeeper recommends: "Obtain some top-quality alfalfa, 3-way, a mineral salt block, a dairy mineral mix (and a box in which to feed it).

"Her main feed should be top-quality alfalfa—second or third cutting. Feed her free choice in a keyhole feeder. Don't continuously feed more than she will eat or she will pick out the tastiest bits and leave the rest. A goat is fastidious and will waste any feed that is soiled, and a keyhole feeder will minimize waste. Grain should be fed 1 lb. for each 3 lb. milk produced. Three-way is a good feed for goats and may be mixed half and half with ground barley. Top off the grain with 2 T. apple cider vinegar for each goat. This will aid in preventing mastitis and in keeping down the parasite problem. In the spring, introduce fresh pasture gradually. Feed plenty of hay first and only leave the goats on pasture for a short time. Never turn them out for their first spring grass onto wet or frozen pasture, for this may lead to bloat.

"In addition, provide ... a mineral salt block and ... a good dairy mineral mix. It will probably have salt in it; if not, mix it half and half with salt. If your area is deficient in selenium, it should be provided here. Put this mineral mix in a feeder high enough off the floor that it isn't easily soiled. And ... provide a natural cattle block. This is a protein

mineral supplement. Be sure it has no urea. Urea is poisonous to goats and should never be fed to them. This block should contain molasses, which is good for them any time but is necessary during the winter and 2 months before kidding. They will eat whatever they need of these additives. If they have not been provided previously, they may devour them at an incredible rate at first. After they have obtained what they need, this will drastically decrease."

Goat Reproduction

GOAT FACTS OF LIFE: Goats are in their prime generally from 3 to 6 years of age. It is best to breed young does from 15 to 18 months, or at least 10 months old. Too early breeding will stunt growth and heighten risk for dead babies and poor milk production. The usual number of kids for a mature doe is 2—or 1—or even 3 or 4. Keep records on your does. They will tend to repeat themselves.

GOATS IN HEAT: Young goats may vary about when they come into heat the first time—breeding them for the first time at about 10 months is ideal. Older ones that birthed in the spring won't come into season again until fall. In that case, the first chill frosts of September will bring it on. Don't bother looking for heat signs in summer unless the goat went through the fall and winter without a chance to conceive. Goats come into heat from September to January for 1, 2, or 3 days. So, you have to notice them fast and get them bred fast. The period between heats is 17–21 days. October and November are the months she's most likely to conceive. Dynah Geissal: "Some does come into heat in August. You may want to let your buck run with the does early in the season to allow any early breeding to take place. Winter milk is usually scarce."

Detecting Heat. You can tell when a nanny is in heat because she bleats all day long, runs up and down the fence looking longingly out, and wiggles her tail provocatively and constantly. She is spotting blood if you look closely, and the labia of the vagina are swelled up and red. Dynah Geissal: "Rub a rag on the most fragrant buck available and store it in a lidded jar. In October, display the rag to your doe each day. When she comes in heat, you'll know! Keep track of each heat so you'll know her cycle. Then plan for her breeding. After breeding, watch for her heat to be present or absent so you'll know if she's bred. A doe may be bred at 7 months if she is well grown, approximately 70 lb."

THE BUCK: You can keep a buck of your own, or maybe take your nan to someone who has one when she needs him. Or artificially inseminate. Twenty-five years ago artificial insemination for goats ranged from uncommon to unheard of. Now it's a third good option. Goat breeds are basically the same size except for the pygmies. You can breed a goat of any breed to a goat of any other breed, and the results will be goat and will get born fine (that isn't always true of cow breeds, which vary greatly in size).

Keeping Your Own Buck. The buck is always ready. All you have to do is put them together and he does the rest. A half hour should do it. Bucks are unpopular inside city limits and in crowded neighborhoods because a mature buck goat has a tremendously strong odor. Every time you handle him you'll walk away with a tremendously strong odor, too. If they aren't always handled carefully and gently, they can develop some very bad butting habits. If horned, they can be quite dangerous to small children, because a point of one of those horns could come up and get an eye. I rescued my 2-year-old from being butted against the chicken house wall after a friend played at "wrestling" with our buck and awakened his butting instinct. I had to get rid of that buck. Unfortunately, no matter how careful you are, sooner or later bucks will get that butting instinct awakened.

To get your own buck, you can buy a young one fairly cheaply in the spring. He'll be able to do the job by fall breeding time. Some folks keep the billy goat in a special little house—but I let mine run with the herd. That way I don't have to worry about trying to tell when the nannies are ready for him.

Dynah Geissal wrote: "Once a year the services of a buck will be needed. Keep a buck, [artificially inseminate], or take your does elsewhere. With 1 or 2 does, a buck would be superfluous; but with a larger herd, a buck would be a significant part of the natural order of herd life. Whether you are buying your own buck or renting the services of one, find out his reliability as a stud and the milking and mothering history of his mother. If possible, obtain a purebred buck, and one that the owner assures you is easy to handle. Inexperienced people should consider a hornless buck."

"The best bet may be to raise your own. In this case, breed the best doe (preferably purebred) to the best buck obtainable. Hopefully, she will produce at least one buckling who will be left with his mother. You don't want him thinking that you are mother. Start working with him as soon as possible, but don't make a pet out of him. It could be dangerous if he thinks you are part of the herd. Be firm, even more so than with your does. Put up with no roughhousing, and always let him know that you are boss. Never allow him to get away with challenging you. Teach him early to lead and stand quietly for grooming, shots, hoof trimming, etc.

"Your buck may be used to breed a limited number of does at seven months. He should be separated from the does during breeding season. Otherwise the does will be bred indiscriminately. I once left a 3-month-old buckling with the herd because he was quite small; but surmounting a great difference in height, he managed to breed the entire herd, producing fourteen kids who looked amazingly like him and quite tiny.

"I have never had trouble with the smell of the buck getting into the milk, but it will if the does and buck are closely confined. With plenty of space and fresh air, it shouldn't be a problem. I wouldn't want to separate the buck for most of his life, for he's an important member of the herd."

Rent-a-Buck. If you can tell when your doe is wanting the buck you can take her and bring her back the same day with fair confidence of success. But it may be expensive. If too pricey, that's a good reason to keep your own buck, or check into the availability and price of artificial insemination.

Artificial Insemination. Artificial insemination for goats was uncommon or even unheard of 25 years ago. Now it's a third good option. Ask your county extension agent or local goat folks about local bucks. Or ask Buck Bank about semen, breeding supplies, collection, and training. They offer your choice of champion Alpine, LaMancha, Nubian, Oberhasli, Angora, Boer, Cashmere, Nigerian Dwarf, and Saanen bucks: 541-826-2729; fax 541-826-9717; 2344 Butte Falls Hwy., Eagle Point, OR 97524; dheaney@embarqmail.org; www.thebuckbank.com. Or contact Wayne and Carol Rhoten; Magnum Semen Works: 2200 Albert Hill Rd., Hampstead, MD 21074. To read up on the subject check out *Artificial Insemination and Genetic Improvement of Dairy Goats* by Dr. Harry A. Herman; or *Artificial Insemination Handbook* by Vaughn Solomon and Donna Forsman.

GESTATION: The gestation period ranges from 146 to 152 days (about 5 months). So wait 5 months minus one day, and then watch for her to spring. Dynah Geissal: "If she has little milk, stop milking when she has 2 months left until kidding. If she has a lot of milk, feed her well (not to fatness), and keep milking her. I've had goats who milk well for 3 continuous years with no problem, but they need top quality feed. If she isn't milking,

don't give any grain the last 2 months before kidding, for a fat goat may have birthing problems. Give shots, worm, and trim hooves 6 to 8 weeks before kidding."

Ketosis. Stress, overfeeding, underfeeding, and lack of exercise can all be contributors to this pregnancy-related illness. Dynah: "Symptoms are dullness, disinterest in feed, pressing head against something, teeth grinding, and aimless walking. *To prevent ketosis, provide blackstrap molasses during the last 2 months of pregnancy.* Detection is by using Ketostix to see if her blood sugar is low. The cure is to feed glycerin, exercise her, and keep her eating."

KIDDING: We had a white Saanen buck goat named Miracle. His mother's name was Mary. He was the first goat born on our farm. He was Mary's first baby and neither she nor I had gotten into the farm kidding routine yet. She gave birth to him on a miserable rainy day in late February on the manure pile. Mike and I had been through a birth rather recently ourselves when he was with me in the delivery room, and I cried with the wonder of it when he and I found them, and that's why I named the kid "Miracle." There isn't that much difference in the basics. The miracle of life is the same whether it begins among sterile sheets and bad-tempered nurses or in the rain on a manure pile. And I always cry with joy when it's over, whether it's a goat, cow, or me.

Signs of Near Birthing. When the lips of the vulva swell up and the opening becomes longer and larger and the nanny is springing, delivery is nearing but not imminent. When hollows appear under the tail above and to the left and right of her vagina, delivery will take place within 2 hours. Dynah Geissal: "Kidding may occur as many as 5 days before or after the doe's due date (5 months, 1 day after breeding). Signs of an imminent birth are a full udder and a thin, clear mucous discharge. This is different from the thick yellow mucous pus which may appear as much as a month before kidding."

The Kidding Place. When you know a free-running goat is near kidding, check on her every morning. *If she doesn't show up, go find her.* If your goats run free in the open, you need to discover the mother with her kids as soon after kidding as possible. Goats, in my experience, aren't super picky where they have their kids. If she kids in cold weather out in the open, the kids will die if you don't help them. And we have lost newborn kids to predators. So I would advise that, especially if you live near the woods, keep a goat about to kid near the buildings or in protective custody until she has kidded and her kids are able to run as fast as the rest of the herd. (Kids develop jumping and running abilities very quickly.) Predators are less likely to come in where the human smell is heavy.

Provide a sheltered place—inside a shed or barn. Cover the floor of her shelter with dry bedding such as straw, hay, or sawdust. Dynah Geissal adds: "A lead goat will choose an appropriate place to kid, but a lower one may not because of being harassed. So be sure to isolate her in shelter before kidding. When it's been determined that your goat will be kidding within a few hours, isolate her in a place that is familiar to her. Be sure that it's dry, draft-free, and has plenty of bedding. Provide fresh, clear water in a small bucket (to minimize the chance that she will drop her kid into the water). Give her plenty of good hay."

The Birthing. Kids are usually born in the early morning hours. The mother probably won't need any help from you with the birthing itself. But if she does, here's Dynah Geissal's expert instructions on what to do:

"Generally speaking, a goat should be left alone to kid. If she is very attached to you, she may be reassured by your presence. Most goats, however, prefer to be alone, although they do seem to be more at ease if they are able to see their herd sisters. Be sure to check on her frequently during her labor. It may be many hours before hard contractions start. If

she seems at ease and eats or chews her cud, all is well. When hard labor begins, your doe may lie down, pant, and call out during a contraction. Between contractions, she will get up and resume cud chewing in the early stages. This may last several hours.

"When the kid is showing, check to see which part is presenting. If the front feet are first, with the head resting on them, everything should proceed normally. This stage may last as long as an hour. Unless things proceed rapidly, clean the kid's nose and mouth before it is born."

Assisting in Kidding. Dynah, again: "There are certain circumstances where you will have to aid in the birth or get someone else to help you: ... If the water breaks and more than 2 hours have elapsed and there is no kid in sight, your goat probably needs help.... If she seems to be in great pain, wait no more than half an hour before assisting her.... If she seems exhausted, wait only a few more minutes—maybe fifteen.

"If the kid is presenting, you may have to do no more than pull gently downward with each contraction. This is sometimes necessary with an especially large kid. When the kid is presenting, but in an abnormal position, you will have to enter the vagina. Scrub your hands and arms thoroughly, paying special attention to your nails. Oil your hands and arms. A presentation that is normal except that the head is turned back is easy to correct, but almost impossible to give birth to if not corrected. The same is true if one or both feet are tucked underneath the kid. A kid that is presenting normally but upside down may be turned.

A breech birth may proceed successfully if the feet come first; but there must be no delay once it is presenting. The cord may be constricted in the birth canal. When the kid is coming rump first, it may be born with some help from you during contractions if it is fairly small. Otherwise, you will have to push it back and bring out the feet first.

"If the kid is not showing, but you have decided that your doe definitely needs help, reach in very carefully to prevent rupturing the vagina. In a situation where you cannot feel the kid, the cervix may not be open. In this case, you should consult a vet. Assuming you can feel the kid, determine its position and reposition if necessary. This is probably all that is necessary. On the other hand, when her water has been broken for a long time or if she is exhausted, or if the kid is very large, you may have to also pull the kid during contractions.

"A goat who has serious birthing problems 2 successive years should be butchered. I once had a goat who seemed to be giving birth normally: 2 feet were out but then nothing. When I began to examine her, I found that one leg was much larger than the other; 2 kids were trying to be born at once! I had to push one back to free the first. Then the process repeated itself, and 3 healthy kids were born."

Sue Bradford, Kansas, IL, wrote me: "My best milker, Storm, almost died giving birth. I knew she was in trouble. Phoned my boss, explained, and was told, 'She's only a 2-dollar goat and you're going to lose a day's pay!' She's a pure bred Nubian, but that doesn't matter. She was in pain and any animal in my care will not be left to die. Anyway, this was my first experience delivering. She had delivered a kid hours before. I found she had the next kid sideways. I got him out and of course he was dead, but then out popped a beautiful little girl kid! I gave Storm a pail of warm water with blackstrap molasses to drink. She drank it all, but wouldn't stand up. She wouldn't even look at her kids and wouldn't stand up. I still don't know how I did it, but I lifted her up enough to get enough milk to get both kids started on the bottle. It was a few days before Storm could stand without help, so I held her up every day while my husband milked her. Her next kids were born without problems. I love this life! I was raised in town, but my husband, Lee, and I have lived on his family farm (90+ acres) for 26 years now. We now have a ¼ acre

garden, fruit trees, goats for milk and meat, and chickens for eggs and meat. I've learned to sew, make quilts, can and freeze garden get, make jelly, milk goats, make cheese. I even cut up a deer and goat and made salami."

Doe's Post-Birth Feeding. Dynah Geissal recommends: "Feed mother 1 lb. grain plus warm water containing molasses." That drink of warm water with some molasses in it is a real help to a goat that is kidding. She may drink as much as a gallon. If she seems chilled and seems to be having difficulty expelling the afterbirth, the drink of warm water also helps.

Afterbirth. The afterbirth comes out after the kid. It may take a long time to finish coming out. Leave it alone. I know how miserable it is when the doctor gets in a rush about afterbirth. It will come out in time. You put her more at risk by pulling on it, because that may make her bleed! When she gets done passing the afterbirth naturally, she may or may not eat it. If she does, it's recycling. If she doesn't—well, after all she's not a meat eater by nature.

CARE OF THE NEWBORN KID: Carry a towel with you and dry the newborn as soon after birth as possible (getting born is a wet business). There is no reason for you to tie the cord. My advice would be, in fact, don't. Leave that part of it up to nature. I usually don't find the babies until after nature has taken care of that part anyway.

Dynah Geissal's system: "Have dry, clean towels ready and either iodine or alcohol. When the kids are born, clean the faces immediately. Let mother take over, but if she doesn't do a good job, you should. Dip the cord into an iodine solution as soon as possible (don't dab it on). The cord is a wick to bacteria and infection. 'Navel ill' is an infection of the umbilical cord which spreads to the kid's entire body, especially the joints. It is prevented by dipping the cord in iodine or alcohol immediately after birth. It is treated by antibiotics or sulfa."

Helping Kid Nurse. Dynah: "There are usually 2 kids born and 3 is not unusual. The kids should be up almost immediately. Be sure the kids receive colostrum right away—hopefully within 15 minutes of birth. If not, help them up at least to nurse. If the kids have a strong sucking response, hold the teat and the kid until its initial hunger is satisfied. When the sucking response is weak, get some milk into the kid and then try in a couple hours. If a kid is not nursing on its own, you'll have to help. If the kids are weak, or there are multiple kids, you may have to help for as many as 3 days. You will learn quickly how often they are hungry—usually every 3 to four hours. Once you are certain that a kid has nursed on its own, it won't need your help any more."

"If there is no sucking after several hours, you will have to bottle feed the kid, if you want it. Once is usually enough to get it strong enough to nurse. Give the bottle as few times as possible so the kids learn to nurse the mother rather than depending on the bottle. Don't keep the kid in the house or its mother may reject it and it won't have adapted to the temperature of the barn. If the kids are bottle fed, they tend to become pets. You're their mom and, personally, I don't think livestock should be pets. I have dogs and cats for that. A pet goat is usually intractable and as obnoxious as an untrained dog. My goats are friendly and affectionate, but they are members of the herd, not the family."

Chilled Kid. If a goat kids outdoors in cold weather and the kid seems to be inactive, it's probably chilled. You may even find a kid that's weak, or prostrate from the cold. Just pick up that little baby in your arms and carry it into the warmest room of your house. Keep it wrapped in warm cloth and put it in a cardboard box near the heat source until it dries off and gets warm and is thoroughly recovered. When the kid climbs out of the box and wobbles all over the house nuzzling at everybody optimistically, it is doing fine for a

6-hour-old baby. Its little tail will wag and its disposition already demonstrates the incurable curiosity of goat.

Separation of Kid and Mother. One school of thought advocates taking the kid away from the mother immediately so she won't get attached to it and be harder to milk later. Another is to leave the kid with the mother for 3 days and then separate them. But since the latest research has shown that animals nursed by another animal are more respectful of humans and much safer to have around when mature, owners are trying harder to find a way to keep the kid on the goat. You can't change your mind in the middle because, if the kid is taken away from its mother for the first 6 hours or more, on its return she may well butt it viciously and refuse to mother it. Here's Dynah's system for leaving the kid nursing its mother:

"Kids should stay isolated with their mother for 3 to 5 days or until they are strong, active, and nursing well on their own. Then turn them out with the herd. The only time I have had a problem with this is when a yearling calf crushed 2 kids behind a door. So if you have large livestock sharing their barn, keep them separated a few extra days.

"Check the mother's udder twice a day to be sure it isn't too full. She will probably need milking after 3 days, but if not, you could wait up to 5 days. Except for the grain fed immediately after kidding, don't feed any more grain until your regular milking has begun. That prevents her milk from coming in too fast.

"Let the kids stay with their mother and continue to nurse her until they have grown husky and are eating regular food well. This is usually 2 months for single and twin kids, but closer to 3 for triplets. At this time, begin to separate the kids from their mother all night. That way you have the morning milk but let them take the rest during the daytime. The kids will learn the routine in a few days. Then they will stop crying and will even run into their own sleeping area when you come into the barn at night to shut them away."

Bottle-Feeding. If the kid will be bottle-fed (or disposed of), give mother some grain and milk her. If you haven't milked or handled her much before, you'll find birthing has made her completely gentle and she'll cooperate fine with you. Save that colostrum milk to feed her baby if you will be bottle-feeding. Take the milk to the house, put some into a small pop bottle, using a lamb nipple on the end of it, and feed it to the baby. Just get the nipple in its mouth and it'll get the idea. Never feed cold milk. After a few feedings and a really good warming the baby goat will be fine and can go back out to the barn to live. Or if it still seems to be doing poorly, you could keep it in the house until you feel sure it's strong. If the kid is too weak even to nurse the long, soft lamb nipple, you can feed it with an infant syringe (the rubber bulb you use to clean a newborn baby's nose), available at

drugstores or a spoon.

Don't use a human baby bottle. It's the wrong style nipple. You should have several "lamb" nipples on hand (baby lambs are treated exactly the same way) well before the birthing. It's terribly important to get that first good nourishment into a chilled newborn animal. You'll be amazed at the change. I've found kid goats that looked almost dead. But after they were warmed up and had a meal in their tummy, they stood up, bleated, and wagged their tails. After 2 hours and another meal they were just fine.

Lamb nipples don't have an internal air supply like baby bottles that feed air in through the rim. The kid has to learn to let go of the nipple every so often so air can rush in and equalize the pressure; otherwise the milk will stop coming.

Timing the Feedings. Feed every 2 hours the first day, 4 hours the second day, 8 hours the third day, then morning, noon and night for about 10 days, and from then on morning and night after you milk. Notice how much they are able to take at a feeding. At first they take only an ounce or so. By the end they'll empty a big pop bottle.

Scours. The turds of goat kids should be round and firm, miniatures of mama's. When goat kids (or calves) get a loose diarrhea; it's called "scours." Chilling and overfeeding are the 2 greatest dangers. Sometimes they scour a while and finally get over it, but sometimes it kills them. Goat kids have a hard time on any milk but their natural milk. That powdered fake stuff is the worst thing I know of; powdered milk is next; and cow's milk is best for them. (Bigger kids can handle cow's milk better than little ones.) If a goat kid on anything but goat's milk is scouring, then a half bottle, a bottle, or all goat's milk for several feedings will usually clear it up. I am always very reluctant to sell unweaned kids to people who don't have goat's milk to give them because I know they'll have a hard time keeping the kids healthy.

If you are milking goats and have yearlings, or a poor milker, or they all have triplets—you don't have much choice. You're going to have to kill some kids to insure your family milk supply or else find homes for them elsewhere. You can't afford to buy milk for them. They are worth only a few dollars, if you can find somebody to take them. They aren't as important as having milk for your own children. If you try to raise them on that cheap milk substitute they'll be scouring and sick most of the time, and you'll spend whatever you saved on Kaopectate and antibiotics trying to help them hang on.

Surplus Newborn Kids. I try never to kill a nan kid because it is a waste, but when I have more billy kids than I have extra milk for, and nobody wants them, I kill them. This is hard to talk about and hard to do, but I'm going to tell you how because I'm writing this book for people trying to do real things in difficult situations, and sometime you may need to know this. Dynah Geissal says on this subject: "Before your kids are born, decide how

many doelings you will keep and stick with it.”

If I’m going to kill the kid I get there as soon after birth as possible. I check for sex. Then I take the little billy out of earshot of the mother and hit it as hard as I can on the head with a hammer. That blow probably suffices. The newborns don’t have much stamina, but I hit it a couple more times to make sure. Better have it quick, certain, and complete if it has to be done.

Calf Adoption. It takes about 2 good goats to support 1 calf. Get your goats milking well first, and then you can acquire the calf. One really good goat can support a calf if she can be persuaded to adopt it and let it nurse her.

Kids for Meat. If you do have extra milk, then by all means raise your extra bucklings and cull doelings for meat. If you don’t have a market for them, you might as well eat them yourself. Since goats typically have more than 1 kid at a time, and they can even kid twice a year, you have extras pretty fast once you get started. The animals can be butchered when they’re big enough to suit you. Even a kid 6 weeks old will add 15 lb. of meat to your supply. But the longer you wait the more meat you’ll get—up to a point. Calves keep growing until they are about 2 years old, and the same with goats.

Sexing Kids. What you plan for the kid may depend on its sex. Boy kid goats have small testicles hanging from their tummy, just to the front of their hind legs. They pee from the middle of the tummy so it runs straight down as they stand. Girl goats don’t have those testicles and they pee from the rear, squatting backwards as they do so.

Of Big Kids and Weaning. Incidentally, big babies that are still nursing tug so hard they are liable to pull a rubber nipple off a bottle. You’ll have to hold it on the bottle as they suck. A goat can be tapered off when he is eating other feeds well, weaned completely at about 4 months.

Castrating. Male kids, like bull calves, are usually castrated for easier management. Dynah says, “Male kids should be castrated by one month of age. I use an elastrator and have never had a problem. Don’t wait any longer than a month or it will be too traumatic. I castrate the males so they can run with the herd. If they aren’t castrated, they must be separated from the does by four months.”

GOAT MANNERS: Dynah Geissal: “Goats are very smart and can be taught manners. Don’t allow your goats to jump on you or to jump up to get feed you’re carrying. A slap on the nose and a loud “no” will save a lot of irritation and hassle. Don’t allow loose goats to butt or to steal food from a goat who is confined in a stanchion.”

Goat Vetting and Grooming

See the general section in [Chapter 8](#), “Introduction to Animals.” Dynah Geissal: “Disease is not usually a problem with goats if they are fed top-quality feed and additives, get their shots on time and are well maintained.”

TOENAILS: Some goats never seem to have toenail problems. Others have toenails that grow and grow, and you have to cut them off to keep the goats from becoming virtual cripples trying to get around with all that nail on each hoof. A young goat has fairly soft hooves and you can trim them with a knife. Make them look like a newborn’s hooves, but *don’t go far enough back to get into the quick*. Though it may make them nervous, it doesn’t hurt. On an old goat the hooves are very hard, and you’ll need a meat saw or regular hoof nippers to do the job. I bought an old doe once who had 5 inches of toenail that had to be sawed off from the front of each hoof. The best way to keep up with it is to trim once a month. But don’t trim hooves right before or right after kidding.

PARASITES: Dynah Geissal says, “If other goats come to your farm, assume they have parasites and act accordingly. Never loan out your buck, but have the does brought to him.”

Worming. Dynah, again: “Worming should be done 3 times a year. The whole herd should be done together (within a few days of each other) at least one of those times. Does should be wormed 6 to 8 weeks before kidding. Other times could be before confining for the winter, before turning out in the spring, before breeding, etc. I use TBZ, which can be used during pregnancy and during lactation.”

Lice. Dynah: “You will probably need to dust for lice each year in the spring. Choose a dust that is safe to use on lactating dairy animals and poultry. These are the safest as well as effective. Dust immediately after the morning milking and do it outside. Kids under 8 weeks should be dusted with ashes.”

SHOTS: Dynah: “The best time to inoculate goats who have been confined for the winter is just before turning them out and no closer than 6 to 8 weeks before kidding. Don’t forget your buck. If red water is a problem in your area, you will need to give 8-way. Ask neighboring ranchers or your local extension service. If they vaccinate their cattle for red water, so should you vaccinate your goats. If not, use 7-way.”

HORNS: Dynah: “Horned goats will tend to scatter, then stand and face the predator. Hornless will just run, which encourages chasing and may lead to injury or death.” For dehorning see [Chapter 8](#).

BLEATING: Some goats are very noisy. If your choice is to have a silent goat or no goat at all, get a goat, and if the bleating becomes a problem you can have it debleated at the vet’s. Keeping the kids and mama out of sight of one another and separating them before they have a chance to get really attached helps. A nan in season will be noisy, and actually that’s a convenience because it lets you know when she is ready to be with the billy. To me, debleating is a last resort, but I know some of you have special constraints, living with lots of neighbors and critical municipal authorities.

DESCENTING: At the same time that buck kids are disbudded, they can also be at least partly descented by burning out the scent glands on their heads. Or those can be surgically taken. (Ask a vet.) Castrated bucks won’t develop the odor, but the one you’re keeping intact for breeding will. Dealing with the head glands doesn’t solve the problem entirely; there are also leg glands that produce scent.

OTHER GOAT DISEASES: This information is from Wendy Thompson, Rawlins, WY, who writes a column for Homesteaders Connection called “One to An Udder.” “When you buy goats, make sure they don’t have CAE, or caseous lymphadinitis, or soremouth. Once these are in your herd, it is very difficult to get rid of them. If you have goats with any of these diseases, please take steps to eliminate the disease from your herd, and don’t sell animals with any of these to unsuspecting buyers. I have personal experience with CAE. My first goat, a Nubian baby called Sleepy Moon, was given to me by a dear friend ... We had no place to keep a goat, so Moon stayed with our friend’s herd. That summer, we bought a few more goats. They also lived with our friend’s herd.

“The next spring was the worst disaster we have had with goats. That year we lost about 75 percent of the kid crop for various reasons. Our friend’s method of raising kids was that she left them with their mothers for about five days to get the colostrum, and then switched them to a bottle so that they would be tame. The milk for the babies was all

put together into a lambar. It was not pasteurized. It was depressing to go out to the barn, because we would find a different kid sick or dying almost every day for a while. Most of them had enterotoxemia because we had been instructed that kids or pregnant does should not be vaccinated [...] The babies also were kept in a heated pen too small for the number of kids in it, and with sawdust for bedding. The result was a lot of unhealthy kids that were easy targets for anything that they were exposed to.

"Just when the enterotoxemia epidemic was ending, a few kids came down with different symptoms. At first they just had trouble walking—they walked on their knees or dragged their back legs. The paralysis spread until the kids couldn't move around on their own ... I took one of those kids to the vet, and found out that she had CAE. What I didn't realize was that almost all of them had it because of the way they were raised (pooled raw milk), and that only a few goats with CAE show the most dramatic form of the disease. Of the kids that were sick, only one survived.

"Goats that have been exposed to CAE have those symptoms to various degrees. Even if they don't have big knees or a hard udder, they can spread the disease to other goats through their milk and other body fluids, and also may develop debilitating arthritis at any time during their life. The best way to keep this from happening to your goats is not to own any goats with CAE, but the disease is not always apparent, and can even fool the blood test. The next best answer is to feed kids only pasteurized milk. If you are unwilling to do that, at least don't feed kids pooled milk. Doe-raised kids that only get milk from their own mothers have a much smaller chance of getting CAE than those that get milk from every doe in the herd. Even though all my goats test negative now for CAE, I continue to pasteurize milk fed to kids.

"To pasteurize milk, heat it to 165°F, and stir for 15 seconds before cooling off. For colostrum, it is trickier. The colostrum must be held at 135°F degrees for one hour. If it gets too hot, it will turn into custard. If it drops below 135°F, it might still infect the babies with CAE. You can pasteurize colostrum in a double boiler, or in a stainless steel Thermos. To use the Thermos, heat some water to 140°F, and put that in the Thermos while you are heating the colostrum. When the colostrum is 135°F, dump the water out, and put the colostrum in the Thermos. Check the temperature after an hour to make sure that it has stayed warm enough. After the second day's milk, you can pasteurize it the first way I described."

Goat Butchering

We've eaten a lot of goats. Goat meat is "wild" flavored, resembling venison in taste. I've made goat stew, goat steaks, and goat burger. I prepare those all pretty much on the same basic plan as other meats. If serving goat meat to a guest who isn't used to the taste, I might camouflage it in a wild meat recipe. We never have cut roasts off our goats. I'd rather serve and eat the meat fried, or in burger, or made into sausage, so it's always either sliced or ground. Goats are easy to butcher and cut up. If you've ever done a deer, it's the same thing. Goat meat is technically called "chevon"—and in the Southwest market, "cabritos" or "cabrito meat" means young goat, just like pig meat is "pork" and cow meat is "beef."

OF GOAT AGE AND BUTCHERING: You butcher a kid goat the same way you do an adult, basically—only the whole thing is quicker because there is less of everything. If you need milk more than meat, it makes sense to butcher kids at birth. Use the rabbit butchering directions for that size. Most people don't butcher before 12 weeks of age because you don't get much meat. There is quite an Easter/Passover market for milk-fed kids that are

about 20–30 lb. To maximize their meat production from a buck kid, however, most homesteaders butcher surplus kids at 5–9 months old. That way you have an animal big enough to make small steaks and even small roasts.

After the kid is skinned and gutted you can roast it whole on a spit, barbecued, like for the Fourth of July when you have lots of guests. Or you can quarter it for barbecuing or roasting, a quarter at a time for a regular meal. The other age at which goats are most frequently butchered is “old”—mostly cull does. These are nans that can’t be bred, or don’t give enough milk to bother, or can’t be milked or can’t be controlled. Older goats are generally boned and the meat ground for goat burger or sausage, appropriate uses for strong-tasting, nontender meats.

Goat for the Meat Market. Young goats for the Easter (March) market generally range in weight from 17 to 38 lb. If not sold then, they are usually marketed at 8 months of age. Worldwide about 1.2 million tons a year of goat meat is sold (more than cattle or hogs!).

KILLING A GOAT: Aim from behind it with your gun, at a spot just below the ear, while the goat is preoccupied with a pan of grain, because it probably has some experience with guns and might otherwise be frightened. Or use a hammer, particularly if the goat is a young kid. If you are planning to stun the animal with such a blow, keep in mind that the back of the head is most vulnerable, and that most of the skull is solidly built; these are animals that depend on butting as a defense. Deliver a sharp hit to the head, more if necessary, until the goat is unconscious. In either case, you then cut the throat with a sharp knife to bleed the animal out thoroughly. Hang head down for thorough bleeding out.

This particular set of directions has you skin the goat first, then eviscerate. But it would also work to eviscerate first, and then skin. The skinning directions are here. For details on how to manage the sex organs or mammary gland, see the section about wild mammals in [Chapter 8](#). The information there will apply. For the gutting, use the directions later in this chapter under “Gutting the Cow.”

SKINNING A GOAT: Try not to cut into the meat while you’re working. Cut a slit from the midpoint between the hind legs up to the throat. From the center cut, cut along the insides of all 4 legs. The skin will be firmly attached at the tail. Cut around the rectum, pull it out enough to tie off the connecting intestine with a length of string, then let the tied-off intestine fall into the body cavity. Continue cutting off the skin. Skins to be saved for tanning should be cut off the head as close to the ears as possible. Otherwise, you can simply cut off the head at the base of the skull. Finish removing the hide.

EVISERATING A GOAT: Follow instructions under “Gutting the Cow.”

CUTTING UP: To cut up a goat, follow the directions given in [Chapter 8](#) for cutting up a deer. You have to use your own judgment and cut your meat according to the size of the animal and the use you need of it. How you cut it up also depends on whether you have power meat-cutting equipment available. If you have a band saw, cutting meat is so easy that mini-steaks (the kind you’d offer about 3 to a serving) are fine. But if you have to saw out each one the hard way (sawing through the bone by hand), there is scarcely enough meat on them to make it worth the trouble.

GOAT RECIPES: Use any recipe from the wild mammals section in [Chapter 8](#), especially if it’s suggested for deer. Goat meat is so much like that of deer, antelope, moose, elk, etc. Or get *Chevon Recipes* from Caprine Supply, for more than 70 good goat-meat recipes. And get the *Dairy Goat Cook Book* by C. A. V. Barker, available from *Dairy Goat Journal*.

CATTLE

Cows and humans go way back, at least to the Sumerians in the ancient Middle East, who recorded their relationship in stone, and probably back to the Stone Age. Since a dairy cow can live 20 years or more, producing a calf each year and milking most of that time, she can be in your life for a long time. You use her male calves for beef, her female calves either for beef or raise them to be milk cows, too. With a dairy cow in your life, except during her annual rest for late pregnancy, you'll have more milk than at first you know what to do with. You can use the extra milk in the sorts of recipes I've collected here. You'll still have too much. So use some to raise her calf, and young pigs for your meat supply, and to help feed the hens. Or make cheese, and feed the pigs and chickens the whey that is left from cheese making.

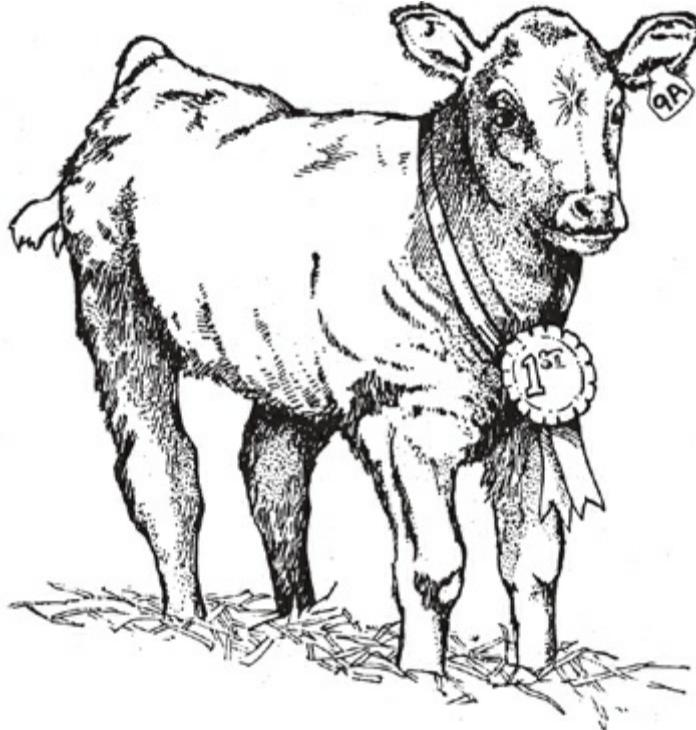

Getting Started

Before you buy your cow you need to consider: Do you want such a large animal, one that must be fed proportionately large amounts of food? Do you have at least 2 acres of good pasture? A large enough outbuilding for her to shelter in and you to milk her in? A place to store a few tons of hay and straw for winter feeding?

CATTLE WORDS

- Bull: A mature male.
- Calf: A young 'un; sometimes they're called calves until they are nearly 1½ years old.
- (To) Calve: When a cow gives birth to a calf.
- Dam: A mother cow.
- Heifer: A female cow before her first calving (or, according to some, a female cow before her second calving).
- Sire: A bull.
- Steer: A castrated male, raised for beef or draft service.

FACTORS IN CHOOSING YOUR BREED: Here are the factors you might take into account: foraging ability; longevity; disease-resistance; food-conversion efficiency; polled or horned; calving ease or problems; gentleness; northern–southern adaptation; amount of milk; size; length of lactation period; amount of muscle (“beef characteristics”); draft usefulness; availability; salability (is there a breed association?); cream content of the milk; price; and risk of genetic defects. That list can be used to judge a beef, a dairy, or a dual-purpose breed.

BREEDS: Worldwide there are literally hundreds of beef, dairy, and dual-purpose breeds, and at least 35 common ones—including both dairy and beef—in the United States. In addition, there are many variations of the cow-related water-buffalo-type animal most common in Asia. In the most heavily populated parts of the world, cattle are the main source of power. They pull the plow and furnish power for grain production to keep people fed. Milk production is incidental, and the meat often is not used at all. In the Western world, cattle are used for milk and meat, rarely now for draft animals. If you are interested in all these different cattle breeds, you'd enjoy the 2-volume set, *World Cattle* by John E. Rouse (Norman, OK: University of Oklahoma Press).

Beef vs. Dairy Breeds. There are 3 big differences between beef and dairy breeds: (1) Gentleness: Beef-breed cows are not usually to be milked by ordinary mortals. Angus, for example, are very excitable animals. You'd never be able to catch one to milk her. If you want to milk a cow, you want one that is born with dairy-cow genes. (Yet somebody somewhere has made a milk cow at some time out of every beef breed there is.) (2) Milk production: The main difference between beef and dairy breeds, besides gentleness for milking, is milk production. A good beef cow has enough milk to raise 1 healthy calf without a grain supplement. A dairy cow can easily raise 2 or 3 fine calves (which you can generally persuade her to adopt by shutting them up in the barn together for a while), with a grain supplement. (3) Difference in build: “conformation.” The dairy cow is lean, bony, has less muscle in places that would make high-priced steaks and roasts. When you buy a dairy-type animal you're buying a greater percentage of bone, but the lower price will compensate for it.

Dual-Purpose Breeds. A “dual-purpose” breed has a beef conformation with a dairy-type ability to produce milk.

QUESTIONS TO ASK WHEN BUYING A FAMILY MILK COW

You could watch the ads or advertise for a “family milk cow.” Don’t buy a milk cow at a livestock auction if you can help it.

1. What breed is she?
2. How old is she? One option—cheapest to get started, longest to wait—is to buy a calf, or a heifer, and raise her to be your milk cow.
3. How many seasons has she been milked? For a milk cow, a bred heifer would probably be most affordable, but a 3–5-year-old cow in her second to fourth year of milking has experience calving and being milked.
4. Has she ever been hand-milked or is she accustomed to machine-milking? Not a problem, you can teach her. But it will help to know.
5. Watch her being milked if possible. Examine her milk for signs of mastitis, such as stringy milk, clots, blood.
6. Is there proof the cow doesn’t have tuberculosis and is immunized against brucellosis?
7. How many calves did she have? Twins? Cows usually have single births, but if she’s had a double you will be forewarned next calving.
8. Any delivery complications? Once a problem raises the odds of having a problem again.
9. Is she fresh (milking) now? Or, when will she come fresh (give birth)?
10. How long has she been fresh (milking)?
11. How much money do you want for her?
12. How many gallons of milk does she give per day? (Or if not fresh, how much did she give last time she was fresh?)
13. How much of that is cream?
14. Any health problems?
15. Behavior problems? Does she go through fences? Does she self-suck (milk herself)?
16. Is she gentle? (Test that by walking up to her. Put your hands on her udder and legs and see if you get kicked.)
17. How much does she weigh; how much food would it take to get her through a winter?
18. How low does her udder hang? (You want to be able to get a bucket under it rather than just a cake pan.)
19. Does she have nice long teats or would you have to milk with 2 fingers and a thumb? Can you reach all 4 teats from one side of her?
20. Is she pedigreed? If so, get her papers because then you might be able to sell a heifer calf for a little more. But avoid paying a breeding-stock price when what

you want is just a family milk cow.

NOTE: *Tuberculosis and brucellosis are rare diseases but are worth taking care about because they can infect humans through the milk. Buy animals that are guaranteed free of these (vaccinated as calves for brucellosis and tested free of tuberculosis). Or get them tested yourself before drinking any milk.*

NOTE: *If you buy a cow that is being separated from her calf for the first time, watch her carefully for the first 12 hours. She is going to be very emotionally upset—enough so as to go wandering all over the country, mooing loudly, if you leave a gate open. Cows are very home-oriented, but she doesn't know yet that your place is home.*

The Shorthorn is a large cow in this category—the “milking shorthorn” more so than the “beef shorthorn.” The Brown Swiss is another beef-dairy combination cow. The river buffalo is a triple-purpose breed: milk, beef, and draft!

Dairy Cattle

Cows, at their best, are really multipurpose animals. They make meat and manure as well as milk. From the beef point of view, milk and all its wonderful byproducts like yogurt, cheese, butter, and ice cream, are just an extra added bonus. And then you can also use the extra milk to raise more meat and eggs by feeding it to the pigs, baby calves, and chickens. I think the most efficient way to get your beef is to have a milk cow and use the extra milk to raise a couple calves a year. You'll get them cheapest if you buy them at 1 day old.

DAIRY COW INFORMATION: Check out Joann Grohman's *Keeping a Family Cow* (1984); Phyllis Hobson's *Raising a Calf for Beef* (1976) (good up to 6 weeks old); and Dirk van Loon's *The Family Cow* (1975). For a periodical, if you're interested in commercial milk-production from cows, subscribe to *Hoard's Dairyman*, 920-563-5551; fax 920-563-7298; PO Box 801, Fort Atkinson, WI 53538-0801; www.hoards.com. Hoard's also offers dairy books such as *Calf Care*, *About Cows*, and *Dairy-Related Careers*. A word of caution: There is a lot of baloney in cow/calf books written for the family farm. Even certain ones I've recommended here have some really stupid misinformation mixed in with the good information.

DAIRY COW AGE: A cow can bear calves annually and be milked until she is 10, 12, 14, even older. The old-timers sometimes kept one going to age 20. But, sooner or later, you'll find it impossible to get her bred again. So a 4-year-old cow is a fine buy.

“Heifer” used to mean a female cow that had not yet had a calf; now some folks use the term to mean a female cow that hasn't calved a second time. Heifers sell cheaper, but they may be unaccustomed to the calving and milking routine—which could be a problem if you are too. They may have trouble calving if it's their first time, and cows, like goats, give only half as much milk the first year they are fresh as they will later on. One way to avoid this calving difficulty is to breed the heifer with a bull of a small dairy breed, like a Jersey, or with a bull of a small beef breed, like a Black Angus, which are deliberately selected for small calves—hence easy calvings.

DAIRY BREEDS: Jerseys and Shorthorns have the reputation of easiest calving. Jerseys, Guernseys, Brown Swiss, and Holsteins are the gentlest and friendliest breeds I've known. Jerseys are the smallest breed, half the size of Devons (and so eat half as much).

Guernseys are next bigger. Milking Shorthorns, Brown Swiss, and Holsteins are next up in size. Red Poll and Devon cows are also dual-purpose breeds. They are exotics and the biggest I'm going to mention. To a certain extent your cow will be priced by the pound, and that makes the larger breeds more expensive. Rare breeds are likely to be the highest priced of all. Milking Shorthorns and Brown Swiss are among the dual-purpose breeds, stocky builds for meaty calves, plus easy calving and good milk production, which are dairy characteristics. The amount of milk you get from an individual cow is a result of her breed, plus how much and what richness of feed you give her.

Ayrshire. Another fine basic dairy breed. For more info, contact the Ayrshire Breeders' Association: 614-335-20; fax 614-335-23; 1224 Alton Creek Rd., Ste. B, Columbus, OH 43228; info@usayrshire.com; www.usayrshire.com.

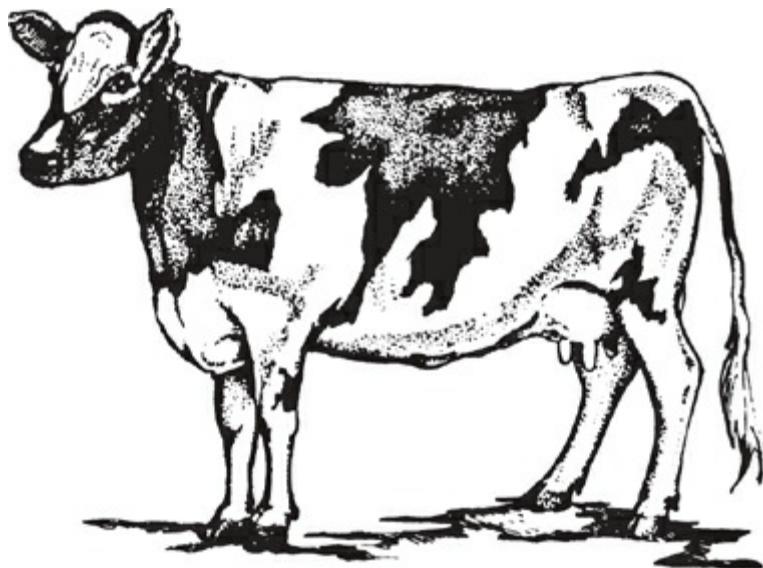

Brown Swiss. A Brown Swiss is large, tan-colored. Brown Swiss may have some calving difficulty on the first calf because they have large calves. Brown Swiss Cattle Breeders' Association: Box 1038, Beloit, WI 53511; 608-365-4474.

Dexter. The Dexter is a small dual-purpose (meat and milk) breed from Ireland. For more info, contact the Dexter Cattle Association, 4150 Merino Ave., Watertown, MN 55388; 952-215-2206; adca@dextercattle.org; www.dextercattle.org.

Guernsey. A Guernsey is yellow and white. Only Jerseys are smaller than Guernseys. The Guernsey has a lower cream percentage to its milk than the Jersey, but more than the Holstein. Guernseys have a reputation for being very docile and manageable, as do Jerseys. Their milk has a slightly yellow tint. American Guernsey Association: 1224 Alton Darby Creek Rd., Ste. G, Columbus, OH 43228; 614-864-2409; www.usguernsey.com.

Holstein. The Holstein cow is a big, lean, black-and-white animal—a bony, pure-dairy type. It used to be that they gave up to 6 gal. per day, but now that's up to 10–14. Their milk has the lowest butterfat percentage of any dairy breed. Because of typical Holstein size, there is actually a lot of beef on a Holstein bull or steer. So a Holstein bull calf could actually be a good choice to raise for a beef calf. Holstein owners wisely breed their heifers to Herefords (a small, beef animal) for easy calving, and later, to a larger-breed bull. Almost the only dairy cow being used these days for commercial operations is the Holstein. Holstein Association USA: 1 Holstein Place, Brattleboro, VT 05302-0808; 800-952-5200; www.holsteinusa.com.

Jersey. The Jersey is a small, dairy-type cow that gives lots of milk with a high butterfat content, the highest of any breed. They are wonderful family cows. A Jersey gives about 3 or 4 gal., 4 in her prime—which for almost any family would be plenty. The Jersey costs less to keep than larger dairy cattle because she is smaller and eats less, but she gives less milk, and the bull calf (your meat) doesn't grow as large as most others. Jersey bull calves sell especially cheap because Jersey fat is yellow. On the market this is confused with old bull fat, so feeders won't touch them. But for homestead use they make fine meat. Jersey and Milking Shorthorn are the 2 most popular in our area for home milk cows. Although Holsteins are the dominant cow in the United States numerically, I've heard that worldwide the Jersey is most common. American Jersey Cattle Club: 6486 E. Main St., Reynoldsburg, OH 43608-2362; 614-861-3636; www.usjersey.com.

Water Buffalo. This misunderstood and underestimated Asian bovine has extraordinary potential. It's large and not particularly good looking, but very gentle. The 2 major types of water buffalo are the swamp buffalo, or carabao, and the river buffalo. Both are good draft animals and good meat producers. The carabao is rarely milked, but the river buffalo is an excellent dairy animal. River buffalo are now being used in Latin America, working in tropical mud that would bog down a tractor. Their working life as a draft animal can be 20 years.

Mozzarella cheese was traditionally made from the milk of river buffalo. River buffalo milk has more butterfat (7–9 percent) and more nonfat solids (18 percent) than cow's milk. River buffalo are the basic milk producers (70 percent) for India, Eastern Europe, and many Middle Eastern countries. Both river buffalo and carabao produce meat that is leaner than beef (50 percent cholesterol), and just as tender. They do better in hot weather than cattle, but still need access to shade or a pond.

Shorthorn. Milking Shorthorns can be fine dairy animals too. But pure white Shorthorn heifers sometimes have an inherited defect that prevents them from conceiving. And in our experience they were somewhat more disease-prone than the average, especially to pinkeye. Shorthorns give plenty of cream. Their butter is white, rather than yellow. American Milking Shorthorn Society: 608-365-3332; www.milkingshorthorn.com.

Crosses. Gardening and food writer Lane Morgan, who reviewed the manuscript of this book, says their milk cow is a Holstein-Hereford cross and a very good family cow!

You just have to decide what is best for you.

Beef Cattle

For raising these animals practicality has to be the bottom line. A beef cow has to raise a calf each year or ... become hamburger. You can't afford to keep beef cattle if it costs you more to raise their only product, the meat calf, than what you can sell it for. Expenses come from feed, medicine, and vet visits, fencing, and the cost of the grassland you pasture them on. As with any business, you have to keep production up and costs down. Rotation grazing on a good pasture works well.

BEEF COWS IN PRINT: *The Cattleman Magazine* comes from the Texas and Southwestern Cattle Raisers Association: 817-332-7064, ext. 131; www.texascattleraisers.org. *Farm Journal* offers "Beef Today": 800-331-9310; www.farmjournal.com.

A Primer on Cattle Marketing Practices That Will Increase Your Bottom Line (1995) by Jay Nixon is available from 830-780-2455, 302 E. Buchel, Karnes City, TX 78118. Acres USA

offers lots of great books on cattle raising.

BEEF BREEDS

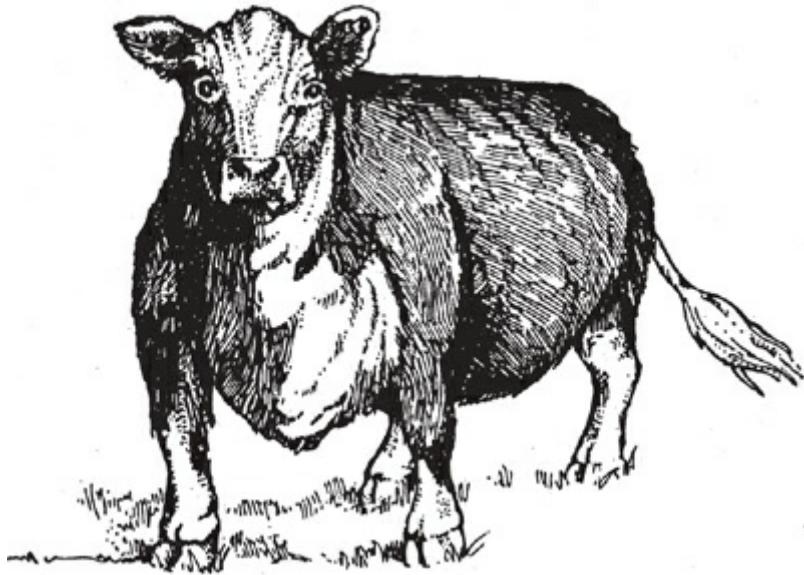

Angus. If you're worried about pinkeye, get the Black Angus breed. They're as good at foraging as Herefords, plus very disease-resistant. Angus are as wild as the proverbial March Hare, so they don't make family milk cows. They're not big, so there isn't as much meat per animal. And their small build causes calving problems; you'll have to get good at recognizing and helping with calving problems.

Beefalo. This is a buffalo-cattle cross with, some feel, the best of both breeds.

Buffalo. This close relative of cattle is a low-cholesterol, low-fat, high-profit meat animal (producers can get \$18 a pound for buffalo tenderloin, \$28 a pound for jerky). If there are plenty of boys and girls, food, and water, and you're lucky, they may stay inside your fencing. They can be fed a grain and hay diet just like a feedlot cow and be kept under similar circumstances. One lady keeps 9 buffalo on 10 acres. Eighty percent of this country's buffalo are now privately owned (Ted Turner and Jane Fonda have the biggest buffalo ranch: more than 5,000 head). However, these animals can be hard to control.

Exotics. Charolais, Limousin, Simmental, and a whole list of new breeds called the "exotics" are simply huge beef animals. Charolais cows tend to have trouble with their first calves because their calves are so big. A farmer nearby who raises them loses about 1 calf in 5 born to his Charolais heifers.

Hereford. The famous red-and-white Hereford cows are small like Angus, with a terrific foraging ability. Their small-boned structure is comparatively efficient at food conversion. A Shorthorn would starve to death on the deserts of southern Idaho and Wyoming, where Herefords can wander and grow fat. But, as with Angus, the smallness also brings less meat and more calving problems. A breed of miniature Herefords is now also available: 979-429-0208; www.mini-hereford.com.

Miniature cattle breeders have a society and registry. They provide info on all 24 breeds of these mini-cows and also publish a newsletter: *International Miniature Cattle Breeders Newsletter* (6 issues, \$25): 253-631-1911; fax 253-631-5774; 25204-156th Ave. SE, Covington, WA 98042; info@minicattle.com; www.minicattle.com. For example, there are Lowlines ...

Lowlines: These black miniature cows were created in Australia. A 14-month-old may weigh 314 kg live. Lowlines are docile, polled, with marbled meat: www.usa-minicattle.com

Longhorns. If you want dramatic (scary) big horns on animals who can look after themselves very well, thank you—get Longhorns.

Scottish Highland. These cows have horns resembling the longhorns, but also coats of long, shaggy hair which makes them very hardy against both weather and predators. Joyce Hetrick gives tours of her operation and sells registered breeding stock, halter-trained and gentle: 501-354-5025; 288 Heifer Creek Rd., Springfield, AR 72157; joyce@heifercreek.com; www.heifercreek.com. The American Highland Cattle Association is the national breed association, offering info, a nice quarterly magazine, and breeder's list: 22 S. 4th Ave, Ste. 201, Brighton, CO 80601; 303-659-2399; www.highlandcattleusa.org.

Oxen: Cattle That Pull

Any bovine that has been trained to pull is a “draft ox” or “bullock.” If you have 2 or more of these trained cows, you have a “yoke” or “pair” of “oxen.” Technically, a steer calf, yearling steer, 2-year-old, or 3-year-old can be pulling, but it’s not until the animal is practically mature at 4 years that it fully qualifies to be called “ox.”

DRAFT BREEDS: Any gentle breed of cow can be trained to pull. Usually people work with steers from a large dairy breed, such as Holstein, because they’re easy to get hold of. The Charolais, a French variety, are very large, powerful animals that were traditionally used as oxen in that country. They aren’t terribly bright but are of a peaceable nature. Best of all are the water buffalo.

OXEN VS. DRAFT HORSES: Farmers argued for generations over whether bovines or horses were better as draft animals. Jared von Wagenen, Jr., wrote in *The Golden Age of Homespun* of “great patient brutes with hooves that grip the earth, mighty shoulders, heaving flanks, and drooping heads, placid eyes, and spreading, gleaming horns—the glorious ox team.” Draft horses are more popular in the United States, to the point where the knowledge of how to train cows for draft work has teetered on the brink of extinction. A wonderful book called *Animal Traction* by Peter Watson (1981, revised 1983) offers solid information on every aspect of using oxen for cultivation.

ADVANTAGES OF OXEN FOR DRAFT WORK

1. Many a pioneer family whose cow pulled their 2-wheeled oxcart or wagon were grateful that she also gave milk and gave birth to calves.
2. Oxen use a far less complex and less expensive, less perishable, harness than horses. They simply have their wooden yoke which is low-cost and easy to make and lasts a lifetime. The yoke gets directly attached to the tongue of the farm implement or wagon, or to a chain that is attached to their load. In the woods, there is no need for whiffletree or trace chains, only the chain going to their yoke. The traditional wooden ox yoke is cheaper than horse harnesses, although the old-timers sometimes harnessed with leather rather than yoked their oxen—and considered them less hard on harnesses than horses!
3. Oxen are generally less likely to jerk and startle than horses, more gentle and docile by nature.
4. A typical ox is heavier than a typical horse, with more pulling power. Von Wagenen wrote, “It was in the rough, hilly sections that oxen were found in the greatest numbers and lingered longest.” But that is hotly disputed; I’ve heard elsewhere, “It

takes 2 yoke of cattle to do the work of one 1,200-lb. team of horses.”

5. The pioneers considered oxen to be better among stumps and stones than horses.
6. Oxen can be shod, but aren’t as needy of it as horses. And don’t shoe your oxen until they’re at least 4 years old because before that their hoof isn’t strong enough yet for a nail. And, once shod, an ox holds a shoe longer than a horse. (If oxen are worked a lot, they *need* shoes. A horse takes a single shoe per foot. An ox requires 2 shoes on each foot, 1 for each half of their cloven hoof. A horse will allow its foot to be picked up and held; an ox usually won’t easily cooperate, but it can be done.)
7. Oxen are claimed by their owners to be healthier than horses. The old-timers believed oxen could do more work on a diet of plain hay and pasture than a horse.
8. The price of a potential draft cow is less than that for a draft horse—bull calves are cheap to get if you have milk cows.
9. Oxen are good in deep snow.
10. An old, or retired ox can be converted to hamburger for the family. Old horses get sold for dog food, but are not eaten at home.
11. Oxen are more patient and less likely to injure themselves. (Horses are faster.)

(For all the good things about draft horses, see *The Draft Horse Primer* by Maurice Telleen.)

RESOURCES

Association of New England Ox Teamsters works to preserve New England traditions:

Linda Wilbur, Secretary; 603-357-4197; 989 Old Walpole Rd., Surry, NH 03431;
cynthia123@attbi.com; <http://home.comcast.net/~cynthia123>.

BerryBrook Ox Supply sells ox equipment: new and used yokes, bows, ox shoes, goads, whips, logging equipment, horn knobs, horn weights, yoke hardware, books, videos, etc. Their newly manufactured logging/farming fore cart and logging scoot are of good quality and reasonably priced: 603-335-4475; 394 Meaderboro Rd., Farmington, NH 03835; berrybrookox@metrocast.net; www.berrybrookoxsupply.com.

Drew Conroy teaches dairy farm management at the U. of New Hampshire, Thompson School of Applied Science, 291 Mast Rd, Durham, NH 03824-3562; 603-862-2625. He’s the expert on training and using oxen as draft animals who wrote *Oxen: A Teamster’s Guide*.

Mid South Ox Drovers Ass’n is for people interested in cattle trained for draft purposes (oxen). Demonstrations and newsletter available. Contact joyce@heifercreek.com for more information.

Midwest Ox Drovers Ass’n holds a wonderful annual meeting and has a regular newsletter (\$10) focusing on education and sharing info: c/o Beverly C. Zimmer, Secretary, 5518 Dull Rd., Arcanum, OH 45304; www.midwestoxdrovers.com.

Tillers International: Take a “Yoke Building and Fitting Workshop,” the “Ox Driving Workshop,” or one of the many other relevant classes in nonelectric skills offered by Tillers International; 269-626-0223; 10515 East OP Ave., Scotts, MI 49088; www.tillersinternational.org. They also sell ox-power publications and products: *The Pride and Joy of Working Cattle*, successful techniques for ox training, by Ray Ludwig; and *In Praise of Oxen* by Terry James and F. Anderson, photos of Canadian teams. Membership in Tillers gets you the *Nigh Ox*, their newsletter. Other ox books from Tillers include *Advanced Training of Oxen; Training Young Steers; Selecting and Teaming Oxen*;

and info on how to build an ox yoke, cart design, single-cow yoke design, yokes, yoke rings, and training videos.

TRAINING OXEN: Begin training with calves, so they have a long time to get used to all that is involved. The old-timers looked for an animal with ambition and that “light-footedness.” True draft breeds or dairy breeds are preferred for their docility, once steered. The old-time English Devon was treasured for its draft ability. Von Wagenen wrote that “the breed had a certain snappy activity and light-footedness.” Nowadays Devons are rare; and Holstein steers make fine oxen, too. Oxen are normally used in a set of 2.

Oxen can be trained to work by voice commands, combined with a prod or whip used by a driver who walks next to them, or to work using a harness and bit and driven with reins like a horse team. In either case you start by getting them used to wearing a halter and teaching them to lead. To drive using a bit and reins, train like a draft horse. Work with them at least half an hour a day. If you work right before their dinner, it ends their labor with a food reward.

Voice Commands. Traditional names for a yoke of oxen are “Tom and Jerry,” or “Buck and Bright” or “Pat and Mike,” or “Duke and Dine.” The traditional voice commands are “gee, gee” for “go right” and “haw, haw” for “go left.” “Whoa” means “stop.” “Ged-dup” means “go.” (“Go” sounds too much like “whoa” to use.) “Back” means reverse, back up. You can habitually combine a command with the animal’s name: such as “Gee Pat” to go right, “Haw Mike” to go left. Training them, like horses, to wear a bridle with bit, combined with the yoke, allows the driver more precise control, but the beauty of using voice commands is that it leaves your hands free and you don’t have to worry about reins.

It takes considerable time and effort to get those 4 terms drilled into them. Teach them to obey voice commands using ropes that force them to do what the voice command means. Or to teach “whoa,” step right in front of the animal while pulling hard backward on its halter at the same time you say the word. You repeat that over and over until the animal does it without the halter pull or the rope (classic Pavlovian conditioning). Cows are brighter than you might think, but, still, they are creatures of extreme habit. What they’ve learned is what they know. That’s why from the first day you assign 1 of your pair to be the nigh (left) ox, and the other to be the off (right side) ox. From then on you *always* yoke them that way. Otherwise they’re “backwards,” and oxen yoked backward will be very confused! If your nigh ox, for example, dies, replace it with another trained nigh ox—or train a green steer. Don’t try to use an off ox there. The old-timers in New England usually called that nigh ox, “Buck,” and the off ox “Bright.” That way they knew which side an ox was trained for by his name.

Gad. The voiced command is supplemented by the “gad” or “whip,” traditionally a 4-or 5-foot length of narrow hardwood sapling with 2-3 feet of thin leather strap attached to the end. Let me make it clear that the gad is used for touches to get Buck and Bright’s attention, to direct and manage them, rather than to punish. Some teams, in some circumstances, work fine with only voice.

Yoke. The traditional hitching system is based on the yoke, a large carved wood shape that fits over each animal’s neck and is held there from underneath by a U-shaped bow under the cow’s neck. To see how a yoke is made, check your local pioneer museum! You can make a yoke by cutting it out of a block of wood with a chain saw and trimming with a knife. The bow under the cow’s neck can be made of any strong, flexible wood, steam-bent into that U-shape.

You’ll be putting them into a series of yokes, of ever-increasing size, as they grow. To fit them properly with a yoke, start by tying them up standing parallel and with their sides 6

inches apart. Measure the distance between their necks and build their yoke accordingly. When they've grown enough that their sides are rubbing, it's time for a bigger yoke.

A modern variation is a bridle and bit on the animals by which they are directed from behind with reins just like with harnessed horses, but combined with a yoke.

Training Oxen to the Yoke. At the center of the single yoke that binds them together there is a metal ring. You fasten the tongue of the farm implement that they are to pull there, and that's it. While still young, they can pull a pole with something noisy attached to it to help them develop calm nerves—later a light sleigh or cart. At 18 months old they can start more seriously working. For tough work like plowing, even 4 yoke of cattle might have been combined in the old days.

Cattle Handling

Cows vary wildly in gentleness from a sweet pet of a Jersey family milk cow to a huge, mean, wild range bull. The following wisdom is specially applicable to working with range beef cattle, but there are wise reminders here for any handler.

Cow Psychology and Senses: Your cow's closest relative on the farm is the sheep. They're both herd-oriented, humble animals. (For least stress and best production keep 2 or more calves or cattle.) There will be a boss cow, same as the boss goat described in that section. Large cattle herds will form smaller subherds with an order of dominance in each group. A cow's best sense is her smell. She can smell her calf 3 or 4 miles away. A bull can smell a cow in heat that is miles away. Cattle have good hearing, too. They dislike high-pitched sounds like the crack of a whip.

Cow psychology is influenced by the design of a cow's body. A cow has 360° panoramic vision. That means she can put her hind foot into the bucket or kick it over on you, and it's not a lucky accident for her. She can actually see beside and behind herself without turning her head. But cows can't see color. Everything is black and white to them, so it doesn't matter what you wear. They are very sensitive to stark black and white contrasts, though, and have poor depth perception. White lines painted across a road can look like a cattle guard to them. It's hard for a cow to tell the difference between a shadow and a hole in the ground so a dark shadow can scare her into going around it.

SECRETS OF SAFE CATTLE HANDLING

1. Move your cattle patiently, quietly. Avoid exciting or hurrying them because a running cow does its own unpredictable thing whereas a slowly walking one is likely to go where you want.
2. Cows follow the leader. If you can coax the first 1 or 2 through a gate, etc., the rest are likely to follow naturally.
3. To turn a cow you can make some noise and make yourself look large by waving your arms widely, but do this from an angle, not right in front of the animal because you may lose. Being straight ahead in the cow's way invites you getting knocked down and hurt.
4. Teach your cattle to come to a certain familiar call to get a treat of grain or a bale of hay. When you feed them frequently and handle them gently they learn to trust and depend on you. Then you can call and lead them where you want. (Always follow the call with the food reward or they'll lose faith.) This, of course, works best if they're hungry.
5. Cows are frightened of new places and made nervous by change in their daily

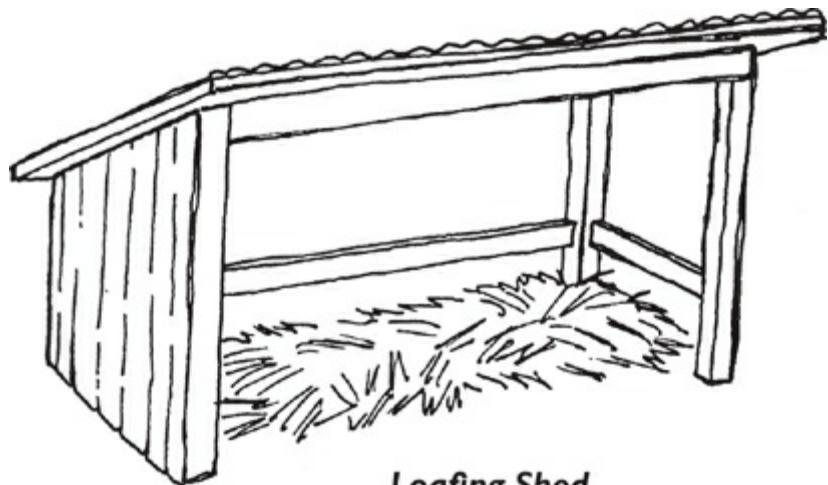

routine. They don't take easily to learning anything new. They resent being forced to do anything. The best approach is true patience and a plan to outsmart rather than outfight them.

6. Build good fences and keep them repaired.
7. Build a corral and a loading chute.
8. A knowledgeable horse or dog can help a lot.
9. Keep a docile, hornless breed.
10. When dealing with a cow-calf pair, have a means of escape available, such as a pickup that you could run around or vault into; the cow's protective instinct might get aroused, in which case she would attack using her head. She's most likely to charge you if her calf bawls. (The strong maternal instinct of beef cattle is a usually good thing. They've been known to protect calves successfully even against lions and bears.)
11. Before you help a calving cow, first halter her and tie her to a fence post, tree, or (worst choice) pickup bumper.
12. Be careful around a cow in heat. She may try to mount you.
13. Be even more careful around a bull. Never forget its potential danger. Never come near it without having an escape route in mind. Never turn your back on it. If possible always have a second person with you. If a bull does become threatening, hamburger it. *Never let children into a pasture or pen that has a bull in it.*

Cattle Housing

Don Fallick, Davenport, WA, wrote me: "Cattle lean on things. And they're heavy. Anything built for use around cattle simply must be very sturdy."

LOAFING SHED: A loafing shed for cattle should be anchored by posts at least 8 inches in diameter, extending below ground at least 3 feet. Old telephone poles work well. The phone company pulls poles when they get too rough to climb safely, but they may still be sound from a structural point of view. The posts can be connected by 2×8 s set 2 feet on center. Skin the outside with exterior grade plywood, no thinner than $\frac{5}{8}$ inch, though $\frac{3}{4}$ inch is better if you can afford it. Particle board will weather better than plywood, but will never stand up to the punishment cattle will give it. Corrugated metal roofing is so good and so cost-efficient, it has virtually become standard. Such a loafing shed is cheaper than one built of cement blocks, and much cheaper than one with concrete walls, but it won't last nearly as long. A good compromise is to build the bottom 4 feet of the walls of reinforced concrete or reinforced cement blocks. Then build the top of the walls of wood.

Loafing Shed

MILK PARLOR: Your “milk parlor” is an outbuilding where you will milk your dairy cow(s). Don Fallick says: “A milk parlor for cattle should be built similar to a barn, but for cleanliness I favor walls of concrete, at least at the bottom. If you use cement blocks, painting them will make them easier to clean. To fasten the frame tops of the walls to the concrete or cement blocks, set L-bolts in the top of the concrete, or fill the cement blocks with sand where the L-bolts will be set, except for the top course. Then fill with cement and set the L-bolts in every third block. The L-bolts will be used to bolt down the bottom plate of the frame portion of the wall. A slick way to position the L-bolts exactly is to drill the bottom plate first and install the L-bolts in it loosely, then use it to position the bolts in the wet cement. After the cement is dry, the bottom plate can be removed and the wall framed, installed, and bolted down.” Believe you me though, says Carla, it can be simpler than that.

Feeding Cattle

Any cow needs grass or hay, water, and salt. (There’s lots more about pasture, hay, and silage in [Chapter 8](#).) Cows that are giving milk have special nutritional considerations (see below). They all always need water and salt. Mature cattle are true symbionts, in that they cannot live without the help of millions of microscopic critters that live in their rumen and do their digesting for them! A cow’s stomach is literally a big fermentation vat in which their friendly bacteria and protozoa are constantly digesting the food and fiber they eat.

NOTE: A cow is designed to eat with her head down. If your feed trough isn’t low enough, her saliva won’t run well.

WATER: Cows need lots of clean water. If you have trouble with it freezing in winter, you can buy an electric heater that keeps the tank warm enough so the water doesn’t freeze. Mike just goes out twice a day and chops a hole with the ax so they can drink and hopes for warm weather and a thaw. It’s nice if you have a way to warm their water in winter, but it doesn’t have to be warm. And, given a choice, cows would much rather drink unchlorinated water and will drink more and produce more milk on it.

SALT: You can get various kinds of salt blocks. Some of them have minerals added. There is even a kind that contains a medicine to help fight the burrowing flies that cause worms in their backs. (Can’t give that kind to milk cows.) Your block will last the longest if you keep it sheltered from the weather.

FEED FOR BEEF Cows: You don’t need to give beef animals any grain. In general, beef fat is

one animal product there just isn't much use for. You can take some beef tallow on the end of a fork and use it to grease a pancake griddle. You could make soap with it. You can grind a little bit in with your beef hamburger, but it's a comparatively high cholesterol fat. Our cows for eating are entirely grass-fed: grass in summer, hay in winter. They've never tasted grain.

SECRETS OF DAIRY-COW FEEDING

1. Provide lush pasture—or the equivalent in hay and supplements. In an average temperate zone your cow can be well-fed on pasture from early May to late November.
2. Pasture is most nourishing when it includes legumes (clover, alfalfa, lespedeza), several kinds of grasses, and a variety of herbs (natural, healthy “weeds” or fenugreek, lavender, marjoram, mustard, rosemary, sage, thyme, etc.).
3. Feed hay during winter: tender, green, cut just as it blooms.
4. Every day feed 2–3 lb. good hay per 100 lb. body weight of your cow, as much as she'll eat during winter. If you're feeding silage, give 3 times that much, since it isn't nearly as nourishing as good hay. If you do feed silage or green chop, best feed some hay too.
5. Feed only an amount of hay that she'll eat up before the next milking. Cows don't like stale feed and the surplus will be wasted.
6. You have the option of feeding your dairy cow only such good hay and/or good pasture. She will still produce plenty of milk for an average family.
7. When pasture or hay quality falls, your cow will give less milk.
8. If you supplement with grain (oats, barley, corn, wheat) and other high-protein foods (peanuts, soybeans, legumes, sorghum, milo, kafir, soybeans, peas), you can increase her milk production by 30–40 percent and prolong her production period. You can buy this type of supplement from a feed store or provide it home-grown. Store feed grains in a covered, metal container to prevent losses to rodents.
9. Feed supplements morning and evening at milking time.
10. If your cow isn't used to them, add them gradually, increasing the amount slowly to avoid bloat.
11. Start feeding supplements after calving and increase gradually as she produces more heavily, then taper off gradually as she slows in production, nearing the end of her lactation. Thus you match your supplementing to her milk production since the reason you're giving supplements is to replace the protein lost in her milk production. She normally peaks in production a month after calving, stays high for the next 3 months or so, then tapers down until the end of her 10 months lactation when it's time for you to stop milking her.
12. Every cow has a maximum ability to give milk, beyond which extra feed is just wasted on her. You can learn that by increasing supplement until her milk supply stops increasing. Then stop increasing—give her a little less than the peak amount for her 8-month production high. An average cow can use up to 1 lb. grain per 3 lb. milk produced. But with quality pasture or hay and ½ lb. grain each day, she'll give about 90 percent of her capacity. And that may be more than enough for your needs.
13. If you choose to supplement and/or winter her only on home-grown food, the easiest system is to give her corn and cornstalks starting in late summer. As long as the corn

is still somewhat soft you won't need to grind it for her. Starting in about November add supplemental hay. Starting in December feed as much good hay as she'll eat, plus several ears of corn, ground, at each milking until the pasture is ready again in late spring. You can also give her root vegetables (carrots, beets—washed and sliced), crushed beans and peas, whole sunflower heads, cabbage, turnips, beet pulp, squash, pumpkins, buckwheat—actually, any grain (see animal-feeding instructions under that grain), and winter-growing green leafies such as comfrey and kale. It takes a lot of root vegetables or leafies to supplement for a cow. Figure about $\frac{1}{8}$ acre of garden per cow to grow her supplementary feed at 25 lb. per winter day.

14. If pasture is overgrazed or the hay is poor-quality, she'll need extra-rich supplements.
15. Or, if she is gentle enough to wear a halter and be staked out—and many family milk cows are—you can put her out to graze on unfenced patches of good green grass in summer and make good use of feed that would otherwise be wasted. A staked-out cow needs a large water container nearby kept filled, especially if the weather's hot; or else somebody must lead her to her drinking place at least 3 times a day.
16. Know your cow's normal appearance. If she's fat, cut back on supplements. She could have calving difficulty from being overweight. *If she's getting thin, give her more feed! If she refuses to eat, call the vet!*

ABOUT ROUGHAGE AND PROTEIN: A dairy cow needs 2 kinds of food in her diet to be healthy: roughage, which can be supplied by any kind of grass, even straw; and protein. Alfalfa hay has both. Straw is high in roughage, low in protein. You have to supplement straw with grain or good alfalfa hay, which is a high-protein hay. Straight grain isn't a good feed because there's not enough roughage. If you can supply your cow good green leafy alfalfa hay, almost any mixture of home-grown grains will be a fine protein supplement.

MORE ABOUT GRAIN FOR YOUR MILK COW: Grains differ in food value. Barley is richer than oats, but more expensive than oats. A good grain treat feed for the milk cow is a mixture of half-chopped oats and half-chopped barley. Any grain that you buy for your animals should be chopped or ground before you bring it home. They can digest it better that way, so they'll get more food value for your dollar. If you raise your own grain, rigging up your own chopper is almost a must. Or you can use the coarsest grind on your home flour grinder. Whole grain is cheaper, so you can save yourself money by doing your own grinding. I give our milk cows about a half gallon of grain morning and night. That's really more than necessary. Oat-pea hay is a good winter feed for them. That, plus some alfalfa, contains everything they need—including enough grain.

ABOUT HAY FOR COWS: It takes a lot of hay. You don't need to give anything else but water and a salt block to nonmilking cows, but cows that are milking or getting ready to come fresh are grateful for some grain every day. Cows have the kind of digestive tract that needs a lot of roughage but also some protein. Alfalfa hay is ideal for them because it has both. But if you haven't got or can't afford alfalfa hay, you could use a poorer hay with a grain supplement to supply protein. Or a straw, alfalfa, grain combo. If you use straw, such as barley straw or oat straw (the stalks left after the combine has taken the grain heads), you should also give them some higher-quality food value in it to keep them in good shape. To winter a cow you figure about 2 tons of hay per cow per average winter.

Cow Reproduction

SCHEDULING: A milk cow can very neatly be put on an annual schedule. Keep your cow

pregnant 9 months out of the 12. Dry her up about 2 months before calving time. (If her feed is mostly grass rather than grain and supplements, it's wise to dry her up 3 months before her due date.) The second time she comes into heat after calving (about 18–22 days after the first heat she'll be in heat again), put her with the bull or A-I. That way you are milkless only about 8 weeks of the year, and she is producing beef calves and replacement heifers about as fast as bovinely possible. Gestation is 285 days, about 9½ months. So she will calve again at about the same time next year, and you get 1 calf a year from her plus all that milk.

HEIFERS: It's better to not let a heifer get bred as soon as she is capable of it or you risk a difficult birth, a cow stunted for life, always a poor milk producer. They can conceive as young as 3 months. Don't let them conceive until they're at least 13 months old. To minimize calving problems, don't grain a heifer before she has her first calf.

Cow HEATS: Usually her heat period is every 21 days, but individual animals can have a cycle as short as 18 days or as long as 24. Her first heat period after giving birth will be in 30–60 days. A cow stays in heat from 8 to 30 hours, on the average about 16 hours. If you notice heat, get her bred immediately, because the next day may be too late!

SIGNS OF BOVINE HEAT

1. Restlessness, stamping around, twitching her tail an unusual amount.
2. She'll be doing a lot of bawling.
3. She may drop a little in milk production.
4. You may see redness and swelling around her vulva, plus maybe a mucous discharge there.
5. If you have other cows (even females), they'll be riding her in the manner of a bull.
6. If a normally peaceable heifer goes through your fence, it probably also means she's in heat.
7. If the neighbor's bull comes through your fence and breeds her, that's an absolute proof.
8. Lane Morgan warns, "Be alert. She may also try to mount you."
9. If she lies down any time in the latter part of her heat period, she'll go out of heat.

BREEDING: From the time of her first post-calving heat on, she'll have monthly heats until she's bred. A less frantic way of arranging her breeding than trying to get the A-I techie there her first heat is to simply mark down her date, then make tentative arrangements for the next heat, which you now know the approximate date of—it will arrive in 18–22 days. Cows can thus conceive—and calve—at any time of year. The best schedule for cheapest food production is to time it so her calf comes in very early spring. Her first breeding may not take. (About 1 in 3 tries don't.) If not, try it again the next "month," and that probably will settle her for sure.

Bull. You don't want to keep a bull unless you're running a serious cattle ranching operation. If you do, the bull needs more feed than a cow, but can make it on grass in summer and hay and roughage in winter. A bull for breeding should be at least 18 months old. *A bull must always be handled with care. They are always potentially dangerous.*

A-I. If you artificially inseminate, you can have a calf that's half anything. A heifer that hasn't had a calf before, or for safety's sake, that hasn't had 2 calves yet, shouldn't be bred to a bull of a larger breed than her own. Cow breeds vary too much in size. An unbred

Jersey cow might weigh 600 lb. or even less before her first calving. On the other hand a Devon cow could weigh 1,600 lb. So you see, you wouldn't want to breed your Jersey heifer to a Devon bull because the resulting calf would probably be so big she couldn't bear it naturally. Breed her to a Jersey bull the first couple of times. Then you could try something bigger. Shorthorn is fine later on, because although the Shorthorn cow weighs about 1,200 or even 1,500 lb. on some of the Australian Illawarra exotics, the calf is not large.

The people who artificially inseminate are certified by the state after taking an A-I course. You can pay the inseminator to come, or you can take a course and do it yourself. The inseminator brings a kit in which he or she carries all kinds of frozen semen for you to choose from. Very fancy stuff—it can be from champion bulls of any breed you choose. The semen will cost an additional fee per ampule, price depending on the source. The cow has to be in heat for the A-I to take.

GESTATION: The length of pregnancy varies somewhat, but in general a cow will calve 285 days from her date of service—in about 9½ months. If you don't dry up your cow that last 6 weeks it's hard on her, and the milk may get "strong" tasting.

CALVING: The same principles apply as with goats. Prevention of problems is the best cure. The dairy breeds of cows all calve easily anyway, as they are selected for that. It's some of the smallest and largest beef breeds that have the reputation of calving difficulty.

Because a cow's birthing instinct is to go hide in a woods and do it all by herself, it's wise to bring her into a pasture near the house in summer or into the barn where you're providing a warm stall with lots of clean bedding if the weather is awful. Do that at least a couple days before her calving date so you can keep a close watch on her. You'll know calving is getting near when her udder swells with a milk supply, her vulva swells, and the flesh seems to loosen around her tail bone and fall away.

After that point, check on her several times a day. You have a big investment at stake here and will want to help or call the vet if she has calving trouble. But ordinarily your cow will calve, and you'll find her standing there nuzzling her baby, and you won't have to do a thing except provide the usual necessities of food, water, and shelter. She may very likely calve in the open. That isn't nearly the problem it can be with goats and sheep because calves generally are harder at birth.

If your cow is obviously in trouble and you live in the country near experienced neighbors, the first thing I'd do is ask them for advice. Most knowledgeable cow people can help you judge what is happening very competently. *If she isn't able to give birth after 3 or 4 hours of hard labor, call the vet to come.* A cow is worth a lot of money and well worth what you'd pay the vet to get her fixed up. And then you save the value of the calf, too. A calf normally is able to stand, though awkwardly, soon after birth and nurse from its mama. If you're there when she calves, stay long enough to make sure that the calf indeed makes it onto its feet and found a teat.

Cow Down. Barbara Stone, Stites, ID, wrote me: "We had a cow that had just calved, but she had lain in such a position that she couldn't get up. She was in the middle of the field, but she found a place where she had her head downhill and her back area uphill. This had never happened to us before, so we didn't know exactly what to do, but we knew she couldn't stay there too long. With the help of a neighbor we got her feet dragged around with both areas on the same level. Put her on her knees and held her so she'd stay there. Within just a few hours she was up as if nothing happened. If this happens again, and it probably will sometime, we'll know what to do. If no one is around to help, use the tractor

or the pickup, tie a rope around the front legs and carefully roll them around until they are straight. Watch the neck that it doesn't get hurt. All of these things a person has to learn sometimes the hard way. After the animal is up, make sure it stays up."

A cow might be down if she's been injured from slipping on a slick surface, or had a blow from another cow, or by calving, or by disease. A "downer cow" is indeed a crisis. She needs to be kept comfortable, fed, watered, and treated as needed. Pro cow operations use a "downer cow skid" to move her if moving is needed. (It takes at least 2 or 3 strong people to roll a downed cow onto even the lowest skid.) *NOTE: But if a cow goes down and can't get up just before or right after calving, I'd start by calling the vet quickly in case she has milk fever.*

Newborn Calves

Take out a big towel or blanket to dry off the newborn calf with a good rubbing. Check to make sure it's in a relatively nice place. Calves are tougher than kids. If you want the cow and calf moved, just pick up the calf and carry it in your arms. The cow will follow. She'll try to hide the calf as soon as she can. That's called "brushing up," and it's an instinct cows have. She'll go to the hiding place several times a day to feed and check on it. (Goats, on the other hand, will stay right by their babies.)

We usually give the newborn calf its Bovine vaccine and maybe some A and D and Combiotic and hang around until it stands and finds its first meal. Even if you leave the calf with the cow you've still got to milk the mother out yourself at least once a day. That's because any milk cow in her second (or more) lactation gives much more milk than a newborn calf can use, and she will be miserable and risking mastitis if you don't help by taking the extra milk.

BUYING A YOUNG CALF: You can often buy a calf from a nearby dairy or farm. If you just want a calf to raise for meat, a male calf of a dairy breed is probably the cheapest to buy. A dairy-beef cross would give you a little more beef; they grow faster and have a meatier carcass. Be sure you have a healthy one. A thriving young 'un holds up its head—back straight, tail out a little. A calf that won't stand or huddles in a corner with its head hanging, back hunched up, and tail down between its legs is probably sick. A bargain calf that brings disease, parasites, and vet expense to you—or even dies—is no bargain. It's best to take care and a little time in buying, though it will cost you more. Ask: When was the calf born? How many days of colostrum has the calf received? What vaccinations has the calf received? What diet is he on right now? How much milk per day? How many feedings per day? How much grain or hay?

AUCTION CALVES: If you buy a day-old calf at a livestock auction you have special problems. Maybe the calf has never eaten. Ranchers may take a calf to the sale ring while it is still practically wet if the sale day happens to fall that soon after it is born. Or the brood cow might have died in calving, and he doesn't want to bother with an orphan. By the time you get such a calf home it will seem weak and listless. You may find that a calf you buy at auction that has been nursing the cow is better started health-wise but is not pan or bottle broken.

Taking Your Calf Home. The best time of year to get a calf is late winter. (Then, about the time it's weaned, it can go on grass and live on that until late-fall butchering time.) If you plan to buy a baby calf at auction and the weather is cold, take an old blanket to the sales yard or provide some straw bedding. A long chilly ride home in the back of a pickup is going to weaken your calf even more. Put a halter on him and fasten it tightly near

where you want him to ride. When you get your calf home give him a place indoors—in the barn with lots of hay or straw bedding and a blanket over if he is shivering or wet or weak. Give an antibiotic “calf starter” pill if he can’t have mother’s colostrum.

Calf Shelter. A calf born in late-spring or summer outside in a pasture will do fine. A late-winter auction calf needs to have a home inside your barn where it’s dry and sheltered from the wind. A mid-spring calf can go to a more humble outdoor shelter consisting of an open-front shed or some such. Provide warm bedding and frequent feedings of warm milk. Later add a water supply and a hay manger if hay will be fed.

White Muscle Disease. We had a calf die of this. It was very stiff in the joints, moved little, slowly, with obvious difficulty, and was in poor health, generally. It couldn’t follow its mother and so didn’t get enough to eat. There is a lot of white muscle disease in our area, and it’s important that we get a calf immunized against it as soon as possible after birth because it’s just about impossible to cure once it sets in. We try to give the immunization shot the same day the calf is born. You can mail-order these and other serums or buy from your vet or vet supply.

Chilled Calf. If you find a calf prostrate, shivering, with tongue slightly protruding and eyes sunk in—one that cannot get up or eat due to the chill on an unseasonably cold night—carry it into the house. Lay a towel in the bathtub. Lay the calf on the towel and a blanket on top and draw in enough hot water to stop the shivering. In the meantime get a hot place ready for after it comes out of the tub so it doesn’t get chilled again. Keep the calf warm even when it seems to be pulling out of it. A chill may give it a fatal setback.

Surplus Calves. These are never just killed and discarded like kids may be. Even a newborn calf is worth at least \$75 or can be butchered for meat. But a normal cow gives plenty of milk to meet both your needs and the calf’s.

Milk for Calves: You can take a calf from the mother anytime from birth on. If you take the calf away immediately, you get it without prejudices about how it should eat and without too much energy to fight your ministrations. If you wait 4 days, however, it has been well-started by the mother, but the mother’s milk production in the long run may benefit more if you take the calf off her immediately and milk her out twice a day.

Colostrum. Feed the calf all the milk you get from its mother for the first 4 days of milking after calving. You can refrigerate surplus until needed. Don’t use it yourself since it’s brownish-yellowish and not very appetizing looking for people food, and more importantly it contains antibodies the calf urgently needs. After that the colostrum taste is out, and you can use the milk, too. The colostrum milk is fine for pigs and chickens as well as the calf, so you don’t need to throw any away.

Calf Adoption. A dairy cow can easily raise 2 or 3 calves. To put a calf on a cow that’s not its natural mother, it works best to restrain the cow while the calf nurses until it learns how to sneak a meal from behind. Some folks put vinegar on the calf and on the cow—on their noses and other places—to try to fool the cow into accepting the calf more readily.

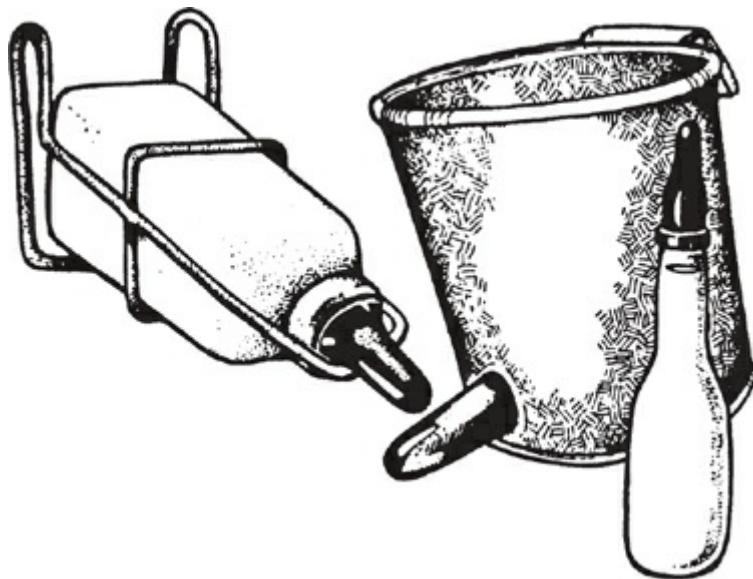

Milk Formula for Calves. If you have no colostrum, give the calf warm milk with egg yolk beaten into it. Cold milk can kill a calf. The egg yolk makes the first meal a little richer and thicker. Continue to give the milk and egg yolk mixture for several meals and return to it if the calf does poorly after that. After that, feed milk from another cow, just as it comes from the cow. If you don’t have that, you can feed fresh goat’s milk, diluted 1:1 with water. Lacking that, feeding reconstituted dried whole milk is next best. Dried nonfat milk is not as healthy but can work.

How Much Milk? A quart or so per day to start with, then work up to 2 qt. per day at 2 weeks, then 3 qt. per day at 3 weeks. It depends also on how much the calf will drink. You

can give more of the cow's milk than of a powdered milk-water mix or goat's milk. Calves of different breeds, hence different weights, will take relatively more or less. A larger calf will be drinking 2-2½ qt. at each of its 2 daily feedings. The older the calf, the more it will take. Too much causes scours. A big calf would happily drink much more milk than it is ordinarily given. We force the calf to share his milk with us because we need it too.

Temperature. The milk should be warmed to body temperature, about 100°F.

Calf Bottle/Feeder. You feed them either out of a pan or from a calf bottle, calf feeder, or a calf group feeder (a box with several nipples). A calf feeder is a bucket with a nipple attached to the bottom. If you're going to use the calf feeder you've got to start with it—the very first time you try to feed the calf. He'll get a fix on whatever he is sucking when he gets his first good swig of milk and will be hard to change over. You coax the nipple into his mouth the first time. Same with a calf bottle, which is a big plastic bottle with the right-sized nipple. Try to stay with small calves drinking out of a calf bottle. Otherwise, they may yank the nipple off, end up inhaling their dinner, and get clinical pneumonia. The calf group feeder is the latest and greatest thing, especially for mass production of beef calves. Let's say you have 5 calves in a pen. At feeding time you bring their milk in a big bucket and pour it into the group feeder. The group feeder sits on legs on the ground or is hung from or attached to the wall. It has 5 equal-sized compartments to hold milk, each of which is attached to an outside calf-sized nipple. The milk-holding part has marked lines on the inside like a measuring cup so you know how much you're feeding. You pour the milk into the little trough; the calf sucks it out through a nipple. Have the group feeder high enough so young calves suck in the natural head-up position.

Pan Feeding. Or use a stainless-steel pan (but any kind will do) about 6 inches deep and about 1 foot across. I warm my milk and egg mix right in the pan. Make it a little extra warm to compensate for chilling on the trip to the barn. The calf has 2 strong natural instincts that you have to consider when you're breaking him to a pan feed: one is to reach up to feed; the other is to suck on a nipple-type object.

So do this: Cup your left hand slightly. Dip your hand in the warm milk. Slip your middle fingers into his mouth. With your other hand scoop up milk and pour it into your feeding hand. Some of it will run down the grooves between your fingers and get into his mouth. You need somebody to hold the pan while you are doing this. And the calf needs to be lying down to make it easier for you. You may have to spend a long time just doing this. Now try to gradually lower your hand into the milk. He'll suck up the milk and it will

go into his mouth. Wiggle your fingers in his mouth a little if he seems to be losing interest. It takes a little effort to get him pan-broken, but once he is, all you have to do is take his pan and set it down and get out of the way. That's helpful when he grows to 200 lb. Note: It's actually healthier for a calf to nurse with his head up than down because that's the way he's designed—so there's another advantage to the bottle method.

Frequency. Feed the calf every few hours (5 times a day) until you're sure you are getting food down it. Then go to 4 times a day for a few days. Then feed him morning, noon, and night for a few days. Then only twice daily. He will be a ravenous glutton, but don't give him all he can drink, as it will make him sick. Twice a day continues until you're ready to start weaning.

Calf Scours. When we have a baby calf with scours we put him in the warmest, driest place possible, give him an extra calf starter pill if it's very bad, and give him half a 12-ounce bottle of Kaopectate. Kaopectate is a mixture of real fruit pectin and kaolin—a natural clay. It really helps. Then I give less milk and sometimes make it less strong by watering it. You just have to experiment to figure out what the individual animal needs. If calves scour on a diet of goat's milk you can't change to cow's milk—the change in formula will make them even sicker. Just give Kaopectate and give them less of what you're giving them. Some baby cereal or scorched flour with the Kaopectate may also help. And so will shots of vitamins and antibiotics.

Weaning: When calves are raised to set records for weight gain and final size—registered championship-type animals—they are usually left on the mother because the plain fact is that given all the milk they desire on a demand schedule, they gain faster and end up being bigger and better-looking than they do on the bucket. Their competition is animals that have had a lot of grain pushed into them from as young as they'd take it. You can wean a calf from milk completely at a surprisingly young age. The bottom line is usually your personal farm economics and convenience. The weaned calf should have a source of water, and a salt-mineral block to lick. To commence weaning a bottle baby, you cut down to one feeding so he's getting half as much milk as before. Then give that every other day. Then not at all.

Late Weaning. If the cow gives plenty of milk for your needs as well as the calf's, you can let it nurse until time to butcher it for veal or baby beef or until she dries up to have her next calf—and save money and hassle. This is basically demand feeding. The calf is shut away from Mum either at night or in the daytime, so the family gets at least one milking a day for their use. The calf eats grass or hay as wanted, and grain for treats and teaching and taming but not a regular diet of it. You can do the same thing with a bucket-or bottle-fed calf when you have abundant milk—wait to wean until they are 6 or even 7 months old. After Mum dries up in preparation to calve again, the naturally nursing calf will give it up forever (in case you have a calf that makes a liar of me and continues nursing, you can buy an anti-sucking device from Nasco), and will be physically ready to, even though still in the same field. Beef calves naturally nurse on this schedule, and thus don't get weaned until about 6–8 months of age.

If you have a mother cow and a pasture of nice grass, you have the most economical way to raise beef. You don't have to pay for the milk or the grass. A calf born in late winter will make the most of the spring, summer, and fall grass. By the time the pasture is going dormant or getting snow-covered it will weigh 800–1,000 lb. You can butcher then and have no winter feeding bill and lots of meat.

Average Weaning. Watch to see when the calf starts taking substantial amounts of other kinds of feed. Then cut back on the milk proportionately. A calf can be weaned partially

when he is eating other foods and completely when he is able to sustain himself on other foods. A husky growing calf will need an acre or more of pasture, or less pasture plus several pounds of good hay each day. On this system he gets more and more milk at first—and then gradually less and less, until he's finally weaned at about 4 or 5 months.

Early Weaning. When grain is cheaper than milk, producers tend to push calves to early (premature) weaning. In this case, you start feeding chopped grain and hay and pasture to calves as soon as they will take it. As soon as they are eating this other food, the milk is cut back. Some growers take pride in a calf that's weaned by 6 or even 5 weeks of age. But be careful of trying this because too abrupt a switch from milk to solid food can result in temporarily stalled growth. *Don't stop the milk ration until the calf has been eating grain for at least a month.* The calf on a grain-based diet will grow fast, but only when mature enough to digest it efficiently. You can gradually increase the amount of grain and hay, if not pasturing, until a 6-month-old calf may be eating 4 or 5 lb. grain a day.

Winter Feed for Weaned Calves. Feed as much good hay as they'll clean up, about 2 lb. per 100 lb. of their body weight each day. Or give corn stalks and cobs; 3 lb. of that equals 1 lb. of hay. Or grain; figure 1 lb. of grain equals 2 lb. of hay. The important thing is to feed what you naturally produce or can economically buy nearby; plant byproducts of almost every sort. But if you want organic meat, of course, then you have to be careful what goes into him. The easiest thing is typically to feed good hay plus some grain.

HALTER-BREAKING: Break an animal to lead while it is a baby, small enough to manage. You can't break an 800-lb. bull to do anything. So put a collar on it. Let the children tie something to the collar and lead it around and around and around until it gets the idea. Keep this up regularly and when it's big you will still be able to put the rope through the halter ring, give it a little tug, and your 800-lb. beast will follow docilely.

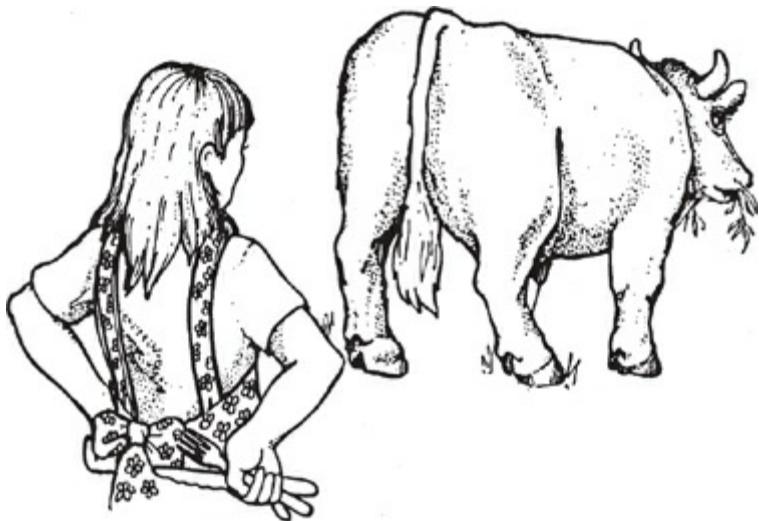

HEEL FLY: I just discovered a new one here. It's a fly called the heel fly that lays eggs in summer under the heel of a cow. The eggs hatch and the larvae crawl clear up the leg of the cow through blood vessels to live on her back. The next summer they bore an opening, change into flies, and leave the cow to find another host. I've got one cow that has this (she had it when I bought her), and the vet tells me at this stage there is nothing to be done. The preventive, an internal medicine, has to be given in the fall of the year. He says anything strong enough to kill them at this stage would kill her too. Oh, yuck!

Cow Butchering

AGES: What you'll call the meat depends on what age the cow was when butchered.

Veal. A calf that is butchered at 8–10 weeks will weigh about 180 lb., dress out to about 100 lb., and be called "veal." Veal is light colored and mild flavored and very tender compared to beef. Veal goes well in recipes for young chicken. In Victorian days when they really went in for a big variety of exotic meats for the tables of the rich—blackbirds in a pie and the gamut to a haunch of venison—veal was a delicate and delicious regular. But from the point of view of somebody raising their own meat, veal is an uneconomical meat because in that last 8 months your calf will put on so much weight that to butcher him before is to be woefully inefficient. However, you can butcher a calf any time from the day he's born, and meat's meat.

Baby Beef. Breeds vary considerably in size, but, on the average, a calf 6–8 months old will weigh 300–400 lb. and about 60 percent of that will be edible. A calf that age is called "baby beef," a meat about halfway between veal and beef.

Beef. A yearling may weigh from 800 to 1,000 lb. An older animal may weigh 1,200–1,500 lb. or more. The butchering principles are entirely the same—only the scale is different. But I would recommend butchering no earlier than 15 months. Let's assume you get a spring calf. You give him milk that spring and summer and he's costing you milk and trouble. Throughout the winter you have to feed him hay, and that's money and trouble again. If you butcher him the next spring, well OK—but wait. If you let him go, he'll feed on all that good free summer grass all the second summer of his life, on through the fall, up to the time you would have to start feeding hay again, when the ground gets covered with snow. That's the natural time to butcher him. He'll put on weight at an amazing rate now that his basic frame is built, and that grass feeding is cheap and easy for you. If you let him go even to 24 months (when he is finally mature in build), he will continue growing all that time.

NOTE: Read “Introduction to Butchering” in [Chapter 8](#) before you begin butchering your cow.

KILLING THE Cow: If the animal is gentle enough, or if it is halter broke, maneuver it to where you want to butcher, preferably right beside the hoist you have in place for hanging it, because with that kind of weight it's a lot of work to move it. Hopefully a heap of grain or a salt block will persuade it to go where you want it. *Don't kill the animal when it is excited or has been running.* If you've just had a big struggle getting it moved to where you want to kill it, go away for a few hours and let it calm down before shooting. That will help the final quality of your meat.

You could use a .22 but a .30-.30 or bigger is surer. *Try very hard to get it right with the first shot.* If you miss with the first shot, the animal may either go on a rampage and hurt somebody (come right through the side of your corral), or it may just turn around and that will make it even harder to get another shot into the right place. We had a really wild Angus heifer that Mike had to shoot 3 times to get down. She turned just at the last and wrong moment on the first shot. So you see, it can happen to anybody, even to a great shot like Mike.

WHAT YOU NEED BEFORE YOU START BUTCHERING

1. Time: It takes about 3 hours for us to butcher a cow and 2½ hours longer to cut up each quarter. If we took the cow to a custom butcher he would charge and also keep the hide and organ meats. It's a lot of work, but it does save money to

- do it yourself.
2. The work will go faster and be much easier if you have a way to get the animal up off the ground.
 3. It helps, too, if you've had experience skinning and gutting some smaller animals like goat or deer. I'd hate to see somebody start on an 800-lb. calf.
 4. Butchering a cow is very hard work. The more experienced help you can call in the better. Cow hide is tough—leather in the making. Cows are big and hard to shift around. Even the innards are heavy, and there is such a weight of them it presents quite a challenge. So before you start have a few friends on hand.
 5. Have ready too, a gun to shoot the animal.
 6. And a bucket or pan to hold the heart and liver.
 7. You'll need sharp hunting knives or skinning knives or butcher knives—plenty of them, plus the stone you rub the blade edge across to sharpen it. You will have to stop occasionally and sharpen your knife.
 8. You need a big washtub for the guts. Even so, they will have a tendency to overflow it. And have a plan for what you're going to do with all those innards. (See [Chapter 8](#) for suggestions about handling the awful offal.)
 9. You also need a meat saw for making the halves and quarters. You could use a chain saw, but it is far from necessary, maybe not even preferable. The saw you use is a regular crosscut or carpenter's-type saw.

Anyway, shoot your cow by mentally making an "X" with the top points on each ear and the bottom points on each eye. Shoot where the lines cross. Tie the cow up if you can and 1 shot will be enough. Shoot straight in. You'll have to move around to do it, or wait until the cow turns to face you. Take your time and do it right. If you get it right the cow will drop to the ground instantly, exactly where it was standing when you shot it.

STICKING: As soon as the cow drops, start running toward it with your best knife to cut the throat. (Don't fall on it!) You want to *open up the throat while the heart is still beating so it will pump the blood out well.*

I used to think you were supposed to cut across the throat from side to side, under the ears or an inch or so back, clear to the backbone on either side of the esophagus, until the head was about half off. It helps if the head is slightly downhill. That's how we did it. But I've since heard that a better way is to cut the throat lengthwise, from the jawbone to the breastbone, and then push the knife under the breastbone and between the first ribs into the chest cavity to cut the carotid arteries. Try not to cut the heart, so it will continue to pump out blood as long as it works.

Work the front leg back and forth for a while as if the animal were walking to help expel the blood. Wait until it gets completely quiet. Kicking reflexes will go on for a while and could hurt somebody. Keep the head downhill and the flow of blood unobstructed while you're waiting.

MOVING THE COW: If the cow didn't drop where it was handiest for you, and you have a tractor or other strong vehicle, use that to drag the body where you want it. Use a towing-type chain. Fasten one end of the chain to the cow around its cut neck, the other end to the vehicle. Then drag the cow to the place you want to skin and gut it—preferably a place where you have a way to hoist it.

HOISTING THE COW: A tractor with a fork-lift (hoist) is the handiest thing for moving and raising your carcass. Cut a place to hook the singletree ends under the tendons of the rear legs. Cut on each hind leg just inside the back of the "knee." Do it just above the first joint. You will be over 2 feet up from the hoof. Don't cut the tendon. Hook up the singletree with the tendons.

Fasten the singletree chain to the fork-lift and raise the animal. If you are working with a pulley or a "come-along," which is a 1-person pulley, hook that up to your singletree and haul away to get that animal raised off the ground, upside down, to a height at which you feel comfortable working. From 18 to 24 inches above the floor is good.

IF YOU DON'T HAVE A HOIST: It's hard to do what needs to be done with the animal lying on the ground—but it's not impossible. We've done it that way. It's the same as when you kill an elk (a cow-sized game animal) in the woods. If the cow is lying on the ground, first cut the head off. When you have the skin and meat all cut through, give the neck a hard twist around and around until you feel it break. Then finish cutting it off. Now maneuver the animal onto its back, exposing the full extent of belly topside. Doing that to a big cow is hard. Propping up one side with a stick for a brace may help. Then use the directions given below, except with the cow on the ground the innards will not fall out by themselves—you'll have to help them out. Proceed to "Gutting the Cow."

CUTTING THE HEAD OFF: Usually a cow is gutted before being fully skinned, whereas sheep, rabbits, or goats are skinned first. Finish cutting around the neck. Turn the head with a hard twist around and around until you feel the neck break. Then cut it all off. You'll have to finish with the saw. Some people use beef head meat to make sausage. Most people discard it except for the tongue. Cut out the tongue and put it in your organs bucket.

(After having already sold 1,500 of these books, I discovered to my awful embarrassment that at this point I left out how to remove the innards of the cow! Bad enough printing pages upside down, but that was worse. All those people depending on me—and I told them to get the animal raised up off the ground and then directly to

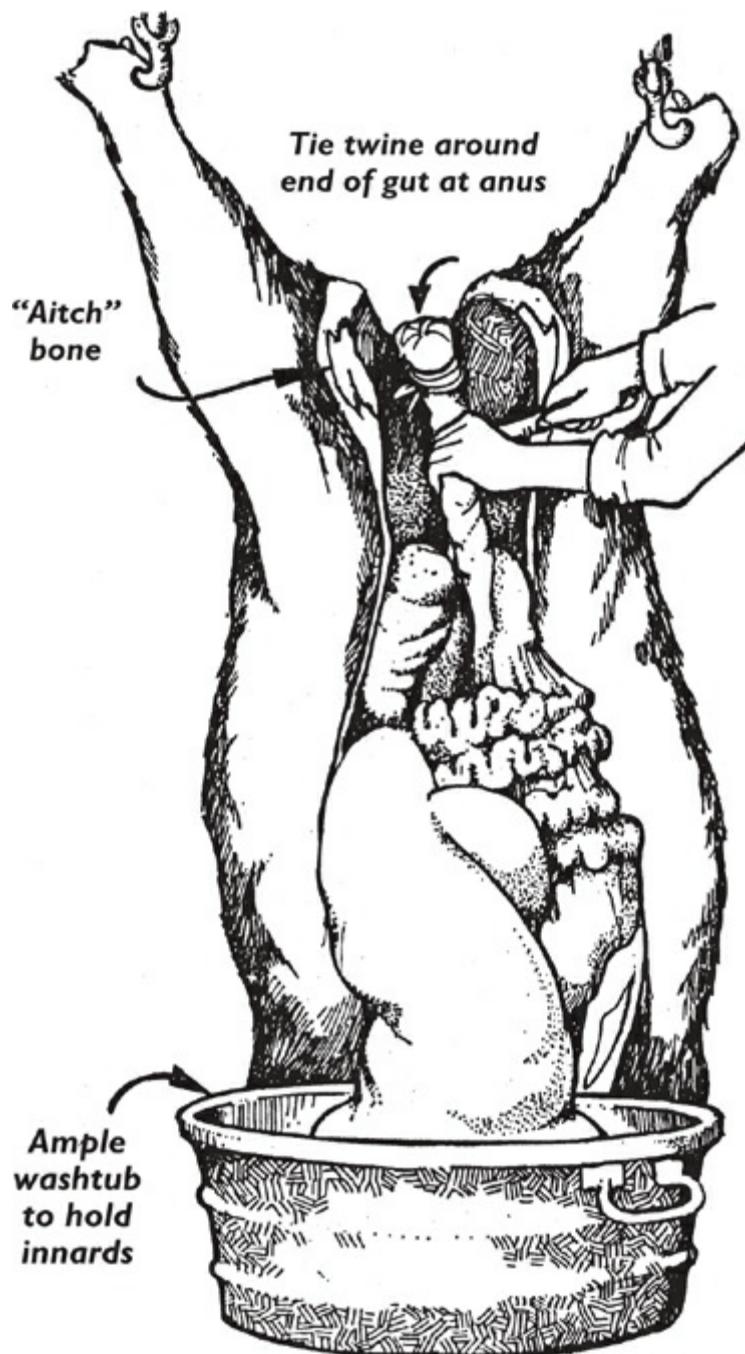

commence sawing off steaks!)

GUTTING THE COW: If you have a male you start by cutting around the genitalia, including a patch of skin around it. Then you slit up the midline (I'm assuming the animal is hanging by its heels so "up" means toward the hind end), cutting the hide first and then around the anus so that you free the gut for tying off with a twine, so nothing in there will come out. You lift free the genitalia along with the cord and then proceed to open the hide on down the belly line. The animal isn't skinned. You'll skin it after you gut it. Most folks run their hand inside the skin as they are cutting down from the outside to push back the intestines and prevent the knife accidentally cutting them open since they are right underneath. If you hear a hiss you did it. But don't despair. That happens a lot to amateurs. It's happened to us, and it needn't harm the meat. Just struggle on. Saw through the H-shaped bone, which is called the "aitch" bone. It's between the hind legs in front of the rectum. Cut all the way down the front before starting to pull the innards out. Have your washtub ready; they are big and heavy. After they are halfway out and the part that's out is in your washtub, you can take time out to find the liver and heart.

Beef Heart. This is really good food, but to find it you'll have to look hard. It's encased in tissue and fat. Cut it free and put it in your organ pail. (Later, back at the house, I give it a good rinsing under cold water, slice, and bag for freezing.)

Beef Liver. This is big and easy to see. Remember to get the gall sac off the liver. You have to cut it out plus discard the part of it by the liver to do it safely, but there will be plenty of liver left. Back at the house, give the liver a good rinsing under cold water and then slice it very thinly and freeze in meal-size bags. Remember to eat up the heart and liver fairly quickly because they don't keep as well as the rest of the meat. If you don't have refrigeration, you'll have to have beef liver for dinner that night and every meal thereafter until you use it up, because it doesn't cure or can well.

Finishing the Gutting. Cut through the breastbone now on down to the throat to finish opening up the belly side of the animal from tail to throat. That will make it easy for you to finish taking out all the innards and the tongue, which is very good to eat.

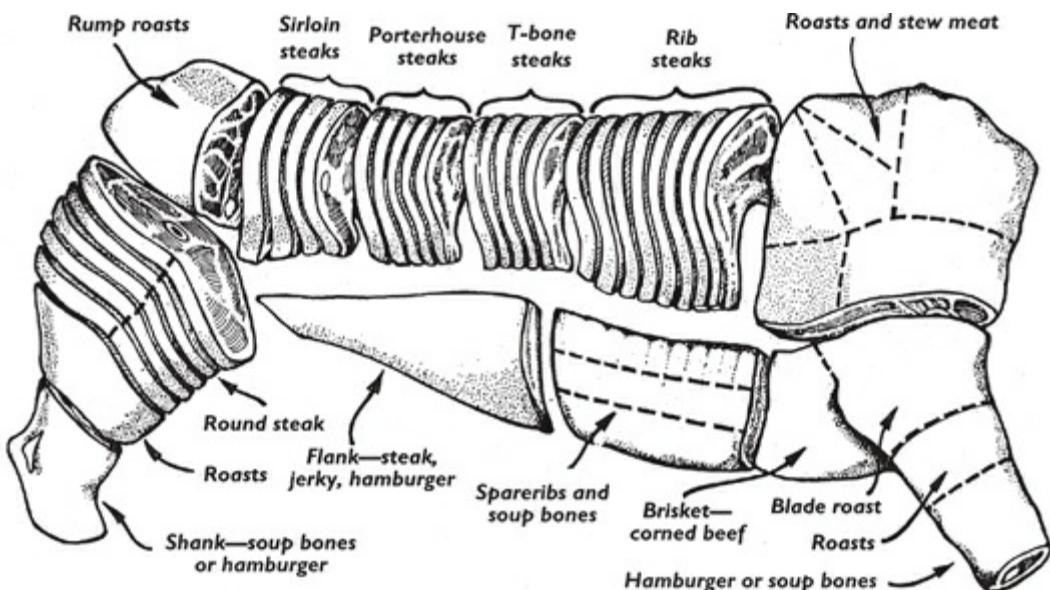

After you have the innards all out, stop and give your hands a good washing in the bucket with vinegar water. Sharpen your knives, if they need it. Now go back to work. Skinning is next.

SKINNING THE COW: This is the hardest single butchering job I can think of—a long job. But stick with it because the cooler the animal gets as the body heat leaves, the harder it is to skin. The reason you butcher a cow first and skin it afterwards is that if you skinned first, those innards might wait in there too long for the meat's good. Use the goat-skinning instructions. There are good directions for handling your hide in the tanning section in [Chapter 8](#).

HALVING, QUARTERING, AND AGING THE BEEF: If you cut the tail off and skin the top part of it, you have the makings for oxtail soup! For the rest of it, read on.

Quartering the Beef. Pork is usually hung in halves and best left just overnight because aging doesn't improve it, but beef is so big you need smaller sections just to be able to carry it around and to help it cool quicker, and aging does improve it very much. If you do the quartering right, each quarter will turn out to be from 90 to 140 lb., depending on

the age of finishing—and all 4 pieces will be nearly of the same weight.

Saw down the middle of the backbone to divide the animal into equal halves. Use a wood saw or a chain saw or whatever you can lay your hands on. It's a mean job, and it helps if there is more than 1 person so you can take turns—one resting while the other is working. Now standing on the "belly" side and starting with the rear end of the cow, look inside the chest cavity to see where the ribs begin and count them. Cut between the third and fourth rib from the rear. When you get the 2 ribs cut part way apart, make a slit between the fourth and fifth ribs and tie a rope through there. That's preparation so the front quarters can be hung by that rope in whatever place you have ready for hanging the quarters. Have someone else hold the front quarter off the ground while you finish separating it, then carry it to the hanging place and hang there by your rope from a rafter or whatever. Get the other front quarter the same way. Now let the hoist down enough so you can untie the hindquarters, and then move them to your hanging place for aging.

The Hanging Place. This should be someplace cat-proof, dog-proof, and fly-proof, if possible (you can use meat bags—even make your own out of old sheets or some such—to help with the fly problem, or, better yet, butcher out of fly season). You need a cool place, too, and if you haven't butchered in cool weather you'll want to put the animal in a neighbor's or butcher's walk-in cooler. But a lot of butchers won't let you use their walk-in cooler now because federal laws have made it illegal to have uninspected homestead-type meat in there with the high-class fast-food-type meat.

Aging the Beef. Tenderizing the beef improves the taste. How, I don't know, but it really does. Age it at least a few days and preferably a week or even a little more. Aging just means letting it wait before you go ahead and cut it up, wrap, and freeze or can. The meat doesn't rot right away because there aren't any microbe seeds in there. It was just alive. When it does start to go bad, it'll start from the outside and work in, so you have plenty of warning and can trim off any bad parts. But handle the tallow (fat that you want to make special use of—maybe for soap) and hide promptly. Once they start going, it's impossible to get the bad odor out.

CUTTING UP

Timing. When the time does come for cutting up the quarters, it's a good idea to do it no faster than a quarter at a time. I mean a quarter per day. Another day of aging will improve the remaining beef, and defrosting could be a disaster for food already in your

freezer when you put the meat in. Defrosting is what happens if you suddenly put a whole beef in there. In my experience it takes nearly 24 hours to get 1 quarter of beef all frozen in a large chest freezer. Or rent a locker or make arrangements to have it quick-frozen and then move it all to your freezer.

Making Cuts. If you're a pro you know exactly what you want. If you're not sure what you're doing, cut steaks off the wide ends, make roasts out of the narrow ones, and hamburger out of the mistakes. Mike thinks that $\frac{3}{4}$ inch is a perfect thickness for steaks. I like $\frac{1}{2}$ inch, but he thinks that's really too thin for any beef steak except maybe round. He says any steak with a bone in it should be at least $\frac{3}{4}$ inch thick. Some people do cut them an inch or even an inch and a quarter, but I think that's way too thick. But, bottom line, how thick you cut is entirely a matter of personal preference. Or economy—a thinner cut yields more steaks!

To saw out steak, cut with your knife all around the bone. Then saw through the bone. The tenderloin is the most tender steak. The round is the toughest. The muscles the cow uses the most (round, hind leg) are the toughest. Don't trim off all the fat—you want some around the edges of your steaks for flavor.

Hindquarters

1. Cut the leg from the body.
2. Starting from the top of the leg, slice off the round steaks clear down to the "knee" joint. When packaging, if you cut the round steaks in half, they will be easier to thaw.
3. The next portion of the leg (working down) will become roasts. If you make them about 2 inches thick or more it's fine. You are slicing the same as a steak only much thicker, and that makes it a roast. If you trim out the bone that can be a soup bone for you.
4. When you get down to where there isn't so much meat, cut the rest of the lower leg into chunks for soup bones that are called "shank boil." Or you can trim off the meat and put it in your hamburger pile, if you want.
5. Cut the belly abdominal muscle flap away from the rest. That goes into the hamburger pile.
6. On the piece that's left you can start from the "front" end, taking odd rib steaks. There will be 11–14 inches of rib steak on a big beef, 6 or 7 on a smaller one. The big hind end of the loin is the rump roast. Saw it off. It will have something of a triangular shape.
7. Now start taking off sirloin steaks. The porterhouse is in the middle. The T-bones are clear to the front.

Front Quarters

1. Remove the "arm" at the joint. Have 1 person cut from underneath as the other pulls the arm upwards. You've got to force it on up and out, under and around that shoulder blade. You now have an arm plus the rest.
2. Cut off the top one-third of the arm for a "blade roast" and trim off some of the fat. Don't trim the roast completely clean either. Some fat around it helps the taste when it's cooking.
3. The next 6 inches can be a roast. And so can the next. Make it into what you like. It could be a big roast or a small one plus some stew meat.
4. You can make the rest of the leg into stew bones or trim the meat away from the bone for hamburger.

- With the meat saw, separate the ribs from the backbone and its accompanying muscle bundles—the tenderloin and backstrap. Saw about 8 inches from where the ribs connect with the backbone.
- You can see what your steaks are going to look like now. Cut off the steaks. You waste less if you saw each one out, but that requires tremendous time and effort. If you're not up to that you can bone out the 2 muscle bundles and make rib eyes of the larger muscle and tips from the smaller backstrap.
- The neck end, which you can identify because it curves a little upwards, can be made into roasts and stew meat.
- The remaining rib area is a vast ordeal of spareribs and soup bones. Here you have the most work for the least desirable cuts. Starting from the rear, cut between one rib and the next all the way until they are completely separated. Then between the next and the next all the way and so on. Then saw across the individual ribs at 6-inch intervals or as your cook likes them. You'll end up probably sawing each rib thus into thirds.

BEEF RECIPES

▷ **DRIED BEEF** Use the jerky recipes in [Chapter 8](#).

▷ **MOCK TURTLE SOUP (CALF'S HEAD SOUP)** Boil a beef or veal head (and feet, if you want) until the meat separates from the bones. Remove bones. Cut meat into 1-inch pieces. Boil an hour more (until tender) with an onion and bay leaf. Add 8 sliced small onions and 1 T. parsley, and season to taste with mace, cloves, and salt.

▷ **BASIC BEEF STEW** Cut 4–5 lb. of beef stew meat into 1½-inch cubes and brown them in a small amount of fat. Add 2 qt. small carrots (or 8 chunked large ones); 3 c. onions, quartered; and 3 qt. peeled potatoes, quartered. To this very basic stew, add your own favorite seasonings, cover with boiling water and simmer until all the meat and vegetables are tender.

▷ **CANNED BEEF BONE SOUP** Saw or crack fresh, trimmed beef bones to release their flavor. Rinse bones and place in a large stockpot or kettle. Cover bones with water. Cover pot. Simmer 3–4 hours. Remove bones. Cool broth. Pick off meat. Skim off fat. Add meat removed from bones to broth. Reheat to boiling. Fill jars, leaving 1 inch headspace. Adjust lids. Process in pressure canner only: pints 75 minutes, quarts 90 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; at higher altitudes, set at 15 lb. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

What's the Beef?

There are more myths out there regarding cows than regarding any other domestic livestock. Why do cows get picked on? Is it because of their size that they're less likely to be part of a family operation and more likely to be in a commercial ranch setting? Because they aren't cute like goats? Cuddly as rabbits? I am astonished to find outrageous untruths/ignorance, even in a how-to book that says it's going to tell you how to raise a calf for beef. Here's a partial debunking.

MYTHS AND TRUTHS ABOUT COWS AND THE BEEF INDUSTRY

No.1: *It is best to use land to raise cereal grains for people, rather than using it to feed animals.*

The answer is ... not that simple. Not all land can raise cereal grains. The most efficient and productive use of land is to raise meat animals off the parts of your land you can't cultivate—hillsides, woods, really dry places, or places with really short growing seasons. Those are natural forage areas. It would be truly wasteful if there were no grazing animals for the natural forage areas that grow enough cheap grass to fatten a cow in spring or enough brush to maintain goats. Even if all your land is tillable, you may not want to expend the time and labor to garden or farm intensively more than a portion of it. You may want to have a wood lot or to leave the land as near a natural state as possible. Your grazing livestock will do the work for you and harvest and put to good use the plants growing on that uncultivated land.

No. 2: If you don't feed grain to a growing beef animal, it will take 5 years to mature enough for butchering—and then be tough.

False. I can't believe I'm looking at that in a book about cow-raising, but I am. The truth is, beef animals, like other animals, don't grow as fast on natural as on concentrated feed; they don't get as big; they don't give as much milk. But they grow almost as fast (not counting fat) and mature at the usual time. And if you want tender beef, butcher a young animal, age 1–1½, not a 5-year-old! It's that simple, grain or no grain. The "tenderness" created by excess grain-feeding is a false tenderness created by the presence of fat inside the muscle.

No. 3: Steers for beef are raised in feedlots under crowded, inhumane conditions.

Again ... it's not that simple. It used to be that most farmers had a few calves and finished them on their own grass and grain for home use and market. Now family farms still may raise 1 or 2 calves for beef, but overall the beef industry has become very specialized, divided between brood cow-calf and feeder operations. I think it's important to understand that cows are not ordinarily fed grain in the cow-calf operations. These cows eat grass in summer and hay in winter. The herd of brood cows stays on the farm and calves every year. The farmer sells the calves when they are between 400 and 800 lb. They are sold at so many cents per pound through the auction ring.

The calves sold by the cow-calf operation at auction may either be bought by a middleman or by a feedlot operator. The middleman is somebody who has surplus grass and wants to make his land pay by getting those calves onto it to eat the grass and put some more weight on before their return to the auction ring. Typically, the middleman doesn't keep brood cows, or doesn't have enough to eat up all the green bounty of his summer pasture. By buying extra calves in the spring, when his grass is starting to come on well, and selling them off in the fall just as his grass is dying back for the winter, he gets a profit from his grass crop. The difference between what those calves weigh when bought in the spring at the auction ring, and what they weigh in the fall, multiplied by the price per pound paid for them, equals the middleman's gross profit for that summer's operations.

Then, unless they go to the grass-fed beef market, which exists but is still comparatively (pathetically) small, they go to the feedlot. *But it doesn't have to be that way. The calves could continue to feed, like their mothers, on grass and hay, to butcher weight.*

No. 4: Trees are being cut down to grow beef.

Not that simple. A good bit of the U.S. landscape once was forested, but now isn't. Cows may or may not be what now grows there. It would be nice if those trees could be replaced. Everywhere trees are being cut down at an appalling rate—to make toilet paper, paper towels, book paper, etc. After the quick profit from timber sales the land is then either tilled or ranched unless it is reforested. In Central America, tropical forests are indeed being cut down by cattle ranchers who want the cash profits of selling beef to fast-

food restaurant chains. (This isn't a large issue in the United States, because we've already cut down most of our original forests and forgotten they were ever there.)

Logging isn't the cows' fault. The cow—of all animals—is the one best suited to take the roughest of all feeds—native grass—and turn it into quality human food. Like the buffalo, the cow is most naturally a dweller on grassy plains. Cow-calf operations are best situated in good, natural-grass forage areas. There, feeding your cows grass is no problem and they'll make the milk to feed their calves. If you have even a few acres of decent pasture, you can get a lot of nice milk and meat off it for your family by means of a cow or cows, anywhere. For unillable, or unilled, grassy land, cows are also an excellent and ecologically appropriate choice. Cows can also graze among growing trees.

No. 5: Cows are fed grain that could end world starvation.

Not that simple. Cows are fed a lot of grain, which, as said, they don't actually require. But if cows weren't eating it, it probably wouldn't go to poor, starving people either because the first problem would be: Which poor, starving people? And the second would be: Who pays the grain grower for it? It costs money to grow every bushel of grain. Grain growing, like all farming, is a business—nowadays a petroleum-based business. The commercial farmer buys seed and makes his payment on the land and machinery and, if it's not an organic farm, also buys nitrate fertilizers, pesticides, and herbicides. When he finally harvests his crop, obviously he can't give it away or he'll not make his land payment, and some more practical farmer will be working it instead. So his grain crop gets sold to nearby bidders with money to buy—among them feedlot operators.

Woody Bernard, the Dairy Agent in Washington State who kindly reviewed this chapter, adds another good point: "Animals utilize byproduct feeds that people won't eat." That's so true. They eat the leftover from pressing seeds for oil, the corn cobs and stalks left after the corn is harvested, the beet pulp after sugar is extracted, seed hulls after the seeds are removed, and so on. Cows are wonderfully complementary to human beings because they can digest and change their food into good foods for us—milk and meat—all from food sources that people cannot eat.

No. 6: Cows have to be fed grain.

Not that simple. You can raise a calf for beef, and a cow for milk, and never feed a mouthful of grain, using instead quality pasture, good hay, and winter vegetables. Beef animals raised this way are called "grass-fed beef," and they're the best that money can buy: best for the environment, best for your health. But cows are generally fed a little grain even on a homestead operation because they love it so much. It helps gentle them. It's a wonderful way to get them to do what you want. They are natural grass eaters, and it's natural for them to love grain, which is grass seed: the goodness of grass in a concentrated form. Grain provides extra nourishment if you want to build up the health of an animal near to calving, or keep a milker going longer, or stimulate maximum milk production. If other foods are in short supply, and grain is ample, then grain is obviously a way to go. And dairy cows will give up to 40 percent more milk if fed a generous grain supplement! But grain doesn't have to be fed. Many buffalo ranchers now feed grain daily to those animals. You think buffalo have to have grain? Of course not. It's just that they love it, so it gentles them, it's a convenient concentrated feed, and they're less likely to get restless and walk through your fence.

No. 7: Feedlots feed animals beyond their normal growth into forced obesity.

True. The feedlot operator buys calves either directly from the cow-calf operation or from the middleman. He keeps the animals confined to a small area called a "feedlot" and gives them a grain-based, rather than a grass-based diet. He wants to put more weight on them as fast as possible and get them up to profitable size and an acceptably fat grade of

beef. The animals are in the feedlot from 2 to 6 months. Then the feedlot operator takes them back to the auction ring where this time they are sold to the meat packer. Some feedlots use the cow manure from the feedlot to feed pigs in an associated swine-growing operation, because the pigs can get food value from the surplus grain that is passed through the cow's system. If the cows were fed only up to a normal growth, the feedlot could be viewed, I suppose, as a space-efficient, work-efficient operation for growing meat so long as the grain is cheap and available. But I see 3 big problems with them: stress for the animals; feeding of antibiotics; and overfeeding to create marbled meat.

No. 8: The USDA meat-grading system protects consumer health.

False. The USDA meat-grading system protects the grain growers who want the feedlot operator's business, and it protects the feedlot owners. It's the big reason feedlots exist, the big reason why supermarket beef isn't good for your arteries.

The trend toward feeding cows beyond their normal growth developed largely in response to the USDA meat-grading system. Up to a certain point, the cow's body keeps its muscle and its fat separate, with the fat on the outside of the muscle. But if calories are forced upon the animal—if, as in the feedlot, physical inactivity is combined with a high-calorie diet—eventually that natural barrier is overwhelmed. Fat begins to appear inside the muscle, between the muscle strands. When this happens to beef muscle (meat), that cut of meat is called “marbled.” “Marbled” beef is what the law and the supermarkets call “choice beef.” But “choice” beef really isn't the best for you. A normal beef animal has red meat with no fat inside the muscle tissue. This is a good thing for humans because beef fat is high in cholesterol, higher than any other domestic meat, and we don't want to eat that cow fat. But according to the law as established in USDA grading standards, beef should be fat, and the fatter the better. The fatter an animal is, the higher its meat will be graded by the USDA inspector. So feedlots pour the grain into them to make them fat.

There's a historical reason for this attitude. During the 1950s there was so much more grain being harvested than there was a market for it, that there was talk even of throwing grain in the ocean to get rid of it. But then certain cowmen bought that cheap grain. They built feedlots and there finished calves cheaper and faster on that grain than they could have otherwise. And the feedlot operators got a meat-grading system put through that favored their product over the grass rancher's beef product. The grain farmers backed that new grading system, too, because it in effect legislated a couple of hundred extra pounds of grain into every cow destined for the supermarket. Thus feedlots and grain for cows got written into the law of the land: marbled beef. Forty years later, it's still there. Through advertising, “choice” beef became commonly accepted as the best beef, and more than 1 generation of people who must eat out of supermarkets have never seen anything else.

Woody Bernard says: “The meat grading system has been changed to reduce the fat in beef. Also, the more exotic breeds don't marble like the old ones.”

No. 9: Feedlot operators feed antibiotics daily.

True. To compensate for the crowding and stress, and because of its growth-enhancing effect, feedlot operators routinely feed low-level antibiotics as part of the cows' daily ration.

No. 10: Beef from commercial slaughter houses is always safe to eat.

Not that simple. Usually it is, but not necessarily. Under the Reagan administration, slaughter houses were deregulated. Now a big operation that once was limited to processing 60 cows an hour may be processing 300 cows an hour. At that pace, it's easy for accidents to occur. *E. coli* naturally occurs in the intestines of all animals. If that animal/ cow is butchered and the contents of her intestines accidentally get on the meat, the meat will be contaminated.

NOTE: It's important, whether in home or commercial butchering, that the contents of the intestine never get on the meat.

If a batch of contaminated meat is mixed in a big vat with the hamburger from many different cows, the problem spreads. That's how hamburger for fast food places is prepared—and how it can become contaminated.

NOTE: Always look and make sure your—and your child's—restaurant hamburger is well-cooked, not pink inside, before eating it. If it's pink, send it back to finish cooking.

No. 11: Cows give off methane gas that contributes to the greenhouse effect.

True, but it's ridiculous to take that source of methane seriously. Other related animal species contribute to the problem, too. But the big reason this particular greenhouse gas is pouring into the atmosphere in unnaturally great amounts is the use of natural gas. Natural gas is mined from "wells" and then piped into homes and industries to burn. Some of the gas inevitably leaks out of pipes into the atmosphere. In fact, it's people who make most of the gases that cause most of the greenhouse effect. I cannot comprehend this ranting against cows. What a convenient scapegoat. They contribute only a tiny percentage—far, far less than what the once-mighty herds of 60–100 million buffalo did. It would do far more good to reduce the numbers and improve the exhaust systems of cars, ban fossil fuel burning of all sorts, and restrict belching industrial plants. Those are the biggest source of greenhouse gases.

No. 12: Cows drink a lot of water.

True, but not as much as humans use. People use (waste?) on the average 77 gal. per day per person. The drinkingest cows, of course, are lactating dairy animals of the largest breeds. They produce as much as 14 gal. milk per day for human use. They drink as much as 30 gal. water per day. The more milk they produce, the more water they must drink. Beef cows drink much less. An average 400–700-lb. steer (a typical size growing for the meat market) drinks 5–10 gal. per day. And cows, if uncrowded and on natural pasture, recycle their water back into the ground as nutrient-rich urine, which help grows their feed. People waste theirs into sewer systems.

No. 13: Cows destroy salmon spawning habitat.

Again, a joke. You try swimming from the ocean up any river and see what happens: industrial and urban pollution running into the water, dams and more dams, development up to the water's edge. And somebody is begrudging a cow drinking at the streamside? The cow, being closely related to the buffalo or elk or moose, is the most natural part of the equation. If there were only cows living in the United States, the salmon would be doing fine.

I can't help but wonder if there isn't some deep human need to identify and pick on a minority and persecute it. All varieties of human beings now being off limits for prejudice, the homely bovine tribe and their keepers are being subjected to these arguments for extermination.

No. 14: Nobody will buy cattle that have been only grass-fed and raised without growth stimulants or antibiotics in regular feed at the price it would cost to raise them.

False. You'd be surprised how many people who can't grow their own are desperately looking for just such meat, from every kind of meat animal! Now you can at least get leaner hamburger everywhere. And in organic-type food stores you can get "grass-fed beef." What is grass-fed beef? It is a normal animal that hasn't crowned his preslaughter experience by standing in a feedlot being inactive and getting obese. When a grass-fed cow goes to regular market, he is the same age as the corresponding "finished" or grain-fed cow—18–20 months, up to 24 months. And no 18–20-month-old cow is going to be tough, grain or no grain—don't let anybody kid you about that! Grass-fed meat is what

the country people who raise their own calf for beef have usually eaten, tender and delicious.

You can either advertise privately and take orders for your meat, or market it through the kind of co-op that's always looking for organic food for their customers. Here are some sources of grass-fed beef:

Coleman Natural Beef: 800-442-8666; 1767 Denver West Marriott Rd., Ste 200, Golden, CO 80401; www.colemannatural.com.

Homestead Healthy Foods: Rt. 2, Box 184-A, Fredericksburg, TX 78624.

Kay's HomeFarm Beef is tender and lean, raised without using synthetic hormones, maintenance antibiotics, or processed feeds. 262-375-1702; fax 262-377-5002; 8707 Kaehler's Mill Rd., Cedarburg, WI 53012; www.kaysfarm.com.

Larsons' Greenfarms sells certified organic beef: 801-645-3033; 13246 W. Sagen Rd., Brodhead, WI 53520; www.larsonsgreenfarms.com.

Lasater Grasslands Beef offers cattle that are finished on grass, never confined in feedlots and fed grain, no growth hormones, no antibiotics, no pesticide treatments: 866-454-2333; PO Box 38, Matheson, CO 80830; www.lgbeef.com.

Rob and Alanna Reed offer all grass-fed Angus and Angus-crosses at Overlook Farm; 724-756-0540; 233 Spruce Rd., Karns City, PA 16041.

The bottom line is that real change for the better has to be market-driven—people who spend the dollars for food have to demand and pay for organically grown vegetables and fruit and grass-fed beef. Then ag chemicals and cows supposedly fed too much grain won't be a problem anymore!

ABOUT MILKING

A Review of Dairy Sex

You can't just buy an animal, walk out to the field, and milk it. Milk comes only from female mammals that have recently given birth and have either been continuously milked or nursed since then by their young or some other species. (For example, you can put bum lambs or a calf on a goat.) So for a cow to be a milking cow, there has to have been a bull in her life about 285 days ago—likewise with a goat, 5 months ago. Even if you buy an animal that is already "fresh" (milking), time is going to run out on you. You can't just keep milking her forever. She will gradually dry up. You have to again give the cow access to the bull or the artificial inseminator at a time when she is receptive (in heat). (You probably knew most of that, but I'm trying to assume nothing. I've had people ask me if they should pasteurize the eggs, or why their chickens won't sleep in the nests but keep climbing up to the hen house rafters, or if a heifer and a Hereford are the same thing.)

Then she has a gestation (pregnancy) of 9 months, calves, and comes fresh (gives milk). Your cow is milking again, but you also have a hungry calf. A cow usually has plenty of milk for everybody, though if it's her first calf she won't be giving as much as she will after subsequent calvings. You can separate the calf from the cow, do all the milking yourself, and feed the calf its share out of a bucket, then turn the cow in with the calf until your family runs out of milk again. Or you can keep the calf shut away from the cow all night, milk in the morning, and then let them run together the rest of the day—meaning there will be no evening milking for you.

How to Milk

When you milk an animal, you're getting into her emotional life. You can't help it, so adjust gracefully. If she's upset about anything, if something scared her, if she doesn't know you or doesn't like you yet, she won't have the contractions that bring her milk down. If in the midst of milking something scares her, or if she has a sore teat and it hurts when squeezed, the milk may momentarily stop coming down.

EQUIPMENT: It's best to milk your dairy animal in an outbuilding, or in a part of one—a place that is special for milking and cleaner than where she sleeps.

Stanchion. If yours is a gentle, experienced animal, you can tie her up to milk her (have a halter on her) or even eventually you could walk up to her in the field and milk her as she stands. I've done it. But usually a stanchion works best. A stanchion is a frame that holds a goat or cow firmly by its neck while it's being milked. Stanchions always have a manger or platform for a bowl in front so the animal can eat a treat while you're milking. (Give and you'll be given unto.)

You can fashion a goat stanchion out of one made for a cow just by nailing a board on it to narrow its grip. There is a manger where the animal's head will be, in which to place grain or hay. The animal sticks its head in to feed in the manger. Then the movable slat is moved over at her neck and fastened so she cannot pull her big head back through until allowed to. Some animals just hate stanchions and will let down their milk better if you milk them in the open. But if you're milking a big herd or have nervous animals, a stanchion really helps.

Stool. A stool for you to sit on is needed to milk a big cow. A sturdy stool about a foot high will suit you and you can milk into a bucket—one with a bail (handle) for easy carrying.

Goat-Milking Platform. Goats are built nearer the ground, so some people have little goat stanchions (or a place to tie her) built on a special raised platform about 12–18 inches above the ground. It has a little manger up front or maybe just a place for you to set a low-sided can with her treat in it. Then you can comfortably sit on a stool, which may or may not be built onto the goat's platform. If your barn floor is nice and clean, you can just sit on the floor to milk. Or you could squat to milk the goat. But it's nicest and cleanest to sit on an extended side of her platform made for that purpose.

SCHEDULING: Milking is done every 12 hours. It works well to milk early in the morning, before the animals scatter to feed. Twelve hours later you'll milk early in the evening; in winter you'll still have some daylight to do it. Either that or you need to carry a lantern to the barn or have electricity in there. If you milk a very heavy producer 3 times a day, you may get even more milk if you need it. Milking is usually done all by hand, but some people raising a calf or goats leave baby and mother together all night. Then you can separate them in the morning and milk for the household supply in the evening. Imogene has a nice little stanchion to milk her goats in. She puts some grain or other goodies in the pan and then shuts the movable slat to hold the goat's head in there so it can't leave if it gets done eating before she gets done milking. Cow stanchions work on the same principle, but are bigger for a bigger animal.

Or separate them in the evening, and then the morning milk is for the house.

NOTE: If you're late milking, the animal's udder hurts her severely. You lose production and increase her risk of mastitis.

STEP-BY-STEP PREPARATIONS FOR MILKING: First you call your milker to where you want to meet and accomplish this. You put her in the stanchion, offer a treat to eat, groom as needed, wash her udder and teats, and then commence seriously milking, from let-down, to stripping, to her release from the stanchion.

Calling. A good milk cow is a gentle creature. After a while she'll come when she sees you or knows that you want her. Once she has decided to adopt you, she'll call out and run to you when you call her. You're her baby and she's going to sustain you. Have a can of grain handy. She'll follow you to the barn.

Putting Her in the Stanchion. You have to start by getting your milker in a situation where you know she'll stand still and where you can comfortably work at her teats for 10 or 15 minutes. You could tie her up or have somebody hold her, but a stanchion is best of all for this. She'll soon learn to come voluntarily, even eagerly, when you call and stick her head right in there if you scatter some grain or other treat in the stanchion feeder area. (Don't expect her to eat all her feed in the 10 minutes you're milking. Her regular feeder will be elsewhere.) Once her head is in place, you close the stanchion so she can't back out again.

Grooming. I'll confess I looked 'em over for problems, but I never groomed a dairy animal. If you're a groomer, then maybe once a day—before 1 of the 2 milkings is a good time—brush to remove dry skin, loose hair, and parasites. Dynah Geissal says they love it.

Washing. Wash and dry your hands before milking. Take a pot of quite warm (120–130°F) water and fuzzy rag to the barn with you when you go out to milk, so you can wash her udder and teats. You may get more milk if you wash the udder and teats, and if she's been lying in the mud it keeps the dirt out of the milk. Debris in the milk means a

high bacteria count—which means it sours quicker and is likely to get an off-taste. An udder that hasn't been washed isn't as easy to grip as a damp one either. And mud that got into the milk, even just dust, will go right through your straining cloth. You'll discover it as a sort of dark sediment at the bottom of your milk jar after it has set 12 hours or more. Woody Bernard, the Dairy Agent for Pierce, King, and Grays Harbor counties in Washington, reviewed this chapter and gave me much excellent advice for which I'm very grateful. He adds here: "Washing stimulates let-down. Wait 1 minute after washing." Then milk.

Let-Down Contraction. Each teat is like a syringe bulb, and the bulbs are empty when the milk is held up high as it is before the let-down. No matter how you squeeze, none will come out. Your stimulation of the teat (pronounced "tit") causes a contraction reaction called "let-down" to occur in the milk-storing area of her bag. This let-down is an involuntary response under both hormonal and nervous system control. That's why when you first handle the teats of a nervous goat maybe nothing happens. It helps if you keep barking dogs and romping, noisy children away at milking time. And that's why some dairy farmers play sweet, soothing music to their ladies. If your animal is happy and relaxed, and expects to give her milk to you anyway, as soon as you handle her teats the upper part of the udder contracts and forces milk steadily down. Then when you squeeze the teat, something comes out.

First Squirts. The teat ends are a hole into her body, and the first milk right there tends to be higher in bacteria. So dairy sanitarians urge us not to use the first 2 or 3 squirts from each teat. Just milk them onto the ground or better yet into a cup for examination for mastitis signs (later discard). The strip cup is a neat little invention: a cup with a screen on top that really makes the strings or flakes or lumps of mastitis milk show up clearly. (You can make a homemade strip cup by putting a small tea-strainer over a cup.)

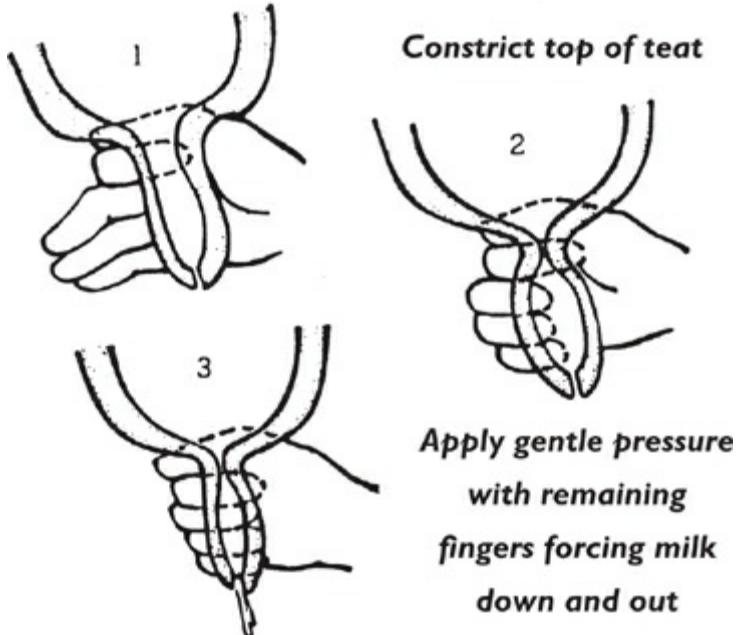

NOTE: If you suspect mastitis, don't use the milk, and get her under treatment.

MILKING—THE MAIN ACT: This milking can be done by machine or by hand.

Milking Machine. Both goats and cows can be machine-milked. Managers of huge dairies appreciate them. You can buy milking machines from a dairy supply house. But with a few animals being milked for home use, a milking machine is as impractical and unreal as a 200-gal. bulk cooling tank would be. The machine is expensive and has to be washed after each use. You can hand-milk a goat as fast as you can machine-milk, and it's simpler and far, far quicker when you include milking machine wash time.

Hand-Milking. Now you've got to milk for all you're worth. The contraction reflexes in the bag won't go on forever, and you've got to get the milk out while it is on. Empty the filled cavity of the teat by squeezing the milk in there out the hole in the end. Then open your hand long enough to let it fill up again from the pressure above, and squeeze it out again. On one of my goats it took about 167 squeezes on each side plus stripping to get all the milk out. In effect, you block off the space above the teat with your fingers so it doesn't go back up, and then squeeze on the rest of it to empty it out the hole. Then open up at the top again to let more milk down. Once you get going, you can really move the milk out if the hole is big enough. The reactions on each side are separate. After you've milked a teat, you might still have to work a little to get the next one going.

Grab high on teat near udder

Squeezing Technique. A cow has 4 teats whereas a goat has 2. Just how you squeeze the milk out of them depends on the shape of the teats. A yearling goat with very small short teats is hard to milk and it takes a long time—even though she doesn't give much. You milk those short teats by blocking off with your thumb and index finger and then adding your next 2 fingers (one at a time) to force the milk on out. Or you can "strip" by starting at the top of the nipple and pulling your hand down to force it between your thumb and forefinger. This will also help to enlarge a small nipple.

You have to keep your hand above or away from the nipple hole or the milk will go everywhere but the bucket. On a good-sized teat you can use your whole hand, and then it's easy. Just block with your thumb and index finger as high on the nipple as you can get, and then add your other fingers one at a time to force the milk out gradually. *NOTE: Don't grab hold above the teat on the udder tissue because that's not natural to her, and it can harm the udder attachment and milk-producing tissue inside.*

Within a few days you can be pretty fast and comfortable with it, though at first your wrists will get tired. My son Danny could milk a goat when he was 4. He fired both barrels at once. Then sat and waited for them to refill. But the usual way is to alternate hands, squeezing with one while the other is filling with new milk. So while your left hand is blocking off at the top and then squeezing, your right hand is relaxing. Then your left hand is relaxing while your right hand is blocking off at the top and then squeezing. Try to develop a smooth rhythm. Speed will come later. Eventually it should take only about 10 minutes total to milk a goat.

Stripping. Dynah Geissal wrote: " 'Butt' the udder gently with your hands several times (light slaps), especially when the milk flow slows, to encourage complete let-down." Woody Bernard writes: "I disagree. Gentle massage is better."

Before milking, her bag and teats will look full and round. As you milk, the teats get a wrinkled, shriveled appearance and a cow's udder develops 2 big folds on the backside. When the flow of milk slows very perceptibly and the teat takes longer and longer to fill, it's time to switch to a stripping motion. Use your thumb and index finger and pull them down over the teat so the teat is pulled through your fingers from top to bottom, and you have the last few drops. (Some owners support a goat's udder with one hand while stripping with the other to avoid unnecessary down-pull on it.) Strip each teat about 5 times. When one teat seems to be empty move on with that hand to another. Then go

back a couple of times before you finish stripping again to get what's left. If you get every last bit you'll keep her milking to the max. If you leave some milk in, she'll produce that much less next time and may never come back up to that earlier level.

Finishing Up. When you're done, open the stanchion. Pat her and say a kind word like, "Thanks, old bag," and then chase her out of the barn. She'll be feeling a lot more comfortable with the tension off her bag since you emptied it. If you've ever nursed a baby, you understand how she feels. A full mammary gland (breast on you, udder on her) is misery. One that's overfull is hell. She was desperate to be milked to relieve the discomfort.

Barnkeeping. Milking stimulates contractions of other parts. Be prepared when your cow spreads her legs and starts to squat, and get yourself and the milk bucket clear away fast, because it tends to splash all over. Goats are so much nicer that way. At regular intervals, like every few days, shovel the scrapings out of the barn into a pile to age and ripen for the garden. It makes the barn nice to scatter straw on the barn floor after you have it shoveled out.

Milking Problems and Problem Milkers

Phyllis Vallette, missionary in Djibo, Burkina Faso, wrote me: "At our semi-desert latitude, the Africans manage their cattle and goats with absolutely no barns, and very limited use of pens. The Fulanis here do make a calf-pen, which they use at milking time—they corral the calves, then a child is posted to let them out one at a time on call. The calf starts to nurse, then the milker-woman takes it off the udder and ties its neck to the cow's front leg (both an anchor and a distraction to keep her occupied). She squats, no stool, and milks into a wooden bowl, then lets the calf free to finish off—and calls for the next calf. If a cow is likely to gouge, a second person holds the head with a long stick and loop around the horns. Goats are milked by taking a hind leg and tucking it into the crook of your knee as you squat! The Fulanis keep the kids around the house and yard all day while the adults are sent off to the bush (without a goatherd, usually) to browse. They cut small branches of leaves to bring to the kids as necessary. About 5 pm the goats return, and the air is filled with the high and low bleats of the kids and goats as they reunite. The Mauritanians keep all the kids and goats together, but they fashion a little bag for the udder and tie it over the back when they want to limit the kids' nursing!"

CHANGING A MILKING SCHEDULE: If you bought a cow that is used to being milked at 6 am and you sleep until 9 am, that's okay. Milk her 15 minutes to a half hour later each morning and evening until you get her on the schedule you want to keep. That way you minimize the drying-up tendency. And give her lots of grain in the meantime to help keep up the milk production.

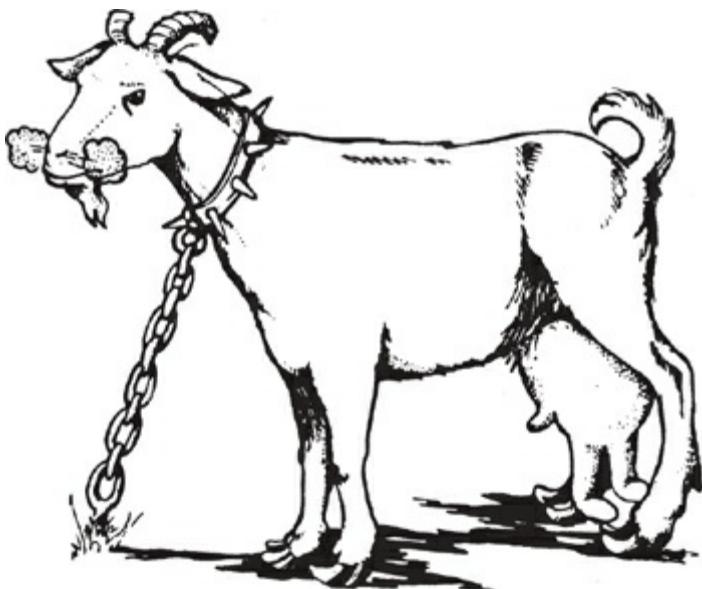

MILK PRODUCTION FACTORS: Lots of things can affect her milk production. If she is standing out in a cold rain with no shelter, not only might she get pneumonia but her milk production will go down. Goats must have shelter available. If she isn't getting a variety of good food—ample brushy range and a little grain supplement in summer; hay, grain, and vegetables in winter—her milk production will go down. She's a wonderful conversion machine. Grass goes in one end and meat, milk, and garden manure come out at various other points, but if you don't supply her with adequate raw materials, she can't do her thing.

The biggest effect on her production is reliable, by-the-clock milking. Her ability to give milk is a long-term investment, and if you skip a milking she starts to dry up—to say nothing of her suffering and pain. If you don't milk her regularly, or if you don't milk her completely dry each milking, you trigger partial drying up. Nature makes automatic adjustments for the "baby's" demands. If you milk your cow completely dry regularly (twice a day), Nature says to that udder that her baby is growing and hungry—he's eating all you have and wants more, so keep making that much, and more if you can. So she produces as much milk as she possibly can. On the other hand, if milk is left in the udder, Nature says to her the baby is eating other food and isn't so hungry now: make less milk. So the next day she produces less milk.

Teat and Udder Size. The speed with which you can milk a goat is—other factors being equal (her state of mind and the quantity of milk)—probably directly proportionate to the size, both length and width, of her teat. It takes a long time to milk a yearling or a goat that hasn't been hand-milked before because her teats aren't enlarged. A good family milker isn't a natural thing. Her udder is abnormally large to cope with saving all that milk for 12 hours when nature meant her to feed her calf or kid much more frequently. Her teats are long and large from hours of being pulled on during hand-milking. So when you see a goat with a big udder and big long teats, she'll probably be a good family milk goat. One reason she's so expensive is because she didn't get like that overnight.

Extra Teats. A 3-teated goat—with 1 normal side and the other with 2 nipples instead of 1—isn't uncommon. Nor is a 4-teater with 2 nipples on each side. You can use them just for brood goats. That means you let them rear kids and don't try to milk them, or you can try to make them into a family milk goat anyway. The third nipple may or may not release milk. If it does, you may have to develop a special way of milking that double-teat to compensate for the problem of 2 nozzles. I had one that I milked from behind, between her legs, because somehow when I grabbed her from that angle I had more luck getting both squirts in the bucket. I wouldn't use the son of such a goat for a breeding billy for

fear the trait could be passed on through him.

Nervous Milkers. Nerves can really affect the amount of milk she gives you. You may get some, but not as much as you'd expect. Feel her udder. You can tell if it's still round and not slack as it should be when emptied. Try milking into food-grade plastic because it is less noisy. Keep everything routine and keep children and strangers away from her, especially at milking time. If other animals are harassing her, isolate her. Speak softly to her, if at all, and be patient. An animal gives milk when a brain signal results in the release of the hormone oxytocin into their system. (Same as humans.)

How to Turn On a Reluctant Milker. Sharon Koskela, Troy, MT, wrote me: "Did you ever have a problem cow that no matter what you do, she just won't let her milk down? We have to inject her with oxytocin every milking—that means no breeding back until she's off that. We've tried milking 4 times a day, bag balm, and hot packs, massage, etc., all to no avail. Just wonder if you've any suggestions. Sure could use some!!!"

A cow that gets a shot of oxytocin to turn her on is going to be less likely to have a normal let-down because the injection has become the let-down stimulus instead of the normal routine of udder washing, gentle massage, and squeezing (sucking). The oxytocin should never have been started.

So how do you turn on a goat or cow that doesn't want to be milked? The answer is: You seduce her. Do a good job with your warm water and cloth washing of her udder and teats. The combination of warmth, wetness, and manipulation (like the baby that would naturally push on her udder) goes a long way toward overcoming hostility and nervousness. If that didn't work—you're still squeezing and nothing is coming out and you're afraid she's going to dry up—I know an absolutely surefire way to get her to relax and let that milk down. Maybe she's upset because she's new in your family, or has just been separated from an old buddy, or because you just knocked her kids in the head and she heard them cry out.

POSSIBLE REASONS FOR OFF-FLAVORS IN MILK

1. Did you use something other than seamless stainless steel, food-grade plastic, or glass to milk into, strain into, or store milk in?

2. Was there exposure to sunlight or fluorescent light? That causes oxidation and off-flavor.
3. Is the drinking water for your milker extra high in iron or copper?
4. Did you add warm milk to chilled milk or let chilled milk turn warm?
5. Is it late in your milker's lactation?
6. Did you feed onions, garlic, cabbage, turnip, or other strong-flavored vegetables or silage closer than 7 hours to milking time? Most of those foods work fine to feed if given right after a milking. But don't ever feed onions or garlic!
7. Are there other strong-tasting weeds in your animal's pasture that she's eating?
8. Did the doe smell strong odors within the few hours before milking, such as from a buck? Or was the buck near the milk?
9. Are you milking in a dirty, manure-filled, ammonia-reeking barn? (The milking place is best separated from more fragrant parts of your barn by doors.)
10. Did any manure, dirt, or hair get into the milk? (It helps to brush your milker before you milk.)
11. Did you wash your hands and her udder and teats, then dry them, before you started milking?
12. Are you smoking around the milk?
13. Do you daily wash milk containers with homemade soap, then rinse with boiling water? Do you boil your straining cheesecloths in water with a little lye before reusing, or else dry them at high heat in a dryer?
14. Are you getting your milk cooled to 40°F or less within an hour after milking and then keeping it cool?
15. Did you serve the milk within 24 hours?
16. Is there something wrong with your milker's health?

Just take the teat in your own mouth and suck a little. She can't resist that—it's too real. Nature will get her and the milk will come. Once the bag contraction is started, you'll have no need to resort to that again. If you'd rather find some more artificial technique, use a syringe from a snakebite kit, and it will have somewhat the same effect. So as soon as you taste the milk coming or can tell it's started, just go ahead and finish the regular way.

But some cows never get easy to milk. You have to squeeze hard and work hard for each stream of milk instead of having a good let-down contraction helping you. She's called a "hard milker" and should be sold off or eaten up and replaced.

Switching a Goat with an Older Kid to Hand-Milking. If somebody sells you a doe with a kid 6 weeks old and keeps the kid, you are going to have a very hard time switching her over to hand-milking. It's much better to plan ahead and do it all one way or the other. The doe with kid at side probably gets milked out a minimum of 8 times a day. By the time the kid is 6 weeks old she is producing a lot of milk, but she never has very much in her udder at any one time. Her teats are short and small because that works fine for the kid. He sucks it out instead of manipulating it out the way we have to. If you try suddenly to milk her every 12 hours, she's almost certain to abscess on you or at least

be terribly sore and miserable. Her udder isn't used to holding all that milk that long. By the time you're ready to milk, she'll be so tight and sore her teats will be hard as rock, and she'll jump and tremble every time you touch her. By the time you've tried to milk out a half gallon, 10 cc at a time, she'll be bruised—and have a very bad attitude. If it has to be done, phase her over gradually by milking rather frequently at first and then making it less and less often all the time. It's a good idea to plan on milking 1 or 2 new nans every year, along with the rest of your herd. It takes about 6 months to get them well broken in. Then let them conceive and kid again, and you'll have a good milk goat.

Yearling Milkers. Dynah Geissal says: "Some does start off slowly, and for the health of the [not yet full-grown] goat, I think this may be best. A yearling milker may give only $\frac{1}{2}$ gal. and $\frac{3}{4}$ gal. a year later. That's O.K. She'll come around later. The best doe I've ever had produced a stillborn kid her first pregnancy. I tried milking her, but her teats were half the size of my little finger and her milk supply was meager. I kept her because her mother had been a fantastic milker and this doeling had excellent conformation. Her second pregnancy produced live kids and a decent supply of milk. Also her teats had grown to small but manageable size. Her third lactation was excellent and her fourth incredible. She's eleven now, only producing one (healthy) kid a year, but producing milk in excellent quantities for 10 months a year. From ages 4 through 8 her production was phenomenal. You can coax a young goat into producing huge quantities of milk by feeding lots of grain, but it makes no sense financially and is probably harmful to her health."

Training an Inexperienced Milker. It helps if, even before the first birthing, you teach the animal to enter the stanchion to get a treat in her manger and then shut her in there and handle her for a bit. Put her through the grooming and udder-washing routine. Gently touch her udder and teats enough to help her get used to the idea of it. Goats soon learn to jump up on the milking stand. All animals learn to put their heads through the stanchion opening without a struggle. Once their bags are filling with milk they learn that going to the stanchion spells R-E-L-I-E-F from the pressure plus a food treat—and so meet you there happily.

How to Dry Her Up. Usually your milker will gradually dry herself up, but some generous animals will go on and on until you make them stop. If you want annual kidding, then you dry her up after 10 months of milking. But you don't have to. You could continue milking her until she dries herself up. My friend Imogene has milked goats as long as 3 years without a new freshening (kidding). (So she only needed to get them bred every 2 or 3 years.) But if you do choose to dry her up ...

NOTE: It's important to dry up your animal gradually and correctly to avoid udder damage and unnecessary suffering for her. (As somebody who nursed 7 babies and stopped dead out of several nursings due to ignorance and reasons beyond my control, I have personal experience and strong feelings about this!)

The way you dry up an animal is to stop milking her all the way out. For her to stop producing milk, you have to leave enough milk in there that there's some pressure. Heavy milkers are harder to dry up. The secret is to allow enough pressure to slow her up more and more without causing so much that she is in pain and her udder bruised, even infected. You (1) stop feeding grain or rich supplements. (2) Temporarily reduce water drinking (don't eliminate it completely!). (3) Don't take all the milk as you milk twice a day. Then (4) milk less and less often, dropping to a once-a-day milking for a week, then to every other day, then to every few days, then once more after a week, and that should do it. (5) Watch her carefully for signs of mastitis; this is a high-risk time for that.

NOTE: If you want to give a worming or a lice treatment, her dry time, when there's no risk of

poisons getting into the milk, is the best time to do it.

To dry up a cow, if she is milking more than 2½ qt. per milking, start gradually taking less about 3 months before her due date for calving. Time it so that you stop milking completely by 8 or even just 6 weeks before she is due to calve.

Culling. I used to be more forgiving, but Dynah Geissal says: "Don't even consider keeping a kid from any but your best does. It is vital to cull ruthlessly and to not be sentimental. Be sure to check for extra teats on any kid you are considering keeping. I wouldn't keep any mature doe (or her kid) who didn't provide at least ½ gal. milk per milking throughout spring and early summer. Near breeding season, production will drop, but there should be a reasonable amount, gradually tapering to about a quart 2 months before kidding."

COPING WITH BAD ATTITUDES AND BAD HABITS: If your cow or goat puts her manure-caked foot right in the middle of your milk bucket just as you are finishing milking her, don't kill her. You aren't the first one it ever happened to.

Kicking. You might think the front end is so far away it couldn't know what the hind end is doing, but a mad cow can kick with hind foot forward, to the side, or back, and she can put that foot right where she aims it; it can really hurt. Some of them really make a habit of it. In that case you'll have to develop a defense. If she does succeed, just consign any contaminated portion of the milk to the animals and try again. A big, tall flat-bottom bucket is more stable, and it's harder for them to get a foot into it.

Bodily Restraint. If she kicks or is otherwise hard to control, you'll have to milk in a stanchion for sure. In the case of a goat you can hold 1 foot while you're milking with the other hand. For a cow, use hobbles on the hind legs of any animal that kicks the bucket or dances around. There are various styles of them. Lane Morgan says, "Another thing we've done with a kicky cow is to have one person hold her tail up while the other one milks. You have to grab it right at the base or you risk injuring the tail. Cows can't kick with their tails held straight up—I don't know why but it's true! After a few days—with luck and kindness—the cow calms down and forgets about kicking."

Some goats kneel on their front feet when you try to milk them. Some have the habit of trying to lie down completely. In the former case you can learn to milk her on her knees. In the latter, you can either rig up a body sling or make hamburger out of her. Part of breaking her of any bad habit is to refuse to stop milking—even if you have to milk on the ground. Then she may give up resistance as ineffectual.

Tails of Woe. One thing that a cow can do to you that a goat can't is switch you right in the eye with a manure-caked tail. If she's got that habit just include her tail in the hobble or get it under your arm and keep it there for the duration. In October you can trim it as short as possible for the winter but let it grow out again by summer to help her defend herself against the flies.

Self-Suckers. Goats are limber enough to do this, and if they get started self-sucking it can turn into a dreadful habit. The cure, unless you sell her or make hamburger, is an "Elizabethan collar" or "side-stick harness." Either one prevents her neck from turning. The collar is just a firm wide collar of metal or wood and wire. The harness is a halter plus a chest strap connected by a wooden stick between her front legs stretching from the chin loop on her halter to a connection located on the belly-side of her chest strap. Some cows can self-suck too. In their case there's an anti-sucking nose ring you can order from Nasco (livestock supplies).

MASTITIS

NOTE: Stop drinking the milk until you get the animal cured. Throw it away. But be careful where you throw it, because it is full of infection. Remember to wash your hands very thoroughly after you milk a mastitis-infected animal, and before you milk another animal, or you can spread the mastitis germs to every animal in your herd.

Cause. Mastitis is an infection of the tender udder tissue by bacteria that have entered through the cow's teat hole or through a cut on the udder. Mastitis is not due to any particular bug—at least 20 different organisms can cause it. Under normal conditions the cow has enough resistance to these microscopic bugs that are all around her to always avoid infection. Unfortunately it's common in both goats and cows. Mastitis is not just a threat to the animal's milk-producing capacity (any lactating female can get it, women also), which is threat enough. I've seen animals near death because it went into a general systemic blood poisoning.

Prevention. Prevention is the best management for mastitis. Best prevention is regular milking. *Mastitis is more common in machine-milked animals than hand-milked ones, and more common among animals pushed to their absolute production limit.* But sometimes it happens for no apparent reason. An overfull udder bruised from the outside or the internal bruising caused by her not getting milked out when she needs to be, makes her more susceptible. Dynah Geissal says feeding apple cider vinegar in their grain also helps prevent it. Woody Bernard says, "Not likely."

Mastitis Symptoms

1. Check the udder for tumors or abscesses. If there are tumors, you can feel them as large, very hard areas. Goats frequently have benign tumors that don't seem to do any harm. However, an abscess is a red, tender swelling of the entire side.
2. But usually mastitis first shows up as flaky, lumpy, or ropy milk. At least once a week examine her milk closely. A strip cup is designed to check the first few squirts of milk from each teat. Or you can just squirt onto a cloth so you can examine the milk closely.
3. The infected quarter of a cow's udder, or half of a goat's, will feel warmer than usual from the fever in it and be harder than usual.
4. It will seem hard to milk out and you won't get as much milk as usual. As the mastitis worsens, the milk will become thicker and thicker until it is a struggle to squeeze it out, and it comes out like toothpaste out of a tube.
5. As mastitis worsens the fluid will turn from milk's pure white to a yellowish color, which reveals pus in it—or brownish or pinkish, which is blood in it.
6. A part of the udder that has had mastitis before will be especially susceptible to it again.
7. Mastitis can also happen in dry (nonmilking) animals, so if you have a sick female see what you can squeeze out of each teat even if you expect her to be plumb dry.

Early Diagnosis. As you milk, morning and night, be alert for mastitis symptoms. *If you can't prevent it you can at least catch it early.* Mastitis will happen only one quarter at a time (a cow's udder has 4 separate quarters, each with its own faucet-teat). If you can catch it while it is confined to one quarter you can prevent it spreading to the others.

Cure. Mastitis is very hard to cure even using antibiotics, which are about the only hope you have. For a suspected case, the vet can test a milk sample. Daily shots of antibiotic give me the best results. Check with your vet by telephone for the kind and amount. *Knock out the infection as quickly as possible before the animal's current and future milk production is jeopardized. Get on it the day you detect or suspect mastitis, and stay on it until it's gone.* Your animal will more than likely have dried herself up a lot before it's over though. Rich feed may help bring her back if she's recently fresh. If she is severely abscessed, you'll have to dry her up, and she'll have a tendency to abscess again next time around. Dynah Geissal says she won't keep a goat who has it twice.

NOTE: *Mastitis can spread from one dairy milker to another. Always milk mastitic animals last. Don't throw their milk away where other milkers might contact it—onto the floor or bedding in the barn. Always disinfect your hands after milking a mastitic animal. Don't give that milk to people or baby animals.*

DAIRY VETTING: Mastitis is the biggie, but here are other possible problems, too. Here they're listed in alphabetical order.

Bang's. This is a disease. Cows that carry it don't show it. But their babies are born dead, and you and your children can catch a human form of Bang's called undulant fever, which is a very grim disease. A friend of mine in the dairy business nursed one of her daughters through it. To prevent Bang's, give your heifers shots at 4–8 months to vaccinate them.

Blood in the Milk. Dynah Geissal says, "May be caused by mastitis, a cut teat, chapped teats, rough milking, or the udder being too full causing small blood vessels to break."

Cuts. Bag Balm is a wonderful product that heals cuts or chapped skin on man or beast quickly. Just rub it into the problem area several times a day.

Chapped Udder. Rub Bag Balm on her after milking.

Cut Teat. Cuts occur often on the teats. Clean the cut. Don't break your milking schedule—even if it takes a long time to milk that cut teat, and the cow suffers, and you agonize in sympathy. She'd suffer more if the milk built up, swelling in that teat under the cut and abscessing above it. You may have to hobble her to keep her from kicking if it hurts.

Milk Fever. This is a disease of pregnant or just-delivered animals. A goat with milk fever, according to Dynah Geissal, “lies down with her head turned back against her side. Other symptoms are muscle tremors, walking unsteadily, and subnormal temperature. The disease is prevented by a good daily mineral mix to maintain a proper calcium/phosphorus balance. The disease is hypocalcemia. The cure is to inject calcium gluconate and works almost miraculously.”

Tuberculosis. Nowadays this isn’t a very common dairy disease because of the long vigilance practiced by dairymen. But it’s still smart to have your dairy goats and dairy cows checked for TB by a vet because the animals can get it from coming into contact with an infected wild animal. It’s worth the money to be sure the milk is safe. *But, according to statistics, you’re far more likely to get TB from living in crowded quarters in the inner city than from a dairy animal.*

ABOUT MILK AND MILK PRODUCTS

Milk Types

COLOSTRUM MILK: It’s very important to get the mother’s first milk into the kid, calf, etc. The general rule is that the milk for the first 4 days is for the baby. Either let the baby nurse those days at least, or milk her yourself and bottle-feed it to her baby. That milk has a special name, “colostrum,” and it looks special—thicker and darker in color than regular milk. Colostrum contains precious immunizations and vitamin concentrates the mother is passing on to her kid, and the kid is likely to be sickly without it. Don’t heat colostrum more than barely lukewarm because it will turn hard as cheese and be useless.

You have to go out within a couple hours after the goat has kidded, take the kid and put it in a warm dry place, milk the nanny mother for her colostrum, and then get her comfortably settled if you are planning to separate them. You can freeze extra colostrum milk (it’s best frozen in a sterilized glass container). Then you can thaw and warm it to feed multiple births or an orphan that may appear later.

➲ **COLOSTRUM MILK CUSTARD** *The Swedes, Lane Morgan, and Kim Carlson (who helped edit this chapter) enjoy this specialty! Lane writes, “Mix 1 c. regular milk with 2 or 3 c. colostrum (second, third, or fourth milking). Add ½ c. honey or sugar and stir. Season with cinnamon and bake or cook in double boiler. The colostrum will thicken and set without eggs because it’s high in albumen. It tastes very rich.” But Woody says, “The milk shouldn’t be used for human consumption for 4 days after birth.”*

WHOLE AND SKIM MILK: “Whole milk” is milk in which the normal amount of cream is mixed throughout the milk by shaking it up. This is always a temporary situation with home milk, as you can’t duplicate the dairy homogenization that shakes it up never to separate. If all the cream has been skimmed or separated out of the milk it is called “skimmed milk” or “skim milk.” Skimmed milk is fine food for chickens, pigs, and the like.

SWEET OR SOUR: Sweet milk is fresh milk. As the days go by, especially at warmer temperatures, the bacteria do their natural thing and your milk (or cream) turns sour. When thoroughly soured, or “clabbered,” it “sets up” and separates into a thick part (curds) and a thin clear liquid (whey). You can make cottage cheese out of this or feed it to the animals. Sour milk can be achieved naturally by waiting, or hurriedly by adding 1 T. lemon juice or vinegar per cup of milk.

The old-timers didn’t feed their chickens very much, if any, grain. They fed them

clabbered milk! Chickens do very well on a steady diet of this sour milk. Or you can give them fresh milk. But it's easier for them to get at the milk protein if you clabbered it before feeding. The clabbered milk is also somewhat more digestible for them. (They need plain water in addition to the clabbered milk.)

CHANGING MILKS: Goat's milk does not taste like either raw or store-bought cow's milk. You may have trouble changing your family over from any one kind of milk to any other. I can remember as a child how awful the store milk tasted to me when we sold our last cow and then how awful the raw milk seemed to taste for a while when several years later we again had a milk cow.

First serve the new milk in eggnogs, Postum ($\frac{1}{3}$ milk), and such. Once your family gets used to drinking it in mixtures, drinking it straight will soon follow. Give babies an especially gradual transition, starting out with one-fifth of the new type and working up gradually. There may be a period of either constipation or looseness until they make the adjustment.

Switching Baby's Milk. If you try to switch a baby over without this gradual introduction, your child can end up in terrible distress. Cow's milk is very constipating for babies who have been on canned formulas. If you try to make a sudden, total switch, your baby might not be able to have a bowel movement—even need surgery. So be gradual when you set out to change a baby's milk type—even one you think is a “big” baby, even a toddler. Watch the subsequent bowel movements carefully. Give that one-fifth part of the new milk. Wait to see how the next few bowel movements are. Then increase the mix one-fifth more, and so on. If there's a problem, reduce the new milk. Some children never do tolerate cow's milk.

Milk Handling

You need a stainless steel or food-grade plastic container to milk into, and quart, half-gallon, or gallon jars to store milk in; Bag Balm for treating teat and udder chapping and nicks; and cheesecloth or another system to strain the milk. There are other possible items but they're optional. Stainless steel is expensive but it lasts a lifetime.

CLEANING HOME-USE MILK UTENSILS: Quick-cooling the milk and using clean utensils can vastly improve milk flavor.

1. Prerinse with lukewarm water as soon as possible after their use. Lukewarm is important because cold water forms solid, hard-to-clean-off butterfat, and hot water

coagulates milk protein and makes it stick to things.

2. Wash with an *alkaline* soap: 1 t. washing soda dissolved per quart of water, or homemade soap, or “dairy detergent.” *Don’t use regular detergent.*
3. A scrub brush helps.
4. Then rinse.
5. Give a final scald with boiling-hot water.
6. Air dry on a rack upside down because if you wipe them with a cloth, you’re just rubbing bacteria back onto them.
7. Before you take your milk bucket out in the morning, you could rinse it out with boiling water from your tea kettle.

STRAINING THE MILK: You’ll have less to strain out if the udder is washed before milking—or at least wiped off to get rid of dried mud and manure that might fall into the milk. Your next chance to prevent contamination is at the straining, when you bring the milk into your house. Straining helps to get rid of hair, dirt, and so on, which cause off-flavors and a high bacteria count. Milk with a high bacteria count will sour fast. You’ll help avoid strong-tasting goat’s milk if you strain and refrigerate right after milking.

Strainers. A regular commercial milk strainer looks like a big metal bowl with holes in the bottom. A ring fits in the bottom to hold down a paper filter disk. The gunk is trapped on the disk, which is thrown away after the straining. For a homemade strainer, pour your freshly milked milk through 4 thicknesses of dish towel, clean diaper, or cheesecloth laid over a large strainer. This won’t catch soluble impurities. They settle as a kind of “dust” in the bottom of your jar and do no harm I know of. Or you can buy that specially designed milk strainer and use throwaway strainer pads. But there’s no throwaway involved if you strain through cloth. Rinse and boil the cloth afterwards to clean it. That’s my preferred system.

CREAM SEPARATION: See the section on cream. In this case you separate after straining but before bottling.

RAW OR PASTEURIZED? Raw milk does not taste like pasteurized milk from the store. The more raw milk ages, the more pronounced the difference becomes. If you’re going to pasteurize, do this after straining (and separating if you choose), and before cooling.

Pasteurizing. Pasteurization is a germ-killing process achieved by the temperature you heat the milk to and the length of time you keep it there. The higher the temperature, the shorter the time. You can pasteurize cream, milk, or any combination thereof. There are pros and cons to this decision.

If you’re selling milk, you usually are required to pasteurize. But if your animals are tested against tuberculosis and brucellosis and clear, pasteurization isn’t needed for healthy home milk and just makes more work and more stuff you have to wash for no reason. I like the taste of raw milk. The process does destroy a goat milk enzyme, which causes it to eventually develop that goaty flavor. But if you’re getting plenty of milk twice a day there’s no need to have it fresh-tasting longer. Pasteurization doesn’t hurt the food value of milk except it decreases vitamin C and thiamin—but milk doesn’t have much of those anyway. *NOTE: Boiling milk or over-sterilization harms the nutritional value of milk.*

Machine Pasteurization. If you’re doubtful about the health of your milk source (pasteurization will kill TB germs and won’t affect flavor much if done right), or just want to pasteurize anyway, the easiest route is to buy a home milk-pasteurizer, which will

pasteurize up to 2 gal. milk at a time, for \$225 from New England Cheesemaking Supply (413-628-3808; www.cheesemaking.com).

Flash System. Set a pan (only glass or quality stainless steel) inside another with water between them, double-boiler style—because milk burns so easily. Put the milk into the top pan, cover, and heat to 161°F. Hold at that temperature for 15–20 seconds, then cool. Don’t let the temperature get higher than 165°F, and don’t keep it up there more than 20 seconds or you risk a cooked taste. Judge the temperature using a floating dairy thermometer. (Another system is to heat the milk quickly in an open-topped container, stirring constantly with a stainless steel spoon.) Then cool the milk fast as possible by setting it in ice water or under cool running water. Stir constantly until it gets down to 60°F, then once in a while until it gets down to 50°F.

Slow System. Create a double boiler as above. Heat milk to 140–150°F and hold it at that temperature for 30 minutes. Stir once in a while with a sterile, stainless steel spoon. Cool as above.

Bottling. Pour the milk into clean, scalded, jars or bottles, and cool it. Cover with lids.

Cooling. You milk the animal, take the milk into the house, strain it, and cool it—all in quick sequence. That’s because warm milk is perfect food for bacteria, and so you want to get it cooled as fast as possible. Fast cooling avoids off-odors from bacterial growth. You can put it into prechilled quart glass jars, and put them in the coldest part of the fridge. But milk will cool even faster if it’s sitting under running cold water, or in a pan of ice water with more ice added as needed. *Your basic goal is to cool it down to 40°F within 1 hour.* If you pour milk into a jar that’s at room temperature and just set it in the fridge it won’t get that cool that fast. It won’t be bad to drink, but it will be more likely to develop an off-flavor if cooled too slowly. Fresh milk keeps best if stored around 34°F.

FRESH OR AGED MILK? On the farm you should drink both goat’s milk and cow’s milk fresh. When you’ve got it coming every 12 hours there’s no reason to use milk over 24 hours old for plain table milk. You can use older milk for baking, cheesemaking, etc.

PRESERVING MILK: Sometimes you will have more milk; spring and summer are peak months for milk, as well as eggs. Late winter may find you really short of milk. Cheesemaking is a way to preserve milk from your surplus times for your lean times. See the section on cheese storage for how to shelf-store or dry cheese. Other ways are to can it or freeze it. Or have enough milkers that you always have plenty—and when you have too much you can raise an extra calf, colt, pig, flock of chickens, etc., with it.

Canning Milk. Strain your fresh milk and cool it. Then pour it into clean jars to within ½ inch of the jar top. Put on your lids firmly. Process in a pressure cooker for 10 minutes at 10 lb. of pressure or 60 minutes in a water bath canner.

Freezing Milk. Pour fresh (as soon as cooled and before the cream has a chance to rise!) milk into straight-sided, lidded containers, quart or half-gallon size, or into food-grade plastic bags. It keeps well for 6 months or more. Don’t thaw and then refreeze milk.

Foods Made from Milk

There can’t be too much milk. You’ll find that in order to get enough milk in the winter for household use, you’ll have to live with a surplus of milk in the summer. That’s okay. When your family doesn’t need it all, you can raise calves, pigs, and chickens on it, feed the dog and cat, and make butter, cheese, and many other wonderful dairy foods. I separate the cream out for butter-making, refrigerate whole milk for cooking and table use, and separate out the curds from the rest for cheese, which you can make and store. The

animals get the whey. My recipes use real cream and butter in them because you are milking and have these. Here are ideas for good ways to use, preserve, store your milk.

MILK SOUPS: Soups made with milk are so easy to make, good-tasting, and good for you. We just finished a lunch of tomato soup. I made it by thickening some of my V-7 juice with flour. Then I added salt, a little pour of molasses, and gradually stirred in milk. I was going to add some soda but couldn't find any. It came out good, anyway.

As a general rule, milk or cream soups shouldn't be boiled. Boiling hurts the flavor and makes a mean scum to clean out of the kettle. Always add the hot milk to the other ingredients at the last minute. You can make a milk soup out of any vegetable using the same general formula as in the following recipes. They're mostly called "cream of whatever" but are really made with milk.

⇒ **CREAM OF FRESH MUSHROOM SOUP** *The old-timers around here go out in the spring and come back with pans of mushrooms. They saute them in butter and eat them right away, can them, or make soup: Wash ½ lb. fresh mushrooms, bruising them lightly if necessary, but do not peel. Chop rather fine. Brown slightly in 6 T. butter. Then blend in 4 T. flour, and gradually stir in 6 c. milk. Cook in the top of a double boiler for 20 minutes, stirring frequently. Season with salt and pepper. Serve with crackers.*

⇒ **ONION SOUP** *Chop about 1 lb. onions. Cook the onions with a couple of tablespoons butter over a gentle heat for a few minutes without browning. Add 4 c. chicken stock and salt and pepper to taste, and cook 30 minutes more. Add a little flour and milk paste for thickening and 2 c. milk. Cook, stirring, until thickened. Good with bread and cheese.*

⇒ **CREAM OF ONION AND POTATO SOUP** *Boil about 4 cubed potatoes and 4 sliced onions together in water until tender. Drain, saving the water. Rub the vegetables through a coarse strainer or blend them into a puree. Melt 2 T. butter and then mix into it 2 T. flour, ½ t. salt, and a pinch of pepper. Gradually add 3 c. scalded milk and the potato water. Stir constantly as you add the liquids. Add the potatoes and onion puree, stir, cook 3 minutes, and serve.*

⇒ **CREAM OF SPINACH SOUP** *Puree ¾ c. cooked greens in a blender or chop fine or rub through a sieve. Combine 2 c. milk, 1 bay leaf, 2 sprigs parsley, and 1 t. minced onion, and heat to boiling. Melt 3 T. butter, blend in 3 T. flour, a pinch of paprika, 1 t. salt, and the milk mixture. Simmer 5 minutes, stirring constantly. Add the spinach to the mixture and ¼ c. cream. Reheat and serve.*

⇒ **CREAM OF TOMATO SOUP** *Peel about 6 tomatoes and cook, or use about 2 c. canned tomatoes. Simmer for 15 minutes after you have mashed them to break up large pieces. Now cool and then puree in a blender or just finish mashing. Add ½ t. soda, 1 T. honey, and 1 t. salt. In a separate pan melt 2 T. butter. Mash in 2 T. flour. Then gradually stir in 2 c. milk, stirring constantly until it thickens. Now stir in your tomato mixture, 2 c. more milk, and 1 T. finely chopped parsley, if you have it. Heat and serve.*

MILK BEVERAGES

⇒ **HOT FLAVORED MILK** *Combine 1 c. or more scalding hot milk and a pour of molasses (or some instant cocoa, or a little honey and vanilla). Beat it up with the eggbeater or put into the blender. Pour into a glass. Sprinkle nutmeg on top. Serve with toasted homemade bread.*

⇒ **BANANA MILK SHAKE** *Slice 2 bananas and beat until creamy, or put through a coarse sieve, or blend. Add 2 c. cold milk, mix thoroughly, and serve at once.*

➲ **GOAT MILK SHAKE** From Sonya Lizarraga, Salome, AZ: "You just freeze the goat milk in small containers (neighbors give me their plastic cottage-cheese cartons). When you want your shake, you cover the blades in your liquifier (blender) with just cold milk, then put in 2 big spoons of carob powder (a good protein) and a banana. Then add as much frozen goat milk chunks as will make it thick, blending to mix up well. Fun to experiment with other flavors too, but banana is our favorite."

➲ **REAL STRAWBERRY MILK SHAKE** Crush about 1 qt. strawberries, and press through a coarse sieve in order to get at least $1\frac{1}{3}$ c. puree. Or blend. Combine the strawberry puree with 5 c. milk and $\frac{1}{2}$ c. cream. Add $\frac{1}{2}$ c. honey, $\frac{1}{2}$ t. salt, and $2\frac{1}{2}$ t. lemon juice. Mix well and chill. Top each glass with a spoonful of whipped cream.

➲ **BANANA-STRAWBERRY SHAKE** Mash 2 medium-ripe bananas and combine with 1 c. slightly sweetened, crushed strawberries. Mix in 1 T. lemon juice, 1 qt. milk, and 1 qt. slightly softened vanilla ice cream with a whisk. You could garnish each serving with a fresh strawberry.

➲ **APRICOT MILK** Put 1 c. cooked apricots and their juice through a sieve, or blend. Mix the pulp with 3 c. milk. Put $\frac{1}{2}$ pint vanilla ice cream in a pitcher and pour the milk mixture over it. Stir slightly.

➲ **PRUNE MILK** Pit and mash the prunes until you have 1 c. pulp. Add that to 3 c. chilled milk, and beat them together or shake in a jar. Pour into glasses and top with whipped cream.

➲ **PEAR AND GINGER ALE MILK** Press 1 c. cooked or canned pears (not the juice) through a sieve, or blend. Mix with 1 qt. milk. Pour into glasses, and to each glass add a splash of fizzy ginger ale (recipe in [Chapter 5](#)).

➲ **MAPLE AND GINGER ALE MILK** Add $\frac{1}{2}$ c. maple syrup to 1 qt. milk, and mix well. Pour the milk into tall glasses and add ginger ale to taste.

➲ **MILK LASSIE** Stir 1 T. molasses into 1 c. milk, hot or cold. Easy and nice.

➲ **BANANA LASSIE** Mash 1 ripe banana until smooth. Stir in 1 T. molasses and a pinch of salt. Add $\frac{3}{4}$ c. milk and mix well.

➲ **ORANGE JULIE** Combine $\frac{1}{3}$ c. frozen orange juice concentrate, $\frac{1}{2}$ c. milk, $\frac{1}{2}$ c. water, $\frac{1}{4}$ c. sugar, $\frac{1}{2}$ t. vanilla, and 6 ice cubes in a blender, and whir until smooth. Serve right away.

➲ **SHAKER SYLLABUB** The Shakers heavily sweetened 1 gal. warm apple cider with maple sugar or syrup and grated a nutmeg on top, then milked the cow right into the mixture and served it at the table while still hot and foamy. Some winter I'm going to try that just for adventure!

CUSTARD: Custard can be made by baking or boiling, or can be thickened with rennet, which causes a yogurt-like result. Custards have to be cooked at a low temperature and not too long or they will curdle. But frankly, I'm always in such a muddle my custards "curdle" more often than not, and they are still delicious. All "curdle" means is that some water separates out. I just pour it off and serve what's left. The best way to regulate the cooking temperature of baked custards is to surround the pan with water. Set the individual custard dishes in a pan of hot water. Make all boiled custards in the top of a double boiler. Milk that is a little sour can also cause curdling.

If the custard does start to separate, remove it immediately from the heat, set the custard pan in a pan of cold water, and beat to redistribute the particles. Any acid such as lemon juice would reinforce the tendency to curdle. Baked custards come out firmer than

boiled custards. You know it is done when the blade of a knife run into the center of the custard comes out clean. The firmness of the custard is also a result of the amount of egg in it. The more egg in your custard, the firmer it will be. Two eggs per cup of liquid is a good general guide. One egg per cup of liquid makes a soft custard, all right for baking in small cups.

➲ **BAKED CUSTARD** Combine 3 lightly beaten eggs, $\frac{1}{4}$ t. salt, and $\frac{1}{3}$ c. sugar. Add 3 c. scalded milk slowly, stirring constantly. Add $\frac{1}{2}$ t. vanilla. Pour into custard cups. Sprinkle with nutmeg. Place the filled custard cups in a pan of hot water and bake in a moderate oven (325°F) for 45 minutes, or until a knife inserted in the center of the custard comes out clean.

For chocolate custard: Add 1½ oz. (squares) of chocolate to the milk and heat until melted. You can't use that instant chocolate stuff.

For coconut custard: Add $\frac{1}{2}$ c. shredded coconut to the mixture.

For coffee custard: Scald 2 T. ground coffee with the milk, strain, and proceed as for the baked custard.

For date custard: Add $\frac{1}{2}$ c. chopped dates to the custard before baking.

For honey custard: Use $\frac{1}{2}$ c. honey instead of sugar.

For rum custard: Leave out the vanilla and add 2 T. rum.

➲ **BOILED CUSTARD** Combine 2 lightly beaten eggs, $\frac{1}{8}$ t. salt, and $\frac{1}{4}$ c. sugar. Add slowly 2 c. scalded milk, and cook in the top of a double boiler until the mixture coats a spoon. Add $\frac{1}{2}$ t. vanilla and chill.

For almond custard: Use almond extract instead of the vanilla, and top with shaved, toasted almonds when ready to serve.

For caramel custard: Use brown sugar instead of white.

For chocolate custard: Melt 1 oz. (square) chocolate in the milk.

Custard making is so simple and yet such an art. My mother's custards were carefully made in little individual dishes. They always came out just perfect, and were such a gift of love it makes me both hungry and homesick just to remember them.

RENNET PUDDINGS: Rennet puddings made from scratch turn out like yogurt. When Little Miss Muffet was sitting on a tuffet, eating her "curds and whey," I figure it was a junket rennet pudding. They used "essence of pepsin" or "liquid rennet" or a "junket tablet" to make them. That's the same rennet that is used in cheesemaking. (See "Cheese" for how to make rennet if you don't buy it.)

➲ **BASIC RENNET PUDDING** Just stir in the acid, let the milk stand at room temperature for about 20 minutes, then refrigerate. Serve with cream and sweetening, or fruit. It's very bland.

➲ **VANILLA RENNET CUSTARD** Combine 2 c. milk, 2 T. sugar, and a dash of salt in a small

pan. Cook, stirring constantly, over low heat, until lukewarm. Remove from heat, and add 1 t. vanilla. Crush 1 rennet tablet in cold water in a cup, stirring until dissolved. Add it quickly to the milk mixture, stirring only once or twice. Pour immediately into a quart dish or into individual dishes. Let stand at room temperature until the mixture is set (do not move) then chill. The custard will set in 10–30 minutes, depending on the temperature of the room. The higher the room temperature the more time is needed. Sprinkle top of custard lightly with nutmeg or cinnamon just before serving. Rennet is sometimes available at grocery stores.

FLOUR-THICKENED MILK: Mrs. Lillie R. Balph, Beaver Falls, PA, wrote me: "My mother served this to us as a breakfast cereal. It isn't a soup. She used flour to thicken the milk to a pudding consistency. She put butter and salt in it and heated it until it was very smooth and creamy. She served it in cereal bowls. She ate it with sugar and more butter, but Father and us children used cream and sugar. My aunt made hers lumpy as did other women in the community. Sometimes I make it for myself."

Kat Atkins, Coquille, OR, speaking of goat milk, wrote me: "I keep a quart made and in the fridge, and I add at least 2 eggs to each quart and thicken with 3 heaping T. flour. Then I just make toast and pour the milk over, after rewarming, add some nutmeg now and then and Instant Breakfast. Also great over oatmeal. Good for people with queasy stomachs. Good frozen. Makes soup and a good base liquid for any cooking. I make it ahead when I'm not busy. It lasts about 3 days. 'Thickened milk' made with a dash of vanilla, poured into a bowl with granola topping even pleases and fills my husband at breakfast."

CULTURED MILKS: Store-bought buttermilk, kefir, and yogurt are the 3 common cultures in use, but they are not the only ones. For more information on these quick milk cultures, read *Making Your Own Cheese and Yogurt* by Max Alth (1973) (also good on cheesemaking); and *Yogurt, Kefir, and Other Milk Cultures or Fermented Foods and Beverages*, both by Beatrice Trum Hunter. You can order the appropriate culture starters from dairy or cheesemakers' suppliers, or start with some grocery-store product. Kefir grains and other specialized products for yogurt and kefir-making are available from GEM Cultures: 707-964-2922; 30301 Sherwood Rd., Fort Bragg, CA 95437; www.gemcultures.com. GEM also sells a culture thermometer (\$7), cheesecloth, and Kombucha Tea Fungus.

CULTURED "BUTTERMILK": Real buttermilk is the liquid left over after you've churned butter. It is delicious and good to use in cooking or to drink straight. Commercial dairy "buttermilk" or homemade cultured "buttermilk" never was near a butter churn. It is made by adding a culture to milk to thicken it. At the dairy, sometimes dots of melted butter are sprayed into the cultured milk to make it look "buttery" (real buttermilk doesn't have any butter in it). They add 1 or 2 percent butter that way—whatever they think the customers want. Then the "buttermilk" is ready for sale.

So dairy-type "buttermilk" is skim milk that has been cultured with a variety of bacteria in the same way you make yogurt. It sets up (thickens) 12–14 hours after the culture is introduced. Then you stir to break up the mass. That's why it doesn't have a yogurt-like consistency.

NOTE: To substitute in a recipe for store buttermilk, you can use your homemade yogurt plus a dab of butter.

⇒ **BUTTERMILK-CULTURED MILK** Mix 2 c. raw milk or home-grown milk with $\frac{1}{4}$ c. store buttermilk. Cover and set in a warmish place for 24 hours. (Read instructions under "Yogurt,"

because it's the same procedure.) You can use $\frac{1}{4}$ c. of your resulting thick milk to start a new batch and so on. You can make cottage cheese out of the results. Both curd and whey are good and nourishing to eat if you want. Any little mold that forms on top can simply be scraped off and given to the animals. Buttermilk culture is the least sour tasting of the three. Sourness also depends on how soon you eat it. The sooner you eat any of these 3, the less sour they will be. The longer you wait to eat your cultured milk the more sour it will be—up to a certain point. You can keep the culture going until it gets contaminated in the same way yogurt does.

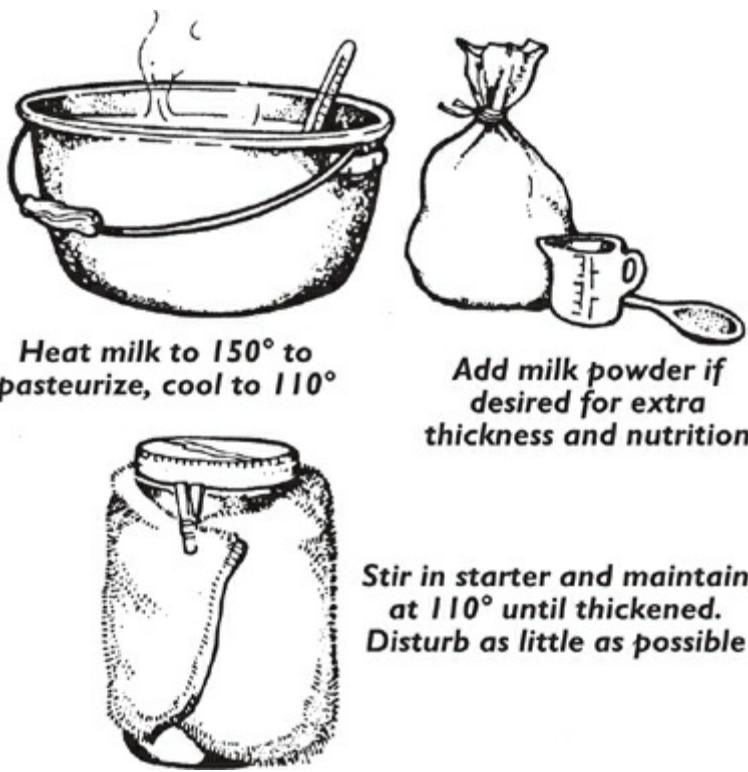

YOGURT: This is milk soured by a selected variety of bacteria. Yogurt is thickened because the bacteria consumes the milk sugar and changes some of it to lactic acid. Once you have made a yogurt culture at home you can keep making more by using a little of your last culture to make each new batch, but eventually the mixture gets invaded by an off-breed of bacteria. In that case you could start over with some dairy yogurt. This happens about once a month. Once you learn to make this wonderful stuff, consider getting *The Stonyfield Farm Yogurt Cookbook* by Meg Cadoux Hirshberg, available from Harrowsmith (see magazine list in [Chapter 1](#)) for 300 yogurt-using recipes. Garden Way offers *Cooking with Yogurt*, Bulletin A-86: yogurt gravy, salad dressing, soup, frozen, etc. Electric yogurt-makers are nice but not necessary.

Getting Your Culture to Start. An easy way to get started is to buy a pint of yogurt and add 3 T. of that to a quart of your own milk. You can use cow, goat, or soybean milk—even powdered skim milk. Or use a commercial yogurt culture for a starter. You can't make your own culture (starter) unless you're a bacteriologist, because that involves isolating a batch of 1 kind of invisible bacteria from all the others and growing it alone.

Yogurt Thickness. The thinnest yogurt is made from nonfat dry milk liquefied with water. Mixing it with skim milk gives you a thicker yogurt. Starting with whole milk makes it thicker yet. Making the yogurt from whole milk with some nonfat milk mixed in gives you thicker yet. If you add evaporated milk, or light or heavy cream to whole milk you get the thickest yogurt of all!

Secrets of Great Yogurt

1. Start by pasteurizing the milk.
2. Cool milk to 105–110°F.
3. If you start from store-bought yogurt, make it an unflavored, additive-free one: 2 T. per quart of your milk.
4. Keep the mix as near 105–110°F as possible while it's working.
5. It takes more than twice as long for yogurt from a freeze-dried culture to get going, as for starts from active yogurt culture.
6. Move from the warm “incubating” place as soon as it has thickened, and chill at least 12 hours; keep refrigerated until used up.

➲ **BASIC YOGURT** From Connie Hughes: "Use 1½ c. canned milk, ⅔ c. skim milk, and 1 t. unflavored gelatin. Put the milk in a 2-qt. pan and sprinkle on gelatin. Let soak 5 minutes or so, then stir with a wire whisk while heating to almost boiling (to pasteurize). Cool to warm (I set the pan in a dishpan with cold water and watch it until it's just warm). Add ¼ cup commercial yogurt (unflavored) and whisk in well. Rinse out small jars with hot water and fill with warm yogurt mixture. Set in a warm place overnight until set. Taste it to see if it's ready or not. Then refrigerate." To thicken this recipe add anywhere from 2 T. to 1 c. powdered milk. From scratch with powdered milk, use 2½ c. dry milk powder with 3¾ c. water.

➲ **CHRISTINE'S YOGURT** From Christine Roelke of Manchester, PA. "I have a yogurt maker/warming tray. Use 1 qt. whole or skim milk and add ⅓ or ½ c. powdered milk (optional for a firmer or pudding-like consistency). Scald, then let cool until it feels lukewarm to the touch. Add vanilla (1 t.) and honey (less than 1 t.). Mix in 2 to 3 T. plain yogurt. Let sit on warm surface for 2 to 4 hours. Cover the containers with a cookie sheet to keep the warmth down where the yogurt is."

➲ **HEATING PAD YOGURT** From Kat Atkins, Coquille, OR: Heat 10 c. goat's milk to 162°F. Cool to 110°F. Add ½ c. noninstant milk powder, 8 oz. Dannon brand plain yogurt, ½ t. honey, and (optional) a dash of vanilla. Pour into 1 -qt. sterile jars. Cover the top of each jar with plastic. Put a heating pad into a canning kettle (36-qt.) and turn pad on to high until the kettle is warm inside. Put a down pillow on top of pad, then the jars—wrapped in towels—then another pillow. Don't leave airspace. Change heating pad temperature to medium and wrap kettle in a blanket. Let go 3 days. Unwrap and put jars of yogurt in fridge.

For Your Next Batch. Save about ¼ c. of your first batch. Keep it in the refrigerator or in a covered container. Use it within 5 days to start another batch of yogurt. And so on until your yogurt gets that off-taste that shows you that some sort of bacteria has moved in on the original variety. That's when you have to get some of the store kind again. You could also buy yogurt culture direct from a dairy supplier if you have use for so much at once.

More Yogurt Recipes. There are so many good things you can make from yogurt.

➲ **FLAVORED YOGURTS** Blend in with the finished yogurt berries that have been put through

a sieve or blended, or any fruit juice. Use about $\frac{1}{4}$ – $\frac{3}{4}$ c. flavoring per 2 c. yogurt. Sweeten with honey or sharpen the flavor with lemon juice as you prefer. Rhubarb sauce and yogurt go well together. Or serve it with any whole fruit. Use it for a vegetable salad dressing combined with seasoning—parsley, horseradish, tomato juice, onion, or Roquefort cheese.

⇒ **VANILLA YOGURT** Mix $\frac{1}{2}$ t. vanilla flavoring into your quart of milk that's going to be yogurt. Sweeten to taste.

⇒ **YOGURT AND CUCUMBERS** Peel 3 large cucumbers and slice into $\frac{1}{8}$ -inch-thick pieces. Combine 4 c. yogurt, 1 clove garlic—ground or finely chopped—and 1 t. salt. Pour over the cucumbers and serve cold.

⇒ **YOGURT-FRUIT DRINK** In a blender combine 1 c. fruit juice, 1 c. yogurt, a little honey, if you need more sweetening, and $\frac{1}{2}$ c. ice, if you want it really cold.

⇒ **BANANA-YOGURT DRINK** Combine in a blender: 1 c. yogurt, $\frac{1}{2}$ c. milk, 1 banana, and honey to taste. Ice is optional.

⇒ **YOGURT SALAD DRESSING** Combine 4 cloves finely minced garlic, 4 T. lemon juice, $\frac{1}{4}$ c. cooking oil, and 4 T. grated onion with $2\frac{1}{2}$ c. yogurt, 2 t. salt, $\frac{1}{4}$ c. chopped parsley, and a pinch of red paprika. Serve chilled.

⇒ **FROZEN YOGURT** Soft frozen yogurt is good topped with nuts, honey, granola, fruit, fruit juice, or any other sweetening. Mix yogurt with fruit (1 c. yogurt to 1 c. fruit). Use fresh fruit, finely cut. The procedure is to freeze your yogurt to a soft mush, then beat it up with fruit, freeze again, and serve.

⇒ **CARDAMOM FRUIT YOGURT** Mix 3 c. yogurt with 1 c. any fruit; add $1\frac{1}{4}$ t. ground cardamom.

⇒ **YOGURT CHEESE** See “Yogurt Cream Cheese” in the “Cream Cheese” section.

KEFIR: This is very similar to yogurt except it is a little different in taste, more fluid in consistency, and made a little differently. To a dairy bacteriologist, kefir is a symbiotic association of certain organisms: a gum-producing microbe that manufactures the polysaccharide grain, a lactose-fermenting yeast, and several lactose-fermenting bacteria (*Lactobacillus bulgaricus*, *Lactobacillus acidophilus*, and *Lactobacillus kephiri*). In plain English, it’s a variety of cultured milk, like yogurt. Yogurt is firm and eaten with a spoon, but kefir is liquid. That’s because it has very low curd tension, unlike yogurt in which the curd holds together. So you drink kefir. Kefir is a great tradition in Caucasia and the Eastern Mediterranean. It’s nourishing and healthy stuff and is supposedly more digestible than yogurt because of the smaller particles. It’s good to drink mixed with fruit juice or fresh or frozen fruit, or sweetened with honey, sorghum, or molasses.

For success make your kefir by stirring the grains (see below) into your home-grown raw milk and let stand at room temperature overnight.

⇒ **EASY KEFIR** Combine 2 c. raw milk with $\frac{1}{4}$ c. unflavored store-bought kefir. Cover and let rest for 48 hours.

⇒ **KEFIR MADE FROM “GRAINS”** Mrs. George O. Nordmann, Topton, NC, wrote me this recipe for kefir: “First, obtain some kefir grains. The surplus may be dried, frozen or held over for a short period in the refrigerator. The grains may be used with any good quality milk: powdered, skim, goat’s, cow’s, or soya milk. When using powdered milk, avoid chlorinated and/or fluoridated water. Place the grains (after rinsing in cold water) in the amount of whatever kind of milk you use in a quart jar and let set at room temperature overnight. Next

day, strain out grains, rinse them and place in more milk in another container. The milk from which the grains were removed is now ready to drink. The sourness depends on the length of time the grains were allowed to stand in the milk. Always rinse the grains in cold water before reusing. The proportion of grains to milk should be about 1 c. grains to 1 qt. milk. They multiply fastest in skim or low-fat milk at about 68–70°F.”

⇒ **KEFIR FROM A BLOB** Alan Clute, Sunnyvale, CA, got some kefir culture from a friend: “Ours is a gelatinous blob, about ½ inch across, which we recently got from a friend. You just plunk it into some barely warm milk and let it sit, covered and wrapped, at warm room temperature—no need for special heat as with yogurt. Next day you fish it out and repeat, sort of like milking a cow. When the blob grows big enough, it can be divided and shared. Our friend said the culture needs to be used every couple of days or so, which means that, as with a cow, somebody else has to care for it while you’re away.”

KOUMISS: A popular old-time fermented milk beverage, this was originally of mare’s milk. Put milk fresh from the cow into a scalded pop or small wine bottle. Fill it almost up to the top and cork tightly. Shake it up thoroughly every day for 10 days. At the end of that time it is koumiss and ready to drink.

CHEESE

Welcome to the world of cheesemaking! It’s easier than you think. In fact, cheese is simply naturally or artificially coagulated milk with the whey poured off or pressed out. The importance of cheese viewed as a traditional food is that it’s the only way to preserve milk when you have no refrigeration. Even so, this is a temperate-zone preservation system. In the tropics the temperatures are just too hot except for storing ghee (see “Butter”). Old-time dairy animals didn’t milk as many months a year as ours do now. And milk in the form of cheese tastes better—rather than worse—with the passage of time! Milk in the form of cheese, after 60 days, is guaranteed free of bad germs because the cheesemaking process kills them; so where pasteurization was impossible and there were health problems with the milk, cheese was the safe way to eat it.

CHEESE NETWORKING

Online. Cheesemakers-L is a list group with a great website. It’s for serious cheesemakers and also folks with dairy animals who just want to make good homemade cheese and dairy products: members.xoom.com/cheesemaker/Cheesemakers-L.htm.

Books. When I first wrote about cheese, in 1971, I couldn’t find recipes anywhere. Now there are lots of them. The best to date are in *Goats Produce Too!* by Mary Jane Toth. Her recipes will usually work for either goat or cow milk. She also has recipes for goat milk soaps, chevon (goat meat), and goat milk ice creams, sherbets, and fudges. Price is \$12.95 plus \$2 s/h: 517-465-1982; 2833 N. Lewis Rd., Coleman, MI 48618; mjt@voyager.net. New England Cheesemaking Supply (413-628-3808; www.cheesemaking.com) published *The Making of Farmstead Goat Cheeses* by Jean-Claude LeJaouen, an expert on French sheep and goat cheeses (70+ goat-cheese recipes, and how to build a cheese room); and a beginner’s text, *Cheesemaking Made Easy* by Ricki and Robert Carroll (60 cheese recipes for both goat and cow milks). *Goat Cheese: Small-Scale Production* by the Mont-Laurier Benedictine Nuns covers making mold-ripened cheeses. Older books are *Cheese Making* by Charles J. Hunt; and *Cheese Making at Home: The Complete Illustrated Guide* by Don Radke (1974).

Classes. Merryl Winstein teaches cheesemaking classes and sells supplies as well. Contact

her at 314-968-2596; www.cheesemakingclass.com.

Demonstrations. Mary Jane Toth gives cheesemaking and cooking demonstrations. Call her to schedule a class (see books). Ricki Carroll (co-author of *Cheesemaking Made Easy*) offers all-day cheesemaking workshops on how to make gouda, homage blanc, creme fraiche, queso blanco, mascarpone, ricotta, whey, mozzarella cheeses, etc. (\$100; spring, summer). Get more info from the American Cheese Society.

CHEESEMAKING MAGAZINES, INFO, AND SUPPLIES

Ag-Innovations sells imported cheese vats, molds, and draining bags. Dr. Larry Faillace and Linda Faillace teach cheesemaking classes: 802-496-3998; localfood@msn.com; www.threesheperdscheese.com.

American Cheese Society schedules cheesemaking courses, conference panels and presentations, tours, a big annual convention with cheese-judging, and a list of American cheese producers: 2696 S. Colorado Blvd., Ste. 570, Denver, CO 80222; 720-328-2788. Their website posts conferences, articles, and their latest newsletter: www.cheesesociety.org.

The Basics of Making Cheese is a terrific British website that describes in downloadable detail the science and procedure of cheesemaking:

www.cip.ukcentre.com/cheese.htm

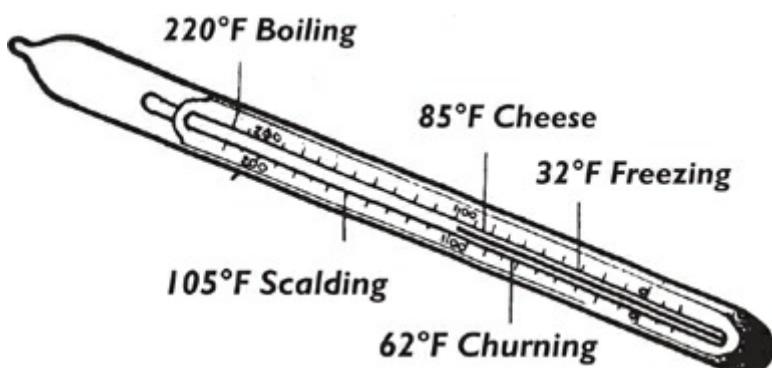

(*The Cheese Reporter Magazine* website has a searchable supplier directory, a wide choice of books and videos, and many links: www.cheesereporter.com.

The Cheesiest Site on the Net aspires to be the most comprehensive guide to cheese online, plus special reports on exceptional cheesemongers, dairies, and cheesemakers. It covers Cheeses, Essential Vocabulary, Links, Cheesemaking, and Cheese Retailers: www.cheese.com.

Jaybee builds and sells "The Vat," a 7–15 gal., 150-lb. stainless steel heater/mixer/pasteurizer for liquids to be marketed (\$8,000): 800-236-3956; www.jaybeeprecision.com.

Kusel Equipment sells 3A vats, finishing tables, air-veyors and curd elevators, presses and molds (such as 40-lb. "Wilson" hoops), submersible brine systems, and cottage cheese systems for large commercial producers: 920-261-4112; fax 920-261-3151; 820 W. St., Watertown, WI 53094; www.kuselequipment.com.

CHEESE MARKETING: Selling cheese is about the easiest way to start selling dairy products off your homestead. You can use raw milk and age the cheeses 60 days, which will kill off the bad germs, or start with pasteurized milk (heat milk to 145–150°F for 30 minutes, then cool to 70°F and make the cheese). You can sell your cheese mail-order, from the farm, or through stores. *American Country Cheese* tells the start-up stories of 30 cheese companies.

DAIRY THERMOMETER: All through this section you'll be reading instructions to have your milk or curds at a precise temperature. For that, you need a "dairy thermometer." This glass thermometer is made to float upright in liquid and be easily readable. It reads a range from about -10° to 220°F. Some are also marked in degrees centigrade. Available from any dairy or cheesemakers supplier.

CHEESE TYPES: There are 5 basic types of cheese: soft, semi-soft, firm, hard, and processed.

Soft cheeses are unripened, fresh ones: cottage, cream, pot, ricotta, gjetost, Neufchatel.

The soft cheeses that ripen naturally in just a few days include Brie, Camembert, and the double and triple creams, which have thin white crusts and almost fluid insides.

The semi-soft cheeses are ripened using specific types of helper bacteria and yeasts or molds: Basic Swiss, Brick, Muenster; Liederkranz, Limburger, Port Salut; Roquefort and Gorgonzola. These are among the most difficult for homestead cheesemakers because of the special organism culture you need and the special "ripening" conditions needed to control how they grow.

Firm cheeses are Cheddars, Cheshire, Lancashire, Caciocavallo, Swiss Emmenthal, Gruyere, Jarlsberg, etc.

Hard cheeses are made like the firm cheeses but are matured to a grainy texture for grating: Asiago, Parmesan, Romano, Sapsago, etc.

Processed cheese is called "American" cheese and comes from factories, and thank God if you don't have to eat it. It's made of chemicals, artificial flavor and color, and a wide variety of other nondairy items with some milk thrown in. Your homemade cheese is just milk plus curdling agent.

THE CHEESEMAKING MOLDS: Three types of mold are used in cheesemaking: white, blue, and red. Some molds are sprayed onto the outside of the cheese. Others are stirred into the cheese curds before they are pressed and aged. Don't be afraid of these molds. They are helpful friends.

White mold is *Penicillium candidum*. It is actually a penicillin mold, so if you're allergic to penicillin, you don't want to eat this. White mold powder is mixed with water and sprayed onto the outside of the cheese when it begins to be aged (or sometimes it is mixed into the curds). White mold cured cheeses are Brie, Camembert, Clommiers, Saint Maure, and certain French goat cheeses. When sprayed on the outside, the mold develops a white soft fuzzy outer coating on the cheese. It causes the pungent flavor and also the soft buttery texture inside these cheeses. The outer rind is also edible and mushroom-flavored. The usual mixture for spraying on is 1 t. *Penicillium candidum* powder stirred into 8 oz. of cool water. You'll need a spray bottle that makes a mist rather than big droplets. Shake each time before you spray to keep the mold off the bottom and suspended in the water.

OF GALLONS AND POUNDS

Dairy operations measure milk by the pound rather than the gallon. Exact weight varies according to your milk's butterfat content.

Volume ... Weight

1 pt. milk equals about 1 lb.

1 qt. equals 2 lb.

5 gal. equals 42 lb.

Five gal. milk should yield you 4–4½ lb. of finished cheese. That's 10 lb. of cheese per 100 lb. of milk, or approximately 1 lb. of cheese per 10 lb. of milk.

Blue mold, *Penicillium roqueforti*, is a spore powder added to Tilsit, Roquefort, Blue, and Gorgonzola cheeses to flavor them. The spore powder is combined with salt and mixed in with the curds before they are pressed. It is thus able to develop inside the cheese and gives these cheeses their distinctive flavor. Blue mold is generally used together with a mesophilic culture and a lipase powder. Blue mold is the most common one. You may have some around the house right now. It's a penicillin-type mold. One problem with making this, though, is the mold tends to spread and you may find it on other things besides your blue cheese, especially if you have a humid environment.

Red "mold," *Bacteria linens*, is a bacteria that is sprayed onto the outside of certain brick cheeses, and Limburger, Muenster, Port Salut, and St. Paulin before aging. During their aging process these bacteria develop their characteristic sharp flavors.

FLAVORED CHEESES: Any cheese, hard or soft, can be varied by adding more or less salt, herbs, chili peppers, onions, chives, caraway, cumin, dried tomatoes, garlic, fennel, star anise, lavender, pink peppercorns, dill, rosemary, and savory. You can mix a crumbly cheese with nuts and dried fruit. Or wrap chunks of aged strong-tasting cheese in grape or chestnut leaves. Cheese can also be smoked.

WHEY: Any time you make cheese, you get "whey," which is the clearer fluid that you pour off from the curds. Don't throw it away. Whey is terrific for animal feed, especially for pigs. In food value, 1¼ gal. of whey equals 1 lb. of ground barley. *NOTE: Don't use galvanized containers for any cheesemaking.*

Making Soft Cheeses

Your homemade soft cheeses—cream and cottage, etc.—will seem different from the store product of the same name. If you read the ingredients on the store container, you'll see why. For example, store cottage cheese may contain various additives, stabilizers, and preservatives, and is usually saltier than homemade. It also may have a creamy substance mixed in.

CREAM CHEESE: Cream cheese and yogurt are actually very similar. Yogurt is cultured whole or skim milk. Cream cheese can be made from more or less rich cream—even from skim milk!—which gives you, in turn, a higher or lower calorie cream cheese. "Cream cheese" made from milk instead of cream is called "Fromage Blanc" (instructions available from New England Cheesemaking Supply Co.). Cream cheese will soon spoil, unlike your hard cheeses, and so after it's made, it has to be protected from air, refrigerated, and eaten relatively soon.

You can substitute your homemade cream cheese in all those good recipes. A 3-oz. package equals 6 T. of your own; the 8-oz. package means 1 c. of your own. Don't store cream cheese in your freezer. You'll cause weeping and destroy the texture, because when the ice crystals form they break up the fine consistency. This cream cheese takes 15–18 hours to set up. You can use yogurt culture or a regular cheese culture or a cultured buttermilk.

You can make cream cheese from regular cream, which contains 24–35 percent fat, but it improves it to add skim milk powder to increase the milk solids and reduce the fat. Pure cream cheese is very buttery. Store cream cheese doesn't contain so much cream. Instead, dairies add a gelatin "stabilizer."

Here are some of the old-fashioned ways to make something like cream cheese without using gelatin or powdered milk.

⇒ **YOGURT CREAM CHEESE** Pour freshly made yogurt into a cheesecloth-lined strainer or colander. Gather the 4 cloth corners and sides in your hands and tie firmly. Hang this yogurt-filled bag where it can drip in a cool, airy place for 6–48 hours (sooner is safer). Then scrape what you have left from the cloth and place it in a jar. Use plain as a spread or flavored with your choice of salt, chopped chives, fresh dill, garlic, oregano, etc. This is a kind of "cream cheese."

⇒ **SOUR CREAM CHEESE 1** Salt sour cream to taste and stir well. Pour into a cloth that has been wrung out in cold water and proceed as above. This has a really sour taste.

⇒ **SOUR CREAM CHEESE 2** Take 1 qt. of cream (the lighter the better, to avoid the buttery taste). Set the dish in a pan of hot water, and warm it almost to the boiling point. Remove and cool to lukewarm. Add rennet. Let stand until thick. Break the curds slightly with a spoon and then tie up in a cloth. Press the cloth lightly with a weight for a half day so the pressed-out whey will drain away. Then re-tie in a clean cloth, rub salt over the outside, and let hang to drip for a day or so more.

⇒ **DEVONSHIRE OR "CLOTTED" CREAM** This is just delicious, and I really recommend that you have lots of milk and cream to play with. Combine 2 qt. milk and 1 qt. heavy cream and refrigerate overnight. The next day heat to a temperature of about 90°F and hold it there for 3–5 hours, or until a wrinkled, leathery look appears on the surface, containing little pockets filled with a liquid resembling melted butter. Don't stir or shake the contents. Don't let it get too hot. When it is very wrinkled and drawn-looking, cool and again refrigerate overnight.

The next day, skim off the thick top cream. This is your Devonshire cream. It is good with canned fruit or fresh strawberries. You'll get about 1 pint of Devonshire cream.

DRIP CHEESES. These are often called "bag cheeses." In making a drip, or bag, cheese, the curds are gathered into a bag made of cheesecloth or muslin and hung to drip. These cheeses usually have the consistency of a soft cheese spread, with a high moisture content. Because of this they are spreadable, but will only keep a couple weeks and need to be refrigerated. But they are delicious. You can vary the taste by adding various herbs and seasonings. Hang them where a drip is okay and where the temperature doesn't get higher than 72°F. A temperature that stays at 72°F is ideal. A higher temperature can produce a gassy, off-flavored cheese. Too low a temperature, on the other hand, and the cheese won't drain properly.

⇒ **VINEGAR QUESO BLANCO** Queso blanco ("white cheese") is a Latin American cheese. There are many variations of this cheese throughout Latin America. It's hard and rubbery, with a bland, sweet flavor. It is good for cooking because it has the unusual characteristic of not melting, even if deep-fried. It browns nicely and absorbs the flavors it is cooked with, very like tofu. In fact, it is a good substitute in any recipe that calls for tofu. Panir is a similar cheese made in India. Queso blanco can be made in very hot weather and in a hurry. Heat 1 gallon of whole milk to 180°F over direct heat, stirring often to prevent scorching. Watch the rising temperature closely. As soon as it gets up to 180°F, gradually pour in ¼ c. cider vinegar. Stir

while you pour. Immediately remove from heat. Let sit quietly until curds have formed. Then pour curds into a cloth-lined colander. Pull up the four corners of the bag and hang the cheese bag somewhere that it's okay for it to drip. Let hang until it stops dripping. Unwrap your cheeseball and refrigerate it.

» **BETTER QUESO BLANCO** *Gradually warm 1 gal. milk to 92–94°F. Stir in 8 oz. cultured buttermilk or ¼ tablet rennet dissolved in 4 oz. of cold water. Stir 1 or 2 minutes. Let the milk sit 30 minutes, maintaining its temperature at 92–94°F. Wait until the curd settles to the bottom of the container. Then drain the whey. Mix in 3 t. non-iodized salt, 1 t. at a time, every 5 minutes. Divide the curds into two equal parts. Lay a slightly porous cloth over a cheese press. Put the curd in there. Fold cloth over the top and press lightly for 3 hours. Remove and store in refrigerator. Dice queso blanco into half-inch cubes and stir fry with vegetables. Or add to soups. Or to a sauce (such as spaghetti).*

» **CHEVRE** *Stir ½ c. warm cultured buttermilk into 1 gallon still-warm-from-the-animal milk or into 1 gal. of pasteurized milk warmed to 85–90°F. Stir in 6 drops of liquid rennet. Stir only 1 to 2 minutes. Cover container with a cloth. Let stand in a warm room all day. Line a colander with boiled muslin. Pour chevre into the colander. Drain off whey. Tie corners of cloth together and hang the remaining curds to drain overnight. Refrigerate. Use like cream cheese.*

COTTAGE CHEESE AND FARMER CHEESE: These can be made of skim milk, buttermilk, whole milk, or goat's milk, but not very well of pasteurized milk because the natural souring process is key to good cottage cheese. If you must use pasteurized (store) milk, warm it to about 75°F. Then add 1 c. cultured buttermilk from the store. It will help also to use rennet (½ tablet to 1 gal. of milk), or, even better, a junket tablet, which has a milder action than rennet. Goat's milk does not thicken as easily and has a softer curd than cow's milk, so to make cottage cheese with it, it helps to mix in one-half or one-third cow's milk. Otherwise it takes about 5 days to get goat milk sour enough for cottage cheese.

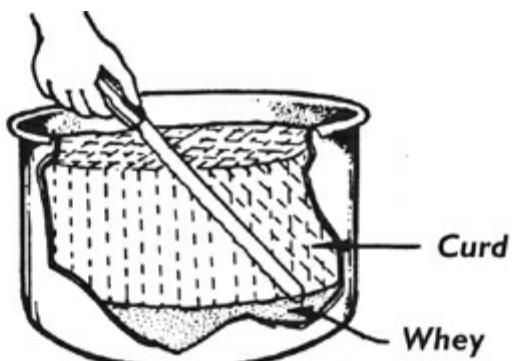

One qt. of milk will make about 1 c. of cottage cheese. You can work with any convenient amount since there are no other ingredients except salt "to taste" in the final stage. The best container in which to "set" the milk is a wide, coverable one. Sour the milk in the same container in which you will make the cottage cheese. A covered enamel roaster, a canning kettle, heavy crockery, or a stainless steel bowl would all be fine. Do not use aluminum.

The larger volume of milk you work with, the easier it will be to control the temperature; 75–85°F is the temperature to strive for through the clabbering (thickening) process. Leave the milk on the warming shelf of your wood stove or some other warm but not hot place, similar to one you would use to raise yeast bread. (If you are using milk that is already sour, you would skip this step, of course.) Temperatures that are too low allow the proliferation of less-desirable bacteria. Temperatures that are too high will kill your bacteria and stop their creation of the lactic acid you need to clabber the milk. They will also toughen the curd.

The clabbering may take a few hours or a few days, depending on temperature and bacteria count. When the milk is "set," it will have a jelly-like consistency. The solids will have formed one large curd, which floats on whey in the bottom. When the milk is sour and clabbered, you are ready to cut the curd.

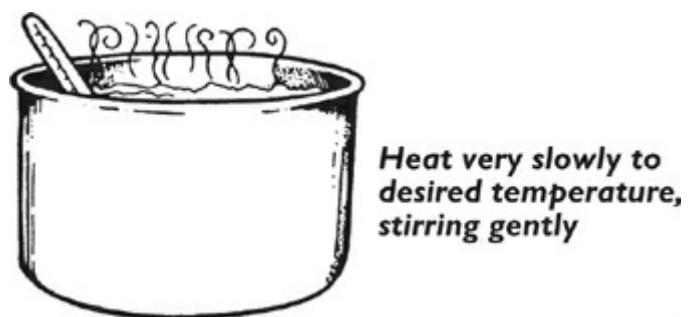

Cut the curd using a clean butcher knife with a blade long enough to reach from the surface of the curd to the bottom of the pan. Make parallel cuts across the curd one way and then perpendicular parallel cuts across the other way to create squares between ½ inch and 1 inch on the side. If you are using a deep pan, rig up a galvanized wire to cut

the curd horizontally at intervals between the top and the bottom of the pan. Now stir the curd very slowly and gently, endeavoring not to break up the curd but preventing it from clumping. The clumping tendency will be most pronounced at first and less so as the curd gets firmer with your final heating.

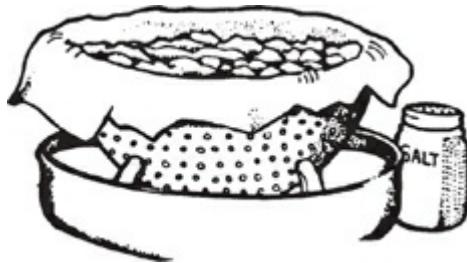

Cut clabbered curd into $\frac{1}{2}$ -inch to 1-inch squares

Now the curd is heated a little more to get it to just the right firmness. This is more art than science and depends on how you like your cottage cheese. The lower the temperature at which you stop, the softer your cheese curds will be. The higher the temperature, the firmer your curds will be. Don't let the milk heat over 110°F for traditional soft-curd cheese. Up to 120°F gives you the tough-curded "farmer" style cheese. One system is to take a half hour heating at the rate of about 2 degrees every 5 minutes to a final temperature of 100°F or so, and then hold it at that temperature until it has developed the desired firmness. That's the laboratory ideal and really can't be duplicated in the kitchen. But have courage—many a fine bowl of cottage cheese has been made under less than perfect conditions!

To test the curd, pinch a little between thumb and finger. If a tiny bit remains on the ball of your thumb it is about ready. When you are satisfied that all the curd would pass the pinch test, you are ready to drain the whey. Dump the curd and whey into a cheesecloth-covered colander or a colander having very coarse holes and substantial interstices to hold back the curd as the whey drains away (save the whey for your animals). You can make something suitable by punching holes in a metal pan or can from the inside out.

If the milk is very sour you can rinse the curd with cold water and drain again. At this point you may want to break up the curd with cold water and drain again. Sprinkle salt over the curd, work it in thoroughly, and let the cottage cheese continue to drain for at least an hour. You could tie the end of the cloth together and hang it from a nail until all the whey has drained off.

Drain whey from curd; salt to taste

You now have dry cottage cheese. It will keep about a week or 10 days in the refrigerator (covered). The usual commercial product is "creamed." You can add cream to yours at this time or before serving, but it makes more sense to do so shortly before serving because creamed cottage cheese does not keep nearly as well as the dry.

If you blend some "dry" cottage cheese with water and add tomato sauce and seasonings, you can make a salad dressing. With blue cheese in it, it's blue cheese dressing; with vanilla and sweetening added, it's a low-calorie imitation whipped cream.

Other ways to serve the cottage cheese are to press it into a dish and then cut off slices or roll it into balls. You could add $\frac{1}{2}$ t. each: grated onion, minced green onion tops, or minced chives per cup of cottage cheese. Or you could mix in $\frac{1}{4}$ c. chopped stuffed olives, and 2 T. mayonnaise per cup. We like it with cream and honey and grated nutmeg on the top, but I've seen the horrified faces of enough cottage cheese-with-salt-and-pepper eaters to know it's all a matter of preference. You can also serve it mixed with celery seed or caraway seeds. Health-food fans might like their cottage cheese mixed with sea salt, garlic, and chives.

⇒ **EASY CURDS AND CREAM (ONE OF INFINITE VARIETIES)** Set your milk in a bowl until it becomes clabbered. Pour the clabbered milk slowly into a curd press (see "Making Semi-Soft, Firm, and Hard Cheese"). Let the press drain overnight. Turn the curds out into a flat dish. Grate nutmeg freely over the top, and serve with heavy sweet cream, more grated nutmeg, and sweetening.

⇒ **DORIS GRONEWOLD'S GOAT MILK COTTAGE CHEESE** You'll need 1 gal. of freshly drawn goat's milk—should be at 100°F. Dissolve $\frac{1}{8}$ of a cheese rennet tablet in 2 T. warm water. Stir in the milk. This will set in 30 minutes. Stir the mixture to break the whey from the curds. Squeeze. Salt, chill, and serve. I sometimes add chives to mine.

⇒ **DRY CURD COTTAGE CHEESE** Sirniki and some other recipes below, call for "dry curd cottage cheese." That means natural cottage cheese with nothing added—no cream, no sour cream. To change store cottage cheese back to dry curd, rinse the "small-curd" type in cold water, then place in a sieve and squeeze the water out.

⇒ **SIRNIKI** From Ann Moran, Vancouver, WA: For this Russian entree, mix 3 c. dry-curd cottage cheese, 2 eggs, 2 T. sour cream, $\frac{2}{3}$ c. flour, and 1 pinch salt. Shape that mixture with your fingers into golf-ball-sized masses. Sprinkle or roll some more flour onto the outside of the ball. Then press it down to a $\frac{3}{4}$ -inch thickness. Dust more flour onto it. Fry in a generous supply of melted butter, first on one side, then on the other. Set this on the table with a container of sour cream and another of fresh or cooked fruit chunks or sauce for people to combine as they please.

⇒ **COTTAGE CHEESE BLINTZES** Blintzes are a Jewish pancake. Beat 1 egg with a rotary beater until white and yolk are blended. Sift together 1 c. sifted all-purpose flour and $\frac{1}{2}$ t. salt. Alternately add flour and 1 c. water, a little at a time, to the egg. Beat until smooth and free from lumps. Break the surface air bubbles with a fork. Heat a 6-inch skillet over medium heat. Grease lightly. Using a $\frac{1}{4}$ -c. measure, pour 3 T. of the batter into the pan all at once. Tilt the

pan quickly so that the entire bottom is covered with a thin layer of the batter. Cook on one side only. Invert on a clean tea towel. The pancake will slip out easily when it is done. Place a heaping tablespoon of the filling (recipe below) on the pancake. Fold the 4 sides over the center and invert on the cloth. Continue with the remaining batter and filling, and grease the pan from time to time as needed. This much preparation may be done in advance, and the blintzes wrapped in a tea towel and stored in the refrigerator; or they may be wrapped in foil and frozen.

At serving time, heat 4 T. oil in a large skillet or shallow baking pan. Place the blintzes in the pan, side by side without crowding. Brown over medium heat or bake at 350°F for 30 minutes (allow slightly longer if the blintzes were still frozen when placed in the pan). Turn over once during cooking, to brown both sides. This makes 11.

For the filling, mix 1 lb. dry cottage cheese, 1 slightly beaten egg, 1 T. sugar, ½ T. ground cinnamon, and ¼ T. salt until blended. This makes 2 c., enough for the above recipe. If served as a dessert, ½ t. vanilla extract and ½ c. seedless raisins may be added. Serve with sour cream, or both sour cream and jam.

➲ **SAVE-THE-SOUR-MILK VINEGAR-CLABBERED CHEESE** *This is a Sloppy Carla's quick-and-easy moneysaver that works for city people, too. You have a container of milk and your kid says, "Yuk, it's sour." Do you throw it out? Not unless you have pigs or chickens, who'll love it. You can salvage it by pouring it into a microwaveable or ovenproof bowl. Toss in a slug of white vinegar. Let set undisturbed until it clabbers—30 minutes or so. Then heat in microwave or oven until the curds are nice and firm and the whey is seriously separating out. Pour off the whey and—if you don't eat the curds on the spot because they're so delicious—use them in cooking any way you would melted cheese, such as in a lasagna. But only make this from just-recently-soured milk, which is still really good food—not truly rotten milk with 3 colors of mold on it!*

➲ **VINEGAR-CLABBERED SALTY CHEESE FROM FRESH MILK** *Here's how to do it right. You can do this with the above milk also. Heat milk to about 185°F. Add (about) 1¼ T. vinegar per 1 qt. milk. Stir vinegar in thoroughly. Let rest until it clabbers. Drain off whey through cheesecloth. Add ½ t. salt per 1 qt. of milk you started with. Mix well. Let drain several hours more. It's ready to use.*

➲ **COTTAGE CHEESE SANDWICH SPREADS** *Mix cottage cheese with finely chopped beet pickles; or nuts and cherries; or chopped green beans and green peppers; or finely cut nuts and pimento bits; or cucumber and celery bits, onion and paprika; or finely chopped Swiss chard and onion and pickle; or tomato chunks and chopped olives; or lemon juice and lettuce; or cucumber slices and tomato slices!*

➲ **COTTAGE CHEESE PANCAKES** *Sent by Bobbi McCollum from Canyon Country, CA: Combine 4 beaten eggs, 1 c. sour cream or yogurt, 1 c. cottage cheese, 1 c. flour, a dash of salt, and 1 T. sugar or honey. Fry on medium hot griddle same as any pancake. You can thin it down and add fruit, or add vanilla to make it caker tasting.*

Homemade Cheese Spreads. American cheese, the familiar processed cheese from the store, is a blend of fresh and aged cheeses that have been melted, pasteurized, and mixed with an emulsifier. This makes the texture uniform and soft and also destroys some of the flavor. The pasteurization discourages further ripening. Commercial cheese spreads also usually have extra moisture and a "stabilizer" added.

➲ **FROM HOMEMADE CHEESE** *Grate 1 lb. of basic cheese, like Cheddar. Combine with ½ c. butter, 4 T. dry mustard, and ¼ c. milk. Cut up some pimentos to mix in, or stir in caraway seeds, or shake in garlic salt or onion salt for your flavoring.*

⇒ **CUP CHEESE** Start with about 4 qt. of thick sour milk. Cut the milk through several times with a long sharp knife, then heat slowly to 90°F, or scald until the curd is very dry. Remove from the heat and place in a wet cheesecloth bag. Press under a heavy weight for 12–24 hours, or until the cheese is dry. Force through a cheese sieve or grate fine. Place in a wooden bowl, cover with a heavy cloth, and keep in a warm place for 3–7 days, or until soft and ripe, stirring occasionally. Then place in a frying pan and cook, stirring constantly, until all the lumps are dissolved. Add 1 t. salt and 3 T. butter, mix well, and pour into cups or bowls. It will make about 3 c. of cheese.

⇒ **DUTCH CHEESE SPREAD** Pour 1 qt. of milk into a crockery bowl and let stand in a warm place to thicken. When the milk is quite thick, pour boiling water over it, place in a cheesecloth bag, and let drain for 12 hours. Rub the cheese through a fine sieve. Work in 2 T. milk and 2 T. cream with a spoon until it is all the consistency of apple butter. Season with ½ t. salt and a very little pepper, if desired. Serve on buttered bread with apple butter.

⇒ **POTTED CHEESE** This is an old recipe that a friend sent me: "Cheese that has gone dry or begun to mold can be turned into a very delicious compound by the following process: Remove all the moldy portions. If dry, grate it. If not, pound smooth. Add a wineglass of sherry and 1 t. of white sugar for each pound. When the whole is a smooth paste, press down tight in small pots or jars and lay a paper dipped in brandy on the top or turn hot melted suet over it until the surface is completely covered. One T. butter added to each pound of cheese, while rubbing smooth, will make the compound rich. It will keep several years. This cheese is better when a year old than when freshly made. Keep in a cool dry place."

⇒ **EASY LONGHORN** From a reader in Willow Springs, MO: Scald 3 gal. clabbered milk (makes 3 lb.). Stir occasionally. Drain and press dry the curd. Place in mixing bowl. Mix 8 T. butter and 1½ t. soda. Mix very well; the better mixed, the better the cheese. Let sit 2½–3 hours. Place in double boiler on stove. Add 1½ c. sour cream and 3 level t. salt (and food coloring, if desired). Cook until it looks like melted cheese. Turn into buttered container. Wait 24 hours, and slice.

⇒ **NEUFCHATEL CHEESE** Recipe from Mrs. Carl Sandburg and Doris Gronewold: You'll need 1 gal. freshly drawn goat's milk, ½ junket or rennet tablet thoroughly dissolved in ¼ c. cold water, and ½ c. smoothly coagulated sour milk (you can use sour cream or kefir or yogurt starters). Also: nuts, olives, onions, chives, etc. Cool milk to 75°F. Add ½ c. sour milk. Stir for 1 minute. Add rennet tablet and stir again for 1 minute. Do not disturb again, and keep in a warm room for 18 hours. Dip the curd into cheesecloth and hang to drip. Drain, but not until the curd looks dry, as the mixture doesn't seem to stick together when pressed. Put curd in bowl, salt to taste, add nuts or whatever you like. (Doris loves it with olives and nuts.) Press in a cheese press (if it's a homemade press, be sure the rough edges of holes in the bottom and sides are to the outside). Line with cheesecloth and ladle in cheese. Draw cheesecloth over the top. Place a wooden follower on the cheese, and apply a 50-lb. weight. The length of time required to press the cheese depends on the temperature and weight (12–24 hours).

⇒ **EASY CAMEMBERT CHEESE** Heat 2 gallons of milk to 85°F. Combine ½ c. cultured buttermilk (or equivalent amount of mesophilic culture) and add to the warm milk. Stir ½ t. liquid rennet into ½ c. cool water. Pour rennet/water mixture into the milk/starter culture mixture and mix well. Then let the milk sit quietly until curd is firm (about 3 hours). Don't drain off the whey. Cut curd into small cubes (about ½ inch). Arrange your cheese mat on supports (such as an oven rack sitting on blocks at each corner) so that it is raised 1 or 2 inches above the table (for better drainage). Set cake pans underneath to catch the drips. Set the Camembert cheese molds on top of the cheese mats.

You can buy these from a cheesemaker's supplier or make them yourself by cutting out the bottoms and punching holes in the sides of plastic containers of approximately the right size and shape (margarine tubs?). A professional Camembert mold is about 5 inches tall and about 5 inches in diameter. It is open at both ends. Fill each mold with curds, clear to the top. Drain curds in the mold for 2 hours. Then turn mold over. Turn molds over again every 4 hours for the rest of the day. (Keep the curds in the mold!)

Dump the Camembert cheese balls out of their molds onto a cleaned (soapy hot water) cheese mat. Shake non-iodized salt all over the outside of each cheese. Dissolve 2 t. of *Penicillium candidum* (white mold) powder in a glass of water. Spray the powder in solution lightly all over each cheese. Move the Camembert cheese balls on their cheese mat to your chosen aging place. The ideal temperature to age them is 55°F.

After 7 days wrap each cheese loosely (plastic is okay for this). This holds in moisture. After two weeks of aging, you'll see a thick white fuzziness on the outside of each cheese. That's the white mold you sprayed on growing. Camembert should be aged at least 3 or 4 weeks before you serve it. After aging is done, eat it or freeze it. In the freezer it will store well for as long as 6 months.

Making Semi-Soft, Firm, and Hard Cheeses

The 2 parts of this book about which I feel the greatest sense of accomplishment are the descriptions of home-butchering and this cheese section of the dairy chapter. The home-butchering is described as a homesteader would do it, using simple language—something I simply wrote down as we did it. The cheesemaking was a different sort of hunt. Professionals wouldn't tell me. They said things like, "You couldn't make cheese without a big factory and lots of expensive equipment and very controlled conditions."

I ordered a government book called *Cheese Varieties* that is full of what appear to be cheese recipes. But every time friends and I tried them—and in total that was a lot of times and a lot of different recipes in the book—it turned out to be a moldy disaster. (A commercial publisher reprinted this book word for word, calling it *Cheeses of the World*, and it is still just as useless from the cooking point of view.)

Finally I got a recipe from Mary Simeone, who at the time was 9 months pregnant and living in a tent two-thirds up the side of an Idaho mountain, while her husband built a log cabin. She was milking 2 goats, and her finished cheese tasted very much like the good strong Greek and Italian cheeses that you can usually find only in city gourmet shops. Her recipe is the one I called "Basic Farm Cheese." I like it because it spares you all the useless detail of the rennet company recipe. She aged her cheese by hanging it on the end of a string under the biggest bull pine she could find. That should encourage any of you who think you can't make cheese without a factory. The fact is, from a historic view, factories are very recent arrivals on the cheese scene. Mary and her husband are from an Italian section of New York City, and they are making it fine now in Elk River, which is really out of the way, even for Idaho.

But my biggest breakthrough was in meeting John E. Montoure, Associate Professor of Bacteriology-Biochemistry at the University of Idaho, at a meeting of the Idaho Purebred Dairy Cattle Association, where my husband and I sort of stuck out like sore teats. A speaker got up and told us how we should be counting our blessings because we belonged to the upper classes and were in the lap of luxury. He must have meant all those guys with 150 head of milking Holsteins home in the dairy barn. I thought of our 3 head of registered Shorthorns that we traded hay for to a desperate man and got hysterical giggling, and practically fell out of my chair.

Anyway, that's where I met John Montoure, who was head of probably the biggest and best university-type cheesemaking laboratory in the country before somebody in the Idaho state capital decided to cut the funding and eliminate the program.

When I talked to Dr. Montoure and asked about making cheese homestead style, he didn't say, "Oh no, you have to have a factory." That man just sat down and started calculating. He knew every recipe I asked for by heart. On each recipe he'd have to start out figuring from 1,000 lb. of milk, because that was what he was used to working with. Then he'd convert every ingredient down to household quantity for me in proportion. I spent 2 long afternoons with him, writing as fast as I could. And he hadn't the slightest hesitation about sharing his information with me though I told him it was for publication, and he wasn't getting paid anything for it.

RENNET: Rennet is used to make these cheeses; you don't rely on the natural souring that you use for cottage cheese because the use of rennet allows you to get out more water and that gives you a different kind and a nicer cheese. Even 3 percent less water makes a big difference in the final product. You can order rennet from the addresses I gave above. Your basic store rennet rule is to dissolve $\frac{1}{4}$ rennet tablet for each 2 gal. milk in $\frac{1}{2}$ c. cool water. Add to milk that is 86–90°F. Stir well. Cover and let it rest an hour, or until the curd is well-formed. If you have trouble clabbering your milk, use more dissolved rennet. Better too much than too little.

CHEESE RECORD

Because the finished product may be ready months after the critical first steps, this will help you remember how you got what you have.

Homemade Animal Rennet. If you cared to, or had to, you could make your own rennet, since it is the salt extract of a suckling calf (that means one that has eaten no grass or solid food). You just take the biggest stomach of a suckling calf (or pig or lamb) that never has eaten anything but mother's milk. The suckling calf has all 4 stomachs, but its rumen is underdeveloped and that fourth stomach, its abomasum, is relatively big; rennet comes from the abomasum. Add salt to it, cut it into strips, and dry it as if you were making jerky. To make cheese with it, cut off a 1-inch square and add it to milk. That would be the equivalent of 2 drops of liquid rennet.

Vegetable Rennet. Yes, you can make this from various plants. It never acts as fast as regular rennet. At best it will curdle milk overnight. You can make veggie rennet from yellow (lady's) bedstraw, nettle, lemon or common sorrel, fumitory, unripe fig sap, or the giant purple thistle. Nettle and thistle are the best. All species of Compositae thistles have the milk-curdling magic. It's best in giant, thorny kinds. Regular purple thistle will work. Globe artichoke is a Compositae thistle variety, and can be used also. Cardoon is another option.

To harvest thistle for rennet, gather the thistle flowers when they have turned brown. If you see thistledown, the plant is over-mature. Get it right after the end of bloom and before the stage where down blows away. Air dry the flowers. You can store them in jars to wait until needed for cheesemaking.

To use your veggie rennet, a quick way is just to tie a bundle of thistle flowers together with string and leave it in the milk until it clabbers. But the more professional way is to pound and extract. You take out enough—5 heaping t. of pounded dry herb will be needed per 1 gal. milk to be curdled. Pound in a mortar with your pestle until quite crushed. Then pour just a little warm water or whey over, just enough to cover. Let soak 5 minutes. Pound 5 minutes more. Repeat the soaking, and repeat pounding until you've pounded at least 4 times total. You should be seeing a dark (brown) fluid. Strain. Add the fluid to your milk. Be careful not to add too much of any veggie rennet herb because excess can, at best, be unpleasant-tasting for the cheese-eater at the end of the line, and at worst, actually cause indigestion.

CULTURE: You're familiar with that word from making yogurt, cultured buttermilk, and cultured cream cheese. Culture is a bacterial organism that you can order in a dried form from the addresses given above. Before 1940 they thought you couldn't make cheese with pasteurized milk. They soured milk the natural way, like for cottage cheese. The result was

that some cheesemakers made good cheese, but some didn't. That's because their luck depended on what kind of bacteria happened to be plentiful in their cheesery. Some organisms will make a bitter cheese. Bad ones break down protein; good ones make an acid. The enzymes will break down some protein, but in a desirable way—so you get the flavor you want.

After 1940, cheese makers learned to pasteurize the milk to destroy the bad bacteria, then to add good bacteria—exactly the ones they wanted—to their “culture.” When you use culture you have a choice to add or not to add rennet. That's because, given time, the good organisms will clabber the milk anyway. Factory cheese operations order frozen cultures, which are shipped by express in an ice chest with dry ice around them. You can also order freeze-dried cultures, and that's the kind you would prefer. Consult with your cheesemakers supplier about what cultures you need if you want to make any specialty cheese.

There are two basic types of cultures used in making various dairy products: mesophilic and thermophilic. Mesophilic bacteria are the most popular culture for cheesemaking and are always the kind used to culture buttermilk. (You can use a pour of buttermilk in any recipe to substitute for mesophilic culture.) Mesophilic culture doesn't like heat. In fact, heat kills it. The milk has to be less than 102°F. Thermophilic bacteria are the kind used to make yogurt. Thermophilic culture is “heat-loving” and can stand heat up to 110°F, and even higher. You can use a spoonful of yogurt in any recipe to substitute for a thermophilic culture.

Both mesophilic and thermophilic bacteria eat the sugar component of milk, lactose. (Milk is about 5 percent lactose.) They consume lactose and then release lactic acid into the milk. The lactic acid clabbers milk and thereby begins the process of making cheese, buttermilk, or yogurt. Sourness depends on how soon you eat it. The sooner you eat any cultured food, the less sour it will be. The longer you wait to eat, the more sour it will be—up to a certain point.

Maintaining Your Cheese Culture. After ordering the dry culture grains, you can keep your cheese culture going, same as you would yogurt. In fact, make yogurt with it and then you have both! Add some to 1 qt. of milk. Let set at 70°F. Every 2 or 3 days, take out 1 t. and add it to another quart of milk to keep it going. Use a clean container and pasteurized milk.

But most homesteaders avoid all this struggle and use cultured buttermilk from the store dairy case to get their starter. They add $\frac{1}{4}$ c. buttermilk starter to 1 qt. milk. Let work 24 hours at room temperature. Add your quart of home-cultured buttermilk to 3–5 gal. milk, warmed to 86–90°F and let ripen 1 or 2 hours. Now you're ready to add rennet. If you skip this step, your cheese may swell and not ripen properly. These are the “good” microorganisms that you want to ripen your cheese. If you don't fill your milk with them, you will have less desirable ones.

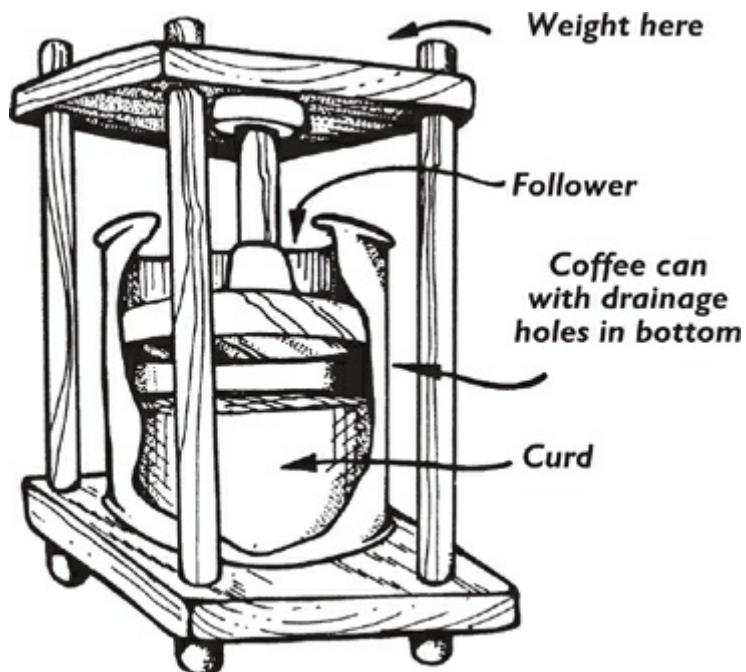

COLORING: Adding this is optional. But do not use butter; it colors only the fat. Butter and cheese colorings are usually annatto, an extract from the annatto tree.

MOISTURE CONTENT: Most cheeses are made of the same thing—milk, usually skim milk. The different results are achieved by slight differences in dryness, acid content, or temperature. The temperature at which you cook it and the length of time you cook it controls the moisture content. More moisture gives you a softer body, a sharper taste, and a faster cure, but there is a tendency to develop off-flavors.

CHEESE-MAKING PROCEDURES

Temperature. This is really important! If you can't control the cooking temperature, you're going to end up with a different cheese each time. This doesn't mean it will be bad cheese though. In making these hard cheeses if you go much above 100–102°F, you will kill off the good organisms, which you don't want to do—ever. This is where hard cheese is different from cottage cheese. Hard cheese is made as much by the curing process as by what you do at the beginning, and it's the organisms working gradually in there that give you the cure.

Pressing. The traditional press for homemade cheese used to be a coffee can with nail holes punched through the bottom and sides. *Now we know not to use coffee cans because some have lead solder. The acid in the whey may leach out the lead into the cheese.* If you get your press from a cheesemaker's supplier, it will be lead-free. It's important to get the curds into the press (wrapped in a cloth) while they are hot. Then put your round wooden follower on top, and weights on that. The combination of heat and pressure drives off the whey and causes the curds to change from individual pieces to a solid mass that won't spoil inside.

➲ **WHEY LEMONADE** Wherever you have cheesemaking you have surplus whey. Lane Morgan tells me she makes a whey lemonade by adding juice of 2 lemons to 1 qt. of strained whey. Sweeten to taste with honey or sugar.

Salting the Curd. It's a good idea to add the salt in 3 portions. Add the first third, stir, add the second, stir again, and so on.

NOTE: Salt in your cheese adds flavor, but also helps release the whey and discourages growth of microscopic stuff that might spoil your cheese. If you want to make salt-free or low-salt cheese, you can do it, but your cheese won't keep as long.

Wrapping the Cheese. Professionals use a foil coated with wax into which the cheese ball is sealed. You could use foil inside of butcher paper. A cloth soaked in vinegar is easiest though. You have to freshen the vinegar at intervals. Paraffin dip is a good mold preventer. Just melt your paraffin, dip the cheese all around into it, and cool.

Storage of Curing Cheese. Curing temperature matters —45°F is best. At 45°F, a Cheddar cheese will have the right kind of flavor in 6–9 months. Curing at 48–52°F can give you an entirely different cheese. Turn your cheese over every day or so for the first month. Grease the bandage and rub it when you do that.

Storage temperature is the place where making cheese at home is rough compared to having the “factory conditions,” which means having controlled temperatures and humidity. So just don’t worry about getting your cheese precisely like the store version. It will still be good food and good cheese. Second, do your major cheesemaking in the fall after the worst of the heat is over. Third, figure out the coolest place you have—the most nearly suitable. (Same problem as with storing apples.) For good-quality cheese, 60°F is too high. Your root cellar might be a good place, although you risk the cheese picking up an off-flavor from the vegetables there. The vital thing about a root cellar is that it remain dark as much as possible and maintain a constant and correct temperature and humidity. That means no windows and a door opened as little as possible. So if you wait until late enough in the summer so your root cellar won’t be above 60°F, you could use it. Before then you could use your refrigerator. You must be very careful to keep all flies out of your curing place or you may get maggots in the cheese.

The size of your cheese also matters. Smaller cheeses have a greater tendency to dry out. Starting with at least 5 gal. of milk will help you here. But the milk shouldn’t be more than 2 days old if you can help it. It’s okay to skim it.

NOTE: Resist the temptation to cut into and taste aging cheese until it’s done. Under-aged cheese is drab in flavor compared to properly aged cheese, and your cheeseball needs an intact rind.

Storage of Finished Cheese. Cheeses with high fat content are the poorest storers. Shelf-cured cheeses will keep a while more on the shelf. Or you can keep any cheese for a while in the refrigerator, much longer in the freezer.

Drying Grating Cheeses. Low-fat “firm” or “hard” cheeses are best for drying. Grate or shred the cheese. In a dehydrator or oven, spread the cheese bits over your drying tray. It helps to lay the cheese on something absorbent like cloth or paper towel to absorb melted fat. Dry at 120°F, stirring once in a while for 6–8 hours or until hard. If you are sundrying, dry in full sun in an airy place. This will take a day or longer. Use dried cheese like Parmesan to sprinkle over casseroles or spaghetti sauces. You can store as is dried, or pour into plastic bags and freeze.

Hard Cheese Recipes

BASIC FARM CHEESE: This process works fine with cow’s or goat’s milk.

1. Fill with whole milk a 9-quart enamel or stainless steel bucket (never aluminum!) to within about an inch of the top.
2. Warm it to 86°F. Use a dairy thermometer.
3. Add ¼ rennet tablet (or a whole junket tablet), crushed, with 1 t. of water. Stir it in. (Your drugstore can order rennet for you.)
4. Let set quietly until it curds, about 20 minutes.
5. Cut into approximately ½-inch squares by cutting one way and then cutting the other (to make a pattern of squares on the top) and then by reaching in to cut across from top to bottom of the bucket.
6. “Bathe” the curds for 2 minutes with your hands. That means to move the curds around in the whey gently and slowly.
7. Set your enamel bucket in a dishpan of water back on the stove. Keep it covered with a cloth so specks and flies won’t fall in or crawl in.
8. Slowly warm to 102°F (dairy thermometer again), stirring occasionally to keep

contents at an even temperature. It will tend to get hotter at the bottom of the pan.

9. Take it off the stove and let it set an hour, stirring occasionally very gently.
10. Put cheesecloth over a colander. Fasten the edges with clothespins. Pour the cheese in there. Save the whey. You can feed it to the animals or make bread with it. All the vitamins are in the whey now.
11. Add 1 T. salt and mix with hands. Add another 1 T. salt and mix again.
12. Tie ends of cheesecloth together to make a bag. Hang it up where you can let it drip for the rest of the day.
13. Put a holding band around the edge of the cheese bag made of cheesecloth like a headband or belt. Put a paper plate with the fluted edge trimmed off over the cheese and one under it, and a heavy weight over it and a hard flat smooth thing underneath, and let it press like that all night. Something flat and iron is good to press it, or use a piece of wood with bricks on top.
14. After it has been pressed all night, let it dry in an airy, cool place, turning it every few days until it forms a hard rind. If it molds, cut the mold away.
15. Paraffin it. To do that you heat a block of store paraffin in a pan almost to boiling (210°F), then brush the hot wax over your cheese or dip parts of the cheese in until you have it all covered. Attach a string in there and you can hang it up in a cool place to age. At first your cheese will be tasteless and have the consistency of a rubber eraser. The flavor comes with aging. Give it 2 months at least. Be careful you have it thoroughly paraffined, or it may get wormy.

COLBY CHEESE: Pasteurize 12 gal. of milk. Cool to 88–90°F. Add 2 c. of your culture (from “Maintaining Your Cheese Culture”). Let it set for 30 minutes. Now add 2 drops of liquid rennet that has been diluted in 1 c. of water. If you use tablets follow the manufacturer’s directions. They’ll say how much for 12 gal. Mix the rennet into the milk thoroughly for 3 minutes and then stop. It will take about 30 minutes to set up.

Put your finger into the milk at a 45-degree angle. If the curd breaks cleanly, in a nice straight line, it is ready. Your finger won’t have goop on it, and the curd can be picked straight up. Now cut the curd. The more uniform the pieces you cut it into the better, because small ones will cook too fast and big ones will be undercooked, meaning they will still be fragile and will shatter. Cut as for cottage cheese.

Let it rest 15 minutes. This is to “heal” the curd so it doesn’t break up when you start to stir it. Now heat it very slowly. The professionals go up 1 degree the first 5 minutes, 2 degrees with the second 5 minutes and so on (100–102°F is the very highest you should go). If you heat higher, your organisms will start to die, and the cheese won’t develop as you want. Use a cheese thermometer (same as a dairy thermometer). It will take about half an hour to get the temperature up if you are doing it just right. Set up some kind of a double boiler—like a 5-gal. pail inside a canning kettle with enough water to come halfway up the sides. That will keep the temperature right.

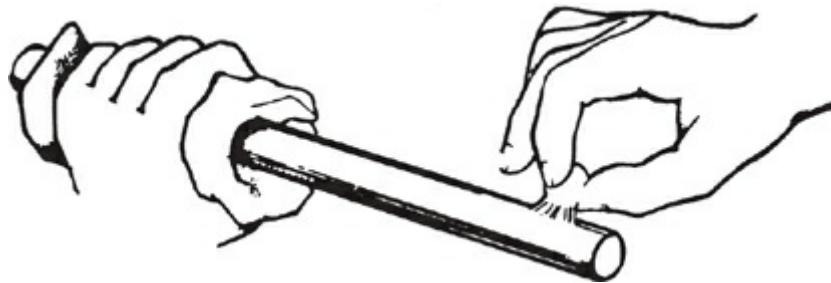

After you have gotten the temperature up to 100°F in this gradual way, drain off the whey, and stir the curd so it doesn’t form a single mass. Add salt to taste—maybe 3–4 T. for 10 lb. of curd. If you are on a low-salt diet you can substitute a potassium salt. If you didn’t salt at all you would get a bland cheese and a different type of fermentation because the salt holds back some organisms. Thoroughly mix. Put it in a sterilized cheesecloth and press. Start with 5 lb. of pressure for the first half hour to give it a chance to knit together. Gradually increase the pressure to 20–25 lb. It will be of a spongy texture

now, not solid like a Cheddar. The cheesecloth closes up the surface of the cheese and gives you a nice product. (Resist the temptation to nibble.) The cloth also acts as a wick and draws moisture out of the inside giving it a path to travel out of the press. So, use a cloth whatever else your pressing arrangements. Press overnight—12–16 hours. Wrap the cheese as above.

Now cure the Colby below 45°F. Curing above that temperature speeds up the process, but you risk a poor taste. If you cured it in your refrigerator it would take 9–12 months, assuming the temperature in there is 38–42°F. For the first month it would taste like “green curd.” At about 3 months you start to pick up a reasonable amount of Colby taste.

Monterey Cheese. Same as Colby, only you “cook” at 100°F, holding it at that temperature for 1 hour and 45 minutes before proceeding.

Montoure Cheddar Cheese. “Cheddaring” removes even more whey from curd after its first heating and draining. Monterey Jack and longhorn are cheddared cheeses also. Cheddaring helps cheese because it makes them have an even lower moisture content. Dryer cheese can age a longer time and keeps better.

To make Montoure-system Cheddar cheese, proceed as directed for the Colby-type cheese until the end of the curd-heating process. The curd should be contracted to about one-half the starting size, firm, and without a tendency to stick when pressed together. Use an ordinary flatiron to make a hot iron test. The curds, when rubbed on the clean hot iron and then drawn away, should show fine threads about $\frac{1}{8}$ inch long. When the curd passes this test, dip or pour off the whey, keeping the curd stirred with your hands as you do so.

When the whey is off, put the curd in a deep, more or less rectangular pan that has a hole punched in the bottom to let whey escape. The top or bottom of an old fashioned roasting pan will work fine for a moderate amount of curd. Don’t let the curd cool off while you are draining and transferring it. Pile it evenly in the roasting pan and cut a channel through the cheese to help the whey drain toward a hole at one end of the pan. Keep the pan slightly tilted.

Put the pan in your oven. You’ll want just enough heat in the oven to keep the cheese at a temperature of 98–100°F. Put a pan underneath to catch the whey. This is the Cheddaring process and will probably require some experimentation for you. Avoid too much heat. After about 20 minutes the curd will be firmly matted. Then cut the curd into blocks 6 inches long. Then turn them over so that what was the top of the curd is now underneath and next to the bottom of the pan. Continue the heating. All during your heating, try not to let the temperature of the curd get below 90°F. You’ll need a thermometer inserted in the curd to keep you informed. Turn the curd pieces about every 15 minutes. At the end of the third turning, pile the curd blocks 2 deep. In 15 minutes pile them again—but 3 deep if they seem dry enough. The Cheddaring process is done when the hot iron test shows you strings from $\frac{1}{2}$ to $1\frac{1}{2}$ inches long. (There is an easier acidity test, but you would have to use special equipment.)

Next cut the curd with a butcher knife into small pieces about $\frac{1}{2}$ inch wide and $1\frac{1}{2}$ inches long. Then stir thoroughly for about 15 minutes before salting. Add 2 or 3 oz. of salt for every 5 gal. of milk that you started with. The best salt is cheese salt, obtainable from a dairy supply or maybe from your drugstore. Its coarse, flaky consistency makes it more readily absorbed by the cheese. Spread out the curd, sprinkle the salt on, let it cool to 86–90°F, sprinkle on another bit of salt, stir thoroughly, and wait for the salt to dissolve. The curd isn't ready for the press until it is dissolved. Maintain your temperature throughout, and when you're ready to press, put the curd in the press at a temperature of about 85°F. Now turn back to the directions for Colby cheese and press and finish the cheese according to that. This Cheddaring process will take about $2\frac{1}{2}$ hours in all. When you're done, the curd is all in little strings that look almost like a cooked chicken breast.

W.S.U. EXTENSION CHEDDAR CHEESE: Use fresh, clean, high-quality, whole milk; 10–12½ qt. (20–25 lb.) whole milk will make 2–3 lb. cheese.

Equipment. You'll need:

A container that will hold 10–12 qt. of milk, such as a pail, kettle, or canner (rust-free)

A dairy thermometer

A long-handled spoon

A knife or spatula with a long blade (to reach the bottom of the container)

Measuring cup and measuring spoons

Dishpan or container for draining curd

Cheesecloth for draining curd (large enough to fit over pan for draining)

A cheese hoop: a straight-sided, 1-gal. container (punch about a dozen holes in the bottom with a nail)

Cap cloths, the same diameter as the hoop, made of flour sack or muslin

A follower: a round piece of wood, 2–3 inches thick, slightly smaller in diameter than the hoop, so it will fit down into the hoop (be sure it is made of seasoned lumber that is not gummy!)

Weights: bricks or something similar that weigh 30–40 lb.

Bandage: cheesecloth or gauze for wrapping cheese Paraffin to cover the cheese

Ingredients. You'll need 10–12 qt. pasteurized or raw milk; $\frac{1}{2}$ c. cultured buttermilk for a starter; $\frac{1}{2}$ t. liquid rennet (or tablets); $\frac{1}{8}$ – $\frac{1}{4}$ t. cheese color; and $1\frac{3}{4}$ –2 T. salt.

Pasteurize. Heat milk to 145°F, and hold it there for 30 minutes. If the temperature drops, reheat slightly. Stir constantly to avoid scorching. Cool the milk rapidly to 86°F by setting the pan in a container of cold running water or in water chilled with ice. (If you use already pasteurized milk—just heat milk to 86°F.)

Add Starter. Add about $\frac{1}{2}$ c. cultured buttermilk for 10–12½ qt. milk. Get buttermilk as freshly cultured as possible. Allow milk to ripen at 86°F for 30–60 minutes. Maintain temperature at 86°F. Apply slight heat if necessary.

Add Color. Optional. Cheese made in the winter without color added will be white. Dilute $\frac{1}{8}$ – $\frac{1}{4}$ t. liquid cheese color in $\frac{1}{4}$ c. cool water. Stir thoroughly.

Add Rennet. Maintain milk at 86°F and add rennet: about $\frac{1}{4}$ – $\frac{1}{2}$ t. liquid rennet diluted in $\frac{1}{2}$ c. cool water. If using rennet tablets, follow directions. Stir in rennet to mix thoroughly. Cover and maintain at 86°F. Let milk remain undisturbed for about 30 minutes to coagulate. (If disturbed, curd may break and become grainy, and the whey will separate before the curd is ready to be cut.)

Cut Curd. Test the curd to see if it is ready to cut. Insert your forefinger at an angle in the surface of the coagulated milk. If the curd splits cleanly, and clear whey fills the opening, the curd is ready to cut. With a clean, long-bladed knife or spatula, cut the curd into $\frac{1}{4}$ – $\frac{3}{8}$ -inch pieces. Cut straight down across curd from one side of the container to the other, being sure to cut to the bottom of the container. Cut several times in each direction, making right-angle cuts. Then turn the knife blade at about a 45° angle and slash at that angle several times in each direction to cut the strips into shorter pieces. After cutting, stir occasionally, being careful not to break the pieces of curd.

About 15 minutes after you finish cutting the curd, heat slowly to 100–102°F (takes about 30–40 minutes). Hold at this temperature until the curd reaches the desired firmness.

Test for Firmness. Squeeze a handful of curd, and release suddenly. If it breaks apart easily and shows little tendency to stick together, it is at the desired firmness. If it is soft and pasty, hold longer. If too firm, the cheese will be dry and corky.

Remove Whey. Allow the curd to settle to the bottom of the container and dip off most of the whey. Pour the curd and remaining whey over cheesecloth that has been stretched over a large container. Allow the whey to drain off. Stir occasionally to keep lumps from forming.

Salt. When the curd has cooled to 90°F and is slightly rubbery in texture (squeaks slightly when you chew it), sprinkle on 1 $\frac{3}{4}$ –2 T. salt.

Hoop. Place 1 cap cloth in the bottom of the hoop. As soon as the salt has dissolved and the curd reaches about 85°F, place the curd in the hoop. Be sure the curd is not below 85°F. If cooling rapidly, begin with curd at 88°F. Place the other cap cloth on top of the curd.

Press. Place the wooden follower on top of the cap cloth and add 12–15 lb. of weight for 5–10 minutes. Increase the weight to 25–30 lb. and press for 30–60 minutes.

Dress. Remove the weights and follower, and turn the hoop upside down so the cheese will drop out on the table. Remove the cap cloths and dip the cheese in warm water (about 100°F) to remove any fat from the surface. Cut a bandage 2 inches wider than the cheese and long enough to wrap around the cheese with a 1-inch overlap. Wrap the cheese tightly in the bandage. Replace the cap cloths and put the cheese back in the hoop. Replace the follower and press the cheese with 30–40 lb. weight for 16–20 hours.

Dry. Remove the cheese from the hoop and wipe away any surface moisture. Be sure there are no cracks in the surface. If there are, remove the bandage and dip the cheese in warm water again to soften the surface, rebandage, and put back under weights for about 1 hour. When the surface is smooth, put the bandaged cheese on a shelf in a dry, cool room. The temperature during drying should be 50–60°F. Turn the cheese and wipe it daily. As soon as the surface feels dry and the rind begins to form—in 3–6 days—paraffin the cheese. (If a rind has not started to form by 6 days, the cheese should be put in a drier place.)

Paraffin. Heat paraffin to 210–212°F in a pan deep enough to immerse half the cheese at a time. Be sure the surface of the cheese is dry. Do not remove the bandage. Hold the cheese in the hot paraffin for about 10 seconds. Let dry, then immerse the other half.

Cure. After paraffining, the cheese is placed again in the dry room at 50–60°F. Turn the cheese often to keep it clean and free from mold. Wash the shelf under the cheese, and dry it to keep mold from forming. Cheese cured for 6 weeks will have a mild flavor. If you want a sharp flavor, cure for 3–5 months longer. The cheese will cure more slowly if the temperature is below 50°F.

GRATING CHEESE: This is a firmer cheese that you grate and use the way you do Parmesan. Make it from skim milk. Clabber, cut, and cook in the whey same as Colby. Only don't

cook just a half hour; cook for 2 or 3 hours. After it is nicely cured, go ahead and grate it. You can add additional seasoning to suit yourself.

PROFESSOR MONTOURE'S DEEP FAT FRIED CHEESE: Fry chunks of pressed curd. The pieces are cut $\frac{1}{2}$ –1 inch long, similar to French fries. They keep their shape and have a nice flavor. Do this with "green curd"—freshly made cheese. You can't do it with aged cheese.

ROQUEFORT CHEESE: You can't make genuine Roquefort unless you have sheep's milk. You can blend sheep's and cow's milk and still get the right flavor. Even 1 part sheep's milk to 9 parts cow's is okay.

BLUE (OR BLEU) CHEESE: Blue cheese is very similar to Roquefort, except you can use cow's or goat's milk to make it. Blue mold is the most common one. You may have some around the house right now. It's a penicillin-type mold. It is also used to develop Tilsit, Roquefort, and Gorgonzola cheeses. This is another case in which you can't be afraid of mold. Unless it's unbelievably foul, you don't discourage the mold. One problem with making this, though, is the mold tends to spread and you may find it on other things besides your blue cheese, especially if you have a humid environment. A cloth soaked in vinegar discourages it. Use a fairly heavy cloth, like good cotton flannel. But the vinegar will evaporate, so you must keep it freshened. This is to protect your other cheeses. Paraffin would protect them completely; mold must have air to grow. If another kind of cheese does get moldy, scrub the mold off with vinegar. Wait until it dries. Then dip into paraffin and it should keep. Some mold on the outside doesn't hurt the inside a bit, even if it is in a thick layer.

Start to make your blue cheese with 5 gal. milk. That will give you $3\frac{1}{2}$ –4 lb. of cheese. Use raw milk—don't pasteurize it. Shake part of the milk to get air bubbles in it. You can put a quart in a blender for 5 seconds and then add it to the other milk. Or shake some in a half-gallon fruit jar or use an electric mixer. Just a portion of it thus shaken will do. Now add your culture. The same as with Colby. Use 1 c. of culture. Now have your milk lukewarm and add rennet—1 drop of the liquid or an appropriate amount of the tablet kind, or $\frac{1}{2}$ square inch of the calf's stomach. When it has set up, cut the curd. Mix well but don't agitate more than 3 minutes. Cut 1-inch-square chunks. These are larger than for Colby. You want a softer curd in this case. Let set 15 minutes. Now turn the curd slowly. You don't want to break up the curds. You don't want dry blue cheese.

Now bring the temperature up gradually and cook for 2 hours at 100°F in your double boiler. Drain. Add your blue mold. You could buy a pound of the freeze-dried mold from a dairy supplier. It will keep practically forever. All you need to make your batch of blue cheese is just a pinch stirred in.

Now mix in $\frac{1}{2}$ t. salt and get ready to drain the cheese. In this case you don't wrap in cloth. And you don't put pressure. Make a cheese hoop by taking a straight-sided can that is about 6 inches in diameter and 6 inches or so deep, like a 6-inch stovepipe, and poke nail holes in the sides from the inside out so you won't have rough edges inside. Make the holes about every 1 or 2 inches on the sides. Make a follower for each end. Any piece of board that was the right size and shape to barely fit into the can or pipe would be fine. Now put the first follower on the table. The pipe goes on top of that. The cheese goes into the pipe. And put the last follower on top of the cheese and turn the whole thing upside down. Keep doing this every half hour for 2 hours. The cheese will be cooling off. Water will be running out. The central mass will be holding its shape well enough.

Take the cheese off the follower and set it instead on heavy burlap, a towel, or 3 or 4 thicknesses of sheeting. But not on paper—that would cause the cheese to get soggy on the bottom. And let it set like that for 12–16 hours. Now rub $1\frac{1}{2}$ T. salt on the surface

(iodized table salt is fine). It won't all go on at first. Do it once a day for 5–7 days. You're salting the curd from the outside. The moisture will come out, grab the salt, and go back in. After the week of salting comes the poking.

Take a $\frac{1}{8}$ -inch knitting needle and poke holes in the side of the cheese, 1 inch apart all over the surface and deep enough so you come clear out the other side. Then tip over the cheese and do the same from the other side. This is to allow air inside so mold can grow inside (because mold must have air). Then let the cheese set at 45°F in a humid place. You don't wrap it, of course. If you set it in the refrigerator everything else would probably mold. Incidentally, this blue mold won't make you healthy eating it—it's different from the one the doctor prescribes. It takes 4–6 weeks to be properly cured. You want mold on the surface as well as in the center. The mold colors will vary from blue to gray. If you get black, wash that off with vinegar and then let it go again. Or use a mild salt solution and a soft brush. At a higher temperature it would be ready even sooner. After it has arrived at the flavor and ripeness you like, you can wax it or put it in a cold place to store. But if you freeze it, it will turn crumbly.

Growing Bleu Mold Starter. Or you could grow your own by getting some blue cheese or Roquefort from the grocery store. Then you set some of the cheese on a damp slice of bread. Any kind of bread will do. And put it in a jar with holes punched in the top lid or with a cloth over the top. In 1 or 2 days, or maybe even as long as a week, your bread with the cheese on top will also be good and moldy. Then you remove one-fourth of your slice of bread, dry it, crumble it, and you have enough blue cheese mold to make a batch of this cheese. Save the other three-quarters and each of them could make a batch, too. Remember, when you dry the bread, don't do it in an oven. Just leave it out at room temperature because you don't want the mold spores to die. You can keep your culture going by taking one-quarter of the molded bread and putting it on a fresh damp slice of bread again. In the good old days, even commercial dairies used this method for growing mold spores.

ITALIAN CHEESE: This is a cheese made especially for grating. Heat 10 qt. fresh milk to 85°F. Add $\frac{1}{2}$ rennet tablet dissolved in cold water. Wait 40 minutes to let the curd get firm, then break up the curd with your hands, and heat it in the whey until it is as hot as your hand can stand. Gather the curd with your hands, and mat it together until it is firm. Remove the curd from the whey and put it in the cheese press. Press one side, then reverse it in the press and squeeze some more. Put the curd in its sack back into the whey and heat (don't let it boil). Remove from the heat and let the cheese stay in the whey until all is cold. Remove and let drain for 24 hours. You could now eat the cheese, but for the proper grating cheese rub it with salt and let dry in your curing room for 3 days or so. When it is dry, put it in a jar of salt brine for another 3 days. Make the brine so strong that there is salt undissolved in the bottom. Then put the cheese in your curing room to dry again for 3 days and rub the cheese lightly with salt every other day until dry. Put the cheese in a crock. Cover the crock with a cloth. Rub it lightly with salt once a week for a month. Then just leave it in the crock for 3–6 months. Now your cheese is completely cured and ready for grating.

TWENTY-MINUTE CHEESE: (This and the next recipe are from "Home Cheesemaking with Goat Milk," a pamphlet available from *Dairy Goat Journal*.) To 3 qt. fresh goat's milk at blood heat (98.6°F), add $\frac{1}{2}$ t. liquid rennet. Stir gently. As it thickens, which is almost immediately, add 1 qt. boiling water and continue to stir gently, separating the curd from the whey and firming the curd so it can be handled at once. Place a reed cheese basket in

a colander and dip the curd into it, pressing down. When all the curd is in the basket turn the basket over, dump the curd out, and put it back in with the bottom side up. Thus the reeds will mark the cheese on all sides. If an unsalted, uncured cheese is wanted, it may be eaten now.

To cure the cheese, leave it in the basket for 36 hours, or until it is firm enough to keep its shape. During this time keep it in the kitchen or any other warm, dry place, and slip it out of the basket twice a day and turn it over. When firm enough, remove from the basket and keep on a plate in the kitchen or pantry. Sprinkle dry salt on the side that is up. Continue to turn as before, each time salting the upper surface and the rim and using a dry plate. When no more moisture sweats out, it can be placed in a stone crock in the cellar. If it molds, wipe with a cloth dampened with salty water. While the cheese may now be eaten or kept for a year, it is perhaps at its best when it's about 6 months old. The color is white, but a yellow cheese may be made by adding a few drops of cheese coloring when the rennet is added to the milk.

CHEESE À L'OBISPO: Get a bottle of rennet tablets for cheese (not junket). Use about 8 lb. milk; put in rather more rennet than suggested in the instructions that come with the rennet. Let it set an hour. Cut curd, and heat to 98°F, no higher. Stir gently every few minutes. Cover and set away for an hour longer. Drain on a sieve lined with muslin and pack into a mold, salting away for 24 hours. A circular piece of stout tin should fit inside the can for a follower. Now for weight, use a quart jar filled with sand. Line the mold with thin muslin. Take out of the mold and set it on a screen tray in an airy place, with a soft folded cloth under the cheese, and a bit of muslin over it to keep off the dust. Press, turning daily for 10 or 12 days, changing the cloth underneath each time. It is now sufficiently cured to eat. Melt paraffin in a tin lid and turn the cheese carefully in it until it is well coated.

Your cheese can be eaten now, or cured for as long as 6 months. In damp weather the cheese will mold on the outside before fully cured. If it molds, clean off with a cloth dampened in vinegar and wipe dry.

ABOUT SWISS CHEESE: This is a very delicate cheese for which everything has to be just right. To get good eye formation (the holes) you need a very large cheese. They cut it up in little pieces to sell it, but if you make a ball of less than 40 lb. (that would require 60 gal. of milk), the eyes won't form right. You also need very little temperature change—the other thing that is difficult to manage at home. Sometimes, even in the factory Swiss cheese goes a little wrong and the gas inside explodes—cheese blows all over the room! Other times it makes no eyes at all.

Swiss cheese makers use a special culture, not the general Cheddar culture but a half and half mixture of *Streptococcus thermophilis* and *Lactobacillus bulgaricus*. They may also add another bacteria, an "eye former" (*Propiono bacterium shermanii*) during the cooking operation. The "eye former" has to be kept refrigerated. The genuine outer rind is really tough on a Swiss cheese in the making.

CREAM

This is where goat's milk and cow's milk are so different. Technically, cream is just the globules of fat that have been held in suspension throughout the liquid.

Cow's CREAM: In cow's milk the globules soon rise to the top due to their comparative lightness (oil floats on water). The longer the milk sets quietly, the more cream there will be—for the first 48 hours. But it isn't worth waiting all that long. You get most after 12 hours, and most of the rest after waiting 24. The heaviest cream, which is called

“whipping” or “spoon” cream, is nearest the top in a thick layer. I prefer cow’s milk because I enjoy homemade butter and whipped cream. I like having a little pitcher of cream to pour over strawberries, or a big one to make ice cream.

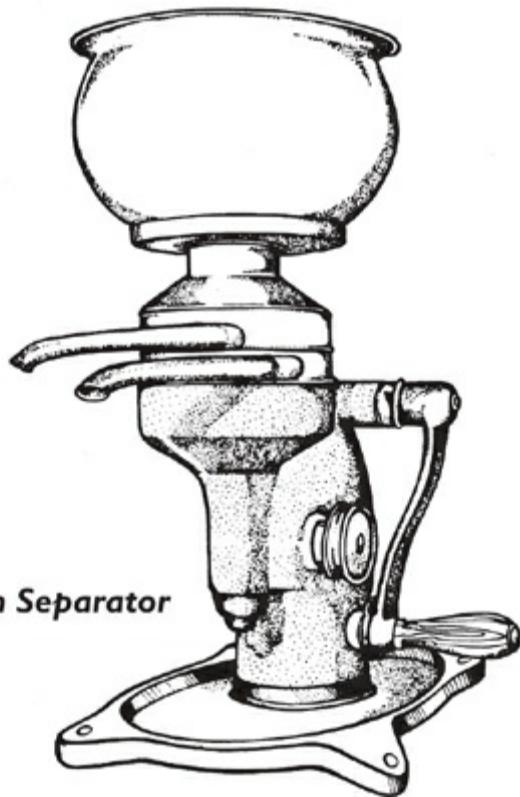

GOAT’S CREAM: You find goat’s cream on the top in the same way, only it takes longer to rise and there is never as much. There is butterfat in goat’s milk—in fact, it averages 3.5–4 percent! But goat cream doesn’t come nicely to the top for skimming like cow’s cream does. You can get some goat cream if you let it set long enough, but by then it’s almost sour. So to get goat’s cream you have to use a mechanical separator. Or you can get goat’s butter by churning the whole milk.

Separating the Cream

SKIMMING: I keep my milk in gallon jars or 5-gal. buckets (when I have that much) in the refrigerator. I skim the cream off at the end of 24 hours unless I need it sooner. The best thing is a regular skimmer. Mine are antiques. I don’t know if you can still buy them or not. A skimmer is a long-handled utensil with a cup fastened on the end. You set the cup into the cream so that the rim is just barely below the liquid’s surface. That way the part of the liquid that flows over into the cup of the skimmer is the top cream and not the milk underneath.

When you get used to it, you can do a very precise job of separating the cream from the milk and getting the cream out. Your jar, of course, has to have a wide enough mouth so the skimmer can easily fit in and out. Old-fashioned recipe books often say to let the cream rise in a shallow, wide container. I can’t understand why. I find the cream is much easier to skim off from a tall, deep container. When you skim cream, you never get it all because the lighter portion stays mixed in with the milk—though if it sets longer, a greater percentage rises and can be skimmed. So a 48-hour sit yields more cream than a 24-hour sit. But the first cream is denser and better for whipping and butter-making.

SEPARATORS: These separate cow’s milk from its cream content very thoroughly. The separator is set to deliver cream at a certain percentage of butterfat—for example, 30 percent. Some people like them. Mostly they’re the people who milk a lot of animals and sell their milk and cream. Or else it’s people who have numerous goats, because their separator makes it possible for them to enjoy goat cream and butter. You have to take them apart, wash all the parts, and dry them after each use. It’s a lot of work. My separator has 18 disks, 17 other parts, the wrench—plus jars and milk pails to wash morning and night. Because of all that cleaning, it’s much easier for me to get cow’s cream by just letting the milk set in a gallon jar for 24 hours and then skimming. I used to separate but don’t bother now.

Cream Separator

Buying a Separator. For years it was impossible to find a hand-cranked cream separator except at an auction. Now you can order one from any dairy supply company. Lehman Hardware offers a hand-cranked model whose bowl holds 11½ qt., very like the one my parents used. You can also get them from New England Cheesemaking Supply Co. (413-628-3808; www.cheesemaking.com). Separators can be adjusted to manage the percentage of butterfat you remove from the whole milk.

Using a Separator. Separators work on a centrifugal principle. The milk is supposed to be put through while still warm, at least 90°F. For separating in winter, you could flush some warm water through the separator first. But I know people who put it through cold and it seems to work all right. A table-type separator has to be bolted to a very sturdy tabletop. The hand-cranked ones won't separate properly unless you have the crank moving at the proper speed. It is supposed to click. You keep going faster until it just quits clicking and stays at that speed. If you crank too fast you're going to throw away a rather high percentage of your cream. Don't go by the clicks of somebody else's separator unless it is the same model and the same make. Different ones require different speeds.

Separating Goat's Milk. Goat's milk is hard to separate even with a cream separator. Make sure you have a model that can be set specially for goat's milk. Otherwise it won't work. You can save your milk for several milkings, and then separate it all at once. It even works with cold milk if you have the right setting on the cream percentage. The special thing about goat's milk is that the fat globules are so much smaller.

➲ **CARAMELS** Combine 3½ c. sugar, 2½ c. white Karo syrup, 6 c. cream, and 4 T. butter. Cook to hard-crack stage, stirring constantly (it's okay to get this cream hot!). Add 1 t. vanilla and cool several minutes. Beat hard until it loses the glossy quality. Then pour out onto a large, buttered baking sheet. Cool. Cut.

CREAM CHEESE: See "Making Soft Cheeses."

COOKING CREAM: Cream added to a highly acidic dish—one with fruits or tomatoes—is likely to curdle, especially if it's overheated. A dish with lots of cream in it that will be cooked

should be cooked slowly and at a low temperature, best in a double boiler.

PRESERVING CREAM: The cream does have a tendency to get ahead of me when the milk is really in season—in spring after the babies come. Cream can be frozen. But I prefer to make butter and then freeze the butter; takes up less space. (For tropical living, see “Ghee: Hot Climate Butter Storage.”)

Sour Cream

Home-cured cream is different from dairy soured cream the same way home-soured milk or buttermilk is different from dairy yogurt or cultured buttermilk. Home-soured cream has more of a tendency to separate into curds and whey. Just pour off the whey or stir it up and proceed with your recipe.

➲ **QUICK SUBSTITUTE FOR SOUR CREAM** If you are baking and the recipe calls for sour cream and you don't have any, you can make a substitute by adding 1 T. lemon juice or vinegar per cup cream and mixing well.

➲ **REAL SOUR CREAM** Most recipes today mean dairy sour cream when they call for sour cream, and you can't always substitute home-soured cream with success unless you have a very smooth, mild-flavored one. You get that by pasteurizing your cream. (Heat in a double boiler to 185°F, stirring constantly. Move to a pan of ice water, and stir until cool.) Pour into a clean (scalded) jar. Add 2 T. cultured buttermilk per 2 c. cream. Put lid on. Shake well. Let stand in warm place 24–48 hours. By then your cream will be thick and sour.

➲ **SOUR CREAM GRAVY** Use this as a basic “stroganoff” sauce with “chicken paprika” Hungarian style. It is also good with chicken, veal cutlets, liver, kidney, tripe, rabbit, or any game. Cook a chopped onion or more in butter or in the grease left from cooking in your pan. Blend in flour enough to take up the grease. Season with salt, paprika. Add mushrooms, if you have them, and their juice, if canned. When the base is ready, add sour cream gradually, stirring constantly. Heat just to boiling. Don't overcook! Stir while you are heating and as it is thickening. Then remove, pour over the meat, and serve immediately.

➲ **SOUR CREAM COOKIES** Combine 1 c. real sour cream, 1 c. sugar, 1 egg, 1 t. vanilla, and 1 t. soda, with enough regular flour to make a dough. The dough should be thin enough that the cookie will spread out a little as it bakes, but not pancake-flat. Optional: Add nuts, chocolate chips, raisins, or chopped dried fruit. Drop dough by teaspoons onto an oiled baking sheet. Bake at 350°F, 10–15 minutes.

Whipping Cream

SECRETS OF WHIPPING CREAM

1. Success partly depends on your dairy animal. Milks—and creams—are different. Store-bought “whipping cream” is different yet, containing the likes of “mono and diglycerides, guar gum and carrageenan.” But you can whip your home cream without those added ingredients.
2. If your top cream seems too thick to whip you can add some milk before whipping—but not too much, because cream has to have at least 30-percent fat, or more, to whip properly.
3. Fresh cream doesn't whip well. Age it from 12 to 24 hours before whipping.
4. Forty percent butterfat or higher, pasteurized, freezes best, and will still whip up after freezing.

5. Whip chilled cream because warmth thins it.
6. Use a big deep bowl to whip in so it won't splash all over.
7. Stop whipping when the cream gets firm enough to hold a peak when the eggbeater is pulled out. If you keep going, it makes butter—which happens quickly and can't be reversed.
8. One-half cup whipping cream gives you about 1 c. whipped cream.
9. With a very sweet dessert you can use unsweetened whipped cream, and it will taste fine.
10. Don't add your sweetening if it is a liquid, like honey or molasses, until you have your cream all whipped. Then stir it in gently. A couple drops of vanilla improves whipped cream's flavor.
11. You can make ahead a stabilized whipped cream by sprinkling $\frac{1}{2}$ t. unflavored gelatin over 1 T. cold water in a small bowl. Set that bowl into hot water until gelatin dissolves. Let cool. Whip 1 c. cream to almost stiff. Add dissolved gelatin, and finish whipping to stiffness. Cover. Keep in refrigerator. Mix with a spoon right before you serve it. Optional: pinch salt, $\frac{1}{2}$ t. vanilla, 1 T. sugar.

⇒ **QUICK CREAMY CHOCOLATE FROSTING** Whip 1 c. cream. Gently stir in $\frac{1}{4}$ c. instant cocoa or chocolate milk drink powder.

⇒ **LEMON CREAMY FROSTING** Combine 1½ c. heavy cream, $\frac{1}{4}$ c. sugar, 1½ t. grated lemon peel, and several drops yellow food coloring. Beat to stiffness.

⇒ **STABILIZED MAKE-AHEAD WHIPPED CREAM** Sprinkle $\frac{1}{2}$ t. unflavored gelatin over 1 T. cold water in a small bowl. Set that bowl into hot water until gelatin dissolves. Let cool. Whip 1 c. cream to almost stiff. Add dissolved gelatin, and finish whipping to stiffness. Cover. Keep in refrigerator. Mix with a spoon right before you serve it. Optional: pinch salt, $\frac{1}{2}$ t. vanilla, 1 T. sugar.

Butter

To churn butter, you shake, beat, or agitate the cream until the butterfat has separated out and formed a big glob. Goat's butter is white rather than yellow and has a different taste than cow's butter—doesn't taste as buttery to me. There's a difference among cows' milks, too, but not nearly so much as between cow's and goat's. Butter-making is also affected by your cream's whipping ability. You may find that your particular cow's cream is harder than the average to make butter from. Sometimes the farther a cow gets into her time of milking, the harder it is to get the butter.

NOTE: The latest medical research has established that people who eat real butter over a lifetime live longer than margarine-eaters! I have that directly from 2 friends who are medical doctors and who are now urging everyone they know to switch back to butter.

BUTTER CHURN TYPES

Plain Jar. If you don't have a butter churn, the simplest way to make butter is probably to put your cream in a quart or half-gallon jar and give it to the children to roll back and forth across the floor. It takes 15–30 minutes for the butter to churn.

Rotating Barrel. You can buy one of these from Lehman's Hardware (888-438-5346; www.Lehmans.com). It is sold as a "pressure washer" for washing clothes (and it is useful for that), but if you have more than a little cream, it also makes a great butter churn.

Drill Churn. There is an electric drill attachment for stirring paint that could also churn butter if you simply put an electric drill through a hole in the metal top of a widemouthed gallon (or larger) jar and rigged up paddles to fit, and then fastened on the drill.

Electric Mixer. Butter can be churned using an electric mixer, but you have to watch carefully and remove the mixer just before the butter starts to come. Finish by beating it with a spoon or churning it in a jar as first mentioned. Otherwise the mixer would shred the butter and it would be very hard to gather together again.

Blender. Food writer Lane Morgan says, "I think a blender is the way to go for small batches of butter. It's easy and *fast*—4 or 5 minutes instead of 20 or so. Also, you can see what's happening. You just pour in the cream and turn it on a low setting. Scrape down any of it that whips and pretty soon it will separate into butter and buttermilk. I've made many a pound that way. (And I'm with you; I like sour milk best for butter.)"

Crank-and-Jar Churn. Our Sears and Roebuck's Farm Catalog carries 2 sizes of electric churn: a 1-gal. jar (it will churn 3 qt.), or a motor and dasher, which can be fitted on a 2-, 3-, or 5-gal. jar, or used on a crock. You can get an electric or nonelectric jar churn from Lehman Hardware.

Dasher Churn. A familiar sight in antique stores is the tall, upright crock churn with a lid through which is run a wooden dasher. You stand or sit by the churn and work the dasher up and down until the butter comes.

CREAM CONTENT: Anything from whole milk to "spoon cream" (so thick it won't pour), either sweet or sour, can be churned for butter. However, churning whole milk is hardly worth your while, since a quart of milk makes only about a teaspoon of butter.

CREAM TEMPERATURE: About 60°F is ideal. If the cream is too warm, the butter is long in coming and is too soft to handle. If it is too cold, it also takes too long to come, and only part of the butterfat separates from the cream, leaving a very thick buttermilk. The cream may churn easier if you wait until it is not too sweet. The taste of your butter is affected also by how sour the cream is that you use. I prefer butter made from sour cream, but not so sour that it has 3 colors of mold on it. I've heard that the feed your cow has been on can also affect the churning, that cottonseed meal and timothy hay for some reason are trouble. Sweet cream takes longer to churn and doesn't give as much butter proportionately.

THE CHURNING: Don't ever fill up a container in which you want to churn, because as it whips it doubles in bulk and will slop out the top. Leave it at least half empty. It churns easiest

when the container is only one-third full. So for the average paddle churn of 3-gal. size, use about 1 gal. cream.

The churning should be done at a set rate and not too fast. It takes about 20 minutes of steady churning until you first hear the splash of butter and feel the stiffness in churning. It is best to churn past the first coming of butter to be sure you get all the butterfat from the cream. If you are using a big barrel churn with a bunghole to let out the buttermilk, stop turning when the granules are the size of wheat grains. You can tell with experience because the sound of the cream in the churn changes. Let the buttermilk out through the hole and run it through a strainer to catch any particles of butter.

WASHING AND GATHERING: The next step after churning is to wash and gather the butter. Some wash first and gather after. Some do both at once. If you are working with a large churn that has a bunghole, you could add pure clean water and twice as much buttermilk as you drew off after replacing the cork. Rotate the churn about 4 times, then drain that wash water, and repeat with clean water. Then commence to work the butter. About $\frac{3}{4}$ oz. of salt is added per pound of butter, or according to your taste.

To work the butter by hand pull the bung on a paddle churn and drain off the buttermilk. With a spoon remove the butter to a bowl, and scrape the butter from the paddle. Remove pieces of butter in the buttermilk. You will get $2\frac{1}{2}$ -3 qt. buttermilk and about 1 lb. of butter from 1 gal. cream. If the temperature is 80°F or so, you can't work butter until you've chilled it. Pour cold water on it to chill it. Now gather it into a ball, press it into a thin layer, and then gather into a ball again, *ad infinitum*, until all the salt is well worked in and the buttermilk is worked out. There is an old-time machine called a "worker" that you rinsed with hot water and then with cold, and then used to press the butter into a thin layer, fold it into a pile, and press again. It was great for large quantities of butter and for mixing the salt into the butter.

To wash and work the butter at the same time, put the butter from the buttermilk into a large bowl of ice water, and squeeze it gently between your fingers until it feels smooth and waxy. It should go through several bowls of cool water. When the water stays clear, repeat 1 more time. Then shape into a cake and pat to remove the extra water. Next salt to taste and work the salt in well. The habit of salting butter originated from the preserving power of salt. Unsalted butter does not keep as well. In some countries like Australia all butter is unsalted. Butter can absorb odors if it isn't kept covered. But ours usually doesn't last that long.

COLORING: The color of cow's butter may vary. There is a coloring product on the market for butter and cheese. It isn't the kind that is dangerous to health. But color never did matter that much to me.

STORING BUTTER: Make sure all the buttermilk is out. You can brine the butter first by making butter balls the size of a baseball. Cover them with brine strong enough to float an egg. Cover and store in a cool place. This is good for months or even longer under cool temperatures. If you have the salt you can cover them with layers of pure salt.

Ghee: Hot Climate Butter Storage. Certain volatile fats in butter can get rancid. If it is heated enough that they're driven off, then it doesn't taste like butter any more, but it keeps much better. This is what folks on the Indian subcontinent and in Africa do. You heat the butter at simmering about an hour. Don't let it brown. Skim off the scum that rises to the surface again and again. At the end you'll see a clear yellowish fluid in your pan. Pour through a few layers of damp cheesecloth to remove the sediment that went to the bottom. More strainings give you greater keeping power. Pour into a scalded container.

Cover to keep air out. It will store nicely now for months, even at hot temperatures.

➲ **ETHIOPIAN SPICED GHEE** Gradually melt 1 lb. butter (*unsalted*) in a pan and then bring to a simmer as above. When foaming begins, add 4 T. chopped onion, 1½ T. chopped garlic, 2 T. grated fresh ginger, ½ t. turmeric, 2 crushed whole cardamom seeds (or ½ t. ground cardamom), 1-inch stick cinnamon, 2 or 3 whole cloves, and ⅛ t. ground nutmeg. Simmer, uncovered, until solids have gathered on bottom and the middle liquid is clear. Strain 3 times through damp cheesecloth for longest keeping.

SHAPED BUTTERS

Butter Molds. Before using a butter mold, scald it, then soak it in cold water for an hour. Pack it solidly with butter and level off the top surface. When the butter is molded it can be pressed out.

Butter Balls. Scald a pair of wooden butter paddles, then soak them in cold water for about an hour. Measure the butter by teaspoonfuls so the butter balls will be about the same size. Have the butter firm but not hard, and roll each spoonful lightly between the paddles to form the balls. Drop onto a chilled plate, onto cracked ice, or into ice water. Or press each ball slightly to make it round on the side and flat on the top and bottom.

Butter Pats. Shape your butter into a rectangle the shape of the commercial quarter pound. Let it cool to firm. Cut neat squares off the end to be your pats. To decorate you could dip a fork in hot water and draw on them or put a little sprig of parsley on each one.

Butter Curls. These were traditionally made with a “butter curler.” It was dipped into hot water and then drawn lightly and quickly toward you across the butter. This made a thin shaving of butter that curled up. The butter curler was dipped into hot water after each curl.

Whipped Butter. For a soft, fluffy spread, bring ¼ lb. butter and ¼ lb. water to room temperature. Whip them together with the mixer. You might need more water. That's all there is to it.

FLAVORED BUTTERS

➲ **LEMON BUTTER** Cream butter until fluffy and add a few drops lemon juice. Use for sandwiches, canapes, and fish.

➲ **HERBED BUTTER** For each ½ c. butter add about 1 t. of your choice of dried herbs (basil, thyme, marjoram, dill are fine) or chopped fresh herbs. A dash of garlic salt is good, too.

Buttermilk

CHURNED BUTTERMILK: This is the milk substance left after you have churned your butter. It may have an acidic flavor and it may not. It depends on how sour the cream was when you churned. Sour cream makes a sour-flavored buttermilk. If you want nice buttermilk, don't let your cream get too rank before you churn. The “dried buttermilk” that you used to be able to buy in the grocery store was the real thing—dried.

BUTTERMILK RECIPES: There are so many great things you can do with buttermilk. In any of the following recipes you can use store-bought buttermilk or the yogurt—butter mix I mentioned, or your homemade buttermilk left over from churning if it's nice-tasting. In baking you can use even a pretty strong-tasting buttermilk, and it will still turn out deliciously. It makes a fine gravy.

➲ **BUTTERMILK CHEESE** Go through the usual steps. It will make the best cottage cheese or

hard cheese of all!

- ⇒ **STRAWBERRY-BANANA BUTTERMILK** Mash and beat together 1–2 c. strawberries, 1 banana, and 2 c. buttermilk. A very special beverage.
- ⇒ **ORANGE-HONEY BUTTERMILK** Combine 4 c. buttermilk, the juice of 2 oranges, and 2 T. honey.
- ⇒ **BUTTERMILK COLESLAW DRESSING** Combine 1½ T. sugar, 1 c. cold buttermilk, ½ t. mustard, 1½ T. lemon juice or vinegar, and ¼ t. salt.
- ⇒ **BUTTERMILK VEGETABLE SOUP** Slice 2 medium-sized cooked potatoes. Chop 3 green onions (the white part very fine, the green part not so). Mix with 1 qt. churned buttermilk. Add salt and pepper to taste. Heat to the serving temperature and serve (don't boil it). You can use big onions instead of the green ones by chopping and prefrying them. Bacon bits are good, too.
- ⇒ **BUTTERMILK RAISIN SOUP** Moisten 1 T. flour with 1 T. buttermilk, and heat 1 qt. buttermilk to scalding temperature. Add the flour and beat with your eggbeater until it is well-distributed. Add ½ c. seedless raisins, 1 stick of cinnamon, and a pinch of salt. Cook until the raisins are puffed. When it's ready to serve, add sweetening and ¼ c. heavy cream, whipped.
- ⇒ **BUTTERMILK PORRIDGE** Boil ½ c. barley slowly in 3 c. water for about 2 hours. Add 1½ qt. buttermilk, stirring until it boils, cook a few minutes, then add ½ t. salt. Serve with syrup or other sweetening.
- ⇒ **BUTTERMILK BISCUITS** From Ruth Brant, Stayton, OR: Combine 2 c. flour, 2 t. baking powder, 1 T. sugar, salt to taste, and 1 c. buttermilk. Mix, roll out, cut. Let stand 15 minutes. Bake 12 minutes in a 450–500°F oven.
- ⇒ **BUTTERMILK WAFFLES** Sift together 2 c. flour, 2 t. baking powder, ½ t. salt, ½ t. baking soda, and 3 T. sugar. Combine 2 beaten egg yolks, 2 c. buttermilk, and ¼ c. melted butter. Add liquid to dry ingredients and beat well. Fold in the 2 stiffly beaten egg whites and bake on your waffle iron.

Ice Cream

The old-time name for ice cream was “cream.” Old recipes usually contained lots of cream and eggs. It was considered a confection and was manufactured by the same people who made bonbons. If you like to make ice cream, you'd love *Ben & Jerry's Homemade Ice Cream & Dessert Book* by Ben Cohen and Jerry Greenfield.

INGREDIENTS

The Cream. If you get a buttery taste it may be either that the cream was overwhipped or that it is too rich in butterfat. You can fix that simply by using a more thorough skimming so the cream won't be quite so rich. It is better not to use absolutely fresh cream. Good cream will double in bulk while freezing.

Fruit. Fresh fruit for frozen desserts should be very ripe. If it doesn't seem ripe enough, cook with a little water. A fruit “puree” in a recipe could be cooked fruit put through a sieve or raw fruit grated or pulped, as with the ripe fleshy fruits like apricots and strawberries.

Ingredients for Lightness. Refrigerator ice creams usually contain whipped cream and/or beaten egg white to give them their lightness. Crank freezer ice creams gain a light consistency from the cranking process.

THE FREEZING: Ice cream can be made in your refrigerator's freezer compartment or in a crank freezer. The stirring breaks up ice crystals and improves the texture. "Refrigerator" ice cream contains so much cream, eggs, and/or gelatin that ice crystals and texture aren't a problem. But even if the dessert is to be frozen in the refrigerator or freezer, it helps to remove it when it is at the mushy stage, put it in a chilled bowl, and beat it vigorously. A second beating later on would improve it even more.

In a Refrigerator. In the freezing compartment the amount of time needed to freeze depends on the mixture, its depth, and the refrigerator; the average time is around 2 hours. The temperature should be under 20°F. It helps to use cold ingredients and to chill the mixture well before putting it in the freezer. Don't try to make ice cubes at the same time. The sweeter the mixture the more difficult it will be to freeze. It's best to freeze at the coldest setting you have—the quicker the desserts freeze the better they hold their lightness. But after freezing is accomplished they are improved by resting to mellow for a couple of hours. It helps the flavor and the texture.

In a Crank Freezer. If you buy a crank freezer (Lehmans Hardware sells them), directions will come with it. The crank freezer will consist of a wooden or metal bucket that holds the ice-and-salt freezing mixture and a nonrusting metal can with a tight-fitting lid for holding the cream to be frozen. The ice cream is stirred by a paddle inside the can, which is turned by a crank on the outside—or in some cases by an electric motor.

You usually need about 12 lb. of ice for a batch. You could freeze milk cartons full of water in your freezer and then dump out the ice into a bag and pound it to chips with a wooden mallet. You need rock salt, too, for the freezer. The recommended proportions vary. Usually you can use just 1 part rock salt to 8 parts crushed ice during the freezing process. Alternate layers of ice and salt to a point higher than where your ice cream will be in the can. After freezing the ice cream you can repack it for mellowing—use 4 parts ice to 1 part rock salt. Then cover the freezer with newspapers or a piece of rug. In winter you could use snow instead of ice. If the salt doesn't act rapidly enough on it, add a cup of cold water.

But I never bother mellowing our homemade ice cream. The children are so anxious and it tastes fine enough to me when it's first done. I don't worry about measuring proportions of salt and ice either. I just pour in ice and then pour on salt. The can shouldn't be more than two-thirds full. Turn the crank slowly at first until the ice cream is mush, then more rapidly until it is too stiff to turn. You might want to take off the lid occasionally to scrape the harder ice cream off the sides of the can and back into the middle. Be careful to wipe off the top of the freezer can each time you open it, since even a little of the rock-salt brine getting in could spoil your batch. If your recipe contains nuts or fruit, it will work better if you don't add them until the mixture is mush.

STORING ICE CREAM: A good temperature is 0°F. Use it within 2 weeks. Don't let it thaw and then try to refreeze because it will get hard and not be nearly as nice. To keep your ice cream, repack it in nonmetal containers; it deteriorates very rapidly in metallic ones.

➲ **BPO ICE CREAM** My favorite for big occasions is a mixture of 1 mashed ripe banana, 1 c. crushed pineapple, and 1 orange (peel and seeds discarded). More fruit makes it better. Stir in maybe $\frac{1}{4}$ c. honey, if the fruit needs it. Then I fold in 1 c. of cream that has been whipped into the fruit mix. More of that doesn't hurt either. This really doesn't make very much. I usually double it.

➲ **VANILLA ICE CREAM** Here's the family recipe for vanilla ice cream from Margaret Kerrick, West Roxbury, MA: Mix 1 qt. light cream, 1½ T. vanilla, and $\frac{3}{4}$ c. sugar. First put the

cream mixture into the freezer can, set the can in the freezer, adjust the top, and fill in around the can with ice and rock salt in layers. Use 3 parts of ice to 1 of rock salt. Then turn the handle of the crank, slowly at first, then faster as it begins to freeze. This makes for a smoother ice cream. When you feel that it is becoming harder to turn, you can open it up and see if it is done. "Then you can lick the paddle. Pull it out and gather around with spoons and dig in. If there isn't enough for everyone to have a taste from the paddle, let them eat from the freezer. We always made the ice cream before we went to church. After we had our licks, my father packed it, poured off the water from the melting ice, added fresh ice and salt and covered the freezer with a burlap bag with the remains of the ice in it. Then after we came home from church and had our dinner, we unpacked the freezer and ate huge dishes of ice cream."

➲ **FRUIT MOUSSE** Whip 2 c. heavy cream. Combine with 1 c. of any pulped fruit. Add a trace of vanilla, sweeten if needed, and freeze.

➲ **ICE CREAM SANDWICHES** Between thin slices of devil's food cake (or whatever you like) place a serving of vanilla ice cream (or whatever you like). You can make your own paper cases and store them in the freezer.

➲ **NEAPOLITAN ICE CREAM** Pack a mold in salt and ice or have ready a mold to go into your freezer. You'll need to have ready your 3 preferred varieties. Strawberry, vanilla, and chocolate are traditional, but you can vary that. Spread the first variety of ice cream smoothly over the bottom. If it is not very firm, cover, and let it freeze a few minutes. Then spread a thick layer of the next variety on it. As soon as this hardens, spread over the last kind. Cover and freeze.

➲ **APPLESAUCE ICE CREAM** Combine 1 c. applesauce, a pinch of cinnamon, a pinch of nutmeg, 1 t. melted butter, and 2 t. lemon juice. Chill. Fold in 1 c. whipped cream and toasted flaked coconut or chopped nuts, if you want it extra rich, and freeze until firm.

➲ **MILK SHAKE** Mash fruit, fresh or frozen, such as strawberries. Add ice cream and some milk and continue mashing. Add more milk and mix gradually until your milk shake is thinned as much as you like it.

➲ **LOW-FAT ICE CREAM** From Oregon State University, via "Gertrude": "Dissolve 1 T. plain gelatin and 1½ c. sugar in 1 qt. warm water and bring to a light boil. Cool to 100–110°F. Add 1 c. instant nonfat dry milk and mix well. Chill mix to below 40°F. Add 3 c. chilled whipping cream. Pour all into freezer tub. Add 2 T. vanilla. Stir and freeze in ice cream maker until desired firmness is acquired. It will be ½ gal. to start. Should make, with air added in the freezing, nearly 1 gal. ice cream."

➲ **FROZEN YOGURT** From Phyllis Vallette, spouse of a Wycliffe Bible Translator, Djibo, Burkina Faso: "You tell in the yogurt section how to serve frozen yogurt with fruit. I wish you had a cross reference to it in the ice cream section. For us it fills the same function as ice cream, but is easier, cheaper and less rich. I make a nice 'ice cream' of yogurt and guava sauce, about 50-50, sweetened to taste. When I'm not in Africa I do the same with apple sauce (cinnamon optional). For some reason yogurt seems to freeze smooth without long ice crystals, and I don't bother to mush it up at the halfway point."

➲ **HOMEMADE SNOW CONES** My neighbor Kay Morey, a very dear friend who has dug me out of many a hole, gathers clean snow and packs it into cups. She pours fruit juice or syrup over this, and the children love it.

I used to think that bottle-fed animals would just naturally be the most gentle and manageable for their humans. I was so wrong. After numerous tragic farm incidents of injury by animals, veterinary researchers now say this: *For males you plan to keep for breeding and for females of large species, use natural nursing by the animals' own mothers or adoption by goats, another cow, or other mammal. Bottle-fed males and females of all species think people are their species, and later, when they're old enough to mate and show instinctive dominance behavior, they may harm a person. An animal raised by another animal ends up being safer to have around people than a bottle-fed one!*

But two other old principles are still true: Be gentle and kind to your animals, and be patient. Don't force a bottle into the mouth if you can help it. Don't drag or carry the animals if you can help it. Take the time to coax and teach good habits. Make your animals respect you, and don't ever let one win a battle if you can help it, because you don't want them to think that it's possible.

A goat or cow with good manners, who has friendly feelings toward human beings and is well-trained in what is expected is worth the top price. An angry (mean) animal that won't cooperate is a cull and is worth only the bottom price—to say nothing of all the grief it's going to cause you.

The principles you live by shape the outcomes of your life. Principles, definitions, and measures can be applied to human beings as much as to elements in a laboratory. How do you define yourself? What do you measure yourself by? A lot of how well you do in life depends on the wholesomeness, soundness, and success of your own standards and design for your life—and your self-applied definitions and measures. If you have been defining yourself in one way for a long time and then are suddenly forced to change your self-definition, it's hard.

I went through several major changes in the 24 years since I began this book, including separation and divorce from my husband Mike after 18 years of marriage. I had to change from defining and measuring myself as Mike's wife and the mother of his children. I

learned that in every ending there is also a beginning—small and curled up, like the promise of a flower's bud—that must be sought out and nurtured. I learned how to let go when you have to, even if that means letting go of a lot of your self-definition, hanging loose for a while, and waiting to see what your new self is going to be. A major change of self-definition like that leaves you like a child, born—reborn—new into the world. You need time to grow and gradually become acquainted with your (new) identity. I had to do that after Mike left: slowly discover who I was going to be without him, gradually learn that I could be okay without him.

Nine years after that divorce, 9 years spent devoted to doing the best job I could of raising our 7 children, and that task is almost over too. I can look back on both being a wife and being a mother with a clean conscience, for in both cases I honestly gave all I had, my very best every day, for all those years. Now a new time of redefinition, remeasuring, is upon me. Within a few more months the 2 youngest children will be off to college, and I'll be alone in a whole new sense. I won't be a "mother" in the old occupational way any more. It's an exciting next transition.

As with the divorce, at first I was horribly depressed about this and cried a lot. But then I shook myself out of that and realized I was entering a whole new era of exciting options I didn't have before. The kids are all going to be fine without me. Totally unencumbered now for the first time in 30 years, suddenly I can plan to travel freely, visiting old friends and making new ones. I'll be free to research new books where I choose, as I choose. I'll be free to join a club, or clubs, take up hobbies ...

With nobody needing me at home, I'll be free to spend more evenings out at various interesting events than I spend at home. I've already made myself free enough to devote some effort and money to a major improvement in my appearance, freely answered an ad in the personals that intrigued me, freely chose to accept a dinner invitation from a handsome gentleman ...

When other people demand their freedom, by default you get yours back too!

PIGS' FEET

INTRODUCTION

January 1994. Today I'm writing the last page for the ninth edition of this book. It's a funny feeling. I've been working on this book for 24 years—and it's finally finished. So many years have passed since I wrote the table of contents (which is still basically the same) ... It's taken me this long to get it right. But I always had the same dream: to create a one-volume reference work in the field of family food production that would tell people how to grow every kind of food, every step of the way, and would include all the logical supporting information.

There are now almost a million words between these two covers, and that's just huge. I wanted to create a book so fundamental, so complete, and so dependable that it would be considered essential to have in every home, whether in the city or country. I wanted to make the book as reliable, standard, and useful as a dictionary.

Was it really God who was speaking to me, wanting me to write this book? I'll never know for sure. The older I get, the more I know I don't know, and the less I take for granted. Maybe it was something deep inside me, something I had to make happen to meet my own personal needs. That's the theory I find most convincing. Or maybe I'm just the kind of person who sees a need, envisions a way to meet it, and accepts fulfilling that need as their personal responsibility and life's duty.

At the time that I made my lifelong commitment to completing this book, I felt that God was responsible for the thought that kept coming to me, insisting that I should and could accomplish this task. There were two reasons I thought this: because our church's minister and my friends in the church told me that a thought that keeps returning is from the Lord, and because I couldn't see any earthly way I could do something so clearly impossible. Now I'm much more sophisticated, and I understand that a person can have a strong inner urging that expresses itself in a repeated thought, an urging that is simply a personal mechanism for achieving a personal goal. I know I do have another agenda that this book serves; this book is not my final task. With luck, and God willing, I'll get to the ultimate finish line.

This latest edition has some unique contents. It presents the latest, safest USDA-approved canning instructions and extension-approved canning recipes for every sort of food and pickle—the updated methods the USDA issued after researchers discovered that all the old canning instructions had problems. Other material that's unique or hard to find elsewhere includes the detailed, accurate growing information about wild rice and Asian rice; the very complete procedures for harvesting grain without using any machines or petroleum products; the directions for having a baby if you're all by yourself; the instructions for training a team of oxen; and the procedures to follow if your child eats something that looks like a mushroom but isn't one. Also, this new edition tells how *E. coli* can get into a fast-food hamburger and how to make sure a restaurant hamburger is safe for your child if you go out to eat. It tells how to cope with a changing climate and where not to build a house. And more: It provides herb-growing instructions and recipes; how to make quince seed hand lotion; how to turn your garden snails into your supper; how to cure olives; and which simple kitchen item, if mixed with water, will kill and/or drive off even African bees.

Which brings me back to business here: the subject of beekeeping. Read on ...

BEES

If you are buying honey rather than producing it, try to get it wholesale, direct from the beekeeper. Buy it by the 5-gal. pail. You'll save money, and that amount will probably be a whole year's supply for an average family. If you want to produce your own, read on. I hope to have lots of honey this summer. I even have a batch of bees living 2 feet away from the back door, in an old refrigerator that used to be a smoker. It's a beehive now since they moved in. I kind of enjoy their neighborly buzzing. But I've had high hopes before, and sometimes they get dashed. Beekeeping is a very special sort of livestock-raising, and getting your bees to produce isn't all that easy. It's easiest if you have a long flowering season and mild winters, and definitely no drought that keeps the flowers from blooming. A severe winter, a dry summer, an epidemic of some unfortunate bee disease—

and they can all die on you. Even if you do get started with bees, figure that they probably won't be able to spare you a significant amount of honey until the third year. That allows them 1 year to get going and you 1 year to make mistakes. Without mistakes, you'll be there by the second year. Bees are essential to agriculture and to flowering plant life in general because of their function as pollinators. Beekeeping for a living can be an economic roller coaster, even worse than the usual for farming. Professional beekeepers have to study their small subjects for years—their biology and the plants they can gather food from—plus learn how to market their product. But beekeepers have less control over market prices, weather (drought, extended rain and flood, prolonged freezing), neighbors who spray pesticides that kill bees, or sudden onslaughts of disease or parasites in the colony.

There are rewards, too. If you learn what to do and pay close enough attention to your bees so you can do what needs to be done, they'll provide the sweetest of all foods—and do so at a bargain—as well as produce a crop that there's always a good-paying market for! You'll be welcomed into the very exclusive ranks of local beekeepers and have lots to tell as well as ask about at their meetings. You can keep a few bees because they're interesting and you want honey for your own family, and, if you're lucky, you'll still have some to give away: Raise 1–12 colonies.

In a temperate zone, with your still-limited experience, you should count on only 1 or 2 gal. of honey per hive per summer—though with practice and luck you'll come up to the average of 4–5 gal. Then you could keep more hives and sell surplus honey for a side income—say from 12 on up to 200 hives. Or you could go into beekeeping as a full-time occupation, in which case you'd expect to handle enormous quantities of bees and make all your living at it. Kim Flottum, editor of *Bee Culture* (who very helpfully reviewed this section, corrected my errors, and added important new information; I am truly grateful to him!), advised, "You need about 700 to 1,000 colonies to make a living full-time." A pro beekeeper who lives in a prime beekeeping area may average as much as 200 lb. of honey harvest per colony, but the national average is less than 50 lb. per colony. With bees, the uncertainties of harvest are greater than with most other crops.

The commercial beekeeper has to produce as much honey as possible with the least possible expense and then sell that honey for the highest possible price. Beekeeping on this scale is very hard work. Before setting out to sell honey, find out what the local, current regulations are. And you'll have to plan for what containers you'll package it in. You can probably sell wholesale or to retail stores. If you live on a well-traveled highway, a produce stand is a means to sell your honey at a maximum profit.

There are about 150,000 beekeepers in the United States. They keep about 3,000,000 honeybee colonies. They keep bees as a hobby or as a profit-making business, selling honey, pollen, beeswax, propolis, or royal jelly—or bees. They may rent bees for pollination service or move their hives onto land in summer in exchange for a share of the honey. It's possible but very, very rare to find a self-contained operation in which the beekeeper plants the crop (such as rapeseed) that the bees will make honey from. Beekeepers, even more than most farmers, need to network and stay informed about the ever-evolving bee diseases and parasites and matters relating to African honeybees, as well as new types of equipment, marketing opportunities, and regulations. If you're a newcomer to beekeeping, you have even more work ahead of you.

Learning to Beekeep

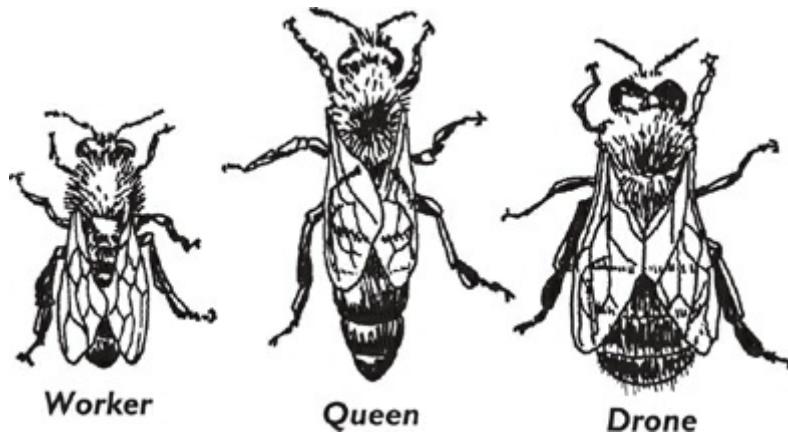

Raising bees is a lot trickier than the manuals make it out to be, and I speak from sad experience. My general impression is that people usually expect more honey than they

actually get. Maybe in the South it's better, but in these more northern climates it takes a couple years—at least—to get built up to where your bees will be keeping you in honey. *Above all, you can't just install and then ignore this tiny livestock.* Professional beekeepers visit their bees at least every 3 weeks to check for signs of trouble.

Of all the subjects in this book, beekeeping is the one I feel is hardest to learn from a book—mine or anybody else's. You really need to learn it in person. So try to find a local beekeeper who will let you visit, take you through a hive, and show you the workshop where hives are made and how extracting is done. Watch the technique. Learn to see and recognize the different kinds of cells and bees. You'll catch the professional beekeeper's calm. If a pro gets stung, he or she takes a half minute out (or maybe not even that) to cuss and then proceeds with the job. You'll need to learn a bunch of facts and procedures ...

MAKE SURE YOU ASK AND LEARN:

1. What is the organization of brood and honey?
2. What does each type of bee look like (queen, drone, worker)?
3. What does each type of bee cell in the frame look like?
4. How do you find the queen?
5. What do the eggs and larvae look like?
6. Where and how is the honey stored?
7. How does the system of movable frames work?
8. How do you use a smoker to quiet the bees?
9. What other types of equipment does a beekeeper use?
10. How do you check the strength of your colonies?
11. How do you clean dead bees and debris out of the hives?
12. How do you make sure the queen is okay and laying well in the spring?
13. How do you add supers (the upper hive compartments in which your bees will store honey)?
14. How can you minimize swarming (which would halve the size of your colony)?

CLUBS: There's too much to grasp in a single casual visit with a beekeeper. Clubs: Beekeeping has to be both studied and practiced. Many areas have a local beekeepers' club. That's your best place to look for help to get started. Nowadays beekeeping is a highly organized, closely supervised occupation. Don't let that discourage you. The club

will tell you the laws affecting apiculture (beekeeping), about possible inspection of hives, local zoning regulations, state registration requirements for beekeepers, and labeling regulations for honey you plan to sell. Your county agricultural extension agent may be able to put you in touch with local beekeepers. Or ask a bee supply outlet for local names. Or look in past issues of Bee Culture. Or network with beekeepers on the internet at the bee discussion lists: bee-1.com/index.html. Or write or call one of the following organizations.

American Beekeeping Federation, 404-760-2875; fax 404-240-0998; 3525 Piedmont Rd, Building 5, Ste. 300, Atlanta, GA 30305; info@abfnet.org; www.abfnet.org.

American Honey Producers Ass'n, www.americanhoneyproducers.org.

The Canadian Honey Council, #36 High Vale Crescent, Sherwood Park, AB CANADA T8A 5J7; 1-877-356-8935; www.honeycouncil.ca.

Eastern Apicultural Society of North America, Inc., www.easternapiculture.org.

Western Apicultural Society of North America, PO Box 956, Grants Pass, OR 97528; groups.ucanr.org/WAS.

Florida State Beekeepers Ass'n, Eloise Cutts, Executive Secretary, 5002 N.W. 16th Ln, Gainesville, FL 32605; 941-723-2337; www.floridabeekeepers.org. (Local beekeeping clubs meet more often.)

BEE Books: Go to a beekeepers' (apicultural) school. Your local extension service can guide you to a class or program. If hands-on training from a neighborly beekeeper is not available to you, there are convenient alternatives: books, videotapes and slides.

First Lessons in Beekeeping by C. P. Dadant and *Starting Right*, a basic manual that's been in print for 70 years and is regularly updated by editors at the A. I. Root Co. (120 pg, \$7.99), are a good place to begin. This is where Kim Flottum works, editing current editions of the famous Root publications for beekeepers. (Kim helped me with this bee section.) Kim also recommends *The Beekeeper's Handbook* by Sammataro and Avitabile (1988), and says that *Hive Management* (1989) and *A Practical Guide to Beekeeping* by Dick Bonney (1993) are also good. Other useful books are *The Complete Guide to Beekeeping* by Roger A. Morse (1980, reissued 1994), the *How-to-Do-It Book of Beekeeping* by Richard Taylor (1984, reissued 1994), *Beekeeping for Gardeners* by Richard Taylor (1982), *How to Keep Bees and Sell Honey* by Walter T. Kelly (1991), and the *Guide to Bees and Honey* by Ted Hooper (1976). Sue Hubble wrote two fun anecdotal bee books. Also, *Plants and Beekeeping*, by F. N. Howes (1979), covers forage plants for bees.

Also check out *Beekeeping: A Complete Owner's Manual* (1986), a user-friendly book by Werner Melzer, a German expert who presents the European bee scene. *The Honey Bee: A Guide for Beekeepers* by V. R. Vickery, a Canadian, reads like a textbook but is up-to-date and thorough. *The Hive & the Honey Bee*, newly revised and enlarged (1,324 pages!), edited by Joe Graham and published by Dadant, is more advanced reading, has often been used as a college entomology and apiculture text. The *ABC and XYZ of Bee Culture*, edited by Kim Flottum and Roger Morse, first published in 1897, was in its 40th edition last I heard. It's encyclopedically complete, including history, anatomy, hive styles, etc. Also check out *Bees and Beekeeping: A Year in the Life of an Apiary* by Keith S. Delaplane. *The Beekeepers Handbook* (1998) by Diana Sammataro, Alphone Avitabile, and Roger Morse, covers the life history and behavior of bees, bee management, disease control, and honey removal and processing.

MAGAZINES

American Bee Journal is an excellent monthly, \$20.95/year, from Dadant and Sons. Free sample copy: 217-847-3324; fax 217-847-3660; 51 S. 2nd St., Hamilton, IL 62341; www.americanbeejournal.com.

APIS is an entomology newsletter, now out of print, but archived on the web at entnemdept.ufl.edu/news.

Bee Culture: The Magazine of American Beekeeping appears monthly. They offer a free sample. Also, "Who's Who in Apiculture," a list of bee organizations and government bee specialists, is published every May in *Bee Culture* and available at www.beeculture.com. It's \$21.50/yr from the A.I. Root Co.: 330-725-6677; 800-289-7668; 623 West Liberty Street, PO Box 706, Medina, OH 44258-0706; beeculture@beeculture.com.

Bee World, the *Journal of Apicultural Research*, and *Apicultural Abstracts*, are all published by the International Bee Research Ass'n: international tel. 44 (0)29 2037 2409; international fax 44 (0)56 0113 5640; 16 North Rd., Cardiff CF10 3DY, UNITED KINGDOM; info@ibra.org.uk; www.ibra.org.uk.

Canadian Beekeeping offers news, interviews, features, and ads, both in the text version and on the website where there are also current and back issue samples; \$21.40 in Canada; \$20 in U.S.: 905-936-4975; Box 678, Tottenham, Ontario, CANADA L0G 1W0; editor@canadianbeekeeping.com; www.canadianbeekeeping.com.

New Zealand Beekeeper comes from the National Beekeepers Ass'n of New Zealand; 11 issues per year (Feb.-Dec.). Overseas air mail costs U.S. \$170: PO Box 10792, Wellington 6143 NEW ZEALAND; 64-4-471-6254; www.nba.org.nz.

The Speedy Bee, "The Beekeeper's Newspaper," is a monthly for \$17.25/year. Free sample copy is available from Troy Fore, Jr.: 912-427-4018; PO Box 1317, Jesup, GA 31598-1317; www.thespeedybee.com.

BEEKEEPING SUPPLIES

Blossomland Supply sells both beekeeping and candle-making supplies: 269-695-2310; fax 269-695-2510; 311 W. Front St., Buchanan, MI 49107; beeyard@blossomland.com; www.blossomland.com.

Brushy Mountain Bee Farm offers a free 84-pg catalog of beekeeping equipment and supplies, protective clothing, candle-and soap-making supplies, books, beekeeping videos, etc.: 800-233-7929 or 336-921-3640; fax 336-921-2681; 610 Bethany Church Rd., Moravian Falls, NC 28654; www.brushymountainbeefarm.com.

Dadant is the largest bee equipment supplier. Ask for their dealer subsidiary in your area: 888-922-1293; 51 S. 2nd St., Hamilton, IL 62341; dadant@dadant.com; www.dadant.com.

Mann Lake Ltd. offers a free 84-pg catalog of beekeeping and candle-making supplies: 800-880-7694; fax 218-675-6165; 501 S. 1st St. Hackensack, MN 56452; www.mannlakeltd.com.

Rossmann Apiaries sells supplies for beekeepers, including package bees: 800-333-7677; PO Box 909, Moultrie, GA 31776; www.gabees.com.

Western Bee Supplies manufactures and sells a full line of bee equipment. Order online, or request a catalog: 800-548-8440 or 406-883-2918; PO Box 190, Poison, MT 59860;

About Bee Stings

The notion that you can work with bees and never get stung is a kind of romantic fiction perpetrated by bee handlers for fun. Two beekeepers in the presence of an innocent have a traditional conversation that goes like this: First beekeeper: “Have you ever been stung?” Second beekeeper: “No, never. Have you?” First beekeeper: “Never.”

The fact is that even with the best preparation, you’re almost certain to get stung about once for every trip to the beehives you make—and much more if you aren’t wearing the right kind of bee costume. Some people get almost immune to the stings, and then the stings don’t bother them much more than a mosquito bite.

But suddenly that can reverse. Some people, even after years of beekeeping, become allergic to bee stings. Benadryl is a treatment for this allergic reaction, but Benadryl by mouth can’t solve a severe crisis. It doesn’t get absorbed in time. You need a shot. If you have a severe allergic reaction, you can die within 20 minutes of the sting. *If you suspect an allergic reaction, head to the closest hospital right away!*

Three steps toward prevention: First, if you’re considering beekeeping, get tested for allergies to bees or bee stings. If you’re allergic, obviously you want to take up a different hobby or occupation. Next, wear your protective costume, especially around your head and neck, which are the most dangerous places to get stung, and don’t get any more stings than you can help. Finally, work together with somebody else so that if one of you gets sick, the other can drive; a person in anaphylactic shock is confused (lack of blood to the brain!), very sick, and not fit to drive.

Kim’s clarification: “A ‘sting’ is the organ (pointed) that enters the skin. A ‘stinger’ is the insect inserting the sting.” Okay. So the place where a bee stung you itches like crazy because of the sting in it, which is full of venom. If stung, scrape the sting out quickly with your fingernail or a hive tool. Honeybees are good guys (girls?). They don’t usually sting unless you are actually opening up the hive, moving around the frames, and harvesting honey. If you are merely peacefully watching bees come and go in their doorway, there’s very little chance of being stung.

OF BEES AND “BEES”: So, first of all, please clearly distinguish between honey-making bees and the yellow jacket/wasp/hornet tribes. It really isn’t correct or fair to call all of them “bees” and teach children to be afraid of all equally. Honeybees can sting only once because when they sting, they leave their sting mechanism in you. They’ve given their life for that cause. So bees are much less likely to sting than wasps.

Wasps, on the other hand, will sting at the slightest provocation and can sting again and again. Wasps and hornets don’t gather nectar from flowers as bees do. Instead they are aggressive scavengers that like to eat fruit, sweets, and meat. I used to say that if they were to become extinct, I’d shout, “Hooray!” But Kim taught me this: Wasps like to eat bugs and, in fact, live mostly on them. Kim wrote, “A yellow-jacket nest will consume 1,000–10,000 vegetable pests in a home garden in a season. Better, much better, than pesticides!” (Incidentally, do you want to hang out with pesticide haters? That’s one more reason to join the bee club! They’ve suffered mightily from the modern delight in bugicide.)

BEE BREEDS: In North America alone there are more than 3,500 species of wild bees. They are helpful for pollinating, but they don’t store honey at all. There are only 3 basic “races” of bees that beekeepers choose among: the “Italian,” the “Caucasian,” and the

“Carniolan.” The Italian bees are yellow and black, hardworking, and don’t like their hive opened on a rainy day. Caucasians are considered to be less likely to sting than Italians. Carniolans are said to be the gentlest kind of all. You can also buy a hybrid queen, a cross of 2, or even a cross of all 3.

AFRICAN BEES: The Africans are another race of honeybee. When they breed with domestic bees, all their aggressive qualities tend to get passed on. Because of this genetic dominance, an African—domestic bee cross equals an African in outcome. A true African-domestic hybrid just doesn’t exist.

How aggressive are they? The African bees are some 30 times quicker to take offense than regular bees, sting 10 times as often, and tend to attack *en masse*, having a stronger chemical system for calling their brethren to the project than do regular honeybees. Having thousands of bees attacking you all at once would be disconcerting, to say the least. Wherever there have been African bees, there have been deaths of people and livestock. They have been steadily migrating northward since the originals escaped from a research lab in Argentina. The African bees have made it north to Texas, New Mexico, Arizona, and California. They are expected to ultimately spread throughout the southern third of the United States but no farther north than that.

If African bees move into your neighborhood, you’ll find out suddenly and traumatically as you’re being chased down the road. Incidentally, the first line of defense against African bees is running away. If you can run 15 miles per hour for 5–7 minutes, you can get away from them. (That’s 8–10 city blocks.)

If you encounter a nest or hive of African bees, don’t try to be a hero and attack them. Kim Flottum explained to me that if you were to go in there in full bee regalia with a couple cans of Raid, the Raid would accomplish no more than to ensure that thousands of furious and still-healthy bees would attack you within seconds, and significant numbers would succeed. If there is even the slightest flaw in your outfit, say a loose legging, you’ll have 200–1,000 stings within seconds. *If you encounter a nest of Africans, don’t try to eradicate them yourself; call for help from authorities.*

There is a silver lining to this. Turns out Africans are vulnerable to something: soapy water. A fire truck loaded with soapy water can wipe out a colony.

NOTE: If a person is being attacked by African bees, spraying them with soapy water helps—it kills the bees. If there are African bees in your area, make a bee bottle (soapy water in a sprayer) part of your basic vehicle, tractor, and picnic pack. Mix 1 c. powdered or liquid detergent per 1 gal. water. Shake it up, and spray. A 2½-gal. Hudson sprayer is good for family-level defense. This has been tested, and it really works.

For more information, read *Killer Bees: The Africanized Honey Bee in the Americas* by Mark L. Winston (Harvard University Press, 1992). Despite the book’s sensational title, it’s a wonderful combination of readable, practical, and scholarly information for beekeepers.

In this new era we must adapt to African bees as just another of the problems beekeepers have always routinely, and successfully, dealt with. Beekeepers, by definition, are not fearful persons!

Southern-Area Beekeepers. Winston predicts that the government will probably eventually be imposing a mandatory quarantine, so that colonies possibly infected with African-bee heredity do not travel out of the area. It would be a good idea to also do annual hive inspection for genetic infection, and annual requeening from a source of guaranteed pure honeybee line. All this means a higher level of training for old-time beekeepers. It also means that “hobby” beekeepers are going to have to be much more expert and involved with their bees than used to be necessary—or they’ll have to give it

up. Also, in these areas there needs to be a wider distribution of bee-sting kits and information about how to use them.

Northern Beekeepers. Some Canadian bee experts advise northern beekeepers that their self-defense against Africans is to stop importing queens and bees from southern areas, instead sticking to their own, or other safe northern, stock—or keeping queens alive over winter so the keepers won't need to buy new ones. This would be difficult to implement, though. The current practice is that, in addition to the mail-order queen-and-bee-package business from southern suppliers, every spring thousands and thousands of bee colonies are moved north for the pollination season.

All this spells not just risk but also opportunity. Basic agricultural economics suggests that the best time to go into a business is when others are leaving it. Agriculture *must* have bees. So there *must* be beekeepers, despite the newest hardship—the perpetual fight against African bees!

Getting Started

As with all livestock, it's vital that you have a suitable place for these critters to live.

SITING THE HIVES: Obey your local zoning regarding beekeeping. And place the bees in such a way that they don't bother your neighbors. Bees, like airplanes, take off and land in front of their hive. This is their flight path, and they guard it. So don't place the bees where their flight path will cross a place where your neighbors are likely to be—their garden, swimming pool, or sidewalk. Bees are also irritated by vibrating noises, so don't place them where somebody will be coming within 10 feet with a lawnmower or similar source of noise. (A. I. Root offers a free pamphlet about beekeeping in residential neighborhoods.) Place them where the early morning sun will reach their hive and stimulate them to get out and find nectar.

It doesn't matter if your own yard is very small or in the city; bees will fly for miles to find appropriate blossoms and will bring back the nectar. But it's not wise to crowd too many bee colonies into a small area. About 25 colonies per "bee yard" is the maximum if you live in the city. In the country, limit it to 60. You don't have to own the land your hives sit on, but you do need to have the permission of the person who does. Most farmers will be agreeable to letting you set your bees on their land in exchange for a share of your honey crop each year.

BEE/EQUIPMENT INSPECTION: State laws vary but it is against the law to sell used equipment for beekeeping in Florida, for example, without a certificate issued by the Florida Apiary Inspection Service. And every Florida beekeeper is required to register with the Florida Department of Agriculture. But some states don't have any inspection service at all and have fewer laws applying to beekeepers. For bee inspection or questions regarding it, contact your state's department of agriculture to get the name of your state apiary inspector, if there is one. He or she will help you contact a local inspector. An inspector is a good person to look over a colony of bees or any used equipment that you're thinking of buying. The bees can be examined for disease; the equipment can be tested for it. Contagious disease is such a huge problem for beekeepers these days. Some states (Washington and Ohio) have very good inspection services; some have none at all. You need to find out what the laws and services are in your particular state. Are the bees you buy going to be inspected where they come from, or after they arrive where you are, or at the border (California)? To sell bees, you want a certificate from an inspector guaranteeing their health. This service sometimes costs (Californians pay for mileage as

well as an hourly rate for inspections) and is sometimes free (in Ohio, for example).

MOVING A HIVE: You could plug up the door of the hive with cloth or grass, but folded window screen stays put more reliably. Be sure to use something that's porous; if you plug it airtight, you'll smother the bees. If the plug comes out while you're moving the bees, you'll have a really, really big problem. Don't let this happen!

GETTING BEES: It's easiest to start small (with 1 or 2 hives) and expand gradually. You have to choose and order your bees and choose and order the hive you'll install them in. You can find bee producers from which to order in any popular bee magazine. Southern or California growers typically supply bees to northerners in the spring or sell "NUCS," which are colonies of about 1,000 bees that have queens that are already laying. Order package bees early, several months before you want them delivered. Orders are filled on a first-come, first-served basis, so if you order too late you may not get any bees at all. You want them delivered at your local fruit-tree blooming time. Package bees won't give you much of a crop the first year because of the low starting population. The alternative, buying a hive together with the bees in it from a neighboring beekeeper, is also best done in the early spring. In fact, I recommend that you start by buying hives from a nearby beekeeper. Then you'll get an already established hive in which everything is going right—one that has lots of workers ready to go and a fine producing queen. Buying from a neighboring beekeeper has another built-in advantage: neighborly advice if something doesn't seem to be going right.

Homemade Hives/Local Bees. Professional beekeepers used to make their own hives, but now they usually assemble them from pieces purchased from suppliers. If you start purchasing from a particular supplier, you may have to stick with him or her because components from one line often won't fit with those from another. So study and shop carefully before your first start-up. If you buy from a neighborly beekeeper, the bees will cost you from \$25 to \$50. You will have an already established hive in which everything is going right, one that has lots of workers ready to go and a producing queen. You'll probably get the bottom 2 boxes—your brood chambers—and would have to pay extra, around \$8–\$15 each, for supers. But in these disease-ridden times, you may prefer—or be required—to buy only inspected, certified disease-free bees and equipment.

Mail-Order Start-Up. You can get a good hive going by ordering bees from Montgomery Ward's catalog. But Kim says you're wiser to "order from a bee equipment supplier whom you can call and get help from. Ward's won't help you. A 3-lb. package of bees gives you 9,000–10,000 bees—not a bad start!" The hive comes disassembled, and you put it together yourself. Nothing to that. You don't have any finished comb to start with when buying mail-order; that's the drawback. But, given time, good conditions, and good care, mail-order bees will establish themselves and do fine.

Catch-a-Swarm Start. You can't get a hive going just by putting out a hive and hoping to get a swarm to move in. I've tried that too. If you're a beginner, catching a swarm is asking a lot of yourself—not that it's hard, but when you see a swarm of bees and everybody nearby in a panic over them, and you've never handled bees before, it often doesn't seem easy.

Starting Additional Hives. Once you have a start of bees, you can get all the other hives you want off your own bees. An old-time beekeeper would think it foolish to buy more when you could start your own. To start another hive, prepare a brood chamber around May 1. Now go into your best-established hive, the one with the most bees; it will be on the verge of swarming anyway.

MINIMIZING STINGS

1. Wear white-colored, smooth-surfaced clothing. The more white you wear, the better. White and smooth doesn't irritate bees as much as dark and rough-textured clothing. (Above all, don't arrive in a dark-colored, deep-pile coat, which would for sure set off your bees' instinctive bear alarm!)
2. Make sure *all* entrances to your body are safely closed off (bees crawl into dark crannies!).
3. If possible, work with your bees during sunny, warm weather near midday, when most are out of the hive harvesting from flowers.
4. Use a smoker to quiet the bees.
5. Raise a gentle breed and take all possible precautions against African bees.

Take 4 frames out of that well-established hive. Choose frames that have brood cells (which worker bees will hatch out of), some honey, and some bee bread (pollen), which means cells filled with a sort of yellowish grainy stuff. The frames will almost certainly have some workers crawling around on them; if they don't, dump lots of worker bees in there, or scrape them off other frames. The frames will almost certainly have queen cells, too. There is usually at least 1 queen cell per frame if the bees are making queen cells at all. If need be, you can cut one out from a frame and stick it into a new frame. You can start a new hive with every queen cell.

Install the frames in the new hives. Put on the lid and stuff up the entrance loosely with grass to give the bees a chance to feel at home. Then go away and leave the bees alone. The workers will do the rest, including making a queen out of one of the eggs if you didn't give them a queen cell.

Protective Clothing

You can buy your outfit ready-made or make your own. I recommend the ready-made, which sounds out of character for me. But it's really important to have a good bee costume so you don't have to be nervous. That way you can just go in there and do what you have to do. The worst things that can happen when working with bees are for you to panic or for your nose to itch. A really safe bee costume on a hot day is hot inside. There's no escaping that. It helps to wear as little underneath as possible. I know a lady beekeeper who goes naked inside hers. It makes her less at risk for heatstroke, and she's not in danger of attack bending over a hive of bees from anything but a bee!

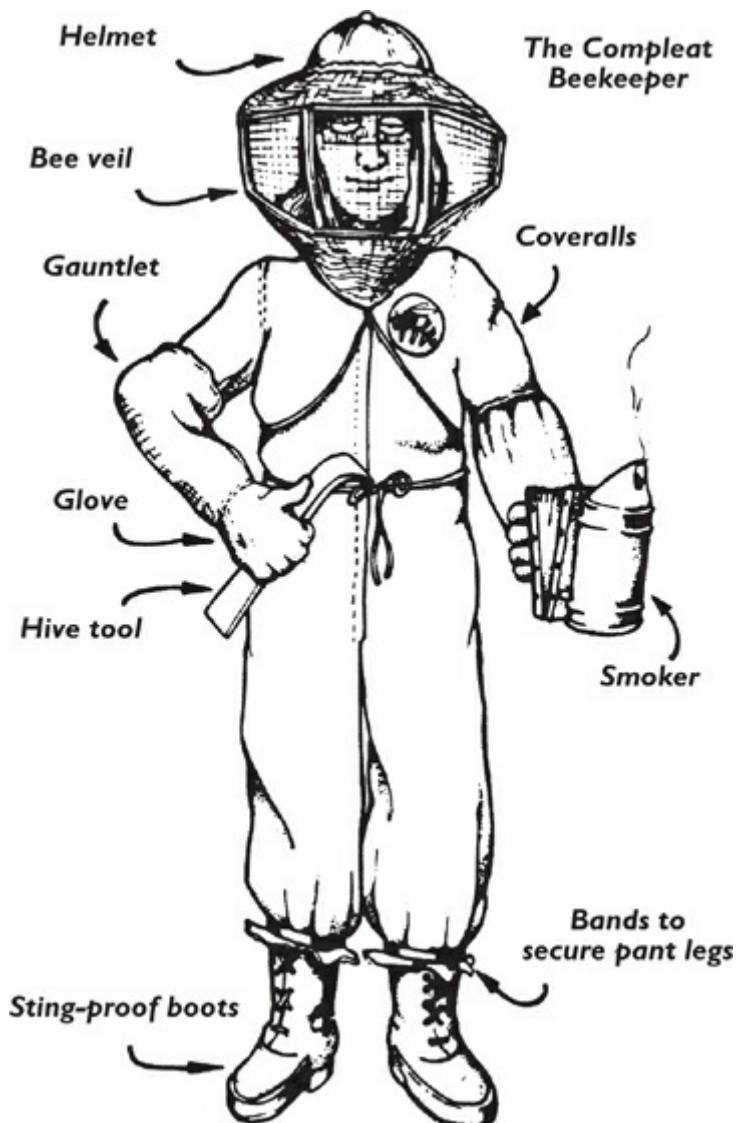

HOMEMADE BEEKEEPER'S COSTUME

Protecting Hands and Arms. Wear gloves. Kim advises: "You don't need very thick gloves. Some use rubber gloves. If too thick, you can't pick up frames or manipulate the hive tool." Gauntlets protect the area over your wrist and forearm. You can make a homemade gauntlet and sew it at the top of the work gloves. Make it long enough to reach high above your elbow, with elastic at the top to hold it firmly on. Use canvas that is thick and stiff and bags out well. The bagging out is your best protection. A favorite spot the bees sting is right at the top of your gauntlet, where the elastic presses them close to

your arm. And they'll really try to sting your hands. Getting gloves of even the toughest leather isn't absolute protection. Sometimes they can sting through leather, too. The bees will crawl around on you and keep poking their sting down, trying to hit pay dirt.

Protecting Feet and Ankles. Wear work boots or cowboy boots. Both are absolutely beeproof, but work boots are better. Tie your pants tightly to the outside of the boots with a strip of inner-tube rubber or elastic so the bees can't crawl up your legs. Or use the top cut away from an old army combat boot—the canvas wraparound that straps tightly to hold your pant leg close against your boot. Bees crawl up. They won't just sting you on your ankles if they get in; they'll go way up so fast it'll amaze you. This is the voice of experience talking. Don't assume they can't find the gap; that's really underestimating bees. Early in my beekeeping, I went out to the hives with my pant legs tied down, but I was wearing a winter coat rather than coveralls. I figured that would be good enough. Suddenly they found a way under that coat clear up under my shirt, and I ran all the way back to the house slapping bees. I had about 12 stings around my waist and above it on my back and chest.

Protecting Your Body. Wear white, 1-piece, baggy coveralls, complete with gloves, gauntlets, boots, and a firm fastening on your pant legs outside your high footwear to protect your body. If you make the 1-piece, zipper-in-front coverall out of rip-stop nylon, the stuff they make tents from, you'll avoid stings because bees can't get a foothold on it. It's far better than cotton in that regard because cotton has fibers the bees can get into with their feet. And if bees can get their feet dug in, then they can sting.

Protecting Head and Neck. Use a tropical-type helmet (a construction hard hat) or a beeproof straw hat. Whatever type of hat you wear, it should have a firm, wide brim. You'll also need a bee veil, which you can mail-order. The bee veil top fits around the upper brim of your hat. The crown of the helmet fits up through the top hole of the bee veil. You tie it firmly around the crown with a drawstring. Now turn up your inside collar. Tuck your hair inside it. Draw the bottom drawstrings of the veil tight around the base of your collar. Make sure there isn't even a small hole. Then bring down the strings, cross them over, draw them around to your back, cross them there, and bring them on around to your front again, where you tie them firmly. Why? So that when you lean over, your bee helmet doesn't flop off, taking veil and all with it. Wearing all that in hot weather is bad enough.

Order in Which to Put It All On. 1. Coverall. 2. Boots. 3. Elastic to hold pant legs down. 4. Bee helmet and veil. 5. Gloves and gauntlets. (Dishwashing gloves work, too.)

STORE-BOUGHT BEEKEEPER'S COSTUME: These you buy from a beekeepers' supplier. Their bee gloves come equipped with gauntlets. You can buy a white coverall with helmet/bee veil that zips into place around the neck. It's worth the money if you can afford it. They come in all sizes and various styles.

Equipment

New, as opposed to used, bee housing and equipment is expensive, but it helps you understand what the ideal format is. The argument for starting with good stuff is that the lifetime of bee equipment is very long, easily 20 years and possibly 50. The hives should be purchased or built months before your bees are expected, so you'll have plenty of time to be certain they are ready and set up in the planned location before the bees arrive. You have a big problem if you have bees and no hive.

You'll need hive-working equipment such as your bee costume, smoker, and hive tool. Then each following year you can try to upgrade somehow: Increase the number of colonies or improve your efficiency. Or you can buy with an eye to the budget and not buy new equipment but purchase working colonies. Or, if you are a good woodworker, you can make your own hives and purchase package bees or NUCS to populate them. But there's much more to it than this. I haven't the space or personal knowledge to tell you everything you need to know. All I can do is give you a basic orientation and point you in the right direction to get more detailed information.

BASIC BEEKEEPING EQUIPMENT: Most beekeeper suppliers have a basic beginner's assortment along these lines.

1. One (or 2) standard 10-frame hives, each with bottom board, entrance reducer, foundation, frames, inner cover, and outer cover.
2. A package of bees, with a queen for each hive.
3. A smoker.
4. A hive tool, which you will use to pry the hive and frames apart when you examine the bees.
5. A bee brush to brush bees off a honey frame when you are getting ready to take it away from the hive.
6. A feeder to feed sugar syrup to your bees until they have enough numbers to gather nectar and enough flowers to gather it from.

BEE-GO-AWAY ITEMS: These all gently, diplomatically, make bees go away.

Smoker. The smoker has a burning chamber with an attached small bellows that you can pump. A. I. Root says that most beekeepers consider the smoker to be “their most important piece of equipment.” The smoker is valuable because the presence of smoke triggers a bee instinct to drop everything else and fill up their honey stomach with honey. That keeps them peacefully busy, quiet, and not paying attention to you. Smoke also interrupts the communication of alarm signals between bees. But there is such a thing as too much smoke. Use only as much as you need.

Start your fire with a piece of crumbled paper, which you light and drop into the smoker’s canister. Then add your solid fuel such as pine needles, dry grass, dry wood, wood chips, a piece of burlap bag (not one that has been treated with insecticide, which would kill your bees), corn cobs, or a piece of cotton rag. You want a fuel that will smoke rather than burn fast, so don’t use fuels that create high heat in there, as charcoal or chemical fluids would. If you slowly pump the bellows, it will help your fuel get going well. Once your fire is burning, add the rest of your fuel and close the lid. Ideally the active fire will then stop, but your fuel will still be smoldering. Light the fire just before you’re ready to go to work on the hives (after your bee costume, except gloves, is on). Even after your fire is started, give the bellows a little pump now and then to keep the fire from going out.

At the hive, stand to one side of the entrance (out of the flight path—bees instinctively react to obstruction of their flight path, especially the last few feet of it before the hive entrance)—and blow some smoke into the entrance. After a minute, take off the hive cover and blow more smoke through the hole in the center of the inner cover—if you use one (many beekeepers don’t). Blow more smoke into the hive. Especially before you examine a bee-filled section, waft smoke over the tops of the frames. Then remove frames to look closely at them. Blow the smoke at the bees whenever they seem overly concerned with you rather than being about their own business.

Whenever you need to blow smoke at the bees, slowly pump the bellows. (Pumping too fast gets your smoker fire too hot and would pump out burning ash.) Experience teaches you how to best use your smoker to keep the bees under control.

Bee Brush. You can use the bee brush at honey-harvest time to brush any remaining bees off frames of harvested honeycomb that you want to take to your house. Brush them off gently near the hive entrance so they can easily find their way back home. At all times, avoid pinching or crushing bees when moving frames in and out. An injured bee releases an alarm odor that arouses other bees to sting.

Bee Escape. The bee escape is an inexpensive product that is used to eliminate bees from the honey-laden supers before you harvest them. It’s a one-way exit that you can put in; then you come back in 24 hours and harvest your bee-free honey supers.

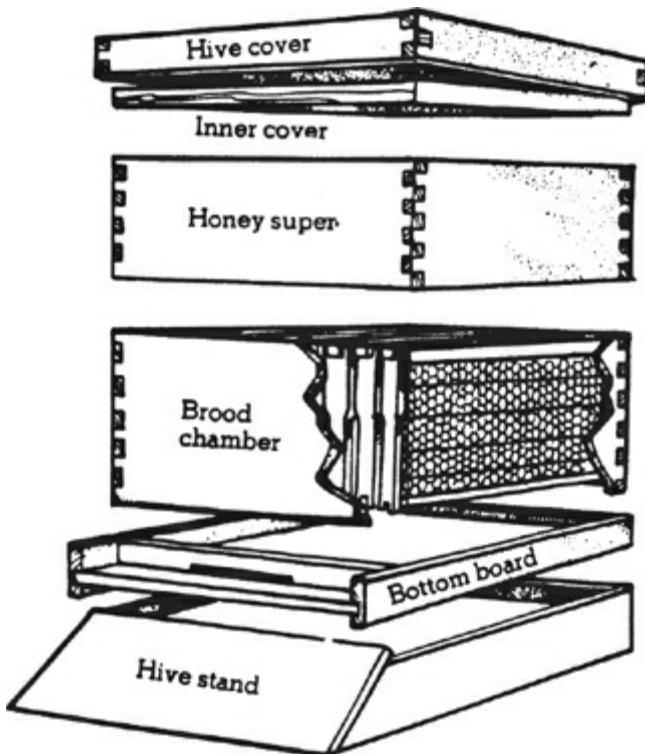

Bee Go. This trademarked product is sometimes used by beekeepers when they get ready to take the supers for extracting the honey. Directions for use come with the product. It’s important not to get any of it on the honey or wax; that would ruin it.

If I were to say much more about your purchase options, I’d just be repeating what the catalogs will tell you.

PARTS OF A HIVE: The start-up structure before the bees arrive consists of the floor of the hive (bottom board); the sides of the first box; which are fastened together at the corners somehow; and the top cover. These parts are detachable from each other just by lifting them apart. Inside that box there are “frames.” Most beehives are now made to hold 10 frames. There are ridges on the inside of the walls to set the wooden top bars of the frames on the hive box. The frames hang in there at an equal distance apart, all across the inside

of the box. Each frame starts out holding a layer of beeswax "comb foundation" onto which the bees build fullscale comb for raising brood or storing honey. The whole thing needs to sit on a "hive stand," which is a platform.

Hive Stand. This platform is needed under your beehives if tall grass is interfering with the bees' flight patterns; it's also used to level the hive and keep out ants. If you can help it, don't put hives in the same pasture with horses or cows because sooner or later, one of the big animals will get rambunctious and knock over a hive. If this happens in cold weather and you don't notice right away, you'll have a hive of dead bees. They need the shelter their hive's enclosure provides. Skunks will take bees. They get outside a hive and scratch the front door. As the bees come out, the skunks eat them.

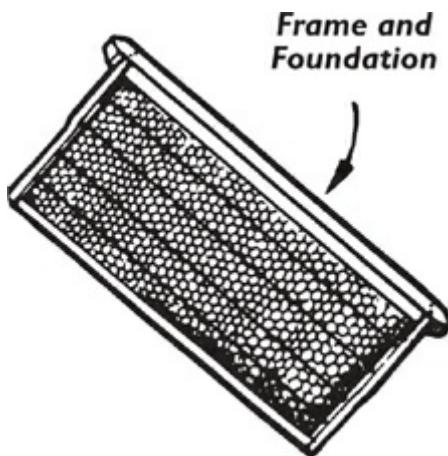

Brood Chamber. The bees live in the bottom box, which is usually called a "brood chamber." There the queen stays and lays eggs; most of the cells in there have baby bees in them rather than honey. The next layer up usually ends up being mostly brood cells, too, with maybe some honey around the sides and top. A layer is called a "super." Those 2 bottom boxes are what you get when you buy bees from a beekeeper, and you never want to break up that comb to try to get any honey. Just leave it alone.

Supers. The supers are (usually) shallower boxes that you set on top of these bottom 2 brood chambers. They are the ones that the bees store extra honey in. The bees work from the bottom up, and that's why you need more supers in a good honey year and fewer in a bad one. Supers that you buy come in your choice of heights. The deeper ones aren't really desirable because if they do get full of honey, they are almost too heavy to carry. Each super or brood chamber holds 10 parallel frames, hung vertically so that they don't touch the bottom or sides of the box. Bees build beeswax cells on the frame to contain brood, honey, or pollen (bee bread).

Foundation. Beekeepers usually buy their comb foundation from a beekeepers' supplier. Foundation is a thin sheet of beeswax already pressed into the 6-sided shape of the bottom of a bee cell. All the bees need to do is build the sides and top (cap). When you put the foundation into the frames, you use wire to support it and add strength. Professional beekeepers have a choice of 2 special tools for heating the wires so they'll easily sink into

the foundation. One sends a jolt of electricity through the wire that heats it.

You can make do with nylon fishing string (or even plain string if desperate). Put it through the hole and draw tight. If you don't use wire or string, the foundation will wilt in the summer heat and get out of place. If the foundation is not exactly where it's supposed to be, exactly the correct distance apart from the next layer of foundation, the result will be that you can't raise frames efficiently to look for the queen or queen cells because the frames will get stuck together by the bees where the frames are too close. If you put the foundation in right, the bees will build a neat sheet of cells along each side of the foundation and leave themselves an open-air walkway between each and every frame. That makes it easy for you to pull out an individual frame and look it over. If all goes well, at the end of summer, the frame will be covered with brood cells by the bees in the brood chamber or built into comb in the supers and filled with honey.

Experienced beekeepers may harvest the wax comb, which can be sold profitably in addition to the honey, or they may return it to the bees for refilling with honey. Beginning beekeepers sometimes don't realize that they can't have honey until they have honeycomb. Every day the bees spend making the honeycomb is a day they can't be gathering and making honey. But Kim says that since bees can make comb even faster than honey comes in, there's no delay problem.

If beekeepers choose to reuse the comb, they just slice the end off the chambers and make the honey pour out of the inside by centrifugal force in an extractor. Then they give the comb back to the bees for them to refill.

Homemade Foundation. The old-timers used to make their own. In those days the Root Company made rollers for rolling the wax into foundation. Now you can't buy the rollers anywhere that I know of, unless you can find one as an antique. You can buy the foundation only from various supply companies. The old-time rollers were made of hardwood maple and were carved by hand. The roller has to be carved or built with a hexagonal impression pattern in it; otherwise the bees won't build it into comb. The way the old-timers made the sheets of wax for rolling was by taking an 8-or 10-inch board, dipping it into hot beeswax once or twice, and then letting it cool. When the wax was firm, they slit it on the side and peeled it off. They rolled that with their patterned roller, and that was their foundation. Kim Flottum says it worked okay but was expensive—lots of wax wasted—and slow.

Plastic Comb. This is a 1-piece, frame-foundation, completely drawn plastic honeycomb. Kim wrote, "Plastic foundation is like wax foundation—embossed with the 6-sided cell but made of plastic and coated with wax. The bees draw the cells from the plastic base, fill them with honey, and then cap them with wax. You take these in and out like the regular

frame and foundation. They can go into an extractor.”

Working with Your Bees

I know this is inadequate. There’s really no substitute for going to the hives with an experienced beekeeper—no matter how well written or illustrated your manual.

WHEN YOU LOOK AT A FRAME: The cells that are capped dark-brown are brood cells. Those are the ones the bees hatch from. The ones that are capped light-colored contain honey. The cells will be in sections of either one or the other. Queen cells are very easy to find, about an inch long, kind of hanging away from the rest of the comb. They look like a peanut shell. Drone cells stick out too but not nearly as much as queen cells. Drone cells stick out like little lumps with bullet-shaped tops. The worker cells are just exactly level with the rest of the comb. In short: the queen cells are the biggest, the drone cells are next in size, and worker cells are the smallest.

The Queen Bee. Before you start moving stuff around, find the queen in the hive—so you’ll be sure not to hurt her and you can have her end up where you want her. To do this, pull out frames and look them over carefully one by one until you locate her. She doesn’t look like any other bee at all. She’s about an inch long and tapers clear from her front to her tail. The other bees will be somewhat spread out away from her. They don’t crowd her.

A queen bee might sting you if you grab her, but usually the only stinging she does during her life is directed toward other queen bees. When the first new queen hatches out, she’ll go around and sting the others to death right in their cells. There can be only 1 queen in a hive. The drones haven’t even got a sting. Only the workers sting you. The drones are big, fat bees with very large eyes. Their only function is to compete with one another on the queen’s mating flight and earn the privilege of fathering the new hive offspring. A queen bee is a marvelous creature that can live 7 or 8 years—a long time for an insect! They are really good for only about 3 years, though, and that’s why beekeepers talk about “replacing” the queen. Your honey crop depends in part on the vigor of your queen. It takes 21 days for workers to hatch, 16 days for a queen to hatch, and 24 days for a drone to hatch. The more eggs the queen lays, the more workers there are to make honey. But it also depends on the weather.

Queen Excluders. Excluders are made of a wire grid that allows a worker through but is too small for a queen. Kim wrote, “An excluder is used to keep the queen from moving into honey supers and laying eggs. You do not want brood in your honey supers. Excluders should be used for cleanliness and sanitary honey production.” He also told me that excluders can’t be used to separate queens because queens can and will sting each other through an excluder.

GOING INTO THE HIVE: This means to open up the hive and carefully remove and look over every single frame to find the queen, look for queen cells (but only in the spring), and generally assess how many bees there are, how many and what type of brood cells, how much honey is coming, and whether the bee colony needs more supers. You want to give them plenty of supers if they need them because overcrowding leads to swarming. (Sometimes they swarm anyway.) If you’re very lucky, you may need 5 or 6 supers by summer’s end—but more likely you’ll need fewer. It will depend on the hive. Each hive has its own history each summer; there are seldom any 2 just alike.

Get into your bee costume and get your smoker going. Take either a hive tool or a screwdriver. (Kim: “... only if nothing else is available. They really wreck a frame.”) Use it

to pry apart the lid from the hive and supers from brood chambers. The nearer you get to the bottom, the harder it will be to get things apart as the comb gets bigger and firmer. You can set the supers on the grass while you are working in the brood chamber. Kim: “Set your cover (top down) down first, and set supers on this. That way if you miss the queen and she falls off, she won’t get lost.”

To put a super back on the brood chamber, do it so as to kill no more bees than necessary. Start it at one end and slide the super slowly onto the brood chamber so that you slowly shove the bees that are on the edge off the sides. They’ll find their way around to the door again.

Water and Food

WATER: The bees should have a nearby source of water. In an urban setting, be sure and provide their water so they don’t habituate a neighbor’s swimming pool. The water supply should be fresh and running. Stagnant water has been named as a factor in bee disease. Bees bring water in to evaporate and cool their hive in hot weather and to dilute honey for feeding brood. If you don’t have a nearby creek, let an outside faucet drip down onto a board set slantwise. If you have a heavily populated hive, the weather is hot, and you see bees clustering outside the hive entrance, they have a heat problem inside beyond what their water-carrying can handle. In southern states, hives are typically placed where they will have shade during the worst heat of the day. Or you could put the hive under slatted lath. Or make the hive entrance larger, or stagger the top supers to create a half-inch ventilation space.

BEE FOOD: Shakespeare said, “Where the bee sucks, there suck I.” To me that means honeysuckle. It’s a wild vine with pretty trumpet-shaped orange flowers. It grows up the trunks of trees and flowers among their branches. The children love honeysuckle time. To get the nectar, you pick some of the pretty, long, orange flowers when they are fully developed. Pick them with the tiny green bulb on their base intact. Then nip off that green bulb with your fingernail. Put your mouth to the opening you made at the base of the flower and suck. You will get a tiny taste of nectar. Some honeysuckle flowers have more of it and some less. Nectar is bee food, too. It’s the only food they can eat. How much honey your hives yield for harvest is basically a result of how much and what quality of flowering plants were available. But bees are very good at finding, collecting, and storing it!

Bees gather flower nectar and carry it back to their hive, where they change it to honey. They like herb flowers—such as basil, bergamot, borage, catnip, fennel, hyssop, lavender, lemon balm, marigold, marjoram, oregano, rosemary, sage, savory, and thyme. They like almost any fruit blossoms. An orchard is a good place for your hives in the spring—as long as it doesn’t get sprayed with pesticide. In southern California, where bee pasture is available nearly year-round, bees can make honey from flowers on the eucalyptus trees or from citrus and other trees that are in flower in winter, like the lemon.

Flower Flavors. Whatever type of flower your bees are gathering nectar from, that’s the flavor the honey will have. Buckwheat honey is very dark in color and heavy in flavor. Clover and alfalfa blooms make a light-colored honey of delicate flavor. But if your bees get their honey from wild-flowers, carob trees, and oxalis, it’s likely to be rich, dark honey that the USDA would grade “Number 4”—meaning not fit for human use. Which is simply ridiculous. But commercial standards favor the sort of honey you get from a big sweet clover or alfalfa field, which is pale. “Number 4” is edible, and some people get along fine with weird-tasting honey. Food and gardening writer Lane Morgan says, “I have heard

that people with allergies can use honey from the allergen-making plant to lessen their sensitivity. It's sort of a homeopathic treatment." But she also told me about "cabbage flower honey—which really is pretty much inedible."

Insecticides. Don't use pesticides yourself. Ask your neighbors not to use them. Even a shot of spray here and there on plants or gardens will kill a few bees. When entire fields and orchards are sprayed or dusted, the resulting loss to a bee colony can be devastating. The beekeeper sees a large accumulation of dead and dying bees at the hive entrances. If spraying is to occur in your area, you need to know about it in advance. If possible, work with the farmer and the pesticide applicator so their efforts will safeguard these valuable pollinating insects. Your risk from spraying comes not only from blossoms on cultivated crops but also orchards, orchard ground covers, and sometimes uncultivated areas such as roadsides.

Ask that insecticides not be applied to open blossoms. Be sure the sprayer knows that the safest time to apply insecticides is late afternoon, after bees stop foraging. (Early-morning applications are less dangerous to bees than those in midday.) Finally, persuade the sprayer to select an insecticide that has the least impact on nontargeted insects and animals.

If you're not successful getting these assurances but you can get a few days' warning of a spraying that you know will harm the bees, move the hives at least 2 miles from the spray area. If notice is short and the spray plane is coming right over your hives, drape them with damp burlap. That protects against a direct hit. Then you'll have to remove it and accept some loss of bees. But if a bee colony is repeatedly exposed to pesticide, there will be fewer and fewer living bees until at last the remaining ones can't survive.

If your bees are suffering due to pesticides or herbicides, tell your beekeepers' association, the state extension agent, the person or business that did it, and the spray inspector if it's a conspicuous wipeout. Kim Flottum wrote that no insurance compensation is available for this. "Don't even try. If you are able to prove neglect, however, you can sue the applicator."

Herbicides. These aren't good for bees either because they tend to kill flowering plants. Public spraying of herbicides around road edges and shorelines to fit some artificial notion of which plants are okay and which are not unnecessarily kills flowering plants that could support bees.

Weather and Climate. Bees gather what they find. They can work only when flowers are in bloom. So they have more chance to gather honey in climates where flowers blossom during more months. In northern climates the heaviest honey flow is usually in June. But a summer so dry the flowers can't grow or don't bloom well is a bad one for bees. I've seen dry summers when the flowers didn't bloom until the fall rains came, and the bees made hardly any surplus honey at all. Southern bee growers have a longer flower season and so tend to get larger honey harvests. In southern California it's not unusual to take as much as 100 lb. of honey from one 10-inch super twice a year. In an exceptional summer or in an exceptional climate (like Hawaii), each of your hives might yield 200 or even 400 lb.! An extra-cold, long winter shortens their harvest season and lengthens the time they must live on stored, or owner-supplied, food.

Winter Food. To get your bees through, a colony needs a young queen, a large cluster of adult bees, 50–100 lb. of honey, and a few combs of pollen. They should be in a 2-story standard hive with 1 brood chamber and 1 honey super (the removable top section where the bees store honey). Starvation—not cold—is the biggest risk for your bees! Bees don't hibernate during the winter. They are very much awake inside the hive, clustered in a ball in which they generate heat for each other. But they have to eat all winter long to have

the energy to make that warmth, or they'll die. If they get low on honey, you'll have to provide supplementary sugar. Feed them a syrup of 2 parts granulated sugar to 1 part water. You can buy a substitute for pollen from a bee-supply dealer. Feed them that after the honey harvest in the fall, before winter sets in.

As long as there are blossoms, the bees will make honey. Around here they are done with most of their honey-making by the end of August, when everything dries up. That's the time to get the honey. We use 2 brood chambers and 2 supers, taking 1 super for our use and leaving the bottom honey super for the bees to winter on. You have to estimate how much honey they need to winter on—different parts of the country have a longer or shorter cold season—and take only what's surplus beyond that. If the bees don't have enough honey over the winter, they will die of starvation. You'll go out in the spring to look at them and just find a bunch of dried-up little bodies.

So check them in cold weather, too. You won't even need your bee suit. They'll be huddled in the brood chamber trying to keep alive by buzzing to make warmth.

Sugar Feeding. If they seem short of food, dump in a bunch of white sugar. Never, never feed them brown sugar. Dump sugar on an inner cover (not directly into the hive), between the frames, or onto the outside. They'll survive on it. A dear friend of mine who is an experienced beekeeper told me, "Big honey producers nowadays feed their bees thousands of pounds of sugar every winter to carry them through and also through dry seasons. If you aren't feeding your bees sugar, it takes them a lot longer to accomplish anything." So even under bad flowering conditions, a beekeeper can feed sugar to the bees and have a good honey crop. But honey from sugar-fed bees can be only for home use. If you sell honey made from sugar, you are breaking the law! Commercial beekeepers may feed sugar to build up their bee population to take advantage of the coming nectar flow but *not* to make honey for sale.

I've been working on this book for over 20 years, and I'm making some major additions or changes now for the eighth time. I tell other authors that I meet, people with a string of fine titles to their credit, "All my life I've written one book." That's generally good for a shared laugh, but there's a bittersweet private sadness to the fact for me. I have indeed come back to this book again and again, trying to make it more thorough and more accurate, and it makes me happy to see it improve. On the other hand, I have written, or tried to write, other books. None of those others have ever yet made it into print. Maybe some day. I've tried so hard. I read that a writer needs to write the first million words just for practice. Well, I've accomplished that. In fact, I think I'm somewhere in the second million. The breakthrough should be coming any day now! There's something else I want so much to say.

DEALING WITH SWARMING: This is common in the first half of June here in Idaho, earlier in the south—as early as March! There can be only 1 queen in the hive. If extras hatch out, many of your bees will fly off with the young queen to make a home and a new hive wherever they can; what's left of your hive won't give you much of a crop. If you don't want to start new hives, pinch out all the queen cells to prevent swarming. The more workers populate your hive, the more honey they will bring home. If you go into a hive and find queen cells but no queen, it probably means the old queen swarmed.

Then you'll hear from the neighbors. Sometimes bees move into house walls. They can get between the outside walls or between upper and lower floors. If they do that, don't poison them. Kim Flottum wrote: "You can trap them out using a funnel-shaped screen. The bees can leave a space between walls, etc., but can't return. An empty colony is

placed outside and the bees move in. Eventually the old nest is empty, and you can then fill in the entrance solid so it can't happen again."

There's really no way to determine who owns the bees after they've left the hive, but once you've acquired a reputation as a beekeeper, the phone is sure to ring around swarming time. There'll be a hysterical voice on the other end yelling something like, "Your bees have swarmed to a bush in my yard, and nobody dares leave the house." You can tell the caller that swarming bees don't sting. It's almost always true. (If you see a photo of somebody whose face is covered with bees, they're probably swarming bees.) In fact, putting the word out to extension agents, police and fire departments, beekeepers, and anybody else in your area who might receive a "swarm!" call is a good way to build up your bee population on the cheap.

When swarming bees cluster, they all just hang there—solid bees, a little over a foot long, with lots of extras flying around outside. Well, if they swarm onto a branch, they are easy to get, all clustered up like that. You can even do it without your protective gloves on. Just cut off the branch with the bees on it. Hold it over a brood chamber or even an empty cardboard box, anything that will hold all the bees and can be closed up after they're in. Then shake or lightly brush the bees off the branch into the brood chamber. You can do it with a brush or a leafy limb. You can set the hive on a stepladder if it's a higher branch. Bee professionals carry around an extra brood chamber in the pickup just in case they see a swarm they can catch.

At least, that's how it's supposed to work. But bees are very independent. I remember once a swarm was clustered on a branch only a few feet off the ground. The beekeeper set up a hive that was left open on top right underneath the swarm, even put some honey in it. He gently brushed the swarm with a limb into the hive. Then he went away for the night. The next morning all the bees had taken off for who knows where. (If they had been in the hive, he would have put the lid on, blocked the entrance, and taken them home.)

On the other hand, I know a case where the swarming cluster was on a limb 40 feet high. The property owner was pretty insistent about getting rid of them, though, so the beekeeper—mostly to oblige her—left a hive sitting underneath the limb and, by throwing a rope with a weight on the end over the branch, managed to shake a few off and get them scattered on the ground below. Then he went home, fully expecting the problem to have flown far away by the next day. But he got a phone call early in the morning to tell him that—Lo and behold!—the swarm of bees had moved into his hive.

Bee Diseases, Parasites, and Pests

Like any other form of farm livestock, your bees can have these problems. You need to stay in touch with other local beekeepers to know what is currently going around, what the symptoms are, and what the prevention or treatment is. Most states have an "apiary inspector." They're listed in "Who's Who in Apiculture" and they, or a local inspector, can help if you suspect disease. And there is probably an expert in your beekeepers' group. That person can tell you whether your problem is one that legally must be reported and what treatment is advised or legally required.

BASIC BEE HYGIENE: *Don't introduce disease into your hives!*

1. Don't buy honey for feed from an unknown source because honey may carry American foulbrood disease.
2. Buy bees and queens only from reputable dealers.

3. Buy used bee equipment only after consulting with your apiary inspector.
4. It helps avoid disease if the bees draw new combs from foundations every 2–4 years for the brood chamber.
5. Learn to identify and treat diseases, parasites, and pests by taking a course or working with an experienced beekeeper, so you'll be able to detect a problem quickly and take appropriate steps.
6. Be alert for those signs of disease each time you open a beehive.

BROOD DISEASES: “Brood” means the eggs and larvae of the colony. The “brood nest” is made up of all the combs that have eggs and larvae in them. “Brood diseases” thus are ones that strike the immature bees inside their cells. U.S. beekeepers currently have to be on the lookout for American foulbrood, European foulbrood, and chalk brood. A healthy brood nest has few unsealed brood cells. The cell caps are slightly convex. Their color is a uniform pale brown. Normal larvae are plump, a lovely mother-of-pearl color, and have no odor.

Chilled Brood. This is the most common reason for a dead brood. It happens in early spring, if the population is rapidly expanding and then there is a period of very low temperature. The problem isn't disease in this case. It's that there is more brood than there are bees to keep them warm. The bees do their best, but the outer edges of the brood are just too far from the heated area, and they get too cold and die. This is different from an actual disease problem in that you will find dead brood in *all* stages, both very small and very large. With disease, the dead are all at one particular growth stage.

Chalkbrood. A fungus is the problem here. The cell caps will look either light or dark, and some will be punctured. The dead larvae in sealed cells are first white, then grayish black, hard, and chalklike. You should cut away and burn infected combs. Other than that, there is no treatment except that it helps to move the hives to an area with better air circulation, and the disease will then run its course and subside.

American Foulbrood. This is the worst of the brood diseases. A bacterium, *Bacillus larvae*, causes larvae to rot in their cells. Foulbrood can be contracted by your bees if they invade an infected colony of wild bees in some nearby old building or tree.

The cell caps look off-colored, sunken instead of convex, and punctured. There are dark scabs at the base of the cells. The larvae look brown, slimy, and dead. If you stick a straw or match into a cell and draw it out, you'll get only stringy substance. There is a gluey, rotten-egg smell. *American foulbrood must be reported to the state bee inspector.* Treatment must be as mandated by the state.

Last I heard, foulbrood is prevented with a medicine the bees eat twice—once in the fall, after you take out the honey, and again in the spring. It is a Terramycin powder that you sprinkle on the outside edges of the frame tops. In the fall, after you take out the honey, you sprinkle 2 T. of the stuff on each brood chamber; then do it again in spring. (But read the label in case it says something different.)

European Foulbrood. When you examine the brood nest, you'll see discolored cell caps, sunken and punctured as you would find with American foulbrood. The larvae also look brown or dark brown and something from doughy to slimy. Odor is sour rather than gluey. But the real big difference can be determined by the straw test. In this case—and with sacbrood—the straw does *not* pull up stringy filaments. There is no treatment for European foulbrood. The disease will run its course during that brood season.

Sacbrood. This is a rare brood disease caused by a virus. Cell caps look dark, sunken, and punctured. Larvae turn gray to black, die head up, a mix of watery and granular in

consistency. No filament from straw test.

Stonebrood. This very rare problem results from a fungus that causes cells to look greenish and mildewy. Larvae cling to cell edges and look greenish-yellow, hard, and shriveled. There is a musty odor. The bees can treat this disease themselves by chewing off and throwing out the diseased cells, and they will defeat it.

ADULT BEE DISEASES: For adult bees, Nosema disease is one of the most serious. Two parasitic mites, *Acarapis woodi* and *Varroa jacobsoni*, cause the most serious bee ailments.

Acarine Disease. *Acarapis woodi* bores into the air passages of bees that are 1–8 days old and sucks their blood. The bees are unable to get enough air and can't fly; they just hop in front of their colony home. The best treatment is to keep your bees out-reproducing the parasites; that works really well in the South but not so well in the North. For northern beekeepers there is a Terramycin treatment. A few years ago this disease was uncommon. It's very common now and is still deadly.

Nosema Disease. Most bees carry a single-celled parasite called *Nosema apis* in their intestinal tract. If bees get run down from lack of pollen (their protein source), the nosema can increase to the point of killing their hosts. Affected bees have swollen abdomens and crawl about with trembling wings outside the hive. Nosema disease is most likely to strike in the spring, when pollen supplies are running out. Prevention is easy: Make sure your bees have sufficient pollen, and use a preventive medicine called Fumidil-D.

Varroatosis. *Varroa jacobsoni* is an immigrant mite from India, where it coexists with some kinds of bees without seriously damaging them. For European bees, however, it is deadly and will kill untreated colonies in a single season. It is visible to the naked eye. The mites are light brown, oval, and measure 1 × 2 mm. (Males are round and 0.8 mm in diameter.) There is a 6-legged bee louse that is harmless. Varroa has 8 legs. Varroa mites seek drone cells for a critical stage of their life cycle. Kim Flottum wrote: "Treat with the plastic, pesticide-treated strips. If you don't treat, your colony will die. Count on it!"

OTHER PESTS

Birds. They do eat bees, but only sick or dead ones—unless they catch a young queen on her mating flight.

Mice. These can be a fall and winter problem. The prevention is to narrow the entrances in the fall to just $\frac{1}{4}$ inch wide.

Wasps. These predators kill honeybees and can enter and rob a small or weak colony. A bigger problem is when fall hunger hits and wasps try to get into the hive because, like bees, they too love honey. A strong hive will defend itself successfully. But you can help the bees by blocking off part of the entrance at summer's end so wasps can enter only one at a time. They're easier for the bees to kill that way.

Waxmoths. These offenders lay eggs on combs, inside the hive. The larvae (caterpillars) that hatch out eat the material in the comb left by the bees, and they burrow through the comb while doing it. They will wreck combs. You can be sure the problem is waxmoth if you see fine gray webs lining paths eaten into the comb. If you have a strong, well-populated colony, the bees cope by murdering each hatching waxmoth larva. Store unused combs where light and air circulation are good to keep these pests to a minimum.

Bears. Kim Carlson, one of the editors who worked on this book, asks, "What about bears? My father stopped beekeeping after bears ruined the hives for the second time. Maybe there's not much you can do to stop them (short of installing electric wire). This was in the Bitterroot Valley of western Montana, though—probably not much of a problem for most

readers."

HARVESTING THE HONEY

Beekeepers usually have 1 big annual extraction. This involves taking the honey-filled supers from the hives and removing the frames. Slice the tops off the wax chambers in the comb of those frames. Then, using an extractor, force the honey from the insides of those storage chambers by centrifugal force—or cut and package the comb directly for comb honey. Extracted honey must then be strained—and bottled and marketed if you plan to sell it. If you've already made the acquaintance of a commercial operator, she or he may be willing to extract and strain your honey for you for a reasonable fee. Then either return the emptied comb in its frame back to the bees, or give the bees fresh foundation on the frame on which to build new comb.

When to Harvest?

Harvesting takes place in the fall when the crop is taken off and packed. All those pounds of honey have to be removed from the hives. That means carried away in the supers in which they've been stored by the industrious bees. Professionals wait to harvest until the major nectar flow is over. That's when the flowers are mostly gone—about August. You can begin as early as late June or as late as mid-September. But too late a harvest risks leaving the bees with too little honey since they have less time to replenish their stores.

How Much Honey to Take?

An average-sized family can use about 5 gal. of honey a year. Our large one uses about 10. To harvest that amount of honey, a family needs 2 or 3 hives. But don't take that much (or any at all) unless you can leave the bees with enough honey—60–100 lb. per colony, depending on how long and cold your winters are—to survive until the next flowering season. *Bees can gather food only when there are flowers. The rest of the time they must live on their stored food.*

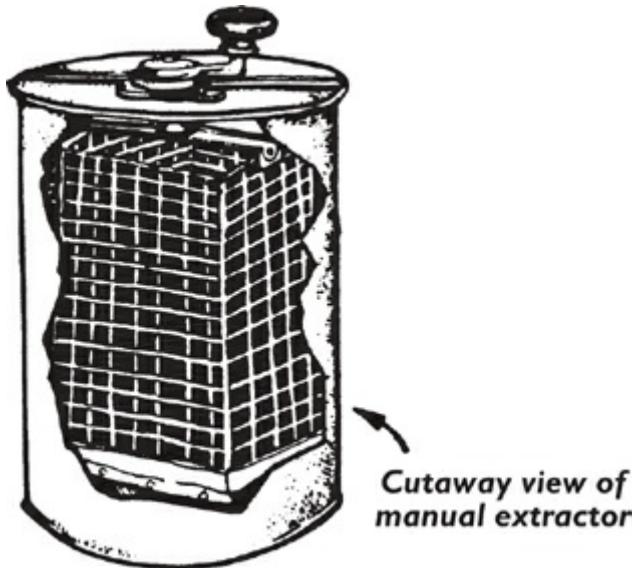

COMB HONEY: You can eat your harvest right out of the frame, in the comb, just as the bees made it. The wax is fine to eat—not really food for humans, but not harmful to eat. You can spread comb honey like any thick spread. Eating comb honey avoids the expense and struggle of the extraction process. All you need to eat your harvest comb honey is a sharp knife to cut blocks of it out of the frame. If you want to learn more about producing this gourmet market item, read Richard Taylor's *The New Comb Honey Book* (1982). To preserve honey in the comb, save your nicest combs with the caps on, stand them edgewise in a crock or metal can, and cover with extracted honey. For commercial sale of comb honey, beekeepers used to put little wooden square boxes into the hive instead of regular frames. The boxes for comb honey were made out of basswood because it bent easily. But that sort of comb honey is seldom sold any more.

UNCAPPING THE COMB: The beekeeper's equipment probably consists of an electric knife to uncap one side of the frames, or else a hollow knife with steam run through it so the knife is hot. Either one slices the caps off the honey cells very nicely and easily. You can mail-order an electric knife from your beekeepers' supplier that is perfect for that uncapping. Keep the frames in a warm room before extracting so the honey will flow out easier when the centrifugal force is applied.

PROCESSING CAPS. I watched an expert beekeeper do this. He had a special vat for the slicings to fall into. They are valuable as beeswax as well as for the bit of honey still

clinging. Heated coils help separate the slicings in the vat from the honey sticking to it. A little stream of melted wax comes out one side and the honey comes out the other. That is the only wax a professional beekeeper harvests—just the caps. He keeps the rest for the bees to use again.

MACHINE EXTRACTING: Then the beekeeper put the entire uncapped frame into the extractor. The commercial extractor is a big round drum that will hold 30–140 frames at once. (I've also seen a small manual style that holds just 3.) The uncapped frames are set into holders inside the extractor, their uncapped side facing the outside of the extractor. Then the extractor is made to whirl them around very fast, which causes the honey to flow out by centrifugal force (the force flings it against the wall of the drum). It flows down the wall and is collected at the bottom, being piped directly to a big holding tank. Smaller versions of an extractor can be bought through the Root Catalog, among others, but you don't have to have one.

HAND EXTRACTING: I have heard of squeezing honey out from the wax by hand, but that is an awful waste of drawn comb. A better system is to cut off the tops of the honey cells, and hang the frames up over a heat source like a wood stove. The honey will melt and drip down. Have something under there to catch it, of course. You have to do one side of the frame, and then the other. Or make a Rube Goldberg contraption with an electric drill top and a “barrel” bottom that will grip and spin your uncapped frame.

If you need the wax for candle-making anyway, the easiest method of all to get honey without an extractor is to melt the whole thing down together. Just make sure you use frames that are clean and don't have baby bees in them—they'll mess up the taste of the honey. You need frames that are solid honey. Leave the frames with some baby bees in them to feed the bees in winter. Cut the honey, comb and all, into chunks in a great big stainless steel fry pan. Melt it. Skim the whitish wax off the top and strain it into a separate pan. Strain the rest of the honey through a cloth set over a deep pan. Pour that strained honey into quart jars. You can let the honey with all the wax in it cool until the wax rises to the top. Then you can easily take it off. The honey that was with the wax can be reheated and poured into another jar. It's all that simple.

NOTE: Don't heat honey in an iron kettle. That will cause it to darken.

WAX IN THE HONEY: If the honey looks messy, heat and strain it. It wouldn't hurt you a bit to eat wax, but there are better things to do with it. Melt the honey-wax mixture in a double

boiler over gentle heat. Take off the scum with a skimmer as it appears. You can sell the wax, make new foundation with it, or make candles. Pour your now wax-free honey into widemouthed jars and seal.

CLEANING BEESWAX FOR CANDLES: Beekeepers sell unfiltered wax for \$1–2/lb. You can get it by the 10-lb. chunk. Or prepare your own. To make candles out of beeswax that has come fresh from the hives, a good way to do the first step of cleaning is to place it in a box on top of a beehive. The bees will promptly come and within a day they'll have every last speck of honey cleaned off it and carried back into the hive. But don't leave it there after the bees have it cleaned off because then wild animals will carry it off. Take it back in the house and finish cleaning it by melting and straining the wax. The very best filter for beeswax is sweatshirt material. Cheesecloth is much too porous. In factories they force it through canvas under great pressure, but sweatshirt material is better. Wrap the filter around the beeswax; as the melted wax drips down, the impurities are left behind. Beeswax melts at 130°F. A very gentle heating can be accomplished in a solar wax melter.

Here's another system to clean and lighten your wax if it's dark and dirty looking: Add a little cider vinegar to the wax and some water and hold it at 135–140°F for 2 or 3 days, if possible. The dirt settles to the bottom, and the honey collects in a layer just below the wax, which floats on top.

Storing Honey

Honey keeps easily—better than just about anything else. It doesn't need to be frozen, canned, or even refrigerated. It keeps just fine in glass, plastic, pottery, or metal, inside or outside. Don't refrigerate honey because that hastens the granulation process, and, unlike many other foods, it doesn't need to be kept cool. But store where it won't get warmer than 75°F since above that temperature it may lose flavor and color (the higher above 75°F, the faster the change).

A wide-topped container that you can scoop out of is handier than a 5-gal. can with a 2-inch opening. If the contents of a narrow-necked container crystallize, you have to melt the whole supply every time you need a quart—and each time you heat it up you may lose nutrition and flavor. Honey that isn't frozen will crystallize, eventually. And a 5-gal. can of honey weighs 60 lb. and thus is too heavy to accomplish much with easily. Best of all, pack your honey in widemouthed 1-gal. jars. Then keep a quart container of honey in your kitchen for current use. And keep your kitchen honey in a fairly warm place. Chilly, stiff honey won't mix with other ingredients very easily.

CRYSTALLIZED (“GRANULATED”) HONEY: Any liquid honey may crystallize into a stiff, whitish texture if stored in a cool place. Sometimes this happens after only a week or so, sometimes after several months. This process is called “granulating” and is normal. It doesn't harm your honey a bit. It doesn't change it at all, once you've remelted it. Or you can use crystallized honey as is. It won't affect your recipe, except in that you've added a bit less liquid.

Re-Liquefying Crystallized Honey. When my honey in the can gets sugary on top, I just put the can on the back of the wood stove or on very low heat on the electric stove, and the sugars will go back into solution as fast as it warms: 130°F (water no hotter than you can bear your hand in) is a perfect temperature for the job. You can warm a quart jar of honey in a double boiler. Honey in a glass container can be reliquefied in a microwave oven. (Remove the cover first! Then cook on high 30 seconds or until clear.) No matter what your method is, be careful not to overheat. *Don't boil the honey because that ruins the*

delicate flavor. Just keep it at about 130°F until it reliquefies—it may take hours, or days, depending on how much honey you're working with.

Storing it in a warmer place will help avoid a repeat. Unlike most food storage, storing honey at a warm temperature, in a closed bottle, does not result in any loss of flavor.

OTHER BEE PRODUCTS: Pollen, propolis, beeswax, and royal jelly can also be sold. Propolis is the resinous substance bees use to fill holes and gaps in the hive. It takes a lot of work to produce royal jelly, and there isn't much market for it. Beeswax sells well, but you need many hives to produce much.

Using Honey

NOTE: Don't feed your baby honey. Botulism spores can be in it. These don't harm adults when directly eaten, but in the intestines of infants under 1 year of age—especially under 6 months of age—they can grow. This was discovered in 1976 and is now thought to account for at least some cases of Sudden Infant Death Syndrome. Keep these small babies out of soil (where botulism spores are) in general.

HONEY AT THE TABLE: Get 2 small syrup pitchers. Fill one with honey and one with molasses or sorghum. If you grow it, or can afford it, you could keep a third with real maple syrup in it. Keep the honey pitcher in a warm spot in your kitchen—over the pilot light or on the warming shelf of your wood stove. Serve both pitchers whenever needed at your meals. Honey complements the taste of any herb tea just perfectly, helping to bring out the flavor. Basically, you can use honey anywhere you can use sugar: to sweeten any beverage (tea, coffee, warm milk), stirred into plain yogurt, dribbled onto cold or warm cereal, mixed with margarine or butter, or blended with any nut butter to make a spread.

COOKING WITH HONEY: Honey has been around longer than refined sugar. Honey is composed of simple sugars, mainly fructose and glucose. Plain white sugar adds sweetness to a recipe, but honey adds flavor as well as sweetness. The sweet taste of honey tends to be more concentrated than that of sugar, so you can substitute $\frac{2}{3}$ – $\frac{3}{4}$ c. honey for any 1 c. sugar and end up with it equally sweet-tasting. You can substitute honey for sugar in any recipe, but because honey is a liquid you then decrease the liquid in the recipe by 2–3 T. per $\frac{3}{4}$ c. honey, or by $\frac{1}{4}$ c. per 1 c. honey. Honey is easiest to measure if your measuring container has first held the oil or other fat for the recipe, or if you first coat the spoon or cup with oil (or with nonstick pan-coating spray). Then the honey won't stick in the measuring container and you'll be able to get it all back out easily. Combine honey with other liquids in the recipe.

PRESERVING WITH HONEY

Freezing Fruit with Honey. Don't make a heavy syrup. Use 1 c. honey to 2 c. water. That will give you what the recipes call a "medium" syrup. For a "thin" or "light" syrup, use 1 c. honey with 3 c. water. Then allow $\frac{3}{4}$ –1 c. syrup per 1-qt. freezer container. Measure your syrup into the container. Slice fruit directly into it and freeze. You won't need any ascorbic acid when you freeze fruit in honey syrup. The syrup itself will prevent the fruit from changing color. Add a crumpled piece of freezer paper to keep the fruit forced down under the syrup. Peaches and strawberries are especially good this way.

⇒ **HONEY FRUIT JAM** To make Doris's gooseberry jam combine 3 c. green gooseberries and 2 c. clover honey. Cook slowly until mixture jellies on a cold dish. Put in jars and seal. This is simple and very good, and you can apply the same principle to other fruits.

⇒ **UNCOOKED BERRY-HONEY JAM** Mash fresh berries (raspberries or strawberries are very good in this). Put the mashed berries in a blender with a package of pectin and blend. Taste. Now add as much honey as you think it needs to be sweet enough, and blend again. You can make only a little bit of this at a time because blenders don't hold much. Store it in the refrigerator.

⇒ **LEMON-HONEY JELLY** From Nanci Falley, Lockhart, TX: Combine $\frac{3}{4}$ c. lemon juice and 2½ c. honey. Bring to a full rolling boil. Add $\frac{1}{2}$ c. liquid fruit pectin, stir vigorously, and boil about 2 minutes. Pour into hot sterilized jars and seal.

Canning with Honey. Honey can be used as the sweetening agent in canning, jelly-making, and other preserving. Since different types of honey vary in darkness, so do honey syrups, but they're invariably at least somewhat darker than a sugar syrup. This darker syrup will tend to darken light-colored fruits like pears and peaches. But the flavor will be delicious, so don't worry about the color. Honey syrups, compared to sugar syrups, have more of a tendency to foam when heated; use a larger kettle and watch it carefully to avoid boil-overs.

⇒ **HONEY SYRUP FOR CANNING** When canning apples, tart cherries, plums, and strawberries, try 2 c. of honey per 3½ c. water. For syrup over blueberries, black cherries, peaches, pineapples, and raspberries, try 1 c. honey per 2–3 c. water. These proportions can be experimented with and varied according to your personal taste and need. It is entirely up to you how much or little honey you use. You can use plain water or pure honey or anything in between. The canning process and times are the same no matter what the type and amount of sweetener.

Prepare your fruit for canning. Place it in a pan, cover with the syrup, and heat thoroughly. Put into prepared jars, filling to within $\frac{1}{2}$ inch of the top. Put on lids, tighten them, and process in a boiling water bath the appropriate amount of time for your size of jar and type of fruit.

⇒ **HONEY-FRUIT JELLY** Combine 2 c. high-or medium-pectin fruit juice, $\frac{1}{2}$ c. mild-flavored honey, and 2 t. lemon juice. Bring to a boil and stir in all at once 2 T. powdered pectin. Let boil 10 minutes, and pour into your jelly glasses. For low-pectin fruit juices, use 4 t. lemon juice and 3 T. powdered pectin. If you want to use homemade pectin, substitute 2 c. homemade pectin for both the lemon juice and powdered pectin.

BAKING WITH HONEY: Marilyn Gordon and her husband raise and sell honey at Boone, CO. She wrote to me: "To substitute honey for sugar in a baking recipe use $\frac{3}{4}$ c. honey for 1 c. sugar and reduce liquid in the recipe by $\frac{1}{4}$ c.—like in cakes. If liquid isn't called for in your recipe, add 4 T. additional flour for each $\frac{3}{4}$ c. honey used in cookies. Bake at a temperature 25 degrees lower than called for, as baked goods with honey will brown faster. Cakes, cookies, and breads will be moist and stay fresh longer because of honey's moistness."

Honey is acidic. If there is as much as 1 c. of honey in the recipe, you can add $\frac{1}{2}$ t. baking soda (per 1 c. honey) and get a leavening action as well as neutralize the acidic quality.

These next few recipes were presented to me by Shawna Marie Thurman, 1988 Montana Honey Queen, courtesy of Western Bee Supplies.

⇒ **BEEHIVES** In a mixing bowl combine $\frac{1}{4}$ c. honey, 1 beaten egg, and 1 t. vanilla. Beat until well blended. Stir together 2 c. shredded coconut, 1 c. chopped walnuts, and 1 c. chopped dates that have been coated with 2 T. of flour. Now add them to the honey mixture. Drop your beehives by tablespoonful onto a greased cookie sheet. Bake at 325°F for 12 minutes or until

done.

➲ **HONEY-APPLESAUCE COOKIES** *Cream together 1½ c. honey and 1 c. shortening. Add 2 beaten eggs and beat mixture until smooth. Add 2 t. soda to 2 c. applesauce. Sift in 2 t. cinnamon, 1 t. nutmeg, 1 t. salt, and 3½ c. flour. Stir in 2 c. quick-cooking oats (or rolled wheat), 2 c. raisins, and 1 c. walnuts. Drop on cookie sheet with a spoon. Bake at 325°F for 10 minutes.*

➲ **HONEY-FUDGE BROWNIES** *In a saucepan over low heat, melt together ½ c. butter, 2 squares unsweetened chocolate, ½ t. salt, and 1 t. vanilla. Mix well. Remove from heat. Blend in 1 c. honey, ½ c. unsifted flour, and 1 t. baking powder. Add 2 well-beaten eggs. Beat the mixture well. Pour into a thoroughly greased 9-inch-square pan. Bake at 325°F for 35 minutes (or until done in center). Cool on wire rack 15 minutes before marking in 16 squares.*

OTHER HONEY RECIPES

➲ **CARAMEL CORN** *Combine ½ c. honey with ¾ c. brown sugar and 2 T. margarine. Heat until sugar is melted and bubbling around edges. Pour over large bowl full of popped, salted popcorn, and mix well.*

➲ **STRETCHED HONEY** *You can stretch your honey by mixing 1 c. honey with ½ c. sugar and ¼ c. water. Heat and mix together. Serve warm. Stretch it even further, if need be, by combining ½ c. water and 1 c. brown sugar per 1 c. honey.*

➲ **HONEY SYRUP** *To use straight honey for syrup, warm in a pan of hot water before serving so it will pour easily, or else mix with about one-fifth water. A honey-butter syrup for immediate use can be made by melting about 3 T. butter per ½ c. honey. Serve while hot, and stir when necessary to redistribute butter, which will tend to float. Or swirl before each pouring to mix.*

➲ **HONEY LEMONADE** *Stir ½ c. honey into a quart of very hot water. Add fresh lemon juice (from about 4 lemons) or some form of lemon juice concentrate, to taste. Serve warm for a wonderful winter treat, or chill to serve in the hot summertime.*

➲ **HONEY-CREAM SAUCE** *Whip ½ c. cream, then beat in ½ c. honey and 1 t. lemon juice.*

➲ **ORANGE SAUCE** *Combine ½ c. butter, ⅔ c. honey, 1 T. orange juice, and 1 t. grated orange rind.*

➲ **HONEY TEA** *A bee man taught me this one. Put water on to boil. When it's boiling, add 3 t. honey per 4 c. water and boil a few minutes more until thoroughly in solution. Add tea leaves to make tea. Steep, strain, and serve. For iced honey tea, make as above, then chill.*

➲ **HONEY DRESSING FOR FRUIT SALAD** *Combine half honey and half lemon juice. Add a bit of yogurt and some cinnamon. Store, covered, in the refrigerator.*

➲ **CRACKER JACKS MADE WITH HONEY** *From Marilyn: "Blend ½ c. melted butter with ½ c. honey. Heat until well blended. Pour over a mixture of 3 qt. popped corn and 1 c. chopped nuts. Mix well. Spread over cookie sheet in thin layer. Bake in preheated 350°F oven for 10 to 15 minutes until crisp. Be careful, mixture is very hot."*

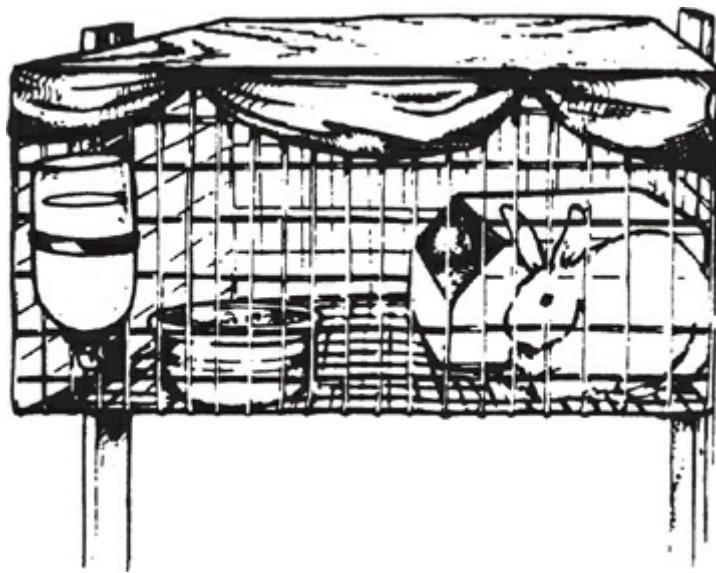

➲ **BROILED HONEY TOPPING** *Also from Marilyn: "Mix ¼ c. soft margarine or butter with ½ c. honey, ½ c. shredded coconut and ½ c. chopped walnuts. Spread over top of hot 9-inch-square cake. Broil until topping is bubbly. Tastes best served warm. Or heat ingredients in saucepan, thin with several spoonfuls of milk, and serve over ice cream or pudding."*

RABBIT

I'm used to living way out in the country, and that is where I went through my rabbit period and quickly raised 30 or so rabbits with no neighbor problems (it was the goats we had complaints about). But that was near a community of 300, and we had 3 acres. In town, even for just 1 rabbit, learn the zoning rules first. Usually, there's no problem keeping a few rabbits, but sometimes the law specifies how many or where the hutches must go. Of course, some folks keep illegal rabbits, even enough for meat or marketing breeding stock. Being small and silent—unique and wonderful in that way among livestock—rabbits are the easiest of all to hide.

I used to think rabbits were rodents like rats and mice, but now I know they belong to a different group of mammals. They are "lagomorphs." Whatever you call them, rabbits are lovable, docile, quiet, small animals. They make good pets or can be raised for meat. They are so gentle even a child can manage them, so unobtrusive that even a covert backyard farmer can raise them. So you can raise rabbits almost anywhere: in town or country, in backyard or garage, in a house—even in an apartment!

Rabbits, of course, are also famous for their reproductive abilities. Lane Morgan says, "My elder daughter wants a pair of bunnies so she can raise babies. I told her the only way we were raising lots of baby bunnies was if we were going to butcher them, so she is brooding over this hard bargain." Yes, that's how it has to be. If you're going to make rabbit part of your meat production—or if you're going to keep 1 or more for pets—here's what you need to know.

Getting Started

MAGAZINES: *Domestic Rabbits* comes out 6 times a year from the American Rabbit Breeders Association, PO Box 5667, Bloomington, IL 61702; www.arba.net. The magazine, *Standard of Perfection*, and breed guidelines are available to members—\$15/yr for adults, \$8 youth. Send \$2 for their beginner's booklet, \$5 for their rabbit cookbook, or \$1 for a bumper sticker "Get into the Rabbit Habit." It's a good place to find local rabbit clubs, rabbit products, and basic breeder stock.

BOOKS: Check out *Rabbit Feeding and Production* by Peter Cheeke (1987), *Rabbit Production* by Peter Choate (1987), *Raising Rabbits Successfully* by Robert Bennett (1984), *Practical Rabbit-Keeping* by Katie Thear (1981), *The American Rabbit Breeders Association Official Guide to Raising Better Rabbits, Rabbits and Hares* by Robert Whitehead, *Rabbits: A Complete*

Pet Owner's Manual by Helga Fritzsche, and *The Book of the Domestic Rabbit* by Carl Naether. Older classics in this field include *How to Start a Commercial Rabbitry* by Paul Mannell, *Domestic Rabbit Production* by George Templeton (1968), and *Raising Rabbits* by Ann Kanable (1977). *Raising Small Meat Animals* by Victor M. Giammattel, D.V.M. (1976) has a terrific rabbit section.

RABBITRY SUPPLIERS

Bass Equipment offers the “world’s most complete line of rabbit and small stock equipment”: PO Box 352, Monett, MO 65708; 417-235-7557; fax 417-235-4312; www.bassequipment.com.

Care Zap's It sells an Odor Digester and rabbit care products; send long SASE for brochure: 11727 Leader, Houston, TX 77072; 800-835-9501; www.carelabs.com.

VOCABULARY

Buck: male

Bunny: a baby rabbit, also called a “kit”

Crib: to chew on a wooden cage

Doe: female

Droppings: rabbit feces

Hutch: a rabbit cage

Kindle: to give birth

Junior: young rabbit of either sex

Rabbitry: where your rabbits live

Run: group housing of a “natural” sort

Senior: an adult

BUYING STARTER STOCK

Finding Rabbit Breeders. You could probably arrange to buy your first rabbits from someone exhibiting at the fair, or ask advice of the fair superintendent or extension agent. They may know of rabbitries close enough to visit. In addition, good places to inquire are the local newspaper’s stock-for-sale section, especially if you live in a rural area, and the local feed stores. Look over the feed store bulletin board and ask the clerk for advice. Because most rabbit owners buy feed and/or vet supplies, feed store clerks know who has what—and also have an idea how well cared for the animals are.

Get Good Stock. No matter whether you’re buying papered or mixed-breed stock, get healthy animals—the best ones you can afford. You’ll have a better idea which ones are best cared for and the best stock after visiting several rabbitries. Be cautious, even suspicious. A good rabbitry is clean. The animals look alert and happy—not listless and droopy. Ask what the rabbits are being fed and about other aspects of their care. A good match would be a rabbitry where the animals are fed and managed very like you intend to do.

Try to catch any problem before you put your money down. It’s normal for the rabbit owner to want to unload a cull rather than the best rabbit. Why a cull and how bad a problem are your questions to answer. And all are not necessarily problems; a discard from a classy operation could be a great start-up animal for you. On the other hand, that cull might have a truly unfortunate condition such as a disease or bad genes that could doom your operation.

What to Start With. The minimal option is a single rabbit for a pet or a single bred female to start your rabbitry. You can go from that one pregnant doe to having enough

rabbit for dinner every day and some to sell within 6 months. Rabbits are famous reproducers. But most people choose to start with more than 1, such as 2 bred does and the mature buck that bred them. These rabbits know what to do. Or choose a mature buck and pregnant doe, plus a junior buck and doe. This protects in case of failure by the older rabbits who may have been sold because they were close to stopping reproduction. Or get just a buck and a pair of does, all fairly young. Your trio will probably be plenty to start your own rabbitry.

Changing a Rabbit's Diet. Most livestock arriving new at your home will make the transition better if they don't have a sudden change in diet. Before you take them home, ask the previous owner what the rabbits have been fed, what feeding schedule, and how much of it. Ask the previous owner to sell you enough feed to help them make an easy transition, gradually switching from old to new if you will be feeding them differently.

You change a rabbit's diet by adding a little larger part of new feed and a proportionately smaller part of the old every day until the changeover is fully accomplished. Check their feed container to make sure they're eating the new rations okay. They may refuse a new food. Rabbits can be picky and opinionated. And going from an all-pellet diet to a home-grown one, for example, is a big transition; give it several weeks.

Quarantine. Any time you bring new animals onto your farm, it's a good idea to quarantine them away from other animals of their kind for 2 weeks or so. You may never run into a problem of a new animal getting sick. But if you do, you'll be glad you didn't let the other animals get it.

Rabbit Breeds

A good way to start getting acquainted with your many choices in rabbit breeds is by attending the rabbit exhibit at your county fair. It will be with poultry and other small stock. For a pet, pick any breed that catches your eye. Basically, a rabbit is a rabbit, but for anything beyond a few pets, you'll want to choose your breed carefully.

You have 5 things to consider: (1) Commercial meat breed with good food-to-flesh growth conversion ability and fast growth—or a noncommercial “fancy” breed? (2) Color? The Harlequin is a “calico.” The chinchilla has a “ticked” fur. Many other rabbits come in 1 or more solid colors, such as the white, red, or black New Zealands. (3) Pelt type—long or short fur? Angoras have long, fluffy hair. Rex have a short, velvety fur. And you can find almost anything in between. (4) Size—dwarf, medium, or giant? (5) What appeals to you personally?

OF RABBITS AND PEDIGREES: “Mixed breed stock” may look like some breed or other, may be in fact purebred, but without the paper proof they aren’t “pedigreed” or “registered.” There are 45 recognized rabbit breeds. One listing of rabbit breeds is the *Official Guide Book of the American Rabbit Breeders Association*, free if you join the ARBA. The registering of rabbits has some unusual rules. It isn’t good enough just to have the pedigreed parents and grandparents, and to be a member of ARBA. In order to be registered, the animal must also be an adult. Babies or young rabbits cannot be registered. And rabbits can’t be registered through the mail. They have to have an inspection by an ARBA representative, a “registrar.” The registrar checks your rabbit for physical defects and to see if it measures up to breed standards.

MEAT BREEDS: Rabbits produce more meat for less feed than any other livestock. And rabbit is the leanest land-grown meat. There are only 2 solidly commercial rabbit breeds, the

New Zealand White and the California. Those have the best meat-to-bone ratio, good pelts, and have been selected for fast, efficient growth. New Zealand Whites and Californians both make white pelts (Californians have black spots on their ears, feet, nose, and tail, but they don't show up on the pelt proper). Commercial breeds are white because fur-market buyers prefer white skins—they take a dye. Other meat breeds are Champagne d'Argent, Chinchillas, New Zealand Reds and Blacks, and Satins. Commercial meat rabbits are available from Aspen Hill Farms, Box 753 Anderson Rd., Boyne City, MI 49712; 231-582-6790.

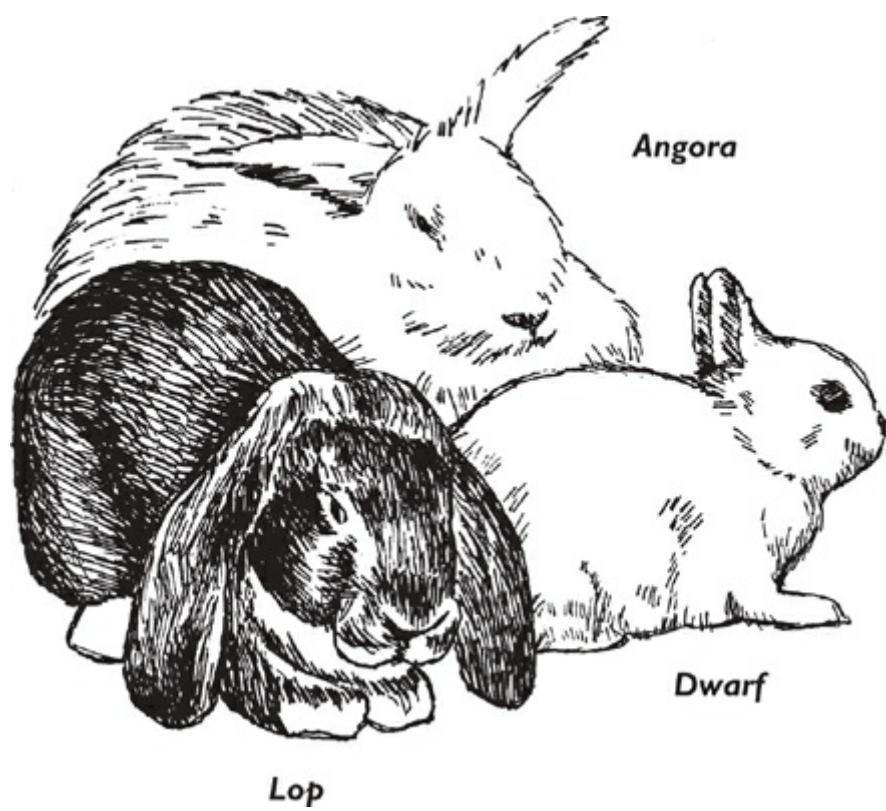

RABBIT SIZES

Dwarf. "Dwarf" rabbits usually have fairly short ears and a stocky build, and grow to weigh only 3 or 4 lb. You could raise a dwarf breed and get meat from them, but there isn't much meat on one, and their feed-to-flesh conversion ratio isn't as good as the standard meat breeds. There are some breeds that have always been small. Others are small versions of some medium-sized breeds, such as the dwarf lops. Popular dwarf breeds are Dutch, Himalayan, Netherlands Dwarf, and Polish.

Moderate-Sized. The 2 commercial breeds described above, as well as Angoras and many of the so-called "fancy" breeds, all weigh from 6 lb. to 10 lb. as adults. That's average "moderate" rabbit weight, with the dwarf breeds coming in lighter and the giants heavier. Other medium-sized breeds are the Angoras, Champagne (and Creme) d'Argent, Chinchillas, English Spot, Harlequin, the various lops (they have long, flopped-down ears), Rex, and Satins.

Giant. I used to believe that the best kinds for meat were any of the giant varieties: Checkered Giant, Flemish Giant (up to 14 lb.), and Giant Chinchillas (the chinchilla rabbit coat plus giant size). But I've since learned that others make far better use of feed to make meat. Giants are relatively big when they're born and, like any rabbit, grow up fast. With luck, a breed like Flemish Giants might butcher out to a 3-lb. carcass at 10 weeks. If you wait and keep feeding, shortly later they'll make a 5-lb. carcass. They are impressive looking. You can get Flemish Giants in various colors. Checkered Giants are a little smaller with a distinctive black-and-white spotted coat.

SHOW BREEDS: How people tend to run after anything they think is new or will make them quick and easy money! In the rabbit field, the Belgian "hare" (actually a true rabbit) was a fad that made early investors profit but caused latecomers to the buying spree heavy losses. They are long and lanky in build, not good meat animals. The Belgian hare is a perfect example of a "fancy" breed show rabbit. These breeds, of course, are fine pets and enable their owners to play the win-a-ribbon game. That's good clean fun but not what this book is about.

Angora

Dwarf

Lop

ANGORAS, THE WOOL BREED: “Angora wool” comes from Angora rabbits. You pull it off them just as they pull it off themselves to make wonderful nests to have babies in. It’s fine for spinning or stuffing, but it takes a lot of rabbits to accumulate enough fiber to work with. They are cute, cuddly things but must be plucked or brushed out to get wool for spinning. You can’t shear them like a sheep. Plucking is work. Whether you have a use or a market for their wool or not, you still have to keep them brushed for the sake of their health and cleanliness.

Angoras are not a good choice if you live in a hot climate. They suffer in heat. The cage of an angora is harder to keep clean because of the tendency of their sheddings to build up on the cage floor, blocking feces from falling through the wire and trapping urine in the cage. So you have to watch angoras carefully for any signs of hutch burn or skin diseases. They’re more likely to get these than regular rabbits, and beginning skin problems are harder to detect under all that fur. Water your angoras from a sipper bottle because they soak their neck fur when drinking from a more open container. When butchering them, you must take care to keep their long hair off the meat.

ABUNDance Acres Fiber Farm offers both French and Giant Angoras, plus black-and-blue Giants: 9713 Crystal Falls Dr., Hagerstown, MD 21740; 240-566-0627; abundance.acres@myactv.net; www.abundantfibers.com.

Housing

NOTE: Plan rabbit housing to protect against heat and predators.

OF RABBITS AND HEAT: An important thing to know about rabbits is that they can’t stand heat. Too much will kill them. Rabbits like some sunlight as long as they don’t get too hot. If you get into terribly hot “dog days” in July or August, take your hose and soak the roof of the rabbit hutch a couple times each afternoon. During the hottest weather, make sure your rabbits always have plenty of water, but feed them only a little during the day, mostly at night. It will help if you set the hutch under a big tree or where a large building will shade it from afternoon sunlight. If you haven’t taken these precautions against overheating, you can lose a batch of very nice rabbits real fast. When they die of heat, they look fine in the morning and in the evening when you look again, they are dead. I’ve had that happen to me.

PREDATOR PROTECTION: The biggest danger to your rabbits, however, is not temperature or disease, but predators. Rabbits have long done service fairly low on the food chain, and the predators around you instinctively know that. You have to consciously and carefully and diligently protect your rabbits from carnivores, whether you live in town or country. Predator protection starts with the good fence around the place where your hutches are, whether yard, garage, or outbuilding.

The common predators are dogs and cats, both wild and tame, as well as big birds of prey, coyotes, and wildcats. Wandering dogs may actually rip at cages trying to get a rabbit, or bite the feet of young bunnies if they step through the rabbit wire flooring the cage. Dogs have even managed to bite through wire net and kill a rabbit. Even if they can’t get at a rabbit in a well-built cage, the scare from the dog trying could cause a doe to kill her babies. Children have to be viewed as possible predators, too. Like the dog, they may upset a new mother and cause cannibalism, or leave a cage door open, or feed a poisonous plant.

HOUSE RABBITS: Rabbits can be litter-box trained! Rabbits have dwelt in houses, apartments, condos—even (secretly, of course) in college dorms. Some house rabbits are kept caged.

Others run free, at least in 1 room—when not confined to a paper-lined cage/house on the deck or some such. The biggest problem with house rabbits is that you have to be careful about taking them outdoors, since they're accustomed to house temperature and comfort. They are more likely to get sick if moved outdoors than an outdoor-raised rabbit would be. To housebreak, just keep papers down where you want the rabbit to potty. The first time, it helps to demonstrate by putting some rabbit feces and urine on the paper. Your rabbit has an instinct to use the same place over and over as its toilet.

RABBIT RUNS: I got a letter from a lady who has about 80 rabbits living in her garage. The garage has a dirt floor. That living arrangement is called a “rabbit run.” Most rabbit runs include an outside, fenced area. Advantages of a rabbit run are low stress, potentially less feeding, better meat because of exercise, better pelts from colder air, and healthier rabbits in that fresh-air environment. The very natural setting for the rabbits reduces their stress. They need less feed because they will eat some grass or whatever good forage is growing in their area. The disadvantages are that they're harder to catch, less likely to act like pets, and harder to keep breeding records on.

Rabbits are communal by nature and not inclined to fight much. People have had up to 100 of them in this arrangement without losing more than 2 or 3 to fights. The letter-writer said most of her does run loose on the floor, and each time they kindle they get a burrow in the dirt ready. Her system of raising the rabbits in an enclosed building is one sort of rabbit run. This housing plan has been around since the time of the ancient Romans, who kept rabbits in walled gardens, and the long-ago Chinese, who kept rabbits in grassy, fenced areas. How high a wall? Might surprise you. Rabbits can sometimes jump a 3-foot fence if they take the notion, so a 4-, 5-, or even 6-foot fence would be better.

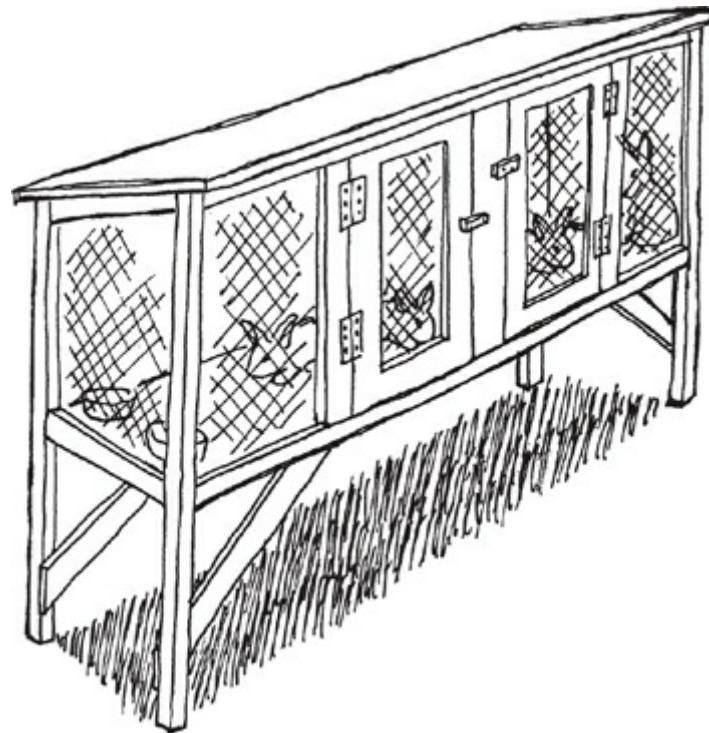

The top can be either open or roofed. Rabbits in the open will become alert to predatory birds and develop places to hide. Or you can put a roof on. One modern variation is a fenced pit with loose hay for bedding and a plastic roof overhead to keep off rain. A variation on this system has breeding stock in cages only a foot above ground level, and the weaned offspring of the caged does running about in the fenced compound below. Besides a wall or fence that goes enough below ground level that rabbits won't burrow under, you need a door to get yourself in and out, and water, food, and bedding for the rabbits. To catch rabbits in a run, regularly feed them in the same corner. Then when you want to catch them, have somebody hold a solid gate across from side to side of the corner behind them. Inside that small space it will be easy to catch rabbits.

Flooring for Rabbit Runs. The rabbits will be happy in any building if you don't mind the floor being covered with manure. You can keep them in a floor run or in wood hutches, or metal cages in a garage, shed, or any outbuilding. A very good floor management system is to place plenty of organic bedding such as straw under the cages to collect the urine for your garden. Once in a while you'll have to shovel out that soiled bedding. If the floor is cement, you can then wash it after shoveling out. Rabbit hutches on wood floors eventually rot the floor. You can delay that by laying heavy plastic over the floor. Extend it so the plastic goes up part way on the side walls. But better flooring for rabbits in or out of cages is dry dirt. Or best of all, put them on pasture!

Portable Pasture Runs. This may well be the ideal way to manage rabbits in any season when you have green things growing. The cage looks like a long A-frame. It has a solid wooden shelter at one end to protect from bad weather. The remaining sides are wire and let in sunshine, which, incidentally, rabbits need to be healthy. There is no floor to the cage. You place it over the green growing stuff, the day's grazing for your bunnies. This way you won't need to feed them as much other food.

RABBITS IN CAGES: Cages can be made of wood or wire. They can be single or built as units in a row, 2 or any number more. Multiple wooden cages are easy to build, but you'd better make them where they're going to stay because they're very difficult to move. No matter whether you're building with wood or wire, space needs and design features for rabbits are the same.

Cage Size. First decide how many rabbits you're going to keep and how large a breed they will be. (The housing, of course, should be prepared before the rabbits arrive.) In general, plan 1 square foot of floor space per lb. of rabbit that will be living there. The minimum though, even for a bachelor buck or pet is $2 \times 2\frac{1}{2}$ feet. Then figure out how your rabbits will be divided up into separate cages. A buck lives by himself and doesn't need as much room as a breeding doe, who will need space for a nesting box and her growing family. Your 9-lb. bunny would be content in a 3-foot square cage, but could you reach her? Don't make any cage so big that you can't reach every corner of it from the doorway with your arm. Otherwise you may be groping in vain for a reluctant bunny that has placed herself just out of your reach. Build either a narrow cage with a wide door, or a big roomy cage with a lid that lifts off when you need to get in there.

OUTDOOR HUTCH: Another housing option is a hutch out in the open. These cages are built solidly enough that they can stand alone outdoors and still keep the occupants warm enough in winter. If you have wood and a little inclination toward carpentering, a wooden hutch is easy to build. Wire hutches can actually be put together fairly easily too, once you get the hang of it. You can make a small hutch for a single occupant or construct multiple units. A good hutch style is a large, airy one set up on legs or posts so air can circulate easily under and around the hutch through its chicken-wire sides and bottom. But if your climate is cold, or during cold times of the year, you may want to protect the rabbits from bottom drafts by adding a wood or cardboard skirt surrounding the legs of the hutch. You could skirt only the sides and front or back, thus leaving one side open for cleaning manure out from under. In the coldest weather you could put a temporary skirt on that last side too.

Hutch Roofing. The hutch top can be made of wood covered with metal or asphalt roll

roofing or even sturdy plastic. Include overhanging eaves that extend far enough over the sides of the hutch to shelter your rabbits from excessive sun and all rain, including what might fall on the outside portion of feeders if you have the style that extends to the outside of the cage.

Hutch Sides. This depends on your climate or season. You can have wire all around, or a solid (wooden) back and wire at the sides and front, or solid 3 sides round and wire only at the front. The wire sides are usually made of 1-inch poultry netting ("chicken wire"). Chicken wire is not the sturdiest of wires. You'll have to check it regularly for tears (a determined rabbit can make a hole in it with its teeth). Also, keep in mind that wire ages. The older it gets, the weaker it gets.

Hutch Flooring. Wooden floors will be chewed on by rabbits, soak up urine, smell, and are considered not as healthy as wire. On the other hand, rabbits can be happy on them so long as they're in good repair and you provide plenty of clean bedding to go over the wood such as sawdust, straw, hay—and clean as needed. The floor will be hardware cloth or "rabbit wire" (½-inch mesh). Be careful when putting in the rabbit wire because it has a "right" and a "wrong" side. The wrong side has a galvanized coating that can develop sharp points that hurt even furry feet. Another problem with rabbit wire is that the holes are so small that droppings mixed with hair may not fall through. You could use wire with bigger holes to floor the cage. That decision depends in part on what breed you're raising—how big their feet are! Rabbits with small feet need bottom wire with smaller holes.

Most hutches have a wire floor so the droppings can just drop right on through. The wire keeps the cage clean of feces, but sometimes it's hard on rabbit feet (see "Vetting"). Galvanized wire, 1 × ½-inch, is usual for medium or dwarf breeds. For larger rabbits, use 1 × 1-inch, 14-gauge. In summer, clean out the hutch if the manure starts building up in it instead of falling through. In winter, the manure in an outdoor hutch may help keep the rabbit warm.

All-Wire Cages: Compared to wooden hutches, these are more exposed to the weather and so must be enclosed in a protective outer building. Other than that drawback, they last well and are easy to clean and to move about. You can buy them ready-made in various sizes, or make your own. Commercial rabbit feeders and water bottles attach easily to the wire.

An Enclosing Shelter for Wire Cages. Your rabbit building should be draft-free for warmth in winter and yet have the option of lots of ventilation for coolness in summer. You can put hutches into almost any kind of ramshackle shelter, and it will probably be good enough for these naturally fur-coated critters. For example, corner poles with cardboard and/or plastic fastened to make sides and roof can work for a while. Don't forget to leave a doorway. For a more proper hutch shelter, screen in the windows helps to keep flies out in the summer.

Water

Rabbits must be kept supplied with plentiful and clean water. Clean out the water dish regularly, for hair and droppings will get into it. It is important to keep it in a well-roofed place so that droppings from wild birds don't get into it—which could give your rabbits coccidiosis.

Hot Weather: Supply as much as 1 gal. of water per day for a cage containing a doe plus her family. The minimum size for a rabbit water dish for them is up to a half-gallon, and you fill it twice a day. In very hot weather, check their water twice a day also—or more

often. Heat is a big risk for rabbits, and having plenty to drink helps them stay cool.

COLD WEATHER: In the winter when their water freezes, go out twice a day with warm water to give them a chance for a drink. If their water dish is full of frozen water, you'll have to take it in the house to thaw first, or pour hot water on top to thaw it. The easiest system is to have 2 water containers for the hutch in freezing weather: 1 to be inside thawing, 1 to be outside serving water.

WATER CONTAINERS: A good size is 3½ inches deep and 6–8 inches wide. Hanging water bottles, like those pet stores use in gerbil cages, can work for a single, indoor rabbit. They are sanitary but have to be refilled often and can't be used for an outdoor hutch in winter because of the freezing risk. Rabbit water and food containers either must be too heavy for them to pick up and dump over (a favorite rabbit trick) or attached firmly to the cage. Crockery drinking vessels don't rust, are too heavy to be dumped, are easy to clean, and have sloping sides and a rounded bottom that causes ice to rise as it forms instead of staying put and breaking the container. Or you can use the bottom half of a coffee can, or some such, cut down with a tin snips and wired to the side of the hutch so it can't be tipped over. Another homemade waterer is a large pop bottle wired on to hang upside down with its opening in a small can that extends on into the cage. For big operations with hundreds of rabbits an automatic watering system saves hours of time.

Food

In the wild, rabbits eat a wide variety of plant foods, but there they have experienced parents to teach them "right" foods from "wrong" foods. Domesticated rabbits depend on their keepers to know the difference. Rabbits have been domesticated for many centuries. The pellet is a very recent invention. So obviously it's possible to raise rabbits on inexpensive, home-grown feed. This does not require great skill in math or an agricultural degree, nor does it take a lot of extra work. Some folks choose to follow the path of home-grown rabbit feed, and they and their rabbits thrive on it. They are rewarded with inexpensive meat, totally free of pesticide residues, which is something you can't get feeding pellets (unless somebody came out with an organic rabbit pellet since I last looked —a great idea that wouldn't be that difficult and would be enthusiastically and gratefully received as would other livestock feeds guaranteed to be free of pesticide-residue.)

FEEDERS: You can set hay right on the cage floor or build a "manger" to feed it from. Cages that are in a row can have a built-in common hay manger between each pair of cages. You can set pellets, grain, or other small food in as is or put it in a bowl. Or use commercial metal feeders. Some styles extend through the side of the cage so you can put feed in from outside the cage without having to open the door. You can make a homemade feeder from the bottom of a metal coffee can. Cut it down to where it's only about 2 inches high. Bend down the sharp top edge to make it smooth. Punch holes (from the inside toward the outside!) down through the bottom of the can if you are feeding pellets. The useless dust that comes along with pellet feed will sift out through those holes. Make 2 side holes to put a wire through and fasten the feed can to the side of the cage.

SECRETS OF RABBIT FEEDING

- Rabbits need a regular feeding schedule: same time each day, same number of

feedings per day, and same order in which various feeds are given. Most people feed them twice a day—in the morning and afternoon.

- Rabbits are physically unable to eat fine foods such as a powder or a finely ground “meal.”
- Cut hay-type feed with a hay knife or fine-toothed wood saw into sections no more than 3 inches long for rabbits.
- Rabbits don’t like oily foods. They may enjoy the meal left after oils are extracted —such as from cottonseed, linseed, peanuts, sesame seeds, and soybeans.
- Rabbits are exceptionally vulnerable to insecticide residues on food. Don’t feed them sprayed foods.
- Wash garden foods before feeding them to rabbits because an accumulation of eaten dirt can make a rabbit sick. Slice root vegetables into sticks like carrot sticks. Don’t feed soggy, rotten portions.
- Introduce any new feed—especially a garden one—gradually, by starting to feed a little, then feeding more and more.
- Don’t feed potato sprouts, eyes, or peels.
- Cow parsnip is as good nutritionally for rabbits as alfalfa and can be substituted for it.
- Fresh greens should be clean, cool, fresh but slightly air-dried, and normal colored —not yellowish.
- To store greens for winter rabbit feed: Pick or cut the greens, then sunshine-cure them in thin swaths 2–4 days. They’ll be ready when they’re sun-bleached (a light green color) and dry (but not yet brittle). Pack in stacks or sacks in a dry place.
- Eating spoiled—yellowish or fermented—greens can make rabbits very sick.
- A rabbit on a natural, home-grown diet needs some exposure to sunlight in order for its body to manufacture a needed vitamin.
- It is normal and necessary for rabbits to eat their own night feces. They do this in the late night and early morning hours. Their droppings at this time are different from day ones. They’re soft and light green, while day feces are harder and brown. The night feces are loaded with B vitamins, especially thiamin, which are produced by certain bacteria that live in large numbers in the rabbits’ intestinal tracts. Rabbits eat the night feces to get the vitamins in them. If you prevent a rabbit for 3 or 4 weeks from eating its night feces, it will die of malnutrition.

How MUCH FEED? Like dogs and people, rabbits vary in the way they relate to food. Some will take just what they need and just the right foods. Some will eat themselves to illness on a single food, or overeat to a state of obesity if you don’t limit them. Overweight does do have a harder time getting pregnant and have more risky kindlings. Obese bucks may lose interest in mating the does. So you need to keep an eye on their weight. How to tell if your rabbit has a weight problem? Well, the flesh should be firm anywhere on her except

the belly, which is naturally flabby no matter what. In fact, the more litters she's had, the more loose skin you can grab in your hand on the belly of a normal-weight doe. Younger does, like young human girls, are firmer in the belly area. The older doe who doesn't have some loose tummy skin is the one who needs to go on a diet. Reduce her food amount.

CONTROLLED FEED AMOUNTS: About the easiest way to keep rabbits in normal weight is to feed them hay, all they want. Rabbits very seldom overeat on hay. Then just give small, measured amounts of the richer foods, if wanted. Rabbit scientists say the average nonpregnant, nonlactating doe can eat 3.8 percent of her weight each day. For a 10-lb. nonbreeding bunny, that translates to a daily ration of 6 oz. pellets, or 2.5 oz. grain plus 3.5 oz. hay. Breeding bucks and does get 6.7 percent of their weight: 10.7 oz. pellets; or 3.5 oz. grain plus 7 oz. hay.

Pregnant and nursing does, as well as young bunnies, are generally allowed to eat all they want. The young rabbits maintain that good life at least until age 6 months (or until butchering weight of 4–4.5 lb.). If fed longer, they could weigh up to 10 lb. or so, but after 4 lb. they gain weight slower relative to feed consumption, so they're costing you more to keep.

PELLETS-ONLY DIET: I've heard that rabbits raised for meat will gain faster on a diet of rabbit pellets. The bulk of the pellet is a finely ground and pressed together mix of alfalfa hay and a blend of grains. Other minerals and vitamins are added. Pellets have many fans because of convenience. It makes feeding a 1-step operation—no guessing, no need to look around for various diet components and put them into the cage one by one. You can buy them "medicated" or "nonmedicated." But you still don't come out money-wise, because of the price of the pellets. Plain alfalfa pellets—which contain no grain—can be used to feed dry does and bucks that aren't breeding but not breeding males, pregnant or nursing does, or growing young rabbits. Feeding hay and grain is cheaper than feeding pellets, even if you don't grow any of it yourself.

HAY AND GRAIN DIET: A diet of mixed grains provides better nutrition than any single grain. Feed mixed grains (just what combination is up to you) for 30 percent of the rabbits' diet by weight. Oats, soft wheats, and grain sorghums are rabbit favorites among the grains. Protein is a small but extremely important necessity in a rabbit's diet. They can get some from grain and some from good legume hay, but they can't get any from nonlegume hay. Chopped grain is better than whole grain, but any grains may be fed whole except barley and oats, which should be rolled, mashed, or ground. Dry corn kernels should be also cracked or some such. Don't get it too small. And don't feed dirty, damp, or moldy grain.

RABBIT FOOD

Edible for Rabbits

Acacia: has no food value, but twigs can be entertainment

Alfalfa: fresh or hay

Apples: all parts

Barley

Beans and bean vines (not soybean)
Beets: both top and root of regular, sugar, or mangel
Bermuda grass
Blackberry bush leaves
Bluegrasses
Bread: dry, or soaked in milk
Buckwheat
Cabbage: some okay, too much causes health problems (goiter)
Canadian bluegrass
Carpet grass
Carrot: root and tops.
Cereals (if fat-free and fresh)
Cheeseweed (malva)
Chicories
Clovers: any but sweet clover
Coltsfoot
Corn
Cow parsnip
Crabgrass
Dandelion
Dogwood
Fescue: red, etc.
Filaree (stork's bill)
Grains: all types, unless dirty, damp, or moldy
Grapefruit: all parts (don't feed too much)
Grass/lawn clippings, grass grains: as long as they bear no insecticides
Hazelnut leaves
Jerusalem artichokes: tops, stems, or roots
Kale
Kentucky bluegrass
Knotgrass
Kohlrabi: all parts of plant okay to feed
Kudzu
Lettuce: all kinds
Lespedeza
Malva (cheeseweed)
Meadow fescue

Milk: fresh or sour, as well as milk products

Millet: foxtail and Japanese

Milo

Napier grass

Oats

Oranges: all parts (don't feed too much)

Orchard grass

Panicgrass

Parsnips

Peas and pea vines

Plantain

Poplar

Potato: but not peelings or sprouts or leaves

Prairie grass

Redtop grass

Rhodes grass

Root vegetables

Rye, rye grass, and Italian rye grass

Sheep sorrel

Sorghum grains

Sprouted grains

Sudan grass

Sumac

Sunflower leaves or seeds

Sweet potatoes: vines or tubers

Timothy

Turkey mullein

Turnips: all parts of plant

Vetch

Wheat

Willow

Not Good for Rabbits!

These range from deadly poisonous, to hard-on-a-bunny, to having no nutritional value.

Amaranth

Arrowgrass

Bracken fern

Bromweed
Buckeye
Burdock
Castor beans
Chinaberry
Chokecherry leaves or pits
Comfrey
Fireweed
Foxglove
Goldenrod
Hemlock, poison/water
Horehound
Jimson weed
Johnson grass
Larkspur
Laurel
Lima beans
Lupine
Mesquite
Milkweed
Miner's lettuce
Moldy bread: or moldy anything
Oak
Oleander
Pigweed
Poppy
Potato leaves, sprouts, or peels
Rhubarb leaves
Soybeans or soybean vines
Spinach
Sweet clover
Swiss chard
Tarweed
Tomato leaves

So feed good alfalfa hay for the remaining 70 percent. "Good" hay for rabbits is very

leafy, has thin stems, and is clean of mold or dirt. It will smell fresh. This kind of alfalfa hay, if analyzed, would show around 12–14 percent protein. To buy that kind of hay ask for “second-cutting alfalfa.” With some grain, or bread, or dairy products added, your rabbit’s protein needs will be met. You can serve it in its natural form except that it should be cut into sections less than 3 inches long.

Thus, when you go to the feed store, get a 70-lb. bale of alfalfa hay and 30 lb. of a combination of grains. Another option is the hay–grain diet, plus about 10–20 percent pellets. One lady I know feeds her rabbits ½ lb. of grain and 1 lb. of that legume hay each day.

HOME-GROWN RABBIT FOOD: The old-timers who wintered their rabbits on food they’d grown themselves fed them such things as stock beets and cabbage in winter as well as their grain and hay. So can you. Pea and bean vines can be cured like hay and make an excellent hay substitute or supplement.

In season, rabbits like anything green, but you must be careful not to feed them plants that are outrightly poisonous, such as chokecherry or rhubarb leaves, or potato peels with sprouts or ones that have been in the sun long enough to get even the slightest touch of green. Other greens are only mildly poisonous in the uncooked state such as pigweed, amaranth greens, spinach, comfrey, and Swiss chard—but for a creature with a small body weight like a rabbit, especially a young rabbit, these can be a problem, too. Much of the reason that people develop fear of growing their own rabbit food, or have bad experiences with home feeding of rabbits is because they don’t understand how very many greens, wild or domestic, are not fully safe to feed rabbits, and which are. Before feeding a leafy green or herb for the first time, check the list under “Edible for Rabbits,” below, to see if there is a warning of any sort about it. Stick to feeding them human-type salad greens unless you know for sure a wild one is safe. If cooking is advised for a green or category of greens (the amaranth family), don’t feed it to rabbits who, of course, would be eating it raw. If it’s in the least toxic, don’t feed it to them. If it might have chemical residues on it, don’t feed it to them.

I plant extra rows of lettuce for them. And when I weed in summer, I take along a bucket to put the pulled edible weeds in for the rabbits. Feeding this way you never have to buy a rabbit pellet and they do fine. When fed home-grown stuff, they’ll grow a little slower (and more normally) to that 2-lb. butchering size. But it’s far cheaper, and I have organic meat because from conception on, they’ve been nourished with home-grown foods and greens, or hay and grain from a source I know is chemical-free.

Vegetables/Greens/Fruits. A combination of grains is better than a single one. A combination of veggies and greens plus grain and hay is better yet. Let your rabbits do some picking and choosing. They’ll choose what they need. They’ll love much of what you offer of this sort, and it’s a nice way to tame them—hand-feeding some veggie treats. For pregnant and nursing does, variety is especially important. Offer the vegetables or leafy greens in season (the longer the season, the better). Garden and kitchen vegetables and fruit scraps can be included also, as long as they’re not on the unhealthy list. If you’re just starting to supplement a rabbit’s diet in this way, go slowly at first until your bunny gets used to it. Limit what you feed so that surplus doesn’t rot in the cage. Rotting surpluses are good for chickens or pigs, but not rabbits. In fact, rabbits can get sick from eating partly spoiled greens. Garden vegetables for rabbits, as for people, are mostly water. Greens are water plus lots of minerals and vitamins. Root vegetables are higher in energy supplied, lower in the mineral-and-vitamin department.

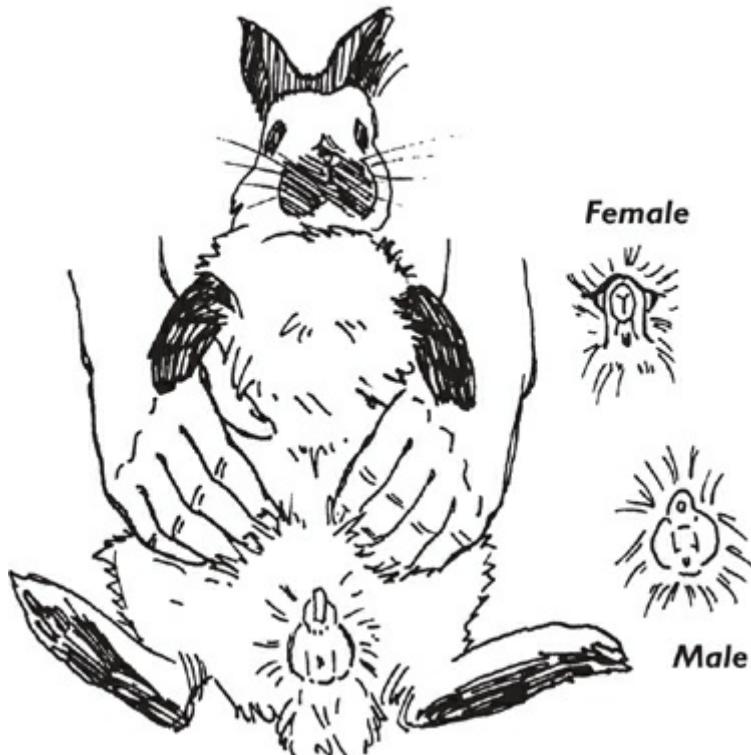

SALT: Rabbits enjoy a salt-and-mineral block in the hutch. They’ll lick it for the food value.

Rabbits with a block seem less likely to gnaw on their cage. You can just break a chunk off a cow-size salt block for them, or give them a lump of canning salt. But don't give them iodized table salt. Some rabbits prefer plain salt and some like the commercial salt-and-mineral mix.

"BONES" AND "Toys": If rabbits have something to chew on, they are less likely to chew on wood parts of their cages and generally seem more content. You can combine a chew-on toy with a salt source by soaking a chunk of 2×4 in very salty water for about 3 days. Air dry it, and then give it to your rabbit. Rabbits also like to gnaw on a hunk of Sheetrock. They like to knock a tin can around in their cage, but, because they're nocturnal, that kind of play may keep you up at night. In that case give them a toy that won't make so much noise.

Rabbit Reproduction

SEXING: The first thing that can go wrong with rabbit reproduction is having 2 bucks or 2 does instead of 1 of each. In determining the sex, it's easy to make a mistake, especially if you looked when they were young. The younger the rabbit, the harder it is to figure out which is which. If they're less than 2 months old, it verges on impossible. After that age the males get a penis you can see, and maybe testicles too. Once the buck is fully grown his testicles will be easy to see. To sex a rabbit, hold it on its back with one hand. The holding hand also has hold of its tail and is keeping the tail out of the way of where you want to look. With your other hand's thumb and first finger press down firmly but gently around the sex organ. With practice you'll learn the difference between male and female. If it's a buck, the sex organ looks more round; the female's looks more like a slit. As the male gets older, its penis will protrude and be plainly visible when you press and you'll see his testicles.

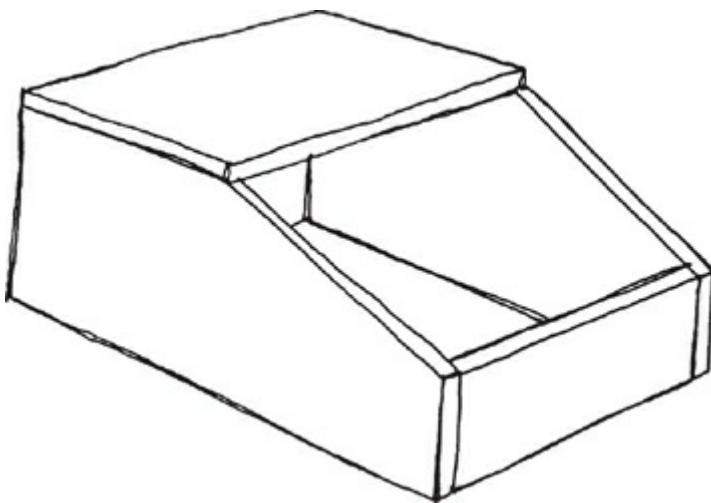

Bucks: For a few does you need but a single mature male to keep the supply going. If you have more, you can eat the others. Or you can keep 2—just in case. If you're doing large-scale rabbit-raising, you need about 1 buck per 10 does. Use a buck up to 3 times a week.

BREEDING: Just put the doe into the buck's cage. *Don't put the buck in with the doe.* It's a fast way to lose a good buck, since the doe will fiercely fight him. This is because the doe has a motherly instinct to be protective of her hutch. After she has lived in there a while, she may attack even if another doe is put in there.

If your doe is not pregnant she will let the buck mount. It happens in a moment—about 1 minute to be precise—and then is over. The buck may tumble over on his side at the conclusion. That's normal and nothing to worry about. In about a minute more he will have recovered and be ready to mate again. If the doe is receptive, you can allow a second mating, but then get her out of there and back to her own cage. It's important to stay there and watch while they're mating. You watch so you know for sure it happened and that the doe is now pregnant. (Write down the date for future reference. In 30 or 31 days, she'll be a mother.) You also watch so you can remove the doe from the buck's cage as soon as possible. *Don't leave them alone together. The doe may come to resent the buck's attention and fight—even injure—him. Or the buck may hurt the doe.*

Human women typically ovulate 1 egg exactly midway between the first day of one menstrual cycle and the first day of their next one—the 14th day of an average 28-day cycle. Rabbits, however, don't ovulate until they have sex, and then they ovulate multiple eggs. That's rabbit rhythm. (That's how I got pregnant with Becca. Hadn't seen Mike for about 6 weeks and then we got back together. Well, it was a rapturous reunion and, even though it was the day before my period was due, I got pregnant. So I can testify from experience that rabbit rhythm can happen to people too!) Because of this, some rabbit-keepers bring the doe back to the buck 6 hours after the first visit to make sure that the eggs she ovulated in response to that first breeding are all fertilized by the buck.

MATERNITY CAGE: When does aren't bred, they can room together. But a doe who is expecting needs separate quarters in a pen that provides her with a nesting box and plenty of room for the growing litter: 7 to 8 square feet, minimum. Make sure the door is big enough to get the nest box in and out and that this cage is sized and shaped so that you can reach into all the corners.

Nesting Box. The nesting box should be like a separate little room inside the larger cage the doe lives in, with its own top, bottom, and sides. If you don't provide her with a nesting box, the babies will fall through the wire, and she'll be so nervous and upset at being out in the open with them she is liable to eat some of them. Fixing her up with the box allows her to pretend she's in a burrow, and that's what her nature needs. You can set a wooden box inside the hutch to be her nesting box or make one out of wire. It should be

roofed at least partly for warmth and to provide a sense of privacy for the nervous mom. The box should have its own floor, which also keeps the occupants warmer. It should be entirely separate and separable from the outer cage. There are cages with built-in or "integral" nesting boxes. Experienced rabbit-keepers complain, however, that they don't stay clean and tend to be unsanitary, hence, unhealthy. It's easy to make a passable nesting box with some boards, a saw, hammer and nails. Or start with an existing wooden box, nail a top on it and cut out the doorway. If your climate or season is warm, you could create a wire nest box out of "rabbit wire." In cooler weather, one of those can be lined with cardboard. Make sure the nesting box will block drafts and won't leak. For cold weather, it should have a nice tight construction.

Dimensions. Commercial-breed-sized rabbits need a nest box about 12 inches by 18–24 inches and 12 inches tall. There should be a doorway just the right size for the doe to go in and out. The entrance to the box should be raised from 2 to 6 inches off the box's floor (higher is better, highest is best) so that the blind, helpless young don't accidentally roll out the doorway. When they have grown big enough to hop over that barrier on their own, they'll be all right out there anyway.

KINDLING MANAGEMENT DAY BY DAY

Gestation. To test for pregnancy you can put the doe into the buck's cage when she's supposed to be 2 weeks pregnant. If she stands still and lets him mount her, she probably wasn't really pregnant. But if you do this "check breed" you better be poised to get her out of there at a moment's notice, because if she is pregnant she'll fight him. Even if she did let him breed her, go ahead and put in her nesting box because there are does, though rare, that will accept the buck even when they're pregnant. Another way to test for pregnancy is by feeling her abdomen. The babies inside feel like marbles. The problem with that, however, is that the only way to feel them is to press so hard that you're likely to harm them. Best not to.

Check the doe for being overweight since an obese doe may die during kindling or deliver dead babies. A too-lean doe is not as much of a risk to herself or her babies. Put her on a diet if needed, early in the pregnancy. A few days of short rations generally does it. Rabbit pregnancy lasts 28–35 days, but most rabbits kindle on day 31 or 32. As her pregnancy progresses, gradually increase the amount of protein you're feeding. Toward the end, when the babies inside her are growing fastest, let her eat all she can clean up. If she doesn't get enough food at this stage, some of the babies may die inside her and she'll abort them. A doe who doesn't get enough (and nourishing enough) food has a smaller litter. Get her moved into a maternity pen with nesting box well before the delivery date.

5 Days Before Kindling. About 5 days before her due date, move a nest box into her hutch. Provide the mother-to-be with ample straw, hay, maybe even some cotton rags if the weather is cold—plus a calm environment. She'll make those nest-building supplies into just a dandy little nest in there. She'll pull out some of the fur off her own body to line it. In cold weather, it will help her if you also supply some extra rabbit hair, or wool. (As you care for your rabbits and find bits of rabbit fur, stash them in a paper bag in a dry place.) From those she can make an even warmer nest. Some first-time rabbit mamas don't catch on in time. If you have one who is failing to pull fur for her nest, it may help to provide her with that soft nesting material even if it isn't cold. With a good box and plenty of soft working materials with which to build her nest, she will herself create a shelter in which her young can survive even the coldest weather.

Also check over the cage, keeping in mind the young rabbits that will soon be romping and exploring in there. For a maternity cage a shared manger isn't a good idea unless it's

built so the babies can't possibly crawl into the next-door cage. Make sure there are no holes a little rabbit could fall or crawl through.

From 4 Days Before, Until Kindling. When she is near to her birthing time, keep things around her as quiet as possible and basically just leave her alone. Rabbits are jumpy critters anyway, and even experienced mamas can go hyper around their kindling time.

Kindling: Day 1. First-time mothers are the biggest worry. If she made a nest but doesn't give birth inside it, the babies will die of exposure or fall through the wire. Or she may birth some babies inside, but some outside of the nest. If you find them and they're still alive, there's hope. In that case, old-time rabbit managers rub a chest salve such as Mentholatum or Vapo-Rub lightly onto the mother's nose while she's outside of the nest and gently return the outside babies before she goes back. The rub helps prevent mom's rejection of them by deactivating her smeller for a bit.

Check if there's enough fur for a warm nest. If there isn't, add more from your rabbit fur bag.

If a mama at kindling time gets very emotionally upset (it happens easily to rabbits), such as by a dog, or a drastic change in feed, or a water shortage, or too much handling, or just is quirky that way, she may even cannibalize the babies. In that case, give her 1 or 2 more chances to raise a family. If she repeats the crime and she's a stock rabbit, eat or replace her. If she's a pet, then get her to a nunnery for a life of pampered celibacy.

Day 2. If all the babies appear to be in the nest, wait 24 hours and check them on day 2 for the sake of mom's nerves. The babies are hairless, blind, and furless. Get the doe out of there, dab salve on her nose, and go to work on the nest. Count the babies. Rabbits may have as many as 16, but usually fewer. Since most does won't successfully nurse more than 8 or 9 babies, more than that are best fostered out. Remove any dead ones from the nest. Healthy babies are squirming restlessly in there. See if they're nursing well. Well-fed babies have bulging tummies. You can actually see the milk through their thin skin. Check to see if mom's breasts are doing okay. Check to make sure the nesting box is not leaking. It should be absolutely dry in there. Make sure the doe has plenty of nourishing food to eat. Otherwise her babies won't be their largest possible size at weaning time.

Day 3. Check again, as above.

Day 6. Check the babies again. If you find any dead ones—and it happens—remove the bodies.

Day 10. Check again. The little bunnies will be opening their eyes about this time and becoming active and fun. You don't need to supply any food for these young babies. The rabbit is a mammal and feeds her babies milk from her own body until they are large enough to come out and share her feed.

Day 21. The bunnies can start eating something besides mother's milk now. Milk-soaked bread is a good first supplement for them. Very young rabbits have delicate digestive tracts. Be careful. Add new foods gradually, watching for difficulties, just as you do for a human infant. Avoid foods that are harsh in content or texture. For example, oat husks can damage their intestines. To feed home-grown grains to young rabbits, crush them and remove the husks. Bigger young rabbits and their parents like to eat very green, leafy hay, as well as grain.

Day 56. Meat breeds weigh about 4 lb. and are ready to butcher as fryers at this time. Average-sized rabbits, butchered at 2 months, will each dress out to an adequate-for-a-fryer 2 lb. It's definitely time to rebreed the doe. Rabbit lore has it that a doe left unbred for too long may forget how and turn sterile. As for the offspring, there's a very sound reason for butchering at that magic number of 56 days, because if they aren't sent to that fate but rather are left in the cage, you'll have all those little boy and girl rabbits growing

together, right? Okay. The simple fact of rabbit life is that an 8-week-old female rabbit housed with a male is about ready to get pregnant and will do so very soon, probably within days. So if you want to keep some of those bunnies to be mothers or fathers themselves, that's the age at which you can start breeding them—or they will start breeding themselves. If that's what you want, instead of butchering them, you give them their own housing, and proceed as above with the cycle of rabbit reproduction. If you want them to continue eating and growing some more but not producing offspring, you had better house the sexes in separate dorms. Unfortunately, the younger they are, the harder it is to tell what sex they are.

Any rabbit you don't want to keep for breeding should be butchered at least by 13 weeks of age, because after that the feed conversion efficiency really goes down.

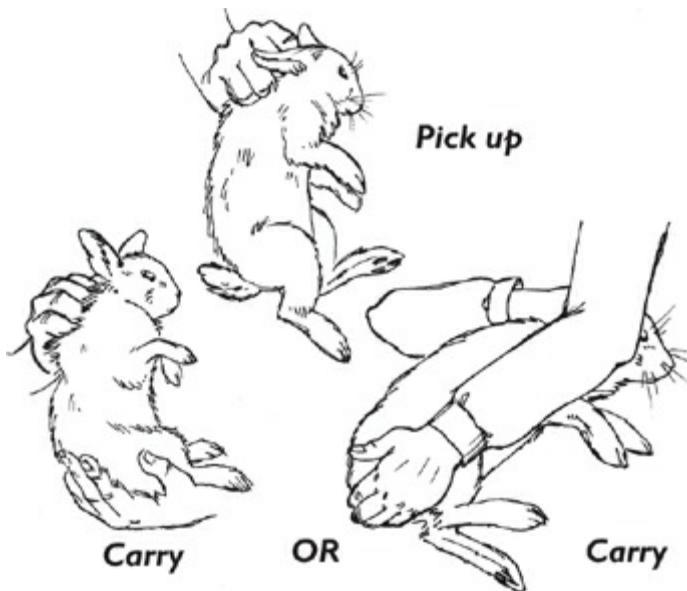

ORPHANS: Once I had a mother rabbit jump out of her hutch and get killed by a dog when her litter was very young. I saved them by feeding them regularly with milk out of an eyedropper until they were big enough to lap milk out of a saucer like kittens.

Foster Mothers. Another way to handle orphans or babies from a too-large litter is to put them in with another litter of close to the same age. To get the new baby successfully adopted you do 3 things: (1) Lure mom rabbit out of the nesting box and over to the farthest-away end of her cage by feeding something there that she loves enough to give it her full attention for a moment. (2) While she's eating, gently sneak the new baby (babies) underneath those already in the box. The underneath placement is important because there they'll have a chance to pick up their new family's identifying odor before she catches on. Then gently pull the nesting material back over the babies. (3) Get some chest rub on mom's nose before she makes it back into the nesting box and repeat for several days so she can't smell the strangeness of the extras. Even so, some does can't be outsmarted and will just say no.

Rabbit "Vetting"

Rabbits are comparatively healthy and simple to manage as far as their health care goes. If you take good care of them and provide good housing and plenty of nourishing food, you probably won't have much sickness. If you do have sickness, it may be best just to replace the rabbit. They aren't worth what a vet would charge and many vets don't know much about rabbit ailments anyway.

HANDLING: *Never hold a rabbit up by its ears.* A rabbit's ears are tender and sensitive. If you are handling a small rabbit (less than 5 lb.), lift it up with 1 hand placed securely under its behind. Lift a large rabbit with 1 hand under it the same way and the other hand grasping the loose flesh at the back of its neck for security. Rabbits prefer to be carried with their head tucked beneath your arm so they feel hidden.

NAIL CLIPPING: Clip to minimize the risk of being scratched by hutch rabbits whose claws are too long. Use a dog-sized nail clipper.

GIVING MEDICINE BY MOUTH: First get the medicine into an eye dropper. Get yourself seated with the rabbit held firmly between your legs or in your lap. Now put the dropper into the back of the rabbit's mouth. Slowly squeeze the medicine out back there.

TAKING A RABBIT'S TEMPERATURE: Use a regular baby thermometer. Be careful, whether for your child or the rabbit, because those darn glass bulbs break off so easily. Put a little grease on it to make it slide better, and insert only about 1 inch up the rabbit's rectum.

USUALLY NONCONTAGIOUS CONDITIONS

Conjunctivitis (Weepy Eye). If your rabbits look like children with pinkeye—with stuck-together, goopy eyes, this is what they have. Use an antibiotic eye ointment and apply once or twice a day. The best ointment is one with an anesthetic so the animals will stop scratching and rubbing their eyes.

NOTE: To prevent conjunctivitis, don't use sawdust for bedding, and keep dust down in the rabbitry.

Hutch Burn/Vent Disease. This resembles diaper rash in that you'll see red and irritated, even scabby places around the rectum and genitals of the rabbit. At worst it's vent disease, which is a very contagious sort of rabbit syphilis. Only your vet can truly tell the difference. Rabbits with vent disease, left untreated, get well from their symptoms and simply become carriers of the sickness, which they give to unborn young. Injected antibiotic cures vent disease.

But your problem is far more likely to be hutch burn, which is merely caused by urine-soaked bedding on rabbit housing with solid floors. The ammonia generated by the urine irritates them. The treatment for true hutch burn is to clean out the soiled bedding and provide better conditions in the future. Or else change the rabbits to wire-floored cages. Treat by smearing Vaseline on the afflicted places. That protects them against ammonia. If the "diaper rash" has gotten infected, treat instead with an antibiotic salve. At its worst, hutch burn can become a blood poisoning of the whole system.

Sore Hocks. Because they often live on wire, rabbits can suffer from hocks that have gotten bruised or even infected. If your bunny's hock loses its hair, or looks red, swollen, or has a scab, it needs treatment.

NOTE: To prevent sore hocks, support a wire floor for heavy breeds so they don't sag, be sure

wire flooring is the right side up, and keep flooring wire clean, disinfected, and free from sharp things. Minimize stress and keep bucks out of sight of one another, because rabbits may thump hard when excited and hurt their feet.

Constipation. Rabbits, like you and I, can suffer from this. The cause may be lack of roughage (hay), cribbing, or eating fur. The first symptom is some very small, very hard feces. Later, a constipated rabbit may lie on its side, obviously in pain. Treatment is making it drink 2–8 cc of mineral oil 3 times per day. Pineapple juice helps them digest hair balls. Giving a rabbit with a severe case an enema might cure it—or it might kill this easily stressed animal.

Abscesses. These lumps full of pus are caused by a streptococcus infection. Usually one starts when the rabbit gets a skin puncture in a fight or from something sharp in its cage. *Cages should not contain sharp, protruding objects.* Unless you seriously want to play doctor, you might just want to replace this rabbit. In any case, don't let it infect other rabbits, or you (wear rubber gloves when vetting).

"Buck" or "Wolf" Teeth. These are genetic (recessive) defects that some rabbits carry. "Buck teeth" are extra long upper incisors. "Wolf teeth" are extra long lower incisors. Eventually, the rabbit can't close its mouth and can't eat normally, and its teeth grow painfully into the flesh. Buck or wolf teeth are hereditary. Don't let an affected animal breed.

Cribbing. Rabbits like to chew. They'll chew on wood in their hutches, even tear holes in their wire. It helps to give them toys to play with, and something okay to chew on, such as pieces of Sheetrock. It also helps to have a salt block in there.

Mastitis. Any milking mammal can get this inflammation of the "breasts." It can be caused by a bruise or bacterial infection. A doe suffering from mastitis acts listless. Her mammary glands feel hot and swollen. Her temperature may be up. The treatment is an antibiotic. If a doe gets mastitis, her babies are usually taken out of the nest and dealt with like orphans with hand feeding, at least until their mother is well.

PARASITES

Coccidiosis. The best approach to rabbit coccidiosis is to emphasize prevention. The disease is caused by wild or domestic birds roosting above your rabbit pens and leaving disease-bearing droppings in the rabbits' water. This is a good reason for having a roof over the hutch (as well as to keep it cool in summer). Symptoms of coccidiosis in your rabbits are weak, listless behavior; weight loss; pot belly; loss of appetite; diarrhea; thinness.

However, most people don't discover they have coccidiosis disease on their farm until they butcher and find a liver that is filled with white spots. Chickens get it as well as many other kinds of poultry, sheep, and rabbits. The treatment for rabbits is to give them a medicine in their water. Make sure rabbits under treatment are in wire-bottom cages so they don't get reinfected by eating their night feces, which rabbits typically do. Don't butcher for at least 14 days after that treatment.

Ear Canker/Ear Mites. Ear mites are the beasties that cause ear canker in rabbits. Examine your rabbits' ears. If you see brownish discharge and crust, mites are likely the cause. Isolate the infected animals to prevent spreading of the problem, and treat them as soon as possible. After applying medicine, massage the ear's base to get the medicine well spread. To try to prevent reinfection, use something like rotenone on the pen and the cage. Be careful that you don't spread the infection.

KEEPING RECORDS

If you want to make a profit on any livestock, you need to keep records. Some people scribble in a notebook or on a calendar. Some have slick computer systems. If you have caged rather than communal rabbits, you'll want to note breeding and kindling dates. That way you can have nest boxes available on schedule. A good system is 1 page for each rabbit and on that page you answer the following questions:

1. What's the animal's name?
2. How many were in the litter it was born into?
3. Who was it bred to?
4. When did it give birth?
5. How many were born? Alive? Dead?
6. Any problems with kindling and mothering behavior?
7. Were there any birth defects?
8. How many were weaned?
9. What date were they ready for butchering?
10. How much did they weigh?
11. How many of them were does? Bucks?
12. Did you choose to keep any of the litter for future breeding stock?

Lice. Fortunately, rabbits don't often get lice—or mange either. If they do get lice, it will most likely happen in winter. A louse infection can be so severe as to make the rabbit anemic, even result in death. A louse powder is the treatment.

Mange. Mange can spread quickly from one animal to another and is not easy to treat. Sometimes diagnosis is difficult. True mange is caused by tiny mites hiding under matted hair. But fungal or bacterial infections can resemble mange. A vet can identify mange by examining a skin scraping. If you suspect mange, an organic response is to butcher the animal and burn its pelt because treatment involves insecticide, costs money, and is likely to not be successful at least the first time. An animal with mange is a source of infection to other animals.

Fungus Infections. Commonly known as “ringworm.” Some rabbit-keepers immediately isolate, even kill and burn or bury any infected rabbit. To treat, cut the hair around the infected area quite short and apply fungus powder or ointment (wear rubber gloves). Sun shining on the affected area can help also.

Worms. Rabbits can get them—most usually the tapeworm—from other farm livestock, dogs, cats, birds, or rodents. Tapeworm can spread by infected cat or dog manure getting into rabbit cages or feed. A rabbit with tapeworm has dull fur and maybe blood or mucous in its droppings. For suspected worms, you can take the rabbit and a droppings sample to your vet, who will examine the feces under the microscope and know for sure. However, there's no treatment for tapeworm that wouldn't kill the rabbit, too.

RABBIT DISEASES

Mucoid Enteritis. Darlene Campbell, Backwoods Home Magazine: "Symptoms: Diarrhea as evidenced by feces on the hind feet or not forming into the usual round pill shape, hunched back, rough coat, grinding the teeth, or sitting hunched over the water dish with front feet in the water. The stomach may be bloated and the eyes appear to be squinting. Cause: Fifty percent of all rabbit deaths from birth to eight weeks are caused by mucoid enteritis. The exact cause is not known, but is suspected to be caused by one or more of the following: coccidiosis, intestinal parasites, fungi, virus, unsanitary conditions, and/or improper feeding ... The death rate is high with mucoid enteritis. It is recommended that all animals that die be disposed by burning or burying."

Pasteurellosis (Snuffles). This common rabbit disease is highly contagious to other rabbits and invariably fatal. It looks like a cold as the rabbit will sneeze, cough, wheeze. Its eyes may run and its nose discharge. If you suspect pasteurellosis, you need a vet's advice right away.

Pneumonia. Darlene: "Symptoms: Rapid breathing, a temperature above 103 degrees, nasal discharge, and a bluish tint to the eye color of albinos. Cause: Drafty, cold, or damp quarters, stress, and a general-run down condition which weaken the rabbit's ability to fight off bacterial infections. The infection invades the lungs and nasal passage. It is a major killer of adult rabbits, and can infect and kill a rabbit within 24 hours. Suspect pneumonia when a member of the herd is discovered dead without any previous sign of illness. Treatment: Speed in diagnosing and treating this disease is important. Inject antibiotic deep into the hind leg muscle following the dosage recommended for rabbits by the manufacturer. Either penicillin or combiotic is effective. Continue the dosage recommended for 2 days past the last sign of symptoms."

Rabbit Butchering

Rabbit meat is the leanest of all nonfish meats—and delicious! It is often compared to chicken, but each has its own distinct flavor and texture. After all, one is a mammal, the other fowl. Precise weight at proper butchering age varies wildly because rabbits' weights can vary so much according to breed, sex, and age. The meat you end up with will be about half the live weight. Young rabbits are distinguished by their soft ears and paws—stiffness is a sign of age. An old rabbit can be stewed like an old chicken. Rabbit meat is almost fat-free.

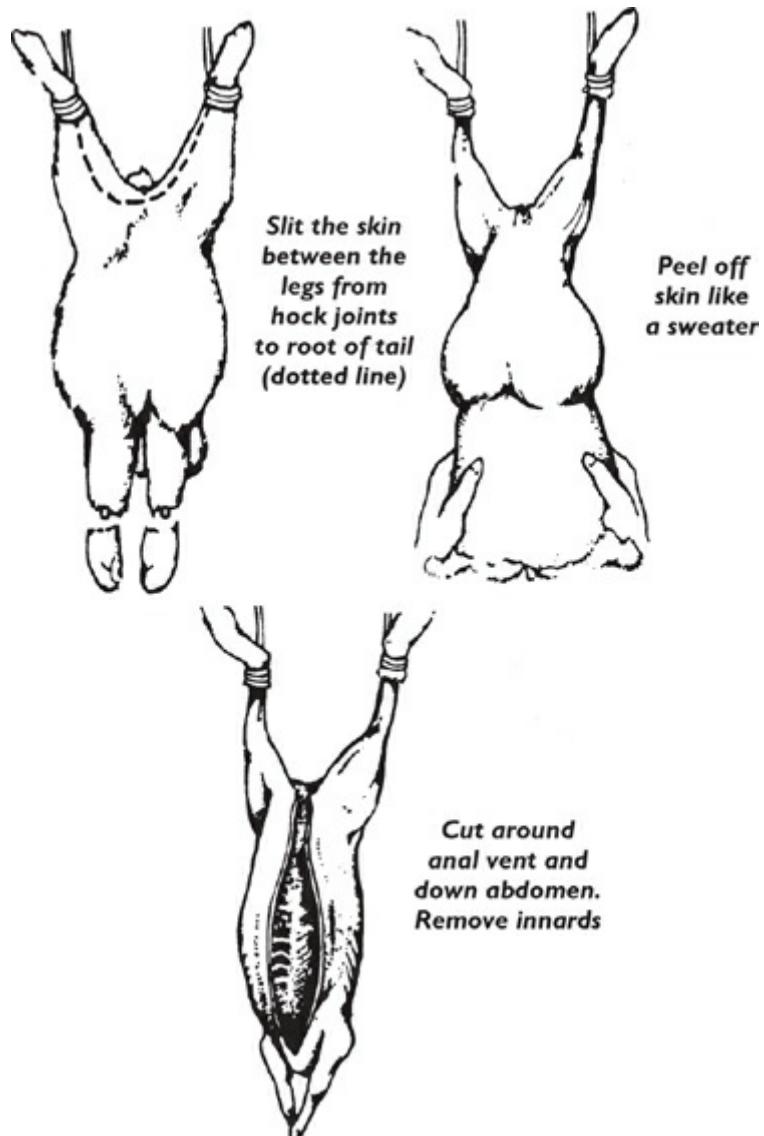

KILLING: Some recommend that you first stun the rabbit with a hard blow on the head, right behind the ears, then chop the head off on your chopping block as close to the head as possible. Other rabbit owners find it very difficult to get a well-placed, effective blow in and prefer to begin by snapping the animal's neck by stretching it with the hands.

To do that, hold the rabbit's hind legs about chest-high with your nondominant hand (the left for me) and hold the rabbit's head firmly around the neck with your dominant hand. With the dominant hand you are now doing 2 motions at once: pulling the body down in tension against your other hand's grip, and bending the rabbit's head up and back as far as possible at the same time as you pull its body down. Keep pulling the rabbit's head up and back with a steady, firm motion until you feel the neck break.

Then proceed, as above, to cut off the head with an ax on a chopping block, or with a sharp knife, cutting through the spinal-column cartilage. To get the rabbit properly bled out, hold it upside down for a few minutes, or hang it. (You can save a mess by catching the blood in a garbage sack).

HANGING: Now prepare the animal for skinning (if it has not already been hung) either by nailing the 2 hind feet about body width apart to a board or skinning table, or by hanging it up. The hanging procedure is the same as that used with larger animals. Cut the skin off just toward the body from the hock joint of each hind leg and peel it back enough to expose the 2 Achilles tendons. Insert the hooks, ropes, chain, or whatever between the bone and Achilles tendons just above the hocks. It will be handy if you have ready a gambrel (hook), suspended about chest high. You can make one out of a piece of stiff wire about 1 foot long. Make a hook at each end to hook the exposed Achilles tendons of the rabbit (which are strong enough to hold the animal's weight even under considerable pulling pressure) and suspend from a tree branch or some such. Or a rope thrown over a tree branch with a hook at each end will work. Or you can just tie a couple loops around each leg as shown in the illustrations.

SKINNING: With the rabbit on the gambrel, you cut off the front feet and the tail. (Later, you can give the tail to the children to enjoy.) Slit the skin between the legs with a very sharp small knife. Start with the hock joint on the inside of one hind leg, cut down to the crotch of the rabbit and the back up the inside of the other hind leg to the other hock joint. Cut the skin from each front leg to the neck. (Do not cut down the belly centerline at this time.) Then peel then skin down off the body, beginning at the hind hocks, like you would take off a banana peel or a sock. Cut around the anal opening and any place the skin is not coming off freely. Pull the skin off like that, inside out, clear down to the front feet, and then it will be completely off. If you have taken the skin off cleanly, you may want to use the very soft rabbit fur. See "Tanning" in [Chapter 8](#).

Easy Skinning. If you don't care about the skin, skinning is easy. Just hold the rabbit by a hind leg and with your other hand pinch the hide at the hock joint and pull downward. The skin will tear at the point of the pull and you can peel it off without a knife. Or remove the head and feet, then pinch up the hide in the middle of the back and cut through it with a knife. Then grasp the hide on either side of the cut and pull in opposite directions. Pull the front half toward the head and the rear half toward the tail. Peel the skin off, rolling it down over the legs. Cut off the head, feet, and tail, and you're done with that.

CLEANING (“DRESSING”): You may either take the animal off the skinning board or down from the hanging position and place on a cutting board, or continue to work with it where you already have it. Cut around the anal vent and then toward the breastbone along the midline of the abdomen, being very careful not to sever any intestines. As you are cutting you might keep your finger inside to hold the intestines away from the knife. You may or may not cut right on through the breastbone, or “brisket,” to the neck. Then pull out the intestines. If you didn't cut the breastbone, reach up into the chest and get the heart and lungs. You will have to help the lungs out since, unlike the intestines, they stick in the cavity. Save the heart. Pause to look carefully at the liver.

NOTE: If the liver has white coccidiosis spots, dispose of the carcass. Do not eat the meat. The liver need not be fully spotted. Any slight discoloration is a sign of infection.

If the liver tissue has white streaks or there are small, white cysts attached to the stomach or

intestinal membranes, that's tapeworm. Don't feed the uncooked intestines to other animals (that would pass the infection on). You may eat the animal, but it must always be thoroughly cooked, like pork.

If you are going to save the liver, carefully cut away the gall bladder part of it. Don't spill any of the dark green bile that is stored in that gall bladder. If you do get bile on any of the meat you'll have to cut away and discard that part of the meat. Rinse the outside of it to wash away any adhering blood or hair or dirt. If you still have it up on the gambrel, take it down now.

CUTTING IT UP: First, cut off both front legs at the shoulder joints and both hind legs at the hip joints. Cut through the ribs on both the left and right sides, parallel to the backbone, to cut free the breast piece of the rabbit carcass. Divide the remaining back piece into 2 or 3 pieces (depending on how large the rabbit is and how large you want your pieces). The big meat pieces are found on the hind legs and the haunches (loins) where they are easy to cut from the body. The loin pieces are the choicest on the rabbit, great for stews. It's a good idea to bone the thigh, leaving the shank intact. The forelegs of a rabbit have very little meat and are better off in the stock pot.

FREEZING: Washed and chilled rabbit or cooked rabbit can be wrapped in plastic freezer bags or freezer paper. If you are including gravy or sauce with cooked rabbit, pack it in plastic containers with tight lids. Fresh rabbit will keep in the freezer for 4–6 months, but use the frozen cooked rabbit before 2 months. Thaw rabbit in the refrigerator and never refreeze. It will take up to 16 hours to thaw a whole rabbit, but smaller pieces will be ready in 4–9 hours. Or you could be modern and put it in the microwave—and be done in a jiff.

COOKING: Fry, boil, bake, roast, or barbecue the rabbit meat, or grind it for rabbit burger or rabbit sausage. Frying is the most common cooking method. Many recipes ask for rabbit meat to be browned. This can be done in a hot skillet for a few minutes then evened out in the oven at 350°F for 5–8 minutes. To preserve rabbit meat, freeze it, can it, or make jerky. Although almost any chicken recipe (and some for veal, too) can be adapted to rabbit, keep in mind that rabbit meat is very lean and delicate. Don't over cook it or let it dry out. To can rabbit, use directions for chicken.

⇒ **OVEN-FRIED RABBIT** Brush pieces of 1 rabbit with $\frac{1}{4}$ c. melted butter or margarine. Sprinkle with salt and pepper and place in a flat baking pan. Cover with foil or a tight-fitting lid and bake at 350°F for an hour or until tender. Occasionally brush on more butter or margarine until the top is light brown.

⇒ **BUTTERMILK RABBIT** Place your rabbit pieces in a casserole dish. Pour 2 T. melted butter over 2 c. bread crumbs, and spread the buttered crumbs over the rabbit in the casserole dish. Add salt, pepper, and paprika, if you like it. Cover rabbit and crumbs with 2 c. buttermilk. Top with 3 bacon strips. Bake at 350°F for 1½ hours.

⇒ **SOUR CREAM RABBIT** Cut rabbit as for frying. Brown in butter. Add 2 c. sour cream, and simmer until tender. You can season with salt, pepper, minced onion, and parsley that has been cooked in butter 2 minutes before being added. Add a little cayenne, if you like things hot.

⇒ **DORIS'S RABBIT STEW** Cut up rabbit. Dredge in flour. Brown all sides. Fry until tender. Cool. Remove bones and chunk meat. Dice white potatoes and cook with thinly sliced carrots. Season. When partially done, add peas, parsley and sliced onions. Cook very slowly for 2 hours. Now take your skillet with the rabbit drippings (where you previously fried the rabbit)

and make a light gravy. Pour this over your done, but not too juicy, stew. Add 2 T. butter and finish seasoning, if needed. This eliminates all wild taste in rabbit.

⇒ **FRIED RABBIT** If the rabbit is very big, boil 10 minutes, drain, and then proceed when cool enough to handle. Dip in egg, then in crumbs, and sprinkle with salt (or into salted flour) and place in hot frying pan that contains plenty of fat. Cover and get the rabbit well done on the first side before you turn it to brown on the other side. If you want to make gravy, 1 c. of milk or cream will go well in it.

⇒ **RABBIT AND BISCUITS** Cut up the rabbit, cover it with cold water, and put it on to boil. Add 1 t. salt and cook until tender. Have biscuits ready (buttermilk biscuits are wonderful!). Break open a biscuit on each plate. Put a piece of rabbit on the biscuit. Thicken a reasonable amount of the broth with flour, add 1 c. of milk or cream, stirring, and pour some over each piece of rabbit and biscuit. Serve at once.

⇒ **ROAST RABBIT** Stuff the rabbit with a regular stuffing or line with sausage. Sew up and truss the shoulders and legs closely to the body or they'll cook to a crisp. Rub the skin with butter, add a little water to the pan, and baste often with butter unless you are using a Dutch oven with a tight-fitting lid. Make a gravy of the drippings with a little currant or wild plum jelly added and serve with mashed potatoes.

⇒ **BARBECUE SAUCE RABBIT** Brown your cut-up rabbit in a heavy frying pan that has a lid. Make a barbecue sauce of 1 t. salt, pepper to taste, ½ c. water, 1 small onion (chopped), a shake of garlic powder, ¾ c. tomato paste, ½ c. catsup, ¾ c. brown sugar, ½ c. vinegar, and 2 T. prepared mustard. Pour the barbecue sauce over the browned rabbit, put the lid on the pan, and bake in a 350°F oven until done (an hour or so).

⇒ **POTTED RABBIT (OR CHICKEN)** Brown meat in small amount of oil in skillet or Dutch oven. Add onions, tomatoes (stewed or fresh), wine, mushrooms (if on hand), and carrots or other vegetables as desired. Cook until tender and sauce is thick.

These recipes are from Nancy Cramer, Kent, WA:

⇒ **BASIC SWEET AND SOUR SAUCE** Dissolve 1 bouillon cube in 1 c. boiling water. Add 2 T. vinegar and 1 T. brown sugar. Heat. Thicken with a flour and water paste (thin) or whatever to desired thickness. Can be used with baked chicken or rabbit.

⇒ **RABBIT AND DUMPLINGS** These are even better than chicken and dumplings. Cook rabbit pieces in water (almost to cover) with salt and a bay leaf until tender. Remove bay leaf. Forty-five minutes before serving, add 2 large onions and 4 or 5 (however many you need for your family) carrots in thick slices (½ inch or thicker). Also add a couple of pinches of sweet basil and parsley. When done, drop dumplings (any recipe) on top and cook until done—enough to avoid gumminess. I like dumplings best that rest on the meat and vegetables, sticking partly above water to cook. But you can make good dumplings in a broth too. When dumplings are done, fish them out with a slotted spoon. Serve dumplings and rabbit in one bowl, the carrot and onion mixture in another. Thicken the remaining broth with flour to make a gravy to serve over dumplings. Makes a nice one-dish meal.

⇒ **BUNNY SAUSAGE** You'll need 6 lb. uncooked rabbit meat, ground; 2 small onions, minced; 2 level T. salt; 2 level t. pepper; ½ c. ground cracker or bread crumbs; ¾ c. milk; ½ t. paprika; 1 bay leaf, ½ t. ground sage; and 1 or 2 eggs, well beaten. Mix the ingredients well together. Mold into small cakes and fry until nicely browned.

⇒ **CANNED OR FROZEN BUNNY SAUSAGE** Pack sausage into clean canning jars to within 1 inch of top of jar and add 3 or 4 T. of the grease in which the cakes were fried. Put on the

cap, screwing the band tight. Process according to regular directions for meat. Or you could freeze it.

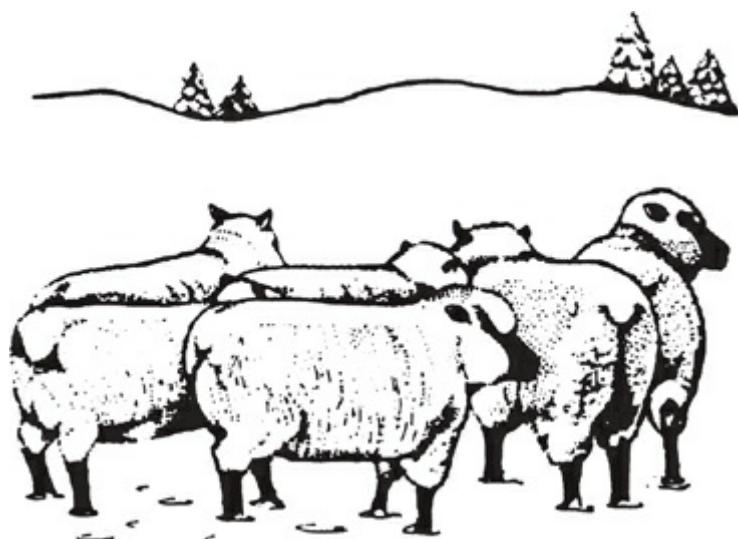

⇒ **RABBIT SANDWICH SPREAD** Mix together 1 c. cooked, cooled, boned, and ground rabbit meat with $\frac{1}{2}$ t. salt. Add mayonnaise or salad dressing as needed to moisten. If you want a spicier spread, add a pinch of white pepper, celery salt, or a seasoned salt. This is great on toast.

CHARACTERISTICS TO AVOID WHEN BUYING SHEEP

- Thin—this may be caused by worms
- Hard or lumpy udder—she may have mastitis
- Udder that doesn't have the proper number of nipples: 2
- Sore feet, lameness—possible infection with foot rot
- Broken or missing teeth

SHEEP

Sheep are grand lawn mowers and land fertilizers and are far less likely to damage your trees than goats are. A lamb is a cute pet that will delight any child's heart. "Lamb" (young sheep) is delicious, healthy meat. Ewes are mellow creatures to have around, and rams are pretty good as herd males go if they were treated kindly while young and were naturally mothered rather than bottle-fed. Sheep are easier to handle and transport than horses and cows. A small flock of sheep is a relatively easy livestock project for a beginner. If you have a well-fenced pasture with a minimal shelter for them, they require only a few moments a day of feeding and watering time—except during lambing and shearing times.

They produce a wool crop as well as a meat crop, both of which can provide cash income. If your choice is between sheep and beef calves, consider that sheep aren't as expensive to buy as cattle. It is possible to milk them, and their milk makes good cheese.

You can feed about 7 or 8 sheep on the amount of pasture that could support only a single cow. The meat crop will be ready 6 months after birth, instead of the year and a half it takes to get a calf to slaughter size, and the smaller animal will be easier to butcher. A general rule-of-thumb is that—in dressed meat—8 sheep equal 1 cow.

Sheep can get most cattle or goat diseases, but they are more able to survive them, and they get fewer diseases than pigs. If sheep fall in a stream, they often can't get out because their wool gets waterlogged. They are more susceptible to predators than the other large stock. Huge flocks on open range are notoriously vulnerable. When my daddy switched from the wheat business to raising cattle and a big herd of about 1,000 sheep on a high mountain ranch, sheep catastrophes sadly became routine: sheep with their flesh torn by predators and maggots crawling around in the wound, freshly sheared sheep and their little lambs dead under mounds of unseasonable snow, sheep crawling with summer ticks.

Yet I have also many lovely memories of my days among sheep—like when the Mormon shearers came up to shear in our long, tin-roofed sheep sheds. How they wrestled with the animals to give them that barber job, sweating in their trousers and long underwear tops. How the wool was packed into long cloth bags hung from a special tall tripod, and 1 man worked inside the bag stomping the wool down until he could walk on top—a very “ticky” job. Every evening Daddy would take off his long underwear, very privately in the bedroom with Mama, and she would pull the day's accumulation of ticks off him. Ticks really thrive on sheep in the mountains in the spring.

I remember in summer the weekly trip Daddy and I made up into the mountains riding horseback and leading a string of packhorses laden with supplies for the sheepherder. Sheepherders caring for a flock of sheep on a big, open range are a very special sort of people—not cartoon characters. There are lots of jokes about them, but the herders I knew in my childhood were real people, working a difficult and desperately lonely job in the mountains for low wages.

Getting Started

In general, learn as much as you can before you get started, and then begin on a small scale.

American Sheep Industry Association offers market, legislative, news, links, etc.: 303-771-3500; 9785 Maroon Circle, Ste. 360, Centennial, CO 80112; info@sheepusa.org; www.sheepusa.org.

Black Sheep Newsletter is a great quarterly for small-flock and colored-sheep owners. \$15/yr in U.S.; \$18 outside U.S.; 25455 NW Dixie Mountain Rd., Scappoose, OR 97056; 503-621-3063; bsnewsltr@aol.com; www.blacksheepnewsletter.net. They also offer *The Black Sheep Newsletter Companion: Writings for the Shepherd and Handspinner*, a collection of the first five years of the magazine, and a lamb cookbook.

Montana Sheep Association offers it all: a terrific website with news, an online magazine, and a supply sales catalog! 406-442-1330; www.mtsheep.org.

Sheep! gives practical advice for small flock owners, articles for small and commercial flocks on wool and related issues, plus an extensive breeders' directory and listing of breed associations and a regular feature on dairy sheep. It costs \$21 for 6 issues/yr. Contact: 800-551-5691; fax 920-648-3770; 145 Industrial Drive, Med-ford, WI 54451; www.sheepmagazine.com.

The Sheep Farmer, for the British angle. Put out by the National Sheep Association: The Sheep Centre, Malvern, Worcestershire WR13 6PGH, ENGLAND, 0684-892661;

www.nationalsheep.org.uk.

The Shepherd, a monthly magazine for both small and commercial flocks, costs \$20/yr:
419-492-2364; 5696 Johnston Rd., New Washington, OH 44854;
shepmag@brightnet.com.

Wyoming Wool Grower, put out by the Wyoming Wool Growers Association. Contact: PO Box 115, Casper, WY 82601; 307-265-5250; www.wyowool.org.

Books: For sure, get a copy of *More Sheep, More Grass, More Money*, an 112-pg book by Peter Schroedter, owner of a large commercial sheep flock in Manitoba (available from *Sheep!* Magazine, \$10 postpaid). The longtime (now updated/revised) classic is *Storey's Guide to Raising Sheep*, by Paula Simmons and Carol Ekarius. It includes breed descriptions, info on predators, herding with dogs, health, etc. *Sheep!* magazine often has pages listing books on sheep production. Other useful books are *The Sheep Raiser's Manual* by William Kruesi (1985); *Sheep: A Complete Owner's Manual* by Gunther Marks (tr. from German and very good); and *The Sheep Production Handbook*, a comprehensive text from the ASI (1990) (303-771-3500; www.sheepusa.org). Another longtime classic by Paula Simmons is *Raising Sheep the Modern Way* (in a revised, 1989 edition).

ATTRA's booklet, "Sustainable Sheep Production," is at www.attra.org/attra-pub/sheep.html. Maryland Small Ruminant Page is a great website info center for both sheep and goat growers with articles plus links: sheepandgoat.com.

SUPPLIES

Canadian Cooperative Wool Growers: Box 130, 142 Franktown Rd., Carleton Place, Ontario CANADA K7C 3P3; 613-257-2714; www.wool.ca.

Sheepman Supply Company provides a wide range of supplies to sheep farmers, including shearing gear, health care products, books, and videos. Free catalog: 800-331-9122; 301-662-4197; fax 301-662-0361; PO Box A, Frederick, MD 21702; info@sheepman.com; www.sheepman.com.

Wiggins & Assoc. offer a nurser bucket for lambs, etc.: 800-600-0716; www.wigginsinc.com.

Vocabulary

Lamb—a young sheep

Bum—a bottle-fed lamb

Cosset—another name meaning bottle-fed lamb

Ewe—an adult female sheep, pronounced "you"

Ram—an adult male sheep

Wether—a castrated male

Yearling—sheep that's around a year old

BREEDS OF SHEEP: Marilyn Jones wrote a classic to help you sort them out: *Breeds of Sheep*, available from her at Jones Sheep Farm, 1556 E. 59th, Peabody, KS 66866. Or go to Oklahoma State U.'s livestock breeds page: www.ansi.okstate.edu/breeds/sheep.

What do you want the sheep for? Pets? To keep your grass mowed? To raise meat for your table—or to sell? To show at the fair? For sheepskins or leather? Or to grow wool that you will shear, card, and spin?

Do you want fast reproduction? Finn sheep have 3–6 babies at a time. But be careful you don't let a Finn ewe get bred by a ram of a larger breed. It could result in dead babies or a dead mama. Or do you want naturally polled or horned sheep? (Dorsets come either

way.)

You do want always to select “open-faced” sheep, on which the wool naturally does not grow around the eyes. “Wool-blind” sheep can’t avoid predators because their wool actually grows down their faces onto their eyes. So even in a wool breed you want an open face. Otherwise you must periodically clip around the sheep’s eyes.

And what about personality? Breeds differ and individual sheep differ. Choose a style that suits you. A calm and pleasant disposition is easier to live with than a tense or aggressive one. On the other hand, Mouflon sheep are the only breed that is said to protect their young aggressively from predators, and that’s good.

Crossbreeds. In the United States there are 9 major breeds of sheep—many of which used to be crossbreeds but now have become accepted as breeds in their own right—and innumerable crossbreeds. There are more people doing homestead-level independent and experimental crossbreeding with sheep than with any other farm species. They are frequently selecting for particular wool colors, but many other characteristics can be selected for also. Unless the crossbreed is obviously a real winner and a sheep of the future, crossbreeds may be less expensive than purebreds.

Wool Breeds. If your interest is wool, what climate do you live in? Fine-stranded wool (from the merino breed of sheep) traditionally comes from breeds suited to warmer climates like Spain. Medium-stranded wool breeds live in the temperate zones like England. The coarsest grades of wool (Lincoln breed of sheep) are associated with the cooler, damper climates. “Coarse” wool means a thick strand. Coarse wool spins faster for hand spinners than fine wools. In any case, when buying sheep for wool, look for a pink skin and a dense coat. A good wool breed like Corriedale should provide you about 10–14 lb. of wool per clipped ewe. (Enough to knit 2 sweaters.) A nonwool breed such as the Suffolk will produce only about a 5-lb. fleece.

Homespun wool has more life and strength than commercially spun wool. It has water-resistance, manageability, flexibility, durability, and warmth. You can choose your wool according to your purpose since wool from different sheep breeds can be quite different stuff, varying in length from 1½ to 10 inches, and in number of crimps per inch, from ½ to 30. Fine wools (such as Rambouillet) yield a softer product (suitable for a baby’s blanket, for example), but are more difficult to spin. Coarse fibers (such as from Karakul or Lincoln sheep) spin more easily into a very durable product, such as a rug. Coarse wools are considered too itchy to be made into clothing that would be worn next to the skin. The medium wools (Hampshire, Suffolk, Cheviot), with fibers averaging 3–4 inches long, stand between these 2 extremes. They are manageable for beginning spinners and can be made into blankets, sweaters, and fabric for other clothing.

Wool Colors. White sheep wool is the standard. Black wool is discounted in regular markets but more valued in specialty spinners’ outlets. Black sheep wool can’t be dyed. White and silver wool mixed comes from an old black sheep and can be dyed. Wool in other natural colors, other than white, is of interest only to hand spinners. But there are lots of hand spinners! Get more info from the Natural Colored Wool Growers Ass’n: Kate Lowder, 918-247-4082; www.ncwga.org. And from American Black Sheep Registry: 4714 Glade Rd., Loveland, CO 80538; carol@blissranch.com; www.blissranch.com/registry.htm. And the *Black Sheep Newsletter* (see “Getting Started”). If you want white, then make sure your sheep has no dark fibers mixed in. Suffolks are a blackfaced sheep with white wool and the most common registered sheep. They usually have a little black color matching their faces around their lower legs but no wool around their lower legs so they have cleaner, dainty looking feet. Hampshires are second most common, followed by Corriedales. Dorsets are all white, available either

polled or horned, and are considered to be exceptionally good mothers. Karakul and Corriedale sheep are white sheep with a higher quality wool for hand spinning that you can get a premium price for.

Meat Breeds. Meat breeds have wool, too, but they are also bred for good meat production. Suffolks, Columbias, and Shropshires are good meat-wool breeds. Don't think that just because a breed is noted for good meat carcasses, it isn't also fine for wool production. Suffolks, for example, grow a nice spinning wool.

Milk Breeds. You can use sheep for milk. Sheep often have inconveniently short teats and a limited lactation period, and younger ones hate to stand still. But their milk tastes good, and it makes wonderful cheese with a dense curd. Try some Romano and see! Sheep don't give as much milk as goats. American sheep produce 1 pt. to 1 qt. of milk a day, but French dairy sheep give up to 3 qt. per day, so Americans are working now to upgrade their sheep dairy herds for productivity. Nevertheless, pound for pound, a sheep's milk will give you 2 or even 3 times more cheese than a cow's milk because it's that much higher in solids. Sheep butterfat is also different in a good way although there is twice as much of it; it's 45 percent polyunsaturated fat. Sheep milk is richer in calories than cow's milk. It provides much more calcium, riboflavin, and thiamin. With all this good stuff in it, don't be surprised that it's yellower and thicker than cow's milk. Sheep milk is naturally homogenized because of the sort of fat in it, even harder to make butter from than goat milk, but it makes super ice cream and yogurt.

Cheesemakers' Journal regularly offers good articles on sheep dairying such as "Sheep Cheeses," "Milk Production in the Ewe," and "Yoghurt from Sheep Milk," in issue 18/19; "Sheep Dairying" in 24; "Sheep Cheesemaking in Poland" in 25; and "Sally Jackson of Washington State—Sheep Milk Cheeses" in 30 (available from 413-397-2012; www.cheesemaking.com). Yves Berger is the shepherd at the U. of Wisconsin's Spooner Research Station, working on dairy sheep research: 715-635-3735; W6646 Hwy. 70, Spooner, WI 54801; www.ars.wisc.edu.

David Major organized a group of Vermont folks to milk sheep. He now makes Vermont Shepherd, a sheep's milk cheese, in his curing cave from wheels of week-old sheep cheese that farmers bring him: 802-387-4473; 281 Patch Rd., Putney, VT 05346; www.vermontshepherd.com. Willow Hill Farm (www.sheepcheese.com) also makes sheep's milk cheese. Sheep cheeses are common in Europe but a fairly new industry here. Roger Steinkamp is president of the North American Dairy Sheep Association, and also a sheep cheese maker in Hinckley, MN. Roquefort, feta, and kasseri are all made from sheep milk, as is Italian-style Romano.

Sizes. Sheep come in different sizes. Bigger sheep require more feed and you can pasture fewer per acre. I've heard that smaller sheep actually produce more meat per acre of pasture, but I don't know if it's been proven.

Specific Breeds. There are so many breeds of sheep, I can't give you info on all of them, but here's a good start.

Border Leicester: American Border Leicester Association, www.ablasheep.org.

Cheviot: American North Country Cheviot Sheep Association,
www.northcountrycheviot.com.

Clun Forest: North American Clun Forest Association, 21727 Randall Dr., Houston, MN 55943; 507-864-7585; bramble@acegroup.cc; www.clunforestsheep.org.

Coopworth: American Coopworth Sheep Registry; 207-563-5851;

pam@americancoopworthregistry.org; www.americancoopworthregistry.org.

Corriedale: American Corriedale Association, Marcia Craig, Secy., PO Box 391, Clay City, IL 62824; 618-676-1046; info@americancoirmedale.com; www.countrylovin.com/ACA/index.htm

Cotswold Breeders Association; Tony Kaminsky, Registrar; 410-374-4383; fax 410-374-2294; PO Box 441, Manchester, MD 21102; www.cotswoldbreedersassociation.org.

Damara “fat tail sheep” are called “low maintenance meat sheep for mowing, weeding, and fertilizing”: (07) 5464-0533; www.damaras.com.

Finn: National Finnsheep Breeders Association, PO Box 55, Milo, IA 30160; 641-942-6402; www.finnsheep.org.

Friesians are European dairy sheep that arrived in the U.S. in 1996. Contact the North American Dairy Sheep Ass'n, www.dsana.org.

Hampshire: American Hampshire Sheep Association, PO Box 51, Milo, IA 50166; 641-942-6402; www.countrylovin.com/ahsa.index.html.

Icelandic sheep are available from Susan and Rex Mongold, Tongue River Farm; 800-422-0474, 5000 CR 4910, Pomona, MO 65789; trf@icelandicsheep.com; www.icelandicsheep.com.

Jacob Sheep Conservancy Registry and Breed Association, spottedsheep@yahoo.com; www.jacobsheepconservancy.org.

Karakul: American Karakul Sheep Ass'n; American Karakul Sheep Registry: 660-838-6340; fax 660-838-6322; 11500 Highway 5, Boonville, MO 65233; www.karakulsheep.com.

Katahdin Hair Sheep International, PO Box 778C, Fayetteville, AR 72702; 479-444-8441; www.katadins.org. Or Laura & Doug Fortmeyer: 785-467-8041; 2285 Falcon Rd., Fairview, KS 66425.

Lincoln: National Lincoln Sheep Breeders' Ass'n; 15603 173rd Ave., Milo, IA 50166; kclaghorn@earthlink.net; www.lincolnsheep.org.

Merino: The American and Delaine-Merino Record Ass'n can provide breeder listings (AK, Canada, most states), detailed info on the breed, and registration paperwork: www.admra.org. This breed, first developed by the Spanish from the 14th through early 19th centuries, is now raised also in America, Australia, Russia, and South Africa. Both polled (hornless) and horned varieties are available. Rated as a medium-sized sheep (rams 175-235 lb.; ewes 135-180 lb.), its “productive lifespan” is 10+ years. Merinos have a tendency to stay together (easy to herd), ability to breed out of season (lets you decide when lambing will happen), and very fine wool. Twins 50 percent of the time. Lambs weigh 100-120 lb. in five months.

Montadale Sheep Breeders Association, 402-884-7555; info@montdales.com; www.countrylovin.com/msba/index.html. Mary HaWaaboo has bred Montadales for 15 years at 3710 A St. SE #3, Auburn, WA 98002; 360-802-6747.

Navajo-Churro Sheep Association: Connie Taylor, Registrar; 575-751-3767; www.navajo-churrosheep.com; Box 94, Ojo Caliente, NM 87549.

Rambouillet: Bluestem Farm is where Walt & Wanda Martens raise both white and natural-colored Rambouillet: 502 Cash Spring Rd, Ozark, MO 65721; 417-581-7485; bluestemfarm@hotmail.com; www.bwoolmercantile.com.

Romanov: North American Romanov Sheep Association, 740-927-3098; PO Box 1126;

Pataskala, OH 43062-1126; <http://home.roadrunner.com/~narsa/>.

Romney: American Romney Breeders Ass'n offers quality fleeces on large-framed sheep: www.americanromney.org.

Scottish Blackface Sheep Breeders Association; 417-962-5466; Richard J. Harward, Secy., 1699 Hwy. HH, Willow Springs, MO 65793; sbsba@pcis.net; www.ramshornstudio.com/scottish_blackface.html.

Shetland: North American Shetland Sheep Association, NASSA Registry, PO Box 51, Milo, IA 50166; www.shetland-sheep.org.

Shropshire: American Shropshire Registry Association; Becky Peterson, Secy., 41 Bell Rd., Leyden, MA 01337; 413-624-9652; www.shropshires.org.

Southdown: American Southdown Breeders Association, Gary Jennings, Secy., 100 Cornerstone Rd., Fredonia, TX 76842; 325-429-6226; southdown@ctesc.net; www.southdownsheep.org.

Suffolk: United Suffolk Sheep Ass'n; Annette Benson, Secy.; 641-684-5291; PO Box 995, Ottumwa, IA 52501; www.u-s-s-a.org.

Texel Sheep Breeders Society: www.countrylovin.com/TSBS/index.htm.

Tunis: National Tunis Sheep Registry, NTSRI, PO Box 51, Milo, IA 50166; 641-942-6402; www.tunissheep.org.

Wiltipoll: This polled meat breed, derived from the British Wiltshire Horn, was recently developed in Australia. They're available from Rita Hough, (02) 6862-6363; Hebron Park, Parkes, NSW 2870 AUSTRALIA; ritahough@hotmail.com. Or David Oakley; (03) 5438-3036; 82 Brooke St., Inglewood, Victoria 3517 AUSTRALIA; www.wiltipoll.com. John and Glenyes Pickering; (08) 8536-0023; fax (08) 8536-0038, RSD 484, Clayton Rd, Finniss. via Strathalbyn. SA 5255 AUSTRALIA.

WHERE TO BUY: You are probably best off buying out of a healthy-looking flock nearby, so that you can drive the animals home yourself. Auction sheep are generally cheaper, but they may be the culls from somebody's flock, going by fast enough that you don't have a chance to find out their problems until too late. It's safest to take your time, take a sheep-knowledgeable friend along, and buy from a reputable breeder. If you want to show at a fair or to go into serious breeding, then you want to buy purebreds from an appropriate breeder.

NUMBER OF SHEEP: You will need to get more than 1 sheep or provide some other companionship because they're herd creatures by instinct. A sheep can be content in a field with a pony or even goats, but a lonely sheep will be miserable and annoy you by bleating all the time. At the other extreme, the more sheep you have, the more sheep problems you have; in other words, a small flock is easier to care for than a big one. A typical-sized year-round family flock consists of 6 or 7 ewes. A good way to get started is to buy ewes that have been recently bred in the fall. After lambing every spring, you'll have the extra lamb population for your good grass season until the fall when your lambs will be sold, butchered, or kept to increase your herd.

AGE OF SHEEP: You can start with any of 3 different age groups:

Bum Lambs. You may be able to get a couple of tiny, bottle-fed lambs for a small price, feed them milk until they can be weaned to grass, then butcher them in the fall, or keep them for breeding. If you have goats or cows and thus plenty of cheap, surplus milk (and children who will be enthusiastic about doing the work), this can be an economical way to

get started. If you have to buy the milk, even using a special product from the animal feed store, it can get expensive.

Weaned Lambs. This is the easiest, least risky system of acquiring sheep as far as animal problems go. Start by buying a couple of weaned lambs. They'll be several months old as compared to the day-old bummers, past the risky stage for scours, and well started on a grass diet. If they are strictly for meat, you get them in the spring, pasture them all summer, and butcher them in the fall when the grass dies back. Or you could keep them for breeding stock. The problem with starting with yearling breeding stock is that they are slightly more likely to have difficulty lambing, and they may be reluctant to let their babies nurse—even reject them completely, which you can deal with when you have experience, but it is more difficult to handle when you're all learning together.

Pregnant Ewes. In the fall—October or November—buy pregnant 2-or 3-year-old ewes that have experience with lambing. When you buy them, be sure and ask the seller when they got bred; you need to estimate their lambing date. Feed them through the winter and lamb them out come late winter; by spring you have a sizable flock. Odds are for every 2 ewes you have, you'll get 3 lambs because of common twin or even triplet births. This is considered a relatively cost-efficient way to get started.

Whatever age sheep you start with, if you buy from a nearby breeder that you feel good about, you'll have somebody to go back to with future questions. In general, look for a large animal compared to others of the breed, with proper conformation if you're buying registered, and good health. Here are signs of poor health:

Teeth. An experienced sheep person can capture a sheep, gently lay it down, open its mouth, pull down its bottom lip, and see what shape its teeth are in. The teeth in a sheep's mouth tell its age. A lamb has 8 "milk" teeth—and they're all in its lower jaw. Somewhere between 12 and 18 months the center pair will be replaced by the sheep's first pair of permanent teeth. You can distinguish permanent teeth from the milk teeth because they're longer and wider. A 2-year-old has 4 permanent teeth. A 3-year-old has 6. A 4-year-old has 8, and that's the most it will get. In the 4-year-old sheep's mouth, all the baby teeth are replaced by the permanent ones. A sheep with those 8 permanent teeth has a "full mouth." The usual sheep produces well until it's 6 or 7 years old and may live until age 12, although after age 6, it's considered to be getting "old." As the sheep continues to get older its teeth gradually slant forward, spread out, grind down, even break off. A "broken-mouth" sheep, meaning one with teeth broken off or missing, is past its prime and not a good buy. If it lives long enough, all the teeth will be gone; that's called a "gummer."

TRANSPORTING SHEEP: You can move a sheep in the back of a pickup. Simply lift it up there! If the pickup bed has side racks, you can leave it loose in there. If the sheep is halter-broke, you can put a halter on it and tie the halter rope to something in the pickup bed. Or you can tie the sheep's legs so it can't walk and transport it that way. When moving sheep, you'll notice what size your sheep is. Transporting is one time you'd be glad for a smaller breed over a larger one.

Foods and Feeding

PASTURE

What Plants Are in Your Pasture? Ask your county extension agent if there are local plants that poison sheep, like lambkill or ragwort. Learn to identify them, and find out how other area growers avoid losses from them. Don't require sheep to clear out brush; that is a job for goats. On the other hand, be open to the possibility that a herd of sheep might well clean up a particular weed problem you have—for example, knapweed. This

nasty green pest takes over very fast, kills off the other plants, reseeds itself generously, is a perennial, and is resistant to herbicides. But sheep eat it, get fat on it, and can eat it to near extinction, certainly down to a very controlled state. (In *The Sheep Raiser's Handbook* there is an excellent chapter on reclaiming brushy, weedy, abandoned pastures using sheep.) Straw and seeds in the fleece are no problem to a spinner, but burrs are a misery, so keep burrs out of your sheep pasture. Any grass is fine. Sheep are natural grass eaters and can live entirely on good green grass. Weaned lambs can grow to market weight on grass alone. Native grass is fine. If you're planting pasture for them, alfalfa, ladino, orchard grass, sweet clover, and timothy are all fine.

Keeping Wool Clean. If your wool is for you or other home spinners, you have a "spinner's flock"—and that means you'll want to take care with their pasture. Minimize burdock growth because its seed hulls are nearly impossible to get out of wool. The burdock plants are annuals. You can kill them by a hard chopping blow about 2 inches below ground level. Get to it before the plants have a chance to drop seeds. Sheep eat burdock, but not if they can find anything better. Chickens, however, will enjoy your thrownaway plants. Thistles, fleabane seeds, Spanish nettles, even the tiny timothy and bluegrass seeds, will be a problem if they get into the wool. (Chickens will enjoy all these discard plants.) Some people mow their pasture twice a year to keep weeds down. Some people bundle their sheep in actual jackets!

When you provide bedding for the sheep, it's best to select straw with long strands—it can be cleaned out of the wool relatively easily. Straw that has been chopped, wood chips, or sawdust all tend to get into the sheep's wool and become a problem to the spinner.

When to Turn Them Out. Some owners wait until the grass is 3–4 inches high before turning the sheep out to eat it. But sheep that have not been on pasture, when freshly turned out to it, may temporarily get loose bowels. It helps to give the sheep and lambs a generous portion of hay in the morning before you turn them out on the green grass the first time.

How Many Sheep? You can put out as many as 6 (or more!) ewes, plus their lambs, per acre if you have topnotch grass; 4 per acre if you have poorer grass; maybe only 2 if the pasture is full of brush and weeds, unless the weeds are a kind sheep thrive on, such as knapweed.

Rotating Pastures. This helps prevent worms. The easiest way to set up pasture rotation is to divide the pasture exactly in half. (Provide water on both sides.) When the grass on one side is eaten down, shift the sheep over to the other side.

Pasturing with Other Species. Because of the specialized shape of their teeth, sheep do eat grass down closer to the ground than cattle can. However, if they're not too crowded, cattle and sheep have been known to share a family pasture successfully. On the other hand, cows—and hogs, too—are much larger than sheep, and there have been cases when a pregnant ewe running with them got injured.

Other species pasturing with sheep have been used in the role of protectors. A donkey in with sheep is quite likely to turn the tables on predator dogs and chase them. Some goats will also stand up to dogs.

WATER AND SALT: Sheep need a reliable supply of clean water and a source of salt. You can buy the salt as a 50-lb. block at the livestock feed store.

WINTER FEEDING: As with all grass-eating livestock, the longer winters are in your locale, the more expense you'll have providing feed, and the more labor you'll have feeding it, and cleaning out the barn come spring. Some good winter feeds are almost free. Sheep enjoy

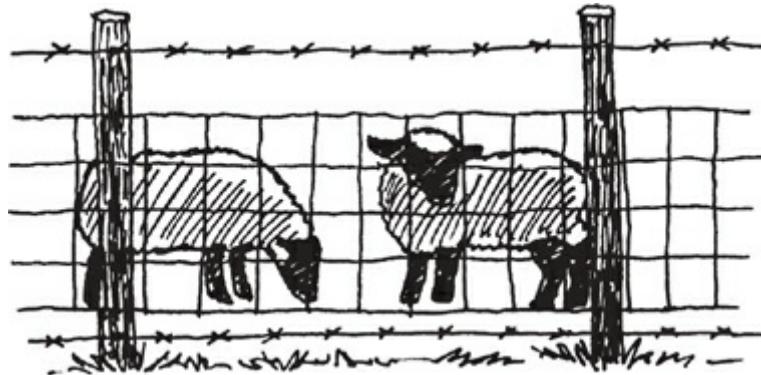

being allowed to glean in harvested corn fields. The old-timers also fed them root crops from the garden in winter to supplement their hay. Some grain is traditionally fed at least in the period before and after lambing. Hay will be the bulk of their winter feed: 2–4 lb. of legume hay per day per sheep. On a basic hay and grain diet, each sheep will need about 10 bales of hay and about 75 lb. of grain to get through the winter.

SUMMER SUPPLEMENTS: To get good wool and normal growth, sheep have to eat. So hay and/or grain are used in summer to supplement if their pasture is poor: anywhere from $\frac{1}{4}$ to $\frac{1}{2}$ lb. of grain per animal per day.

Housing and Fencing

HOUSING: Consider what your climate is and what the climatic origin of your particular sheep breed is. If you are raising only a couple of weaned lambs for meat to make use of your grass crop, you don't need to provide more than shade from the sun—either trees or a shed. Sheep have warm fur coats and don't mind rain a bit. If you are wintering over pregnant ewes, you do need some shelter for them in very cold weather (when temperatures fall below freezing), and at lambing time, and right after they are sheared if the weather turns cold. Other times they can live out in the open. Just about any old building will do, even a 3-sided one—except for during lambing, when pens are also necessary. You can even lamb on pasture ("Spring Pasture Lambing" audio, by Janet McNally; 800-748-9808). A creep (a feeder designed to allow young sheep but not adults to get the food) is advisable.

Don Fallick, my fence and barn expert, agrees: "Unless you live in a polar region, sheep don't really need a barn. A loafing shed to keep off the sun in the summer and protect from wind the rest of the year works fine. Some folks like to bring their sheep into a pen in a great barn during lambing time. With the advent of electric sheep clippers, it has also become common to see sheep brought to the barn for shearing."

HAY RACK AND GRAIN TROUGH: It makes your hay go farther if you provide a hay rack in which to feed it—and the same applies to a feeder trough for the grain. A trough is easy to make by just nailing boards together in a rectangular shape.

MANURE: When you have confined sheep you have sheep manure. I hear it's excellent for lawn or garden because it "does not burn" and can be scattered right onto field, garden, or lawn without harm. Or it can go directly to your compost pile and from there wherever it's wanted.

OF PREDATORS, PROBLEMS, AND FENCING: Of all the big domestic animals, sheep are most vulnerable to catastrophe. They have no natural defense against predators, not much good sense about things in general, and a frequently disastrous instinct to follow the

leader, no matter what. That means if you have 1 sheep in trouble, you likely have more than 1 in trouble. One sheep grower told me, "I've lost over 100 head of lambs to coyotes in the last 8 years." I asked, "How big a herd was that out of?" I was hoping he'd say something like "thousands." His reply, however, was, "That was from about 60 head of ewes."

Sherrie Campos wrote me: "A pack of dogs ran through our back pasture and Sunday morning we found a literal blood bath in our pond. Our mama sheep, Abby, and her 4-month-old lamb were standing in the pond. We had to go in and pull them out. In horror we found huge chunks of flesh missing and her bare bones exposed, gashes all over her neck and back. Abby died in our arms. Her little lamb almost died. Thor, our precious bottle baby was dead with no mark on him. The vet said he was scared to death. We had 2 funerals that Sunday and another just 2 days later. The children had horrible nightmares for months."

Your well-built fence stands between these lovable innocents and all the bad things out there that could happen to them. Sheep need fencing to keep them out of gardens—and to keep predators away from them, especially bears, coyotes, wolves, and wild or uncontrolled dogs. Even when dogs don't mean to kill a sheep they can; if they run it for the fun of it, the sheep dies of exhaustion. Sheep and goats require similar fencing. If you have to build a fence, that will probably be your biggest start-up expense with sheep. Check the fence line occasionally. Sheep will find and enlarge small holes; and if 1 leaves, being groupies, they all will. The most predator-proof fence for them would be 6-feet-high woven wire with a single tight strand of barbed wire at its base and above its top.

Herd Dogs. Sheep owners may be interested in 2 very different types of sheep dogs. One type is the sheepherding breeds. These dogs literally "drive" or chase the sheep to put a flock, large or small, where it needs to go. Sheep don't have high IQs. Sheepherding dogs do. I've read that Border Collies are the most intelligent of all dog breeds. I've owned and loved them for years. They helped me raise my children and saved a little kid's life more times than I like to remember. Mike and I lived on a ranch that was afflicted with rattlesnakes, and that's what our dog (which herded young humans rather than sheep) protected them from. The dog always knew the snake was there before the kid did. It would get between child and snake and bark and carry on, barking and jumping around, until an adult came out of the house and solved the problem. Sheep magazines carry ads offering trained collies. A mature Border Collie is very like having another human being to work with, within 4-legged limitations, of course. All the collies are herd dogs.

Guard Dogs. The other type of sheepdog breed is the guard dog. A good guard dog does not chase or kill sheep. It remains with the herd day and night, following it everywhere, living in the field with it rather than in the house with you. Unsupervised, they will protect the flock from predators, from coyotes, wild dogs, wolves, etc. The typical guard dog is big, about 100 lb., placid and aloof in temperament, able to live and work alone at their post. They typically respond only slowly to human command, but in a battle they move quickly to accomplish their job. Guard dog breeds are Anatolian Shepherds, Great Pyrenees, Maremmas, Komondors, Kuvasz, and Shar Planinetz. The Great Pyrenees dog is the size, shape, color, and texture of a sheep. I kid you not. And the idea is that they live with the sheep, but act like a dog protecting its family if a predator comes around. The guard dog is effective because it's big and it barks. It defends against other dogs because the larger guard dog easily establishes dominance over a possible predator dog, and the predator gets distracted in dog interactions rather than chasing sheep. Guard dogs also will threaten, even attack sheep predators, although they do not pursue a predator if it leaves, remaining instead with the herd. The best guard dogs are mature rather than

young and playful. Not every member of a guard-dog breed makes the best guard dog. One traditional way of raising the best of these is to have a puppy of the breed be adopted by and nurse from a ewe.

For more info, look up “livestock guarding dog” or “working dogs” on the Internet. The Maryland Small Ruminant web page has many articles on predator behavior (coyote, wolf, bear ...), identification (“Something’s been killing my sheep, but what?”) and defenses (fences, management, guard animals): www.sheepandgoat.com. “Using Guard Animals to Protect Livestock” is at http://mdc.mo.gov/documents/landown/wild/guard_animals.pdf. The book ... *May Safely Graze: Protecting Livestock Against Predators*, by Eugene Fytche, has chapters on various guard animals.

Anyway, if you’re serious about sheep, you may well want to get serious about a sheepdog too. Our sheepherders couldn’t have made it without the dogs who would move the herd at the proper signal from the herder. Or try a guard llama. My friend Janice Willard says coyote predation on her flock stopped after she acquired an adult male, notcastrated llama to stay with them.

Reproduction

THE EWES

Fat Ewes. Overweight ewes are difficult to get pregnant. So if your ewes are too plump, they should be dieting starting at least 6 weeks ahead of the expected breeding date. Obese ewes are also at risk for pregnancy toxemia. In that case the heavily pregnant ewe acts listless, walks aimlessly. Her muscles twitch. She grinds her teeth. Then comes a coma followed by death. Obese ewes that are pregnant with twins or triplets and who have been underfed in late pregnancy are most likely to develop this (also called “twin-lambing disease” or “lambing paralysis” or “Ketosis”). There’s no cure, only prevention—the diet before getting pregnant. Then take them off the diet and flush them in the usual way.

Flushing the Ewes. This is done about 2 weeks to 10 days before breeding, when the sheep is ovulating the eggs that will be fertilized by the ram when she is bred. The idea is to persuade her body to make as many eggs as possible, because twins and triplets are extra profit for the grower. And most growers figure that just barely to make it at least half the ewes must have twins—a “150 percent lamb crop.” So the ewes are “flushed” by putting them out on the lushest pasture, or feeding the best legume (alfalfa) hay—as much as they will eat, or by adding a grain ration, or increasing the grain ration by about a half more. Ewes flushed this way do “shed” more eggs and thus have more multiple births.

Breeding-Time: Eye, Tag, and Foot-Check. If the breed is not open-faced owners may “eye” the sheep, which means clipping wool away from around the eyes. At the same time, they typically prepare for the breeding by cutting wool from around their animal’s vaginal opening. That’s called “tagging” or, at more length, “clipping wool from around the dock.” The argument for doing it is that it keeps the animal cleaner and prevents wool from getting in the ram’s way when he’s trying to connect. And while the owner is at it, the sheep’s feet get checked and trimmed as needed. Sheep hooves are trimmed the same as goat hooves. Use a sharp knife, pruning shears, or hoof trimmers from a livestock supply store.

Breeding Season. Except for a few breeds, most sheep have a natural mating season that extends from early September through December. During that breeding season your ewes will go into their sexually receptive, fertile “heat” phase lasting from 3 hours to 3 days on a cycle of about every 13–19 days, 17 on the average.

Because the gestation time is 5 months (143–151 days to be precise), a ewe bred in September will lamb in chilly February. A ewe bred in December will lamb in balmy May, which reduces the risk of a chilled lamb. On the other hand, lambs born in February will be husky enough to go out in the weather and eat grass as soon as it's coming on well, and thus be able to take advantage of the entire grass season for their growth. And they'll be ready for market sooner than May lambs. So either way has advantages. Some growers just leave the ram in with the ewes and let him service them whenever. In that case the ram decides—and he will probably breed them early rather than later. Then your lambs will arrive in January, or possibly February.

Age of Ewe at Breeding. A ewe that is at least 9 months old can be bred. She is a little more likely to require assistance during lambing, but statistical studies have shown no likely damage to her body, and by breeding her that first season, she'll produce 1 extra annual lamb crop over her reproductive lifetime.

THE RAM: Most sheep farmers who have a half dozen ewes or more keep a ram, or else they use artificial insemination. A mature ram can impregnate or “service” as many as 30 ewes. A ram that was born just the previous spring can also service ewes, but not as many—maybe a dozen. However, if you have a small flock, a yearling ram can be a good way to accomplish your breeding. You can buy a yearling ram from off your farm to avoid inbreeding. After he has bred your ewes, you might eat or sell him. That way you don't have to pay to winter him. If you do decide to keep a ram, he will be able to continue doing his job for years, but the number of ewes he can service and the comparative fertility of his sperm will start gradually dropping after around age 5.

People with only a few ewes are more likely to consider the drawbacks of keeping a ram. A ram tends to be larger, more grumpy, even dangerous. For example, a Dorset ewe weighs 125–150 lb., but a Dorset ram will weigh 175–200 lb. Since a ram has to work only a few minutes a year to do his job, some small flock owners avoid the expense and bother of owning one by renting a ram when needed, or taking the ewes to a ram, or by artificially inseminating.

PREGNANCY AND LAMBING

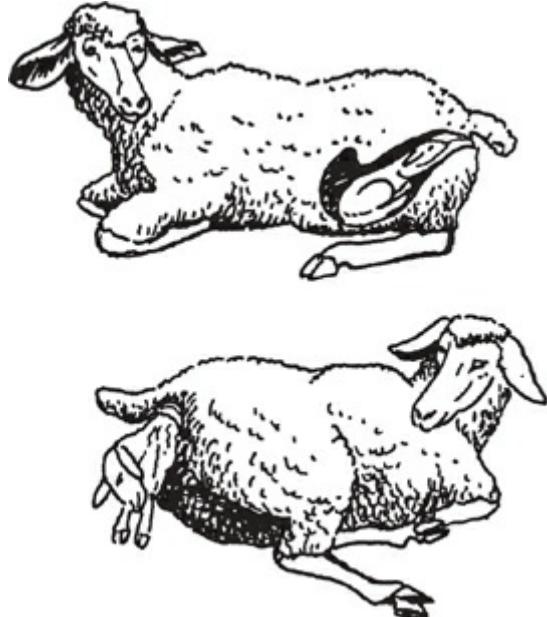

Pregnant Ewes. Make sure that your pregnant ewes are getting enough nourishing food, especially during the last half of pregnancy when the fetus is growing fastest—particularly the yearlings because they are themselves still growing, too. Good legume hay fed free choice as the grass supply dwindles is essential. Growers who feed grain give it to sheep who are pregnant, lactating, or being prepared for the show ring or meat market. They gradually increase the grain ration for pregnant ewes from about $\frac{1}{4}$ lb. at the beginning of gestation to $\frac{1}{2}$ –1 lb. per day in the last 6 weeks of pregnancy. During these last 6 weeks of pregnancy the ewe especially needs generous feeding plus plenty of exercise. This regimen is thought to help prevent pregnancy toxemia.

Lambing Shelter. Your pregnant ewe will carry her lamb(s) for about 5 months, and then give birth. It's important to be prepared for that lambing event. The most dangerous period in a sheep's life is its first 48 hours. Planning ahead for good shelter can help minimize problems.

Lambing Pens. Your lambing pens should be in a place that's roofed at least enough to where it will be absolutely dry inside and thoroughly protected from wind. An easy way to create (and dismantle) pens as needed is to have a supply ready of what looks like gates without fences (about 8 feet long by 3 feet high), plus some baling type wire. When you need to create a pen you take 2 “gates,” arrange them in an “L” shape against a corner

pair of walls, and wire them into place. That gives you an instant square-shaped pen. Or you can arrange them against a flat wall and have a 3-sided pen. Make your “gates” ahead of time and use them year after year. Once you have them made, you’ll probably discover some other good uses for them too.

Lambing. Because the lambs are typically born during cold weather, and because birthing is always a critical time for mothers and offspring, you need to be close by. I remember my daddy and the sheepherder making the rounds at night with a Coleman lantern and a big quart jar of iodine to dab on the babies’ cord ends. When sheep have babies they tend to have them all at once. A flock of a thousand will all lamb out within 3 days or so, and it is bound to be a sleepless, exhausting time for the shepherd because he or she has to check the ewes every 2 hours, day and night, to give help where it’s needed. Even when you own only a few ewes rather than hundreds, they will still lamb near the same time and need to be checked on that frequent schedule day and night until the birthing is accomplished and the lambs are on their feet, nursing, dry and obviously thriving.

LAMBING CHECKLIST

1. Birthing hang-ups: Sheep and goats are born the same way, so these instructions will work for either one. If the fetus is normally positioned you’ll see the front feet and nose first. Usually the ewe doesn’t need help, but once in a while you’ll notice an overly long labor that isn’t producing anything yet. In that case, wash your hands—and arms—well with a disinfectant soap and feel up her vagina. The fetus can get lodged in her birth canal sideways, or it may be coming out backwards, or a leg may be out of normal position and somehow preventing the normal delivery. You gently feel around and try to figure out what the problem is, and then figure out how to fix it.
2. Cord: After the lamb is born, pinch or cut off its umbilical cord 4–5 inches from its belly. Then dip its navel cord into an iodine solution or paint it with the iodine. That prevents infection.
3. Warmth: Have old towels, blankets, burlap bags, warm rags, or some such available in case you need to wrap a chilly lamb. Some growers even supply a heat lamp for drying off and warming newborn lambs right in the lambing shed. Chilling is the problem you’re most likely to have. This is a big reason why at lambing time you

check your sheep at least every 2 hours. If a lamb gets chilled, it can be quickly fatal. If you find a chilled lamb, even one that seems nearly dead, wrap it, get it into the house, warm it up, and then get it dry. For the worst cases, put the lamb into hot water for a few minutes—all but its head. Then dry it, wrap it in something, and put it in a thoroughly warm place such as a box by your wood stove, or under a heat lamp. A lamb in severe chilling crisis can also be helped by giving it warm milk to drink. Warm it thus for a few hours. Then it should be able to return to its mother. If the lamb has recovered from its birthing chill, has a mother that lets it cuddle up to get warm, and nurses regularly, it can endure temperatures that are even below zero—if you have it and its mother in a pen that is at least dry and sheltered from the wind.

4. Has the newborn lamb nursed on its own from the mother within half an hour of its birth? If not, move it gently close to the ewe's udder. Take one of the ewe's nipples in your hand, gently open and hold open the lamb's mouth with your other hand, and squirt her milk right into its mouth. This first milk is the antibody-containing colostrum, and the lamb needs it to thrive.
5. Did a ewe have twins or triplets? Is one of them visibly weaker than the other? If so, make sure that the mother is noticing both of them and nursing both of them, because it is possible she may not attend to the weaker one or may even harm it.
6. Overcoming lamb rejection: If you had to take the lamb away to warm it or if the ewe hasn't clicked into her motherly instinct with it yet, take some of her placenta and rub it across the lamb's body, especially right about the anus. That's the place a mother smells in order to identify her baby. After smelling her placenta on it, she should be satisfied and cooperate in letting it nurse or letting you help it nurse. That system can work to get a ewe to adopt an orphaned lamb. Or adoption can be accomplished by skinning the dead lamb and then draping that skin over the orphan.
7. Pinning: A lamb's first feces tend to be sticky. Sometimes the tail gets literally glued to its body and it can't get out any more bowel movements. This will soon be fatal if not fixed. You just get it loose, clean up the lamb's rear, and give it a fresh start. (Most owners will cut off those tails a week after birth.)
8. Mastitis: Avoid this inflammation of the udder by not overfeeding the ewe. Ewes with access to good grass will do fine without any grain. Ewes being fed grain shouldn't get more than what they were eating before the lambing, as more would cause them to make more milk than their lambs can drink and the backup of milk can cause infection.
9. Does the ewe lack milk? This is rare, but it can happen. In that case you have a bum lamb and need to get it started on the bottle. But don't give up too soon.

BUM LAMBS: A bottle-fed lamb is known as a “bum lamb” or a “bummer” or a “cosset.” It’s perilously easy to turn a lamb into a bum lamb. To avoid this, just coax or force the sheep’s nipple into its mouth. Reflex will do the rest. If you feed it its first meal from a bottle instead of managing to get ewe and lamb connected for the purpose, from that moment on it’s going to look at you and follow you as if you were its mother—and bleat for you when it’s hungry.

Bottle. Any glass bottle with a narrow neck can be a lamb bottle if you have a rubber nipple to pull over the neck of it. (Hold the bottle firmly by the neck to keep the lamb from jerking the nipple off with its forceful sucking and spilling the milk.) Or you can buy lamb feeding bottles from a livestock store—maybe even your local pet store.

Schedule. The lamb will do best if it is bottle-fed every 4–6 hours until it is 3 weeks old, and then every 8 hours or so for the next 2 months. At the beginning don't try to get the very young lamb to drink more than 2 oz. at each feeding. Its appetite will gradually build up.

Milk. You can feed a bum lamb spare goat or cow's milk once it's started, but it's important—if you possibly can—to get the mother's colostrum milk into it for its first few days. That may mean milking her by hand and then putting the milk into a lamb bottle for feeding. When the old-timers couldn't get the colostrum milk into a bum lamb, they would substitute a pint of cow or goat milk with an egg beaten up in it and a pour of dark corn syrup. Livestock stores can get you "lamb milk replacer," which is better food for them in terms of composition than goat or cow milk, but not cheap. But there's no substitute for the antibodies in natural colostrum.

Weaning. Lambs start out completely on mother's milk. By around 2 months old, or whenever the grass is sufficiently up, they'll start eating grass in addition to nursing. Gradually they shift to independent eating completely. Creep feeding is the practice of providing grain to the lambs in special feeders that the adult sheep cannot squeeze into. Creep feeding will cause lambs to gain weight faster than they would otherwise.

LAMB MARKETING: Lambs can be sold to 4-H members to use as fair projects, or kept to raise for family meat, or marketed as spring lamb to ethnic groups that have traditional lamb feasts for Passover or Easter. This market is generally located in big cities and wants a lamb under age 5 months. With the right contacts, it can pay off. Try not to make pets of lambs that will be eaten.

Sheep Vetting

TAIL DOCKING: Something most city folks don't know about sheep is that their tails are generally cut off when they are young—by the knife or by putting a very tight rubber band around its base to cut off the blood supply to it. The arguments for docking (cutting off) the tail are: If you don't dock the tail, fat accumulates in there and it gets pretty big. It also tends to get dirty with a collection of manure, burrs, and so on—especially if the sheep get the runs from a binge of too much grain or being suddenly put out on lush pasture. A build-up of manure under a tail can get maggoty and be a big problem—especially in a rainy, chilly climate. And some growers believe that a tailless ewe is easier for a ram to breed successfully.

The arguments against docking are that if you feed your animals carefully and avoid diarrhea episodes and plan to market or butcher them privately before breeding, there's really no need. A further argument is that long-tailed ewes actually breed fine, too. A final argument is that it's much ado about nothing because there are Mediterranean communities where a fat-tailed sheep is normal, and the big tail is a valuable product of butchering.

The more I know, the more I know I don't know. But as a personal preference, I favor the docking. There are several good ways to accomplish it if docking is your choice:

Elastration. The rubber band is a special type that is put on using a special tool called an "elastrator." The banded tail soon drops off by itself.

Cutting. To cut a tail off, first tie a tough twine very tightly around the tail's base. That cuts off the blood flow like a tourniquet. Choose a cutter that is strong, but not too sharp. (Sharper cutting edges actually make for worse bleeding.) Heat your cutter blades. That's for sterilization and because the hot blades cauterize the wound. Catch the lamb, hold it tightly between your legs with its hind end toward you. Holding it between your legs frees

up your hands. Then simply cut off the tail with your nippers. Cut the tail off 1–2 inches from its base. If you cut shorter, it will bleed worse. Smear on wound-coagulant (“blood stop”) and an antiseptic such as iodine. In an hour smear on wound-coagulant and antiseptic again. Done this way you’ll discover that an hour later your lamb seems just as happy and healthy as if nothing had happened to it. Twenty-four hours later, take off the tourniquet twine and put on a final application of the coagulant.

CASTRATING: The old-timers believed that the meat of full males wasn’t as good. That’s true if you’re going to wait over a year to eat it, but any male lamb that was born in the early spring and killed in the late fall will taste just as good castrated or uncastrated. Nevertheless, if you plan to market those male lambs, you’ll get a lower price for them if they aren’t castrated. A more serious argument for castrating males who are destined to be meat rather than kept for breeding stock is that the uncut males are more trouble to handle and will definitely breed the females among them if they are 6 months old or more. So if you have a planned breeding program and incest isn’t in it, then you’ll have to get the males in separate quarters from the females by that age—or castrate. The usual time to castrate is 2 weeks after birth. For information about castration, see [Chapter 8](#).

PARASITES AND DISEASES: Prevention is always the best approach. Buy from a healthy flock, give good feed, keep their shelter clean, rotate their pasture. Nevertheless, problems do happen. You can buy medicines for common health problems from your vet, or at your livestock feed store, or through a mail-order livestock-products supplier.

Worms. Having worms is the most common health problem that sheep may get. It’s best if you can keep a worm problem from starting. The worms are picked up by the sheep from grazing on an infected pasture. Pasture rotation helps to keep them from grazing too close. If your animals do get worms, then you can give them a commercial wormer.

Foot Rot. Foot rot is fairly common, so if your sheep limps, the cause is quite possibly foot rot. It is treated by first trimming bad areas away from the hoof, then applying a medicine to the hoof. Prevent it by avoiding overcrowding among your flock and keeping their hooves trimmed neatly. A popular medical preventive is to drive your sheep through a footbath that has copper sulfate or formalin in it. The traditional dimensions for such a footbath trough are 1 foot by 6 inches by 16 feet long. Place portable fence sections on either side of the trough (tilted enough outward that the sheep can get through). Or you can paint the copper sulfate on their hooves with a big brush. In areas where sheep are common and sheep services are available, you may be able to get on the route of an itinerant sheep-dipper who will furnish the medicine, the vat, and the effort to run your sheep through it—for a fee.

Fever. Fever is a special problem with sheep because it affects the wool. When a sheep is fevered, the wool growing out of its skin at that time develops a weakness in the strand. Some growers deal with that by shearing the sheep after it gets well (no later than 2 weeks after the fever is best). That way the weak spot will be on the end of the strand anyway and the wool isn’t ruined by having a weak spot in the middle.

WOOL: SHEARING TO SPINNING

WHY SHEAR? Do shear your sheep, even if you don’t use or sell the wool and must throw it away. If you don’t shear, the sheep shed some of it anyway and, unless you live extraordinarily far north or at high altitudes, are miserably hot wearing the rest through the summer.

WHEN? There is no absolute written-in-stone time you have to shear. It's a judgment call. Most sheep owners shear in the early spring. Or in the fall and spring. Most growers believe that if you don't shear them before the weather gets hot the sheep may feel hot or, worse, get worms or be sick. Growers generally wait for spring shearing until just before the sheep go off hay and onto grass pasture. One reason for that timing is that the new grass tends to have a laxative effect on the sheep, and that, of course, dirties the wool around their rear. Some old-timers also claim that warmer weather increases the amount of grease in the fleece, which makes cutting easier and the fleece heavier (it sells by the pound). Unless you have shelter for the sheep and have them in it, and if you live in a harsh climate, it's wise to wait until the warmer weather has arrived to shear because sheep have delicate health, and a night out in a storm immediately after shearing can take an awful toll. That one's from sad experience.

But a few growers shear only in the late fall just before the sheep are moved into winter housing from their pasture. If that housing is good shelter, the advantage of winter shearing is cleaner wool (outdoor living is cleaner) and a better wool market since you're selling in the off-season. Market lambs that will be butchered in the late fall can be sheared at about 5 months of age—or as part of a general fall shearing.

Who Will Shear?

Sheep-shearing isn't easy for an amateur. The goal is to get off the entire fleece in 1 piece, leaving the sheep looking neat—and do it with 1 swipe of the clippers in each place so that the shorn wool is of a maximum, and uniform, length. If you have to take more than 1 swipe to get the wool off your sheep, there will be wool of uneven lengths (called "second cuts"), and that diminishes the spinnability of the wool. You need somebody to do it for you, or show you how, if you've never shorn before. There are shearers who work for hire, going from farm to farm, and people with small flocks who do their own shearing and will also shear for hire. Your basic choice is to hire or learn how.

HIRE A PROFESSIONAL: So ask around of other sheep owners to find such a person. Many sheep shearers have a regular schedule during shearing season. The shearer may require a minimum number of sheep, or a minimum fee. In that case, you might be able to get permission to take your sheep to a place where the shearer is scheduled to visit and have them done there. But hiring a professional is possible only in areas that they regularly visit during shearing season. If you live in an isolated region, or are watching your budget closely, or simply want the adventure of learning this skill for yourself ... read on.

DO IT YOURSELF: Shearing a sheep is challenging for an amateur, but anybody can learn how. It helps to watch somebody else do it first, although plenty of people have learned to do it without even that much help. You can order a 2-hr instructional video, "Shearing Techniques," from Rural Route Videos: 800-823-7703; PO Box 359C, Austin, Manitoba ROH 0C0, CANADA; martin@ruralroutevideos.com; www.ruralroutevideos.com. (They also offer videos on "Starting Your Border Collie on Cattle, Sheep or Ducks," "The Basics of Good Sheep Management," "Working Horses of the '90s," "Old-Time Farming," and "British Sheep Fairs." Price per video: \$29.95 + \$5 s/h.) Don't expect your sheep to look very great the first time. The important thing is just to give it that haircut, to get the essential accomplished somehow. You'll get better at it and more comfortable with doing it every time.

How to Shear

1. CHOOSE A SHEARING DATE: See “When?” above. Also, in very humid weather, the wool would be wet. It’s best to shear after a spell of dry weather.

2. OBTAIN A CLIPPER: Hand clippers are cheap and can be made to do the job, as long as you don’t have a large number of sheep. You could make do with garden-type shears. Have your shears really sharp. Electric clippers are expensive, but you have to buy them only once, and they’re much easier to do a good job with. You can buy straight-bladed manual 6-inch sheep shears.

3. CHOOSE A SHEARING PLACE: Do your shearing in a small pen so that, if your animal does get away from you, you don’t have to chase it all over creation to finish.

4. PREPARE A SHEARING SURFACE: Spread a tarp or plastic sheet on the ground, or shear on a clean floor well away from anything like straw or dirt that could get into the fleece. You want to keep the wool as clean as possible.

5. GET SHEEP: Herd or wrestle the sheep into the pen and onto your clean surface.

6. POSITION SHEEP: Have somebody else there with you to help hold the sheep. Keep in mind any time you handle sheep that you should not grab wool. Wool grabs can hurt your sheep—or mess up the natural appearance of the fleece. Get the sheep firmly between your knees on its side or back, with the head pointing toward your behind. Positioning the sheep on its rear minimizes the fight.

7. CULL CLIP: First you cut off any wool that holds fecal material, called “dung locks.” Also cut off knots of matted wool, called “grease tags.” Cull clippings are most likely to be from around the anus—and in the belly area. Owners of small private herds usually sell their wool to hand spinners, and these people want only clean wool. So people shearing for hand spinners are likely to discard the sheep’s leg, belly, and head clippings if they are dirty or full of chaff, burrs, seeds, thistles, etc. After being cut off, the cull clips are thrown away.

8. DO THE WOOL CLIP: Now you’re doing the serious shearing. Clip away, turning the sheep’s body as needed. Clip as near the body as you can. The sheep’s wool, if you work right, will come off all in 1 piece that holds together nicely, and that’s the “fleece” or “wool clip.” You will sort of twirl the sheep and shear it at the same time. With practice you’ll soon get the moves right and know sheep anatomy blindfolded! The ideal is to shear off the entire fleece so that it remains 1 connected piece and the sheep looks neat and well-groomed when you’re done. In order to accomplish this, here are the important points to keep in mind:

- a. Start with the animal’s head.
- b. If you’re using hand shears, clip across its body from one side, across its back, and across the other side. You work your way thus from its head end toward its rear end until you arrive at its bottom—and by then you have all its wool off.
- c. If you’re using electric clippers, make strokes from head to tail that are as long as possible. Pros can reach from one end clear to the other end of a sheep’s body when shearing. In this case, another way to do it is (again starting with the head end) to first do one whole side (head to tail), then the whole back (head to tail), and then the other side (head to tail)—and then you’re done.
- d. Clip as close to the sheep’s body as you can. The basic skill of shearing is learning to

clip as near the body as possible, using a single cut only and without cutting the animal's skin. When you are just learning to shear, and if you are doing it with hand shears, aim to hold the cutter about $\frac{1}{2}$ inch out from the skin. If you go closer, you risk having a bleeding sheep. With clippers you can go closer. *Be careful not to nick your sheep's ears or teats!* But cut close, because if you cut the wool in the middle of its length, you get short wool that is not good for spinning.

- e. A corollary of the “cut close” rule is: *No second cuts allowed.* That is, no going back and taking more wool where you’ve already cut once—for if you reclip (trying to get what you missed the first time), you just get loose, short strands that are no good anyway. If you do make a second cut for the sake of the sheep’s appearance, just throw the short wool out. It can’t be part of the fleece.

9. TREAT THE NICKS: Beginners—and old-timers, too!—inevitably make a few nicks, so forgive yourself. Treat each with a disinfectant before you turn the sheep loose again.

10. CHECK THE HOOVES: This is the same as the fall prebreeding check-up. Trim as needed.

11. BAG THE FLEECE: Have ready a bag such as a gunnysack. Gather up the fleece and put it into the bag.

12. ON TO THE NEXT: Turn that sheep out and grab the next.

13. PACKAGE THE WOOL: Each fleece should all be clinging together in a single piece. First lay it out and examine it. If you’re selling to hand spinners, trim off any remaining dirty wool. For the commercial market, you can leave so-so dirty wool. Factory-handled wool gets a chemical treatment to dissolve dirt, etc. (which is why homespun feels better next to your skin). If the wool is damp or even wet, let it dry before the next step.

Gather up the fleece with the part that was closest to the sheep’s skin now facing outside. Never tie a fleece with plastic twine, for those fibers can get mixed with the wool

and create a problem at future processing stages. Paper twine—if you have it—is fine. To keep the fleece at home, store it in a loose state in paper bags or cardboard boxes. Never store it in a plastic bag.

14. LOOK FOR TICKS: Now you're done. Go someplace where you can strip naked and have somebody else check you all over for ticks.

Wool

WOOL MARKETING: Wool is sold by the pound. Some sheep keepers are into spinning and weaving, and they keep the animals mainly for their personal wool crop, which they'll card, spin, and weave themselves. Many sell to other hand spinners or to a larger wool buyer. In general, hand spinners like wool in interesting colors like black, silvery, brown, or blue, and will pay 2–10 times as much as commercial wool buyers, depending on how pretty—and how scarce—the color and texture of the wool is. Ask around to find out where other wool growers in your area are selling. You may find some willing to combine with you to make a commercial-sized shipment. The price of commercial wool depends on what is happening on the international wool market, which fluctuates and cannot be reliably predicted.

OF WOOL AND MARKET LAMBS: These will provide 3–5 lb. of fleece each at a 5-month shearing. After a private butchering, those sheep hides can also be tanned for sale. If the lambs had unusual colors or very nice wool, these tanned hides can be as profitable as the meat. (When sheep are sold for meat to commercial buyers the grower can't get the sheepskin.) Your county extension agent may be able to help in this marketing area.

CLEANING A FLEECE: A spinner can take a clean fleece and spin it before washing—it's called spinning "in the grease." But some people prefer prewashing. And many fleeces aren't that clean.

About Lanolin. Any "raw" wool fleece has a greasy feel from the natural sweat and lanolin wax. The older the wool gets before it is spun, the stiffer the wax on it gets, and the harder it will be to spin. Once you have your wool cleaned, it will weigh 30–60 percent less than it did before, because of the weight of the grease removed. But don't try or expect to get out all the grease. Leaving some permits easy spinning and creates a desirable water-resistance in your finished product. Since wool for dyeing must first have all the grease washed out to enable the mordant chemicals to take hold, many spinners seek out naturally colored wools: not just white, but also the shades of brown, black, and gray. Natural wool with some of its oil left in retains its water-repellent qualities. So don't wash all of the lanolin out of the wool. However, wool that you're planning to dye does have to have almost all the lanolin washed out or the dye won't set. To make homemade lanolin, boil a batch of sheep wool, and drain the oil. The lanolin is the oil. If you handle newly sheared wool you get your hands loaded with lanolin. It's very soothing and healing to the skin.

Degreased Wool. If you do remove all the grease in your cleaning process, or if you are working with purchased "scoured" (degreased) wool, you'll need to replace some oil. Sprinkle several drops of olive, mineral, or tanner's neat's-foot oil on your fibers, roll them up, and let them rest at least a quarter-hour before spinning.

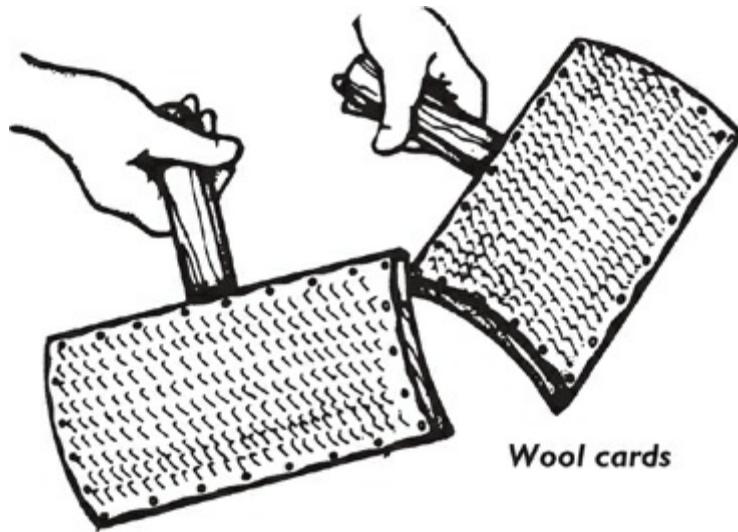

Cautions When Cleaning Wool. A problem with wool is its tendency to be damaged by harsh treatment. When cleaning it, never agitate it in the water. Never wring or twist it; it is all right to squeeze or press it. Always change temperatures gradually. Never immerse it

in any strongly alkaline solution: no bleach, no “super-cleaners” (use mild soap, mild detergent, or washing soda). Don’t use too much soap. If the water is too hot, the wool will shrink and wad up into little knots and you can’t even card it. Wool isn’t that different fresh from the sheep or in the sweater. Remember you’ve got 100 percent wool! Dry the wool in the shade, not in the sun. Or if you choose to dry in the sun, minimize its exposure to a few hours. Don’t let the wind blow it away.

Wool-Cleaning Steps

1. For this first step, you’ll want to work with the wool over a newspaper outdoors. The fleece is probably dirty and has seeds and the like in it. Pull the strands gently apart and let that kind of thing simply fall out. While you’re doing this you may want also to sort the wool somewhat. Any fleece contains more than 1 quality of wool. The shoulders and upper back tend to have the finest, softest strands.
2. Put wool in a tub or other container with warm water (95°F) and a very mild soap or detergent. Let it soak in warm water 10 minutes, drain, soak again, and drain again.
3. Add your cleaning agent to warm water, and make sure it is thoroughly dissolved before adding wool. Some people gently wash the wool, pulling it apart with their hands. Some just let the wool soak in this mixture another 10 minutes, drain, soak in fresh cleaning agent water again, and drain again.
4. Rinse twice using the same procedure as in step 2.
5. Dry by spreading the wool on paper or by hanging it in the shade.
6. At this stage you dye the wool, if you want to. Some dyes don’t require a mordant (a dye fixative). All the lanolin must have been washed out if you use a mordant. You can mordant the wool before, during, or after dyeing. For further information on wool dyeing, see *Growing Herbs and Plants for Dyeing* (1982), and other books and magazine articles probably available in your local library.
7. An optional further cleaning and preparation step is working with the wool using cards.

Wool CARDING: Wool cards are rectangular pieces of thin board with a simple handle on the back, or at the side. To this board is fastened a smaller rectangle of strong leather, set thick with slightly bent wire teeth, like a coarse brush or currycomb. In the early days, the leather back of the wool card was pierced with an awl by hand, the wire teeth cut off from a length of wire, slightly bent, and set one by one. The carder takes 1 card with her left hand and, resting it on her knees, draws a tuft of wool across it several times until a sufficient quantity of fiber has been caught upon the wire teeth. She then draws the second wool card across the first several times until the fibers are brushed parallel. Then by a motion, the wool is rolled or “carded” into small fleecy rolls, which are ready for spinning or to fill quilts.

Navajo-Churro Sheep. Wendy Thompson, Rawlins, WY, who has both LaMancha goats and Navajo-Churro sheep, wrote me a letter: "I was already hooked on spinning wool when my friend Linda told me that she had a breed of sheep whose wool did not need to be carded before spinning. They were called Navajo-Churro sheep. The herd that Linda's sheep had come from had traveled with a circus as a curiosity because Churros have up to 4 horns, which is a rare thing for sheep. And there aren't all that many Churros around anyway. I asked if I could buy a ram lamb."

"When shearing time came I couldn't believe the bag of wool that came from Jojo! It weighed at least 10 pounds! I dug right into the raw fleece and started spinning. It was much easier even than spinning a carded fleece! Churro fleece contains less lanolin than other wool, and is not crimped. The staple length is long (inner coat 3–5 inches and outer coat 6–10 inches). Yes, they have a double coat. It is classified as a rug yarn, but is still soft. The fleece stays together just enough to make continuous drafts, but separates without noticeable resistance. It feels like it just slides onto the bobbin and into yarn."

"Navajo-Churro sheep are descended from an ancient Iberian (Spanish) breed called the Churra, which the Spanish brought to the Americas in the 16th century. Churros are considered to be the original breed of sheep on this continent. The American Indians used Churros for much of their traditional weaving. Today Navajo-Churro sheep are an endangered breed. The Navajo-Churro Sheep Association is a recently established breed registry, with around 2,000 sheep currently registered. Mature ewes weigh about 85–120 lb. Mature rams weigh about 120–175 lb. For more information contact me or the Navajo-Churro Sheep Association, PO Box 94, Ojo Caliente, NM 87549; 505-986-2952."

MAKING A WOOL QUILT: Start with a layer of cheesecloth. Put the wool on the cheesecloth. It should be a $\frac{1}{2}$ -inch thick for a regular quilt, but for a thick comforter the wool layer can be 1, 2, or even 3 inches thick—or as thick as you wish. Put a layer of cheesecloth on top and coarsely stitch it into place with a pattern of diamonds or squares. This prevents the wool from shifting to the corner. The prepared layer can then be covered with cotton, sateen, outing flannel, satin, or whatever is desired. It can be tied with yarn or baby ribbon or coarsely stitched. The cover should be removable because you want to avoid washing the wool very much. I guarantee, if you keep the cover clean, the wool inside the cheesecloth won't get dirty in 25 years and will stay fluffy, light, and warm.

FELTING: This fairly simple craft turns wool into wonderful hats, boots, rugs, clothing, etc. Check out *Feltmaking* by Inge Evers; *Felt Craft* and *Felting by Hand* by Sue Freeman; *The Felting Book* from Louet Sales, PO Box 267, Ogdensburg, NY 13669; 613-925-4502; fax

613-925-1405; info@louet.com; www.louet.com; and *Feltmaking* by Beverly Gordon.

NOTE: For tanning and dyeing information, see Chapter 8.

SPINNING AND WEAVING: “Spinning” means making yarn, cord, or rope by twisting small pieces of fiber (cotton, straw, wool, hemp, etc.) around each other enough so that they then stay together; by spinning you create a far longer, stronger fiber than what you started with. It takes only a few hours, or less, to learn to spin, though the yarn produced by a beginner may have some imperfections. It’s easiest to start learning on a hand spindle and only then shift to using a spinning wheel (which tends, at first, to whip the yarn out of the apprentice’s hands disconcertingly fast). Incidentally, a sheep that was in very poor health at some time during the year may give wool that can be broken and thus won’t spin well.

A spinner is concerned with basically a 3-step process: drawing out fibers to be spun, twisting those fibers together, and arranging the already-twisted fibers. A wheel supplies the twist and may also arrange the spun yarn. I’m not going to tell you more than this of spinning or weaving because, first, I’m not personally knowledgeable; second, on this subject there is a wealth of information in your library already; and finally, this is very much a living craft, with groups of dedicated spinners and weavers to be found in almost any community.

Weaving is the next step, wherein you set up threads on a loom and weave them into cloth.

You’ll learn fastest and easiest from friends rather than out of books. To locate such friends, ask at your local “needle nook,” or look in your yellow pages directory under “spinning,” “weaving,” or “crafts” for leads, or visit your county fair home economics exhibit, find the handmade fabrics section, and sleuth out names and addresses to contact from there.

SUPPLIERS IN UNITED STATES

Alden Amos wrote the *Spinning Wheel Primer* and *The Book of Spinning*. He makes custom spinning wheels and sells supplies: 209-223-3602; 1178 Upper Previtali Rd., Jackson, CA 95642; www.pweb.jps.net/~gaustad/.

Green Mountain Spinnery: 800-321-9665; 802-387-4528; PO Box 568, Putney, VT 05346; spinnery@sover.net; www.spinnery.com.

Harrisville Designs charges \$10 for their catalog, credited if you order: 800-338-9415; Box 806, Harrisville, NH 03450.

Louet Co.: Contact in the United States at 613-925-4502 or 800-897-6444; fax 802-387-4841; 808 Commerce Park Dr., Ogdensburg, NY 13669. Their Canadian address is 3425 Hands Rd., Prescott, Ontario K0E 1T0, CANADA; info@louet.com; www.louet.com.

(The) Unicorn is the United States’ largest mail-order distributor of books on basketry, beadwork, crochet, dyeing, knitting, needlepoint, tatting, weaving, spinning, etc.: 800-289-9276; 1338 Ross St., Petaluma, CA 94954; www.unicornbooks.com. Their 11 × 17 in., 75-pg *Unicorn Textile Book Catalog* is \$3 and worth it.

Vermont Dept. of Agriculture lists fleeces, tools, patterns, etc., direct from Vermont homestead producers, online in the “Vermont Fiber Producers Directory.” Request the list by calling them at 802-828-2416.

Webs: America’s Yarn Store offers a \$2 weaving/spinning/ knitting catalog. Contact: PO Box 147, Northampton, MA 01061-0147; 413-584-2225 or 800-367-9327; fax 413-584-1603; webs@yarn.com; www.yarn.com.

Yarn Barn sells supplies for weaving, spinning (spinning wheels, looms, books, etc.):
800-468-0035; 930 Massachusetts, Lawrence, KS 66044; yarnbarn@sunflower.com;
www.yarnbarn-ks.com.

SUPPLIERS OUTSIDE OF UNITED STATES

Ashford Wheels and Looms offers a full range of fibercraft equipment. There will be an Ashford dealer near you. Their factory/showroom is at 415 West St., PO Box 474, Ashburton, NEW ZEALAND; phone 64-3-308-9087; fax 64-3-308-8664; sales@ashford.co.nz; www.ashford.co.nz. "Send for our FREE *Wheel & Loom* magazine." They also offer instructional books and videos.

Louet Sales Co.: 3425 Hands Rd., Prescott, Ontario K0E 1T0, CANADA; 800-897-6444; info@louet.com; www.louet.com.

Pat Green Carders manufactures quality drumcarders and wool pickers. "Sales are primarily to the U.S. The price list is in U.S. dollars with no tax, duty, or shipping charge. Free brochure." 604-858-6020; 877-898-2273; 48793 Chilliwack Lake Rd., Chilliwack, BC V4Z 1A6, CANADA; www.patgreencarders.com.

Treenway Crafts sells spinning fibers and weaving, knitting and stitching yarns, especially silk! 303-233-7455; fax 303-223-3411; 888-383-7455; 501 Musgrave Rd, Salt Spring Island, BC V8K 1V5, CANADA; silk@treenwaysilks.com; www.treenwaysilks.com.

MORE FIBER INFO

Magazines: *Shuttle, Spindle & Dyepot* is an award-winning quarterly for members of the Handweavers Guild of America. Join for \$35/yr: 678-730-0010; 1255 Buford Hwy., Ste. 211, Suwanee, GA 30024; www.weavespindye.org. Interweave Press publishes *SpinOff*, a quarterly magazine devoted to spinning (\$24/yr); and *Handwoven* (\$27/yr, 5 issues): 800-272-2193; 970-669-7672; fax 970-667-8317; 201 E. Fourth St., Loveland, CO 80537; www.interweave.com. *Fiberarts* is no longer published, but an article archive is available at their website or by calling 800-875-6208; 760-291-1531; 201 E. Fourth St., Loveland, CO 80537; info@fiberarts.com; www.fiberartsmagazine.com.

Books: Interweave Press also offers a free, fascinating spinning/weaving book catalog, including *Spinning Wheel Primer*, by Alden Amos; *Hands-On Spinning and Linen: Hand Spinning and Weaving*, by Patricia Baines. Paula Simmons wrote *Turning Wool into a Cottage Industry* (1991) for home spinners who also raise sheep; and *Handspinner's Guide to Selling, Spinning and Weaving with Wool*, etc. For spinning info, read *Fleece in Your Hands*, by Beverley Horne; *The Art and Technique of Handspinning*, by Allen Fannin; and *Hands-On Spinning*, by Lee Raven. For weaving info, see *Hands-On Weaving*, by Barbara Liebler; *The Key to Weaving*, by Mary Black; and *The Weaver's Book*, by Harriet Tidball.

Directories and Websites: Buy a directory of festivals, spinners, supplies, associations, processing mills, tanners, etc., from Buynne Tramutola, PO Box 216-A, Fountainville, PA 18923. The *Organic Fiber Directory* lists companies that handle organic cotton, flax, hemp, and wool: Organic Fiber Council, PO Box 547, Greenfield, MA 01302; www.theorganicpages.com. An Australian website tracks online info on wool, including markets, technology, spinning/knitting, conferences, and discussion groups: <http://www.daff.gov.au/agriculture-food/meat-wool-dairy/wool>. The Association of Northwest Weavers' Guilds maintains a website of fiber-related links at <http://northwestweavers.org/Suppliers.htm> or try <http://fiberarts.org/directories/links>.

SHEEP BUTCHERING

Because age makes such a difference in the taste and texture of sheep meat, there are different names for different ages. Carcasses are called "lamb" if the sheep was 14 months

old or younger at butchering time. In general thinking, sheep could become meat any time after 3 months. They're considered ideal when they reach 50–70 lb. A 50-lb. lamb will dress out to about 30 lb. meat. Most growers aim for some golden moment when the lamb is as large as possible but still young—and not excessively fat. The meat is called “yearling mutton” if between 14 and 24 months at slaughter time. Mature sheep weigh up to 100 lb., about 60 percent of which will be edible. Sheep is called “mutton” if the animal was over 2 years when butchered.

Killing a Sheep

The following information is from me and from a USDA pamphlet called “Lamb: Slaughtering, Cutting, Preserving, and Cooking on the Farm”: The animal should be tied to a tree or post in a place that you’ve prepared for the bleeding by laying down straw, leaves, or some such to protect the pelt. Stun the sheep with a bullet (.22 caliber rifle or pistol or larger) in the forehead, midway between and slightly above the eyes. Make the first shot right. As quickly as the animal goes down, bleeding should be begun. You do that with a straight boning knife. Hold the animal down with a knee on or behind the shoulder. With a hand on the sheep’s lower jaw, pull the head back to better expose the throat. With the cutting edge to the outside, insert the knife as close to the neck bone (spine) as possible. Cut clear through, cutting from the inside outward, severing the windpipe, esophagus, and blood vessels. Alternatively, you can start the process without using a gun by simply attaching a rope or chain around the hind legs of the sheep, hoisting it off the ground to where its head is about the height of your waist, and there cutting its throat. Or you can accomplish the job with the animal lying on its side.

Skinning a Sheep

You’ll need a bucket of cool water close by to help keep your hands and knife clean and the carcass clean. Dirt and wool on the carcass are very difficult to remove and usually have to be trimmed, so avoid that happening. At this point decide whether you’re going to skin the sheep on the ground (“horizontal”) or by hanging up (“suspended skinning”). You’ll hang it up eventually, either before or after skinning (pelting), and there is a separate set of directions for either choice. It is a matter of your personal preference. (Personally, I’d recommend the horizontal method as being simpler and less hassle.) In either case, you’re going to open the pelt around the legs and along the midline and breast.

THE FELL: In either case, make certain to cut toward the skin to avoid cutting through the thin membrane, the “fell” covering the outside of the carcass. If this membrane is broken, the lean muscles will bulge through and give the carcass an unattractive appearance. (It wouldn’t really hurt the meat any though.) If the fell is broken, try to work around the break to get a new start. After the sheep has been cut up, remove the fell membrane from each sirloin, loin, and rib chop before cooking; the fell becomes hard in frying. When the chop is still cold, the fell peels off easily. Start peeling at the lower end of the chop. Leave the fell on the leg and shoulder roasts while they are cooking, to lessen the evaporation of meat juices. Clean fell on roasts, chops, or stews will not affect flavor.

“FISTING”: This is done by pushing the fist under the pelt with the knuckles next to the carcass and the thumb over the first finger. Press the fist up against the skin, working it away from the carcass. Work slowly and avoid tearing through the fell and muscles. Fisting the pelt off is much easier if your hands are kept slightly wet.

THE PELT: For care of the sheep's pelt after it has been skinned off, see the tanning section in [Chapter 8](#). *This care should start the day it is removed.*

CUTTING OFF THE FRONT FEET: They can be removed by cutting through the joint at the knee or by breaking them at the "break" or "spool" joints. To break the legs there, cut across the tendon between the knee and foot. Grasp the foot in one hand, the leg in the other, and break back and sideways. On young lambs the "break" joint will snap easily and the foot can be removed. On older lambs and old sheep, it will be necessary to cut across the pastern joint and twist the toes off. Don't remove them until the skinning directions tell you to.

HORIZONTAL METHOD: When the bleeding is finished, move the sheep to a clean working area, perhaps on top of a sheet of scrubbed plywood, concrete, or a clean floor. Standing to the side of the sheep, hold 1 front leg between your knees and allow the animal to lean away. Remove a narrow strip of skin down the front of the foreleg, being sure to remove the skin over the knee. Turn the knife (with the cutting edge toward the skin) and make an opening to the neck in front of the breast.

Skin the opposite leg the same way, meeting the cut made in front of the breast. Open the pelt down the neck to the opening made by sticking for the purpose of bleeding it. This will form a V-shaped strip of pelt over the breast. Remove the pelt over the breast by pulling the pelt up and back. Once started, it is best to complete by fistling. After the pelt is loosened over the brisket (breast/chest), stop and skin out the rear legs.

To do the rear legs, stretch one out and remove a strip of skin down the back of the leg and over the hock (the "ankle" close over the hoof, which bends backward). With the leg still between your knees, turn the knife outward and open the skin from the hock to a point in front of the anus. Skin around the hock and "down" the leg. Remove the foot at the last joint, the one next to the hoof. Follow the same procedure on the other leg. Then fist the pelt off the inside of the legs and over the crotch. From the breast, fist down the belly and around the navel to the opening at the crotch. The carcass is now ready to be hung for evisceration.

SUSPENDED SKINNING METHOD: Tie a heavy string around one of the rear legs and suspend the carcass by that leg from a sturdy tree branch 8–10 feet from the ground or a strong barn beam equally high or some such. On the free leg, remove a strip of skin over the hock and past the dewclaws. Turn the knife outward and open the skin from the hock to a point in front of the anus. Skin around the hock and down the shank. Remove the foot at the last joint. Remove a strip of skin along the suspended leg and cut the skin from the hock towards the anus, connecting with the cut from the other leg. Remove the skin around the shank. Fist along the cut between the legs, removing the pelt around the back of the legs, in the crotch, and around the front of the legs. Suspend the carcass by the opposite leg and remove the foot on the loosened leg. Tie a heavy cord around both rear legs and suspend the carcass now with both hind legs tied.

Remove a strip of skin along the back of the front legs from the knee to the foot. Make a split in the pelt beginning at each knee and connecting at the neck in front of the breast. Open the pelt down the neck to the opening made by cutting the throat for bleeding. Remove the pelt over the breast by pulling the pelt up and back. Once started, it is best to complete by fistling. Fist along the belly and around the flanks, meeting the opening made at the rear legs.

Sides and Back. Open the pelt down the midline of the belly, and loosen the navel. Hold the pelt tight with one hand and fist off the sides. Work around to the back and up around

the hind legs. Fist down past the shoulder, around the sides, and up over the rump. From underneath the hock, push up until the pelt hangs by the skin that is fastened to the tail and anus. It will be necessary to use a knife to remove the pelt around the tail. Carefully skin around the tail and allow the pelt to drop. Remove the front feet. Wash the carcass thoroughly before eviscerating.

Gutting a Sheep

PREPARATION: Whether you used a horizontal or suspended skinning method, now you remove the head at the joint closest to the head. If the animal is not suspended, suspend it now by tying a rope tightly around both hind legs and hanging it from a branch or beam 8–10 feet high. Rinse the carcass thoroughly with a hose or by sloshing buckets of water over it.

THE GUTTING: Loosen the large intestine by cutting around the rectum deep into the pelvic canal. Pull the rectum outward, cutting any remaining attachments. Tie a piece of string around the large intestine near its opening, and let it drop into the pelvic cavity. The pelvic bone is not separated. Locate the end of the sternum and split the breastbone with a knife or saw. Do not cut into the body cavity. Make a cut through the male's genital area (cod) or female's (udder) into the pelvic cavity. Make this opening large enough to insert your hand. Insert the knife handle inside the body cavity and, with the blade extended outward, open the body cavity to the opening made at the brisket. Allow the paunch and intestines to roll out and hang down. Do not let them fall, as the esophagus will tear and spill its contents onto the carcass.

Find the loosened large intestine and pull it down past the kidneys, leaving the kidneys intact. Remove the liver by reaching behind and pulling it, while cutting the connective tissue. Examine the liver for any abscesses (yellow or white pus) or scar tissue. Remove the gall bladder from the liver by cutting beneath it and pulling. Be careful not to allow its contents to spill on the liver.

Pull the paunch and intestines outward and cut through the diaphragm (the thin sheet of muscle and white connective tissue that separates the lungs and heart from the stomach and intestines). Make this cut at the edge of the thin muscle. Sever the large artery at the backbone and pull downward, removing the heart, lungs, and windpipe with the paunch and intestines. Cut across the top of the heart and separate it from the lungs.

Wash the heart and liver carefully in cold water and place them under refrigeration. Remove the kidneys and kidney fat, and wash the inside of the body cavity thoroughly.

Aging Mutton

PREPARATION FOR HANGING: Rewash the outside. Carefully trim away any pieces of adhering skin or wool, any bruises, hair, or manure spots. Lamb carcasses are not usually halved and quartered before cooling because of their relatively small size. In cool weather (28–35°F), the carcass can be wrapped in a sheet, hung, and chilled in a well-ventilated shed, but don't let it freeze. Freezing within 1 day after death may toughen the meat. One way or another you need to accomplish prompt and thorough chilling of the warm carcass. After it has been chilled 24–48 hours you can commence with cutting it up.

TIME TO AGE: Extended hanging (up to 3 weeks) tenderizes the meat but also risks spoiling. I recommend you aim for the middle range in aging that older sheep. Hang the meat only about 10 days—and that only if you have facilities to keep it above freezing and below 40°F.

Cutting Up

There are several "correct" ways to cut up a sheep carcass. No single method is required or even recommended. One old-timer told me, "The meat of either sheep or goat is cut up pretty much like rabbit. Peel the shoulders right off the body. Cut through the thigh joint to separate the hind legs from the body. If you are careful you can get some steak off the back from the strip along each side of the backbone—the tenderloin, from the hams (the hind 'thigh'), and the shoulders. Make big chunks into roasts, and grind odds and ends for hamburger."

Here are the USDA directions—a lot more complicated: Begin cutting the carcass by removing the thin cuts—the breast, flank, and foreleg. Lay the carcass on its side and mark a cutting line from the elbow joint of the foreleg to the front part of the hind leg. Most of the flank can be removed by starting the cut between the legs at the cod (or udder) fat where the flank begins. This cut is made in a straight line from the front of the hind leg to the elbow joint. More of the rear flank and lower ribs can be removed by making the cut higher, near the hind leg, if that's your preference. However, the cut across the lower shoulder should be as close to the joint on the foreleg as possible to leave the shoulder roast large.

After removing the thin cuts from both sides, remove the kidneys, kidney fat, and diaphragm, if not removed at slaughter. Turn the carcass over on to the cut surfaces and remove the neck. Cross sectional cuts make neck chops; or the neck may be cut off flush with the top of the shoulder and added to your stew or ground lamb bowls.

The trimmed carcass is separated into 4 primal cuts, each with different characteristics. A cut between the fifth and sixth ribs removes the shoulder. Another cut between the 12th and 13th (last) ribs separates the rib from the loin (the 13th rib remains in the loin). The loin and legs are separated just in front of the hipbones by cutting through the small of the back where the curve of the leg muscles blend into the loin.

Split the legs through the center of the backbone. Trim the flank and cod (or udder) fat off. Remove the backbone from the leg by making a saw cut approximately parallel to the split surface of the backbone and 1 inch below this surface. Saw approximately 1 inch deep, or until you feel a slight slippage when you cut through part of the hipbone.

Be careful not to saw all the way through the hipbone. Insert a knife into the saw cut, find the "slip" joint between the bones, and cut underneath the backbone to complete its removal. Cut off the lower shank bones by sawing where the tendon enters the muscle.

The leg may be further trimmed by cutting through the knee or "stifle" joint to remove the shank. This joint is located about halfway between where the muscles of the shank end and the muscles of the lower leg begin. Cut into the tissues over the bones until you locate the joint and work the knife through it. Continue cutting straight across the heel of the leg.

Several sirloin chops may be removed by knife and by saw cuts made parallel to the cut separating the leg from the loin. Split the loin through the center of the backbone and remove the flank about 1 inch from the loin "eye." Loin chops are made by cutting perpendicular to the backbone. Usually chops are cut $\frac{3}{4}$ –1 inch thick. Doubles, or "English" loin chops, are made from a loin that has not been split. The flank portion may be ground or made into stew.

The rib should be split somewhat differently than the other primal cuts. The backbone is not split but is removed by cutting through the ribs along the ridge where they join the backbone. Continue cutting close to the backbone to separate 1 rib section. Repeat this cut along the opposite side of the backbone to separate it from the other rib section. Remove the breast portion by cutting approximately 2 inches from the rib "eye."

Rib chops are easily made by cutting between the ribs. The breast portion may be

barbecued in a single piece or made into riblets by cutting between the ribs. After splitting, the shoulder may be roasted as is, made into chops, or boned and rolled to make a more easily carved roast. Arm chops should be made first by cutting parallel to the surface made when the foreleg and breast were removed. Only 2 or 3 arm chops should be made. Blade chops are made by cutting between the ribs and sawing through the blade and backbone.

BONELESS SHOULDER ROAST: First remove the ribs and backbone by cutting closely underneath the ribs following their curvature, then cutting along and over the backbone and neck vertebrae to remove them. Start at the rear surface and cut along the lower edge of the blade bone to lift the underlying muscles, exposing the blade bone and arm bone. Cut along the edges of these bones and then lift the overlying meat and cut close to the top surface of these bones to remove them. The blade bone has a ridge that runs close and nearly parallel to its shorter edge. Try not to cut through the skin surface when cutting over this ridge. The boneless meat should be rolled so that the shoulder “eye” is lengthwise in the roast. The shoulder eye is located under the flat surface of the shoulder blade. Roll the meat as tightly as possible, then tie securely with a strong twine or cord. The boneless shoulder may be made into a pocket roast and stuffed with ground lamb or other dressing. The edges of the meat are laced together after stuffing.

The lower shank bones of the foreleg are removed by cutting or sawing through the joint. The foreleg and hind shank are often barbecued, cut into stew, or boned and the meat ground.

Preserving Lamb and Mutton

FREEZING: Ideally, lamb or mutton cuts should be used within 6–9 months after freezing, ground and stew lamb within 3–4 months. They probably would last longer, but the quality wouldn’t be as good.

CANNING: Be careful to remove the thin outer layer of skin, which has a strong flavor.

Cooking

Mike and some friends stole a sheep when they were foolish adolescents, butchered it, built a campfire, roasted quantities of the meat, and ate it on the spot. It made every one of them deathly ill. He hasn’t been willing or able to eat sheep meat since. The moral is to start with a legal sheep, one that’s not too old—and don’t eat mutton rare because of the risk of toxoplasmosis (see [Chapter 8](#)). Toxoplasmosis is more common in sheep than in beef. For great recipes, order *The Black Sheep Newsletter Lamb Cookbook* (503-621-3063; bsnewsltr@aol.com).

COOKING TENDER YOUNG LAMB: This can be cooked with dry heat such as broiling, roasting, and pan-frying. *NOTE: Even tender lamb should be cooked to an internal temperature of 160°F to prevent any possibility of toxoplasmosis.*

COOKING THE OLDER SHEEP: Mutton has a very intense flavor, which some people love and some detest. You almost never see mutton sold in retail stores, except perhaps as soup stock or in processed meat mixtures. Bob Slover, North Las Vegas, NV, wrote me: “You mention that your husband doesn’t like mutton. Well, I do, but I can’t get any anywhere. The last time I had mutton was in 1948 in Brooklyn, New York. I refuse to eat lamb or veal because mutton tastes so much better. Here’s a quote from Humphrey Clinker by Tobias Smollett (1771): ‘As their feeding costs so little, the sheep are not killed till 5 years

old, when their flesh, juices, and flavor are in perfection.' "

An older, tougher animal's meat should be cooked with moist heat slowly, as by pressure cooking or stewing, or ground into burger and cooked that way. If the taste is a problem for any of your family members, use recipes from the wild meat section of this chapter. Cooks with a lot of experience preparing sheep meat insist that burning the mutton fat is what creates the strong taste. They say, if you roast at no more than 325°F, that offensive taste can be avoided.

SHEEP FAT: *Trim away and/or cook away all the sheep fat.* It has the highest melting point of all the fats and so is high in cholesterol. It makes the best candles and fine soap, too, though better if mixed with softer fats. If you pressure-cook the meat until all the lean meat can be easily separated from the bone and fat, then use the meat in other recipes, you can eliminate the presence of fat almost completely. That's also a good way to cook tough meat.

Mutton Burger or Sausage. When making this do not include any portion of sheep fat. Make mutton burger out of 100 percent lean meat. Make sausage out of seasoned plain lean, or by mixing in a proportion (one-third is typical) of lard (pig fat).

Pressure-Cooking Tough, Old Mutton. Cut into pieces that will fit into the cooker. Soak 1 hour. Then cook 15 minutes at 15 lb. of pressure.

LAMB/MUTTON SEASONINGS: Lemon juice, rosemary, mint, tarragon, dill, and currant jelly are the ideal seasonings for lamb. Mutton is appropriately cooked with much attention to generous and interesting seasonings. Other possible good lamb-mutton seasonings are crushed mint leaves, fenugreek, marjoram, thyme, sage, savory, soy sauce, fresh parsley, beef bouillon cubes, chopped green pepper, Worcestershire sauce, chili sauce, ground allspice, nutmeg, sour cream, tomato sauce, green tomatoes and green tomato juice, Tabasco sauce, and red wine—used individually or in compatible combinations.

⇒ **LAMB/MUTTON SEASONING SALT** This is excellent in mutton burgers (4 t. per 5 lb.) or in mutton casserole (mutton, peas, cream of mushroom soup, chopped onion, plus lamb salt) or other lamb/mutton recipes. Combine 1 c. fine salt (popcorn salt that dissolves instantly is best), 1 t. black pepper, 1 t. paprika, ½ t. ground ginger, ½ t. dry mustard, ½ t. poultry seasoning, ½ t. cayenne pepper, and 2 t. garlic powder. Mix well. Useful in the kitchen or packed in a shaker jar for table use with mutton dishes.

RECIPES FOR UNCOMMON SHEEP PARTS: When you're doing home butchering you have all the parts to deal with, and most recipe books tell you only what to do with a typical roast or chops.

⇒ **APACHE TRIPE** Francis Nuno, an Apache lady, told me her family doesn't season its meat except with salt, but they use everything! She gave me this recipe, as well as the next: Clean intestines really well. Coil them tightly around lumps of intestinal fat. Bake. Cut into sections and serve. The tripe will be crispy on the outside. The fat seasons and tenderizes it.

⇒ **FRIED BLOOD AND ONIONS** Carefully save the blood. Cook it as soon as possible (within 24 hours) because it spoils quickly. Fry with onions in a cast-iron skillet. When cooled, it has the consistency of liver.

⇒ **TRADITIONAL ENGLISH SHEEP'S HEAD** Soak the head overnight in salted water. Then rinse thoroughly. Boil slowly for a couple hours with an onion. Cool, separate the meat from the bone, and use the meat in any suitable recipe (for example, any recipes for old stewing hens).

⇒ **SHEEP TONGUES** Soak in salt water. Rinse. Boil until tender. Bake in casserole layered

with bacon and vegetables, until vegetables are tender.

CONVENTIONAL LAMB/MUTTON RECIPES

➲ **LAMB CASSEROLE** Trim fat off of 1½ lb. stewing lamb. Cut meat into cubes. Heat 2 T. oil and saute 2 quartered onions until golden. Add meat and brown. Sprinkle with 4 T. flour and cook, stirring gently, for 1 minute. Add 2½ c. water, 1 t. salt, and ¼ t. pepper. Bring to a boil, then add 5 T. tomato paste, 1 clove finely chopped garlic, and a bouquet garni (bay leaf, thyme, and parsley tied in cheesecloth). Bake 1 hour at 350°F. Then add ½ c. fresh or frozen peas and bake another 20–30 minutes. Serve sprinkled with parsley. Serves 4.

➲ **SCOTCH BROTH (A MUTTON SOUP)** Trim all the fat from about a 1½-lb. neck of mutton or some other piece. Put it in your pan, cover with water, and bring slowly to a boil. Skim off the scum and then add salt and pepper and about 2 oz. of pearl barley. Simmer 1 hour. Add 1 diced onion, 2 leeks (if you have them), some chopped parsley, 1 large carrot, 1 small turnip, and a few sticks of celery. Continue cooking another hour. Cool. Take out the meat, remove the bone, cut up the meat and return it to the broth. Reheat, add a little chopped parsley, and you have your soup.

Here are 4 recipes from *The Good Food Guide to Washington and Oregon*, edited by Lane Morgan (Sasquatch Books, 1992). You can look at these and see how recipes really ought to be! But Lane says, “These recipes should be credited to Angelo Pellegrini.”

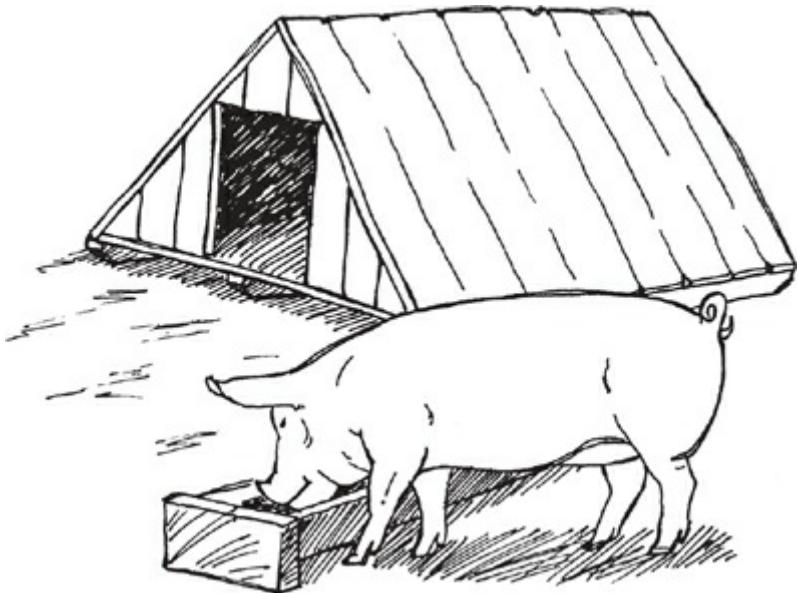

➲ **LEG OF LAMB ROAST** “The preferred flavoring agents, in addition to salt and pepper, are garlic, fresh rosemary, capers, parsley, lemon juice, olive oil, and dry vermouth. For a leg of lamb roast proceed thus: Remove the bone. In the resulting cavity, spread 2 T. of the following all coarsely minced together: 3 cloves of garlic, a dozen capers, and leaves of parsley and rosemary. Salt and pepper. Sprinkle over the whole 1 T. olive oil and the juice of half a lemon. Add a sacramental spray of dry vermouth. Enfold the bone in the cavity; tie the whole securely with heavy twine. Roast it in a 350°F oven in a pan just large enough to contain it. Baste occasionally with its own juices enriched with a bit of vermouth.”

➲ **LAMB SHANKS OR RIBS** “Place lamb shanks or ribs in an iron skillet in the oven preheated to 375°F. When about half done, drain out all the fat. Sprinkle with olive oil; add coarsely cut garlic, a few sprigs of rosemary, a squirt or two of lemon juice fired with a squirt of Tabasco. Salt and pepper to taste. Give the skillet a shake, return it to the oven and reduce the heat to 300°F. In a few minutes the ribs will be done. The shanks will require more time.”

➲ **LAMB CHOPS AND LAMB STEAKS** “For lamb chops and steak: Mince finely garlic and rosemary. Put in a small bowl, add olive oil and lemon juice. Remove what fat you can from the chops, rub them with this mixture, salt and pepper to taste, and cook them in a skillet rubbed with butter. When about done, spray them lightly with vermouth.”

➲ **LAMB FRICASSEE OR STEW** “For a fricassee or stew, cut neck bones and meat from the shoulder in small pieces. Dust them with flour flavored with salt, pepper, and curry powder. Using a heavy skillet, brown them in olive oil. Remove them with a slotted spoon onto a dish. In the same skillet, with no additional fat, saute onion, celery, carrot, and potato, all coarsely chopped and in what quantity desired. To 1 c. stock add a squirt of Tabasco, the juice of half a lemon, 2 T. tomato sauce, and 1 scant t. arrowroot for thickening. Stir well and pour over the saute. The sauce should be dense but fluid. If too dense, add some vermouth. If too fluid, add more arrowroot. Return the meat to the skillet, mix thoroughly, clamp on the lid, and simmer over low heat for 5 or so minutes.”

Pigs are the most civilized barnyard animal there is, yet probably also the ugliest. But Stephen Scott believes that pigs can look beautiful to those who love them and that caring for their welfare should be approached “from a spiritual perspective.” My correspondence about pigs with Stephen started when I got his letter asking the price to mail-order a copy of this book. His letter was well-written, a pleasure to read—such an honest, down-to-earth guy—and in it he mentioned he was an organic pig grower. Staring at that letter, it occurred to me that this articulate man, who had raised so many more pigs than I, could probably teach me a lot! So I wrote and asked if he would add to what I already had about pig raising for the new book.

Stephen wrote back: “I got your letter as I was putting the final touches on, of all things, the new hog fence. Yes, I would be glad to deliver your readers from the folly of store-bought, factory-raised food into the wisdom of home-grown, raised-in-the-dirt food.” And then Stephen seriously set out to explain in writing for me, and you, the things about organic pig growing he felt we really needed to know.

He wrote, “I believe that pigs are people too, and should be treated with respect. If you spend some time with your pigs, you will, no doubt, come to respect them as the magnificent creatures that they are. Watch them work out in the pasture for a while. They are unmatched for sheer brute strength, when they put down their snout and root in the ground. Aside from the good-natured squabbles at the trough, they exhibit a sense of togetherness that humans in confinement would be hard-pressed to match. They have individual personalities too, and my wife and I make sure to name them according to their personalities.

“We enjoy watching the pigs the whole while we have them, but when they are little we must watch them more—not only in order to detect signs of emerging personality but also to see if they seem content. The search for emerging personalities will insure that the right pig gets the right sister-in-law’s name, and the search for contentment will insure that they will not go to bed hungry. You can tell contented pigs by the sounds that they make and by how they look. I should mention, at this point, that you should give them a week or so to settle in and become comfortable with their surroundings. After that, contented pigs will make mellow sounds punctuated with boisterous good-natured sounds. I realize that this is not a scientific evaluation of pig sounds, but, just listen to them. Dirt on the snout, as a measure of contentedness, depends upon where the dirt is. No dirt means not happy. Dirt half way up the snout means happy. Dirt up past the eyes means ecstasy.

"I have heard that it is not a good idea to name and make pets out of animals raised to be eaten. All that I can say on that subject is that if you have given the pigs a good life it is not a problem. Give them as much fresh air and fresh water and good food and respect and consideration as you would any other family member, and sending them off to the butcher will not be a problem. Consider the kind of life that they would have had. Everybody else I know of who raises pigs for a living these days raises them in confinement. The little pigs grow up never to see the sun. Never to feel the earth under foot. Never to put their snout into the ground. Agribusiness men raise pigs like this because they can raise more of them and make more money."

You'll hear a lot more from Stephen in the rest of this pig section. If you don't want to—or can't—raise your own pigs, and want organic pork, contact Allen Moody, who represents a marketing co-op of a dozen organic pork producers: 608-625-2602; Organic Valley, PO Box 159, La Farge, WI 54639; www.organicvalley.com.

Pig growers aren't necessarily male. It's interesting how many women have written me about how they began raising a pig for household pork—and eventually became commercial pig ranchers! Martha Wells of Normangee, TX: "My husband did not know anything about farm life before moving here. And, with his working off the farm, a lot of 'man things' are left to me. I want to let your readers know, a woman *can do* a lot more than she suspects! I knew how to string the hay baler and run the tractor, so guess who gets to do the hay baling each year! (After getting tired of having to fix the baler after the men used it, I took over that job.) I run commercial ... cows. When they get penned and wormed, branded, or whatever, I do the penning and separating. Actually crawling in to castrate or give shots—yes, I occasionally do lose my nerve and require help! I always assist in the delivery of my brood sows and castrate my own boar pigs also."

Nevertheless, everyone should be careful ... *mature boars can be dangerous, and sows with litters should be treated with caution.*

Getting Started with Pigs

Books: For the ag-biz view, see *Pork Production Systems: Efficient Use of Swine and Feed Resources* by Pond, Manes, and Harris (1991). Iowa State U. offers info on raising pigs in hoop structures at www3.abe.iastate.edu/livestock/aen189.asp and www3.abe.iastate.edu/hoop_structures. *Hogs Your Way* (#BU-007641-GO) describes four growing systems. *The Swine Source Book: Alternatives for Pork Producers* (PC-7289-S) combines educational and popular press articles on sustainable hog raising, including hooped structures, pasture production, Swedish deep bedding, etc.: 800-876-8636; fax 612-625-6281; shopextension@umn.edu; <http://shop-secure.extension.umn.edu>. *Fit for a Pig: Low-Cost Sustainable Strategies of Resourceful Hog Farms* (1991) looks at the methods of 10 growers. *An Agriculture That Makes Sense: Making Money on Hogs* (1996) describes and analyzes a 50-sow sustainable hog enterprise in Minnesota (507-523-3366; www.landstewardshipproject.org). Keith Thornton's 1990 book, *Outdoor Pig Production* (Diamond Farm, 800-481-1353; www.diamondfarm.com), also presents alternatives to factory rearing. *The New American Farmer* is a collection of interviews with American farmers, including hog farmers: 802-656-0484; sanpubs@uvm.edu or visit www.sare.org/publications/naf.htm to view or purchase. The Gunthorps are fourth-generation pastured pork producers. Their story is in "Pigs on Pasture—The Gunthorp Farm" at www.gunthorpfarms.com. *A Gentler Way: Sows on Pasture* presents inspiring testimonials from Minnesota and Iowa hog farmers: 507-437-3085; Dwight Ault, Rt. 1, Box 230, Austin, MN 55912; baault@smig.net or visit www.sare.org/

[publications/hogs/resource.htm](#) for access to this and other resources on hogs. ATTRA's info, "Sustainable Hog Production Overview," is at www.attra.org/attra-pub/hog.html. *Raising Pigs Successfully* by Kathy and Bob Kellogg, Dirk van Loon's *Small-Scale Pig Raising* (1978), and Jerome D. Belanger's *Raising the Homestead Hog* (1977) are the best pig books for small-scale growers.

PERIODICALS: There isn't a folksy magazine specialized for small-scale owners and lovers of Ms. Piggy. But check out these more pro-oriented ones: *National Hog Farmer* costs \$14.75 for 12 issues/yr: 952-851-9329; 7900 International Dr., Ste. 300, Minneapolis, MN 55425. The Pork Industry Group (PIG), a branch of the National Livestock and Meat Board, offers info on research, catalog, and free recipes: 312-467-5520; 444 N. Michigan Ave., Chicago, IL 60611. Kansas State Research and Extension: 24 Umberger Hall, Manhattan, KS 66506; www.oznet.ksu.edu/library/ has a terrific swine research program and extensive pamphlet offerings.

VOCABULARY

Barrow—a castrated male pig

Boar—adult uncastrated male for breeding

Drift—herd or crowd of swine

Farrow—a sow gives birth

Feeder—a 40-lb. weaner pig that will be fed up to 200 lb.

Gilt—a female that hasn't had babies or has had only 1 litter (after getting pregnant the second time, she is called a "sow"; an "old gilt" is a female that got to be 1 or 2 years old and never bred)

Hog—grown pig arrived at butchering weight of 200 lb.

Piglet—newborn pig

Piggy—pregnant

Shoat—young weaned pig

Sow—adult female

Swine—one or more pigs

Weaner Pigs—little pigs that are big enough to leave their mother

ZONING: Stephen: "Local governments have rules concerning what animals can be raised in what areas. Some housing developments have rules that are stricter even than the zoning rules. Check with the local unit of government and find out if you can raise pigs where you live. Remember that the smaller the amount of space you have for pigs, the more concentrated the smell is likely to be. But if you have the means to build an attractive pen and fence, it may just be that your neighbors may become your customers. At least, talk it over ahead of time if you have a neighbor in close proximity to the prospective pen. If it turns out you can't raise pigs where you live, move."

BREEDS: Pig prices, like cow prices, fluctuate depending on supply and demand and whether they're generic pigs or brand-name and registered. There are different kinds of pigs, but they're all pig. So it's up to you if you want to buy pedigreed animals for a family meat plan. Names of some established breeds are Berkshire, Chester White, Landrace, Poland China, Duroc, Spotted Swine, Hampshire, and Yorkshire. If you want to have a breeding operation on pasture, you're best off with animals that were raised like

that—no matter what breed they are.

Stephen: "We could go into a lengthy discussion of what breed of pigs you should buy, but I believe that would be an exercise in futility since almost all modern breeds will produce pork quite nicely. What will determine the breed that you buy is more likely to be what breed is raised in your area.... But don't buy novelty breeds, such as Vietnamese potbellied pigs. They are bred more for pets than pork, are quite expensive, and are not a good producer of pork as we know it. What will be more of a consideration is the type of pig that you like the looks of. If you don't like the looks of the little one, then you won't like the looks of it when it grows up."

"... beauty is in the eye of the beholder. My aunt has raised pigs for many years. She raises many feeder pigs from 20 or so sows. She keeps sows for 6–8 years, and as each year goes by the sows get bigger and as far as I am concerned, uglier. But last time my wife and I went to see her, my aunt took us out to the pig barn and showed us her prize sow. It was a 600-lb. behemoth with an 18-inch-long snout and 12-inch-long ears that hung down over the eyes. She went into the pen and scratched this monster behind the ear and asked us, 'Isn't this the most beautiful pig you've ever seen?'

"Well, that sow had given her 12 little ones in each litter and 3 litters a year for the last 7 years. I admit there is a certain beauty in that. So find a pig you like the looks of and you will become more attached to it as time goes on."

Of Lean and Fat. Some growers are really concerned about the trend of selection that has taken animals that were brought to North America by the Conquistadors and after that traveled along with European pioneers—in essence, tough, independent, outdoors critters—and transformed them into dependent, sickly, hothouse animals. Part of the problem is that the latest thing in pig genetics is super-lean genetic lines. The problem with these is that they are so lean they are not a good choice for pigs to go on pasture because they don't have that blanket of fat to keep them warm. And fat and reproductive hormones are linked. A sow must keep up a 20-percent body fat ratio if she is to be fertile and conceive, farrow a big healthy family, and give them plenty of milk. That's just how pigs are. Another problem with the modern pig is that it is descended from umpteen generations of hothouse pigs so qualities of hardiness and resourcefulness have often been lost. Indeed their requirements for food and care virtually demand a confinement lifestyle. But if you're going to raise sheltered pigs, then super-leans are not so bad. Tamworths are good old-time hardy hogs for pasture-raising.

FEEDERS: Most families raising a pig or more for their family pork supply buy feeder pigs in the spring or summer and raise them to butchering size off the summer garden surplus and fall harvest scraps as well as other feeds as needed.

Stephen: "Feeders are pigs that weigh around 40 lb ... a set weight that the pig-raising industry sets to provide a base price for feeder pigs. Many times you will be able to buy a 50-lb. pig for nearly the same price as a 40-lb. one because the farmer is docked in price for pigs that are over the standard 40-lb. weight. Large growers want all of the feeders at 40 lb., so that they will all reach 200 lb. at the same time when they sell them.... they will be docked some for pigs over 200 lb."

When to Buy. "Depending upon how you feed them, it will take about 4½ months to turn a 40-lb. feeder pig into a 200-lb. butchering pig. When it's best to buy your feeder depends on where you live. If you live in the north, then you will want them over the summer. Pigs have a hard time, in the northern climes, putting on weight and keeping themselves warm at the same time. Add to that the fact that they aren't able to go outside and forage for any of the food that they need, thus costing you more money to raise them.

And winter pigs have to have a much more elaborate home and very likely need to be confined in a building, which may cause health problems. I live in Northeastern Wisconsin about thirty miles west of Green Bay. We buy our pigs in late June or early July so that they are ready to butcher in mid-November. If you live north of here you may want to consider buying them sooner and if you live south of here you may buy them later.

"If you live in the deep south, it may well be that you will want to raise them over the winter. In the south the hot weather of the summer may cause them to not be as happy as they would be in the cooler winter, and, as everybody knows, happy pigs will tend to be healthy pigs."

New Pigs. The time pigs are most likely to act weird and emotionally upset, to hide in a corner of the pig house and refuse to come out, or to take off and escape through your fences, are when you first bring them home. Stephen: "We know enough after 10 years of raising pigs to make sure that we stay home for the first few weeks after they have their little truck ride from the neighbor's place to ours. We lock them in the building for the first couple of days and feed and water them in there."

Runaways. Stephen: "This year everything went wrong. We got 3 pigs. Two of them had their transmissions lock up in forward gear and they burst through our fence. It took us 2 days to round up the 2 escapees and bring them back home. It cost my son a case of poison ivy, my wife 2 afternoon naps, and me—well, I had to listen to a lot of criticism about my choice of fences. No serious damage was done and the 2 recalcitrant porkers were soon back home. But then the third one must have heard from the others how great it was in the wide open spaces, because his transmission locked up in forward gear, and he too burst through the fence. He is not back home and it has been 3 months. I caught sight of him once this summer down by the woods, but he outsmarted the dog and me. Try as we might we could not get him."

To recapture a runaway pig, Stephen advises: "Bear in mind that pigs need water at all times. Check around in the area wherever there is water. Check for tracks and signs of rooting near water. If it happens to be a dry summer, you might have a chance of recovering your runaway. Unfortunately for us, this has been a wet year and it would appear we have lost this guy. No doubt, he has paid a price for his freedom already; it is unlikely that he will be able to survive the Wisconsin winter."

Home Sweet Home, For Pigs

Stephen on planning: "I had a farm background and so did my wife, and we had 20 acres and buildings, so we decided to raise some pigs. We were afraid of nothing in those days. We just went to the neighbor's and bought 3 nice white feeder pigs: 1 for ourselves and 2 to sell. Just a short while before we were to pick them up we realized that we hadn't thought of where we would put them: neither house nor fence did we have! That's how I learned that planning ahead eliminates mistakes. It is important to pick a good site. If you choose right the first time, you will not have to go through the hassle of moving the whole she-bang to another site. Think about it, take a walk around your place and consider different sites and different reasons to put them either here or over there."

So, combining the wisdom of Stephen with that of Mike and Carla, here are the essential points of pig housing site selection.

PIG HOUSING SITE SELECTION

1. Consideration of Neighbors—Put pigs where they won't offend a neighbor. Stephen: "If you live near a neighbor consider him or her in your plans as well. Life will not be too joyous for you if you have an irate neighbor to contend with."

2. Downwind from House—Stephen: “We started out with the pig field southwest of the house. And if you get any breeze at all in the summer here in Wisconsin, it will undoubtedly be a southwest breeze. So we got the full aroma of pig wafting over us all night long for 2 years until we finally moved the pen to the northeast of the house.”

3. Shade—Pigs can sunburn. No matter how warm or cool it is, they must have the option of a shaded place to rest in.

4. Provide a Wallow—Pigs are also at risk for fatal overheating. Allow space for their mud wallow. The wallow can be a matter of survival for them. That’s why, in hot weather, pigs roll in mud—it’s to cool themselves. Some sophisticated pig operations provide a misty spray to cool the outside pig runs. But Barb advised, “*Never hose a pig with cold water when it is hot.* It will put the animal into shock and it will die.” Don Fallick, Davenport, WA, explained: “Since pigs do not perspire, their only method of cooling off is the pig wallow.

Pigs do not actually prefer mud, and they will seek cool water to wallow in during hot seasons if given the chance. But you must give them some place to cool off, for their health. If your pigs are housed outdoors, in a hut, this is no problem, but if your sty is inside a large barn, some provision must be made for a hog wallow. If you don’t have running water to the barn, at least in summer, you’ll find yourself hauling an awful lot of water to the pigs.”

5. Clean, Abundant Drinking Water—They must have a lot of water in their trough. When planning where to put them, if you make sure it’s somewhere that you can get water to through a hose rather than by hauling it in buckets, you’ll be glad for your foresight.

6. Consider the Lay of the Land—Because pigs like to play in their water and make mud, you should put their housing in a high, dry site, above their water, above their mud, so they’ll be able to sleep warmly up out of the damp.

7. Shelter from Cold—if you have chilly, or outright cold, weather, they need a shelter such as a little house with a wooden floor or dirt with straw on it. The colder your weather will be, the better-built their housing needs to be. It could be one end of a shed or in a section of your barn.

8. Choose from Indoor/Outdoor Options—You have 3 basic variations to choose from: all-indoor, combined indoor-outdoor, or all outdoor with some shade provided. There are variations on those basic systems: You can either keep them confined in indoor quarters all the time, or just in bad weather. You can connect the indoor quarters chicken-yard-style with a door leading to a fenced outdoor run of whatever size is feasible for you, from a small run to a large pasture. An outdoor run 20 feet on the side would be fine for 1 pig. You could give more for more pigs. If you have a pasture for them you could just put their housing in the middle of their pasture. Or you could locate it along the fence side so there can be a people door on one side and a pig door to their pasture on the other. If space allows, pigs will choose 1 corner of their run or field for their potty area.

9. Loading Facility—Plan and build a way to load them onto a truck. You’ll need that for trips to the vet, or the meat cutter, or to a new owner. This should consist of a corral, which leads to a chute, which goes into a loading ramp. You can have one of these for all the livestock on the place with a system to get the pigs there, or 1 just for the pig housing.

10. Pastured Pigs?—Yes, this is an excellent option. Pigs give great weeding service. Is there a potential future garden spot you want de-weeded, plowed up, and fertilized? They're also good grazers. So you can put them where there is good stuff growing or where you've planted a fodder crop for them. Pigs on pasture will go far toward balancing their own diet, and will live in as nearly natural a way as they can manage. For parasite control they do best with a portable house like an A-frame on sled runners and rotated pastures—keeps pigs off a particular pasture segment at least 1 year before using it again. For example, there might be three 4-acre patches in your rotation, with crops grown on the land in the years that pigs aren't on it. Or you can use modern wormers given by shots, or in their food or water. Obviously, you can produce pigs on pasture for a mere fraction of the start-up cost of a confinement operation. Sows can farrow out of doors from April through November even in temperate-zone areas, and all year round in the south. Supply a well-insulated hut with generous bedding for the cold-weather farrowing.

11. Squeezed-In Pigs—Or you could put them in a space that can't be used for anything else, because—bottom line—pigs are extremely adaptable and forgiving as long as they're fed and treated kindly.
12. Bedding—Wherever they live, provide the pigs with plenty of hay, straw, etc., for bedding. They'll know what to do with it. All you have to do is give them enough. They'll arrange it under themselves to make a warm comfortable bed. In cold weather, they'll have it over themselves also when they sleep, blanket style!

PIG HOUSING

Agribusiness Style. Stephen: "I don't pretend to be an expert in the new high-tech means of pork production, but I have talked to the people in this area who raise pigs in this fashion. They have 500 acres of corn, to which no cultivator has been set. Weeds are killed and crops are fed through the miracles of chemistry. They weren't making enough money selling the corn so they decided that if chemistry could help raise corn, it could also help raise pigs. I was not allowed into the pig-raising building while the pigs were in there, but I saw it and had it explained to me while it was in the construction phase.

"My brother-in-law showed me around. He was building it and marveled at the efficiency of the whole operation. Three rooms: in one the sows; in another, the nursery; in the last, the feeders. He showed me the shower room and the office. One man runs the whole thing. He takes a shower before he starts the day's work and, of course, a shower at the end of the day's work. He showers so he doesn't bring in any diseases with him.

"Paperwork is kept so that the sows that don't meet the average can be culled. Little pigs are born, nursed, and fed up to butchering size without ever seeing the sun or feeling the earth under foot. They are born in that building and they will spend their whole life there. It is a pork factory. My brother-in-law thinks that this system is slicker than snot on a doorknob. I do not. I think it is a disgrace that a sow can live her whole life without ever turning around. Animals are as much God's creation as we are. How we treat them while they are in our care says a lot about what kind of people we are.

"The pigs are given a balanced ration of feed, but it is not their choice what they eat. Their likes and dislikes are not considered. Profit is the only consideration. Also, the pork you eat is laced with antibiotics. [Pigs are fed more antibiotics than any other type of animal.] In nonorganic commercial operations, low doses of antibiotics are routinely fed to cows, pigs, and poultry, all of which are raised in confinement nowadays. It is necessary to do this to insure that if a disease starts in one of these confined animals, it will not spread to all of them in the building. It is done also to increase weight gain, much of which

is only extra water in the meat in my estimation. These days the only way you can get the good-tasting pork from happy pigs is to raise it for yourself—or buy it from an organic pig grower.”

Comfy Pig Housing. Don Fallick said: “Pigs need to be protected from the heat and wind, and, to a lesser extent, from the cold. Their subcutaneous fat does protect them from cold temperatures, especially if they are housed in a cabin small enough to trap their body heat. A proper pig cabin should be large enough for the pig to turn around in. ‘A-frame’ huts are quite common where pigs are kept outdoors. In an indoor barn, the pigs will still need a small enough sleeping area to keep comfortable.”

Stephen described the building of his comfy pig housing to me: “I wanted a pig house with a dirt floor—no bottom on it—so it was important that it be situated high and dry. I wanted the house in a good permanent site, with a movable fence. So I took the tractor and disc and worked the area around where it was to be built ... to make it easier to shovel the dirt into a mound about twice as wide as the house would be. Around the house I wanted the ground to gently slope away. If you have a slope, then when you dump out the water trough to clean it, the water will run away from the house. The pigs will tend to want to wallow in the discarded water and make a small sea of mud near the trough. If you plan ahead and do the extra work to make a mound like that, then you will have a neat and tidy feeding area and a dry sleeping area for your new friends.

“We raised our first pigs under a truck cap. The pigs didn’t mind. They were just as happy as clams poking their heads out of the windows and the rear of the cap. But our second year’s pigs, even though I’d reinforced the cap arrangement, enjoyed knocking their house around so much, they managed to reduce it to rubble by November.

“As luck would have it, the company I work for was throwing out some brand new 3-foot-square plywood pallets. I could not pass them up. I used 10 of them to make a 9 × 9-foot building with two 3-foot doors ... on each end. That’s 3 pallets on the side, and 2 on the ends, with the middle part open to make 2 doors. For the roof I used six 10-foot-long 2 × 6s for rafters, spiked to the pallets. To the rafters I nailed 2 × 4s laid the 4-inch way and covered this over, first with tar paper and then with rolled roofing. I tarred the seams.”

Converting Existing Outbuildings. “If you have an existing outbuilding you can use that, and save yourself a lot of building problems. But if the pigs can get their noses into any holes near the bottom of the wall, they will eventually destroy that section of wall. So go in there and cover up any holes in the walls. If you are going to give them a fenced outdoor yard, they only need enough room in the building so that they can all lie down and stretch out. If space is tight, feed them outside.

“If you don’t have a suitable outbuilding for them, assess your building skills, scrounging skills, financial situation, and ingenuity. Everybody can have a nice comfy pig building. It is up to you to decide if you’re the building, scrounging, or buying type.”

If You Can Build. Stephen: “You can build an A-frame affair that will suit your purposes nicely. Pigs don’t mind what kind of a house they live in as long as it keeps them dry and cool, or warm, as conditions warrant. Most pig-raising books suggest that the building should have a floor in it. I don’t agree. It can get quite cold and wet in Wisconsin in the fall, yet my pig house has never had a floor in it. Instead, I provide lots of straw, or old grassy hay that Jersey Belle, our milk cow, turns her nose up at. The pigs burrow into that. The pigs always make sure they don’t get too close to the cold ground and still manage to cover themselves.”

If Scrounging Is Your Skill. Pigs are indifferent to appearances. Function is all that matters. Stephen: “You can scrounge up a perfectly good pig building such as the old truck

cap we used the first 2 years. I have seen pigs raised in a 1966 Buick LeSabre in a more rustic area of our fair state. When it comes to raising pigs on a subsistence level, the sky is the limit."

Buying Ready-Made. "You need not be ashamed to buy your pig house ready-made. In every rural area there are handymen who are not beneath building pig housing. If you can't find a handyman, go to the local high school and seek out the industrial arts teacher or the agriculture teacher. These guys don't make a fortune teaching and have the tools and the skills as well as the summer off in many cases and may welcome the opportunity to show off a little. In our area there are people who build gazebos and greenhouses and small storage buildings for the city folks. They build them at their home and then transport them to wherever the city folks want them. This would be high end housing for a pig, but if you have the money and don't want any of the hassle it is not a bad idea."

Your Pig Loading Set-Up. Stephen: "Our first year of pig-raising, we lacked a loading set-up. At year's end, after 4 hours of not a little chasing, diving in the mud, and considerable cursing, my family and the neighbor's managed to get 2 of them in the chicken coop. The third was a more serious problem altogether. It required brute force on the part of all 4 of us to physically drag the beast screaming and scratching, backwards, from the field to the loading setup.

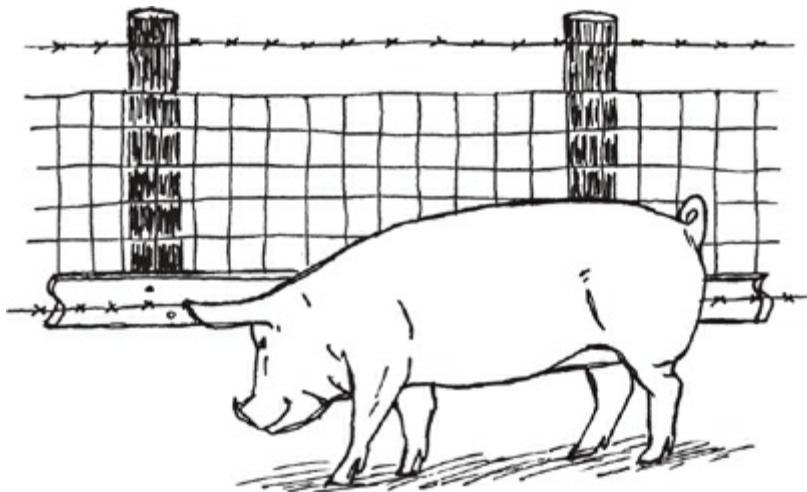

"It's a well-known fact that pigs will do anything not to go in a direction that you want them to go. I figured out if we were to be successful in loading pigs on a truck they must be channeled into an area narrow enough that they can't turn around. I would never again try to load them in the middle of a field. So I built the pig house with 1 door that led into the fence and another to the outside world. I nailed boards over the outside door.

"When it came time to call the trucker to pick them up, it was a simple matter to go out at night when the pigs were sleeping and nail a few boards over the openings that led into their field. When the trucker arrived in the morning we took the boards off that covered the door that led to the truck bed. It would have worked great, too, if it were not for the fact that the pigs decided, since they had never gone through that door up until that day, that they never would! So loading was still really hard.

"The next year I dug in 8 cedar posts and bought 4 pieces of $\frac{5}{8}$ -inch plywood. The day before we were going to ship I nailed the plywood to the cedar posts, forming a corral as wide as the loading gate on the truck. We coaxed them out with a couple of cobs of corn and closed the door of the pig house behind them. It was a simple matter of finding a gate as wide as the corral and pushing them using it on up the ramp of the truck. This is the point that we are still at today. It has been 7 years and the system has always worked well."

Fencing For Pigs

You have to fence any area for a pig very carefully. Stephen agrees: "The pigs don't mind what kind of house, or fence, they have, but in this area it is important for you to care. Quality fencing is essential."

CATCHING A PIG: There's an old saying: "As independent as a hog on ice." If your pigs are used to the slop bucket, so that they know you and look forward to your visits with bucketfuls of that good garbage, all you have to do if they do get out is run get the bucket and they'll follow you anywhere—even right back into their pen! To catch a pig that isn't slop-bucket-broke—well, they're "as independent as a hog on ice" and as hard to get hold of as the one in a "catch-the-greased-pig" contest. You just find yourself a few neighborly football players and try to tackle the pig. Then you carry it, or drag it back by the heels, or whatever your imagination suggests. Even if your pigs will follow the bucket, it's still best to have good fences; if the pigs manage a few hours in the garden while you're not home they'll wipe out your root vegetables. A reader told me that on her wedding day, the hogs got out. She said, "When the hogs get out, you chase hogs ... guys in tuxedos!"

PIGS ON PASTURE: Mike is a firm believer in having pigs preweed the garden. We suffer from morning glory, and after the stuff has taken over an area, he fences it off for the pigs to pasture in. Yes, you can pasture pigs instead of feeding them grains if you have enough land. If they are in a small area like your garden, they will plow and fertilize it for you as well as pasture in it.

Wherever they have ground they'll keep it thoroughly churned up, muddy, and manury. It makes no sense to give a pig a small grassy pasture. They'd ruin it for other grass eaters by rooting up and killing all the grass. On the other hand, if you can pasture your pigs on at least 1 acre per pig, and if the ground cover is lush enough (the more weeds, the better), they'll graze on grass and get fat, and have enough room so they won't ruin the pasture. But keep giving scraps, too. They need that food also.

Stephen agrees: "If you like the taste of real pork, then you should seek out organic growers who raise the pigs on the ground. Pigs find what they need from the earth in the way of minerals and other intangibles in ways that animal nutritionists don't even understand. That is why pigs raised on the ground have a much more well-rounded flavor. If you want to experience this flavor, buy some organic pork, or, better yet, raise your own pigs. You can make a small profit on them as well as provide your family with the very best tasting and most healthful pork available in the whole world. If you can't find organic pork in your neighborhood (or any other organic meat), there is a very good chance you can become a supplier of it. I have ... gone from store-bought, factory-produced, unhealthful pork to frolicking, rip-roaring, snout-in-the-ground, tasty, healthful pork. You can do it too. It is no more tedious or time-consuming to raise your own pork than it is to mow, trim, edge, and fertilize your lawn in town."

The biggest problems with feeding pigs in groups, on pasture or elsewhere, are the chance of wasted feed, and also boss pigs that overeat and push away smaller, less

aggressive pigs from the feed trough. An answer to that problem is using such long feed troughs that everybody gets a fair chance, or, if food is spread on the ground, spreading it over a large enough area that “pigging it” isn’t possible. And you can use creep feeders for the piglets on pasture.

OF PIGS AND ROOTING: Pigs are rooters. The wild ancestors of our domestic pigs lived in the forest, eating roots, grubs, and bugs discovered by that excellent nose—as well as grass, and windfall nuts and fruits. That snout is pure bone and cartilage and it makes them happy to use it. Pigs on pasture with fruit and nut trees in it can be darn near self-supporting, especially in the south. In confinement though, the wonderful snout can be a problem for you. If you have an area of rocky ground, Mike says that would be a good place to put a small outdoor pig run since you can’t use it for much else and they can’t tear it up. Or another answer to this problem is to put a ring in the pig’s nose. That inhibits rooting.

TYPES OF PIG FENCING

Steel Panel Fencing. This is the strongest of all, but the most expensive.

Stone. Stephen: “If you have the stone, the strength, and the time, a stone fence works well. Of course, you have to bear in mind that it is permanent. If you decide that stone is the way to go, you will want to choose some ground that is no good for anything else. You won’t be able to make it large enough to use as a pasture, so you will have to provide all the pigs’ feed. Its function will be to contain the pigs and not much more. It may require maintenance each year since the pigs will try to undermine the walls, and the frost will play havoc with them, too. If you are that special kind of person who likes to work with stone though, go for it. A stone fence can be a thing of beauty if it is done right. Since I have no skills in stonework, no time, no stone, and need to move their pasture each year, you are on your own as to how to construct it.”

Wood. An entire fence made of strong wood panels works better than wire, but it’s more expensive unless you can scrounge. Stephen: “I can tell you a little more about wooden fences. Like a stone fence, this is permanent; you will not be able to easily move it from year to year to change the pig’s pasture area. You can cut down on the amount of wood you have to buy if you can do some scrounging. A friend of mine made a nice wood fence for his pigs by scrounging up wooden pallets and making a modular affair that worked pretty well. He scrounged pallets and nailed them top and bottom to scrounged 10-foot-long 2 by 4s. He had to put a post in every 10 feet because pigs can put a lot of pressure on a wood fence. He huffed and puffed to make the fence, what with posts every 10 feet. He had to do minor repairs on it *weekly*, and major repairs between each new batch of pigs. That is the kind of guy he is—he loves his wooden fence. If that is the kind of person you are, think wood.”

Woven Wire. Fence with “hog wire” if you’re going to use wire. This is a woven wire. Pigs don’t need as high a fence as other large stock, but their fencing must be stronger, and it must be protected below the ground. You can either dig a trench and set your fence in concrete, or bury the bottom part of your wire at least 6 inches underground. Or you can stretch barbed wire along the bottom of your posts. But I’ll tell you from experience that even hog wire is liable not to work. The pigs will go through that wire more and more as they get bigger. They’ll break holes even in the hog wire, and you’ll have to go out with pliers to twist the broken ends back together.

The problem with breaking wire can be solved by putting a 2 × 10-inch board between the posts tightly right along the bottom. But if you’ve got soft dirt, your pigs can dig under

the boards. If you can choose rocky or hard ground, it will help prevent that digging. Nail up a board also between the posts along the top of the fence. That way they can't pull the fence wire down by climbing onto it.

Here's Stephen on woven wire: "My mother used to make woven-wire fences in the beginning of her pig-raising days. She had the money to buy the wire and the time to dig the post holes. Woven wire is quite expensive unless you can scrounge used wire or buy it at auctions in your area. The advantage of woven wire fences over wood fences is that the posts can be placed farther apart, thus requiring less of them. The problem with woven-wire fences is that, no matter how stout the wire, pigs will eventually demolish it, or go under it. You will have to keep an eye out for places that the pigs have softened up. They always root near the fence first and will eventually manage to make a mini Grand Canyon in one place. The grass is always greener outside of the fence, and they keep rooting outward and eventually they will get their snout under the wire and squirt out of the fence. You can delay their escape by nailing old posts or planks to the bottom of the wire. A woven-wire fence is time-consuming to move each year, and it is expensive to make 2 of them if you intend to take advantage of their rooting by planting either food for them or a garden for you. But if you want a permanent fence that will require some maintenance each year, woven wire will do."

Electric. Stephen: "Electric fences are inexpensive to make and easy to move. I have 2 doors in my pig house—one faces north and one faces south. When the pigs are in their south pasture, they come out of the south door and I board up the north door—and vice versa. I dug 6 postholes and planted 6 posts; 2 form the north side of the north fence and 2 form the south side of the south fence. Halfway between them on the north and south side of the pig house and roughly in the middle of the pig house are the 2 posts that form the east and west side of the fence. We use cedar wooden posts, along with enough steel posts so that you have one every 20 feet or so between the wooden posts. I use smooth, lightweight wire rather than barbed because it is cheaper and easier to work with. You will need 8 corner insulators and 2 insulators for each lightweight step-in type post. Get the steel-post insulators where you get the steel posts so they will work together.

"Now take one of the step-in-type posts and step it in the ground near the first corner post. From the spool cut eight 2-foot long pieces of wire. Now take one of the 2-foot pieces and stick it through the hole in one of the corner post insulators. Then go behind the post and, keeping the insulator to the inside of the post, twist the ends of the wire together. This done, position the wire about the post with the twisted part to the back of the post and the insulator to the front. Take a staple and drive it into the post so that the 2 legs of the staple straddle the twisted wire. This should be done at a height of about 6 inches from the ground. Drive the staple into the post so that it sinks in a ways and holds the wire tightly. Follow the same procedure with the second insulator, but this time nail the twisted end of the wire to the post at about 18 inches above the first one. Do the same thing on all of the 3 other corner posts.

"Now go back to the spool near the first corner post and grab hold of the loose end of the wire. Walk toward the second corner post as the wire plays out of the spool, and when you get there, grab hold of the insulator and give 2 or 2½ turns to the right. The hole should be running up and down when you stop turning. Position the wire on the groove of the insulator, making sure that you put it on the groove and not through the hole. The wire may not want to stay in the groove, but don't be concerned about that just yet. Now proceed to the third and fourth post doing the same thing. Walk back to the first corner post with wire still in hand, and stick the end of the wire into the ground near the post. Take out your pliers and cut the wire from the spool, making sure that you will have

enough wire to go around the back side of the post and meet up with the wire you stuck into the ground. (Always cut the wire a little longer than you think you will need it.)

"Now go behind the post and take hold of the 2 ends of the wire and twist them together to make the wire quite tight. You should kneel down while you do this because you will want the wire behind the post at the same level as the bottom insulator. Walk to the second corner post and see to it that the wire is in the groove of the insulator, then grab hold of the insulator and give it 2 or 2½ more turns to the right. Again the insulator should have the hole running up and down. Do the same thing on the third and fourth corner post. Now you go back to the first corner post and undo the twisted wire. Put the longest end in the groove and twist the ends to make the wire tight. Trim the ends of the wire off with your pliers. Go back to the insulator and, making sure the wire is still in the groove, grab hold of it and give it enough turns to tighten the wire, but not so many as to cause it to break. The wire need not be piano-string tight. Follow the same procedure with the second strand.

"Now that your wire is strung, take the step-in posts and step them in at about 20-foot intervals between the corner posts. When you have that done, take the step-in post insulators, and go to each post and fix the insulators to the wire and then to the posts. Your main goal will be to make sure that the bottom wire is about 6 inches from the ground. If the ground is uneven, it may be necessary to put in an extra one here and there to insure that the pigs can't get under the wire at any point. One last thing that is very important: cut from the spool a 2-foot piece of wire and attach the top and bottom wires of the fence to each other. I left this step out 1 year and it caused much consternation, and that is putting the situation in its very best light. Now to get the electricity to the fence will depend upon what kind of fencer you have. If it is a battery-powered one you can build a little box to keep the water off from it and nail the box to whatever corner post is most convenient for you. If it is a 110-volt one, you will have to decide if you want to run an extension cord to it or put it in a building and run pig fence type of electricity to the fence.

"You will notice that there are 2 terminals on the thing. One is the hot one that will go to the wire, and one is the ground that must be placed into the ground in order to make the system work. It is best to have a copper grounding rod, but if you don't, almost any kind of clean, paint-free post or stake will work. You will have nothing but trouble with your fencer if it is not properly grounded. If you have a dry summer, it may be necessary to pour water around the ground stake. In any event, it is a good idea to make sure that the grounding stake to which you have attached a piece of wire cut from the spool is driven well into the ground.

"To test the fence to see if it is electrified, you could be a sissy and buy a fence tester, which consists of a probe and clear plastic handle with a little light on it. You touch the probe to the wire and if the light lights up you have current on the fence. I'm too cheap to buy one of these things so I use the old-fashioned way: Select a blade of nice green grass, the braver you are the shorter the blade of grass can be. Just flick the blade of grass on the fence. If you get a tingle, you have current. If you get no tingle, place the blade of grass on the wire and slide it on the wire until you do get a tingle. If you don't get a tingle at all, then you have to troubleshoot. When you troubleshoot, start with the most obvious thing first and proceed to the least obvious."

10-Point E-Fence Checklist

1. See if the fencer is plugged in.
2. See if it is connected to the fence.

3. See if the 2 wires are connected.
4. See if anything is touching the fence.
5. See if the wire that should be in the groove is touching the wire that goes around the post. These last 2 require you to walk slowly around the fence looking carefully at the wires.
6. If you can't find anything wrong with any of the above, it is time to check out the fencer. It should have a fuse in it; check that first.
7. Check the ground.
8. The regulator should be clearly visible on the front of the fencer. It is a little tin-can-type of affair. Pull it out and it should have 2 prongs on it. You should have a spare; put the new one in and test the fence with a blade of grass. If you still get no action take a deep breath and calm down.
9. Check each thing again.
10. If it is still a no-go, take the fencer to an expert.

Food for Pigs

PIGS RECYCLE KITCHEN SCRAPS: Pigs are important because they eat kitchen scraps—"garbage." We keep a slop bucket in the kitchen for the pigs. Into the slop bucket go peelings, leftovers, extra milk, spoiled foods from the root cellar, the contents from jars of canned fruit that got moldy, bread crusts—if I burned the bottom of the loaf or accidentally baked it 2 hours instead of 40 minutes—and so on. People have asked me if you can feed chickens scraps of chicken meat or pigs scraps of pig meat. Yes, you can. They don't mind a bit. They both eat meat leftovers, cooked or uncooked, although our cat and dog get first pick of the cooked meat scraps. They will eat leftover grease too. But I don't give pigs bones. The chickens can pick on them though. I do give fruit cores and seeds to the pigs when I'm working on fruit in the summer. Pigs are tremendously efficient food converters and they'll change all those throwaways into meat and lard.

Mike told me that in some urban areas there is a law that food scraps of that sort can't be fed to pigs. That just boggles my mind. It is so inefficient. Why throw out good food that could feed pigs, which in turn could feed hungry people? When food scraps are ground and poured down a sewer it increases the general sewage burden. When scraps are taken to a land dump and mixed with metals and papers and buried or burned, that's a disgraceful waste of a valuable recyclable material—food. Everybody should be saving their leftover food for recycling just like the country people do. A city could keep a whole army of pigs and chickens growing! Or that food waste could be composted and used to fertilize land from which more plant food will be grown.

The notion that kitchen scraps are unclean is nonsense. We feed our pigs and chickens the leftovers from our home-grown fruits and vegetables. That means our pork, eggs, and chicken have the same high standard of composition as the other food this family eats: "organic." Garbage only looks unpalatable because the peelings and the leftovers, gravy, and grease are all poured together in it. In the later summer and fall we carry the pigs on culls from the garden and root cellar.

So we get little pigs in the spring and feed them all summer on the leavings from canning and freezing. Come fall we butcher the spring pigs, which are just the right size for that, and buy more feeder pigs. We feed them on the food in storage that isn't making it—the green tomatoes that rotted instead of ripening, the apples that went bad prematurely, the spoiled pumpkins. About the time that source of food is really slowing

down it is early spring and still cold enough for butchering if you pick the right day and the pigs are big and ready. We never need to buy them so much as a cupful of feed and feed them no grain at any time in their lives—milk and vegetables is it. So I take the pig's bucket with me to the cellar every few days to check the food in storage. A big pig gets nearly 5 gal. of this food each day as well as extra milk and table scraps. (There is no way I know to feed a pig more than it can eat.) If I fed it 10 gal. it would manage to eat all that too, but 5 is more than enough even for a big pig.

SPEED OF WEIGHT GAIN: Pigs gain weight very fast. If you get a little pig in the spring, 6 months later it will weigh 200 lb.—butchering size. If you feed a grain mixture they grow to 200 lb. in as little as 4 months. Corn is the richest food for them, but corn feeding makes for lots of fat. If you keep food in front of them constantly, that's when you get your fastest weight gain. They would go on up to 400 lb. if you let them, but, after 200 lb., the bacon just keeps getting fatter, and there is proportionately more lard and less meat. That is not what most people need or want.

OF PIGS AND FAT: How fat do you want your pig to be? If you pen an animal up and keep rich food like grain in front of it constantly (which is the commercial way to raise them), you're going to have more fat and softer meat than if you let your animal rustle by grazing in a weedy field. Also, older pigs have relatively more fat on them. That's the reason for the practice of butchering at 200–225 lb. When you butcher at not more than 225 lb., you get more meat proportionately. More feeding will not be as efficient: above that weight per pound of feed, your pig will get fatter rather than meatier, and your pig will put on less weight per pound of feed than it did before.

Stephen: "Pigs are a lot like humans when it comes to eating. You will have to be like a good mother to them and see to it that they get what they need and not just what they want. The whole exercise is not to see how fast we can get them to butchering size; rather it is to keep them happy and healthy and put weight on them gradually. Pigs gain weight fast enough as it is. I can't imagine trying to rush them with 'high energy/high protein' feeds. But that is just what the experts at your local feed mill will want you to do. Don't allow yourself to be swept up in this whirlwind of salesmanship. 'Salesmanship,' you must remember, is a ship that transports money. The salesman wants to transport your money from your pocket to his. If you have some money that you want to take this scenic cruise between pockets, okay. But otherwise, build a coral reef around your pocketbook so that the feed salesman's ship of sales cannot dock in your peaceful little harbor and fill its hold with your money!"

CHEAP PIG FOOD: So, rather than feeding costly food for quickest weight gain (and nonorganic, antibiotic-laced food at that), I prefer using the cheapest possible pig feed for your area. Here that means household slop and oats, which aren't as rich as corn, and pea "screenings" (the weed seed the mechanical harvester separates out from the peas). Peas, barley, oats, weed seeds, etc., are all fine pig food. Some growers suggest that you soak all grains that have a husk, such as whole oats, for at least 2 days before feeding. (See the sections on the individual grains for directions on livestock feeding.)

Ruth Proctor wrote me from New Plymouth, ID: "Once I got the bright idea of asking a potato processing plant for their trimmings and peelings to feed to our 50 hogs and ended up getting 2 tons every day—the only catch being that we had to furnish the truck and keep the peels hauled off. We found out there is no way 50 hogs can consume 2 tons of spuds every day, but it made wonderful fertilizer for our fields—though somewhat sticky."

FOOD FOR NEWLY ARRIVED PIGS: Stephen: "You will want to buy a few bags of pig starter. It comes in pellet form and is like candy for the little feeder pigs. It will keep them happy and help them settle into their new surroundings. It might be worth asking the farmer you buy your feeder pigs from what kind of starter he uses, and then get the same brand. But I have found it unnecessary to get the same kind of starter because all of it is so good that the little oinkers can't resist it even if it is slightly different than what they are used to. Suffice it to say that you don't want the pigs to stop eating in the upset of changing homes, as that can lead to serious health problems. But get a pig starter that is unmedicated. The 'medication' would be antibiotics, which are unnecessary if you buy your pigs at the right time of year for your climate and have properly prepared their house for dryness."

"The salesman at the feed mill may tell you to give the pigs all that they want of the starter pellets. But since we have them out on the ground so that they can hunt for goodies with their snouts, we start out with three 40-lb. pigs and three 50-lb. bags of pellets. Each pig gets about 4 lb. of pellets per day. You can divide this up into 2 meals, morning and night, or better yet, 3 meals, morning, noon, and night, just like people."

During the first 10 days the pigs are with you, you can gradually phase them into the home-grown diet that they will be on at your home. Or ...

PARTLY COMMERCIAL DIET: Stephen: "When you open the last bag of pellets, it is time to go back to the feed mill. You should be about 10 days into the pig-raising experience. The salesman will now want you to buy concentrated feeds and corn (both expensive), but tell him that all you want is a couple bags of 'balanced ration': meaning some unmedicated concentrate (protein supplement), oats, and corn. Tell him you want oats and corn in a ratio of 2 oats to 1 corn *by weight not by volume*. (This should be ground fine and mixed thoroughly.) Feeding them this way, you will have to work a little to get what they need in the way of intangibles because they'll need to be on good ground, in which worms live and roots grow. Then they will do well without a lot of expensive additives to their food.

"To sum up: you get a balanced ration for them at the feed store consisting of a protein supplement, oats, corn, and minerals. Or you could substitute some other grain for corn, like barley. Any combination of grains will do, so long as there's enough natural variety in their diet. This year, having the pigs as usual on good ground with lots of greens, roots, worms, garden vegetables and sweet corn to eat, we omitted the feed-store corn and bought only oats and some protein supplement. *Caution: If you feed too much sweet corn, your pigs may develop the runs.* We fed about 4 cobs a day to each pig for the first part of the time we had them and 8 cobs a day per pig for the last half."

VEGETABLES: I feed vegetables to the pigs raw unless they happen to be kitchen leftovers, but Stephen cooks them! "I raise vegetables for the organic market in this area and always seem to have more than I can sell of one thing or another from year to year. One year it will be extra potatoes, the next year it will be extra carrots, and every year I have small cobs of sweet corn that I wouldn't want to sell. I can't see just letting this stuff go to waste, so I feed it to the pigs. I harvest the root crops with a potato digger that was manufactured in 1888, bring them into the barn, and put them into large wooden boxes. When I have time, I scrub up some of the veggies and put them into this large cast iron pot that I bought new a couple of years ago from a local foundry for \$114. I build a fire under the pot and by dinner time the veggies are cooked through. I take a pail of them out and let it cool down some. It is usually starting to get cold here about harvest time and the pigs dive right into these warm cooked veggies. The pigs are happier with their bellies stuffed full of

warm cooked veggies on a cold fall day.

"Before I bought my cast iron pot, I used to bring potatoes into the house and scrub them up and put them in a kettle on the wood cookstove. I did this as the last chore of the day and they would bubble away until we went to bed. The veggies would be cold in the morning when we got up, but by the time we got the stove going and a pot of coffee down the hatch, they were nice and warm, and the pigs relished them for breakfast. This is optional for you, but the pigs, after being treated to warm veggies for breakfast a few times, made it mandatory for me!"

FORAGE CROPS FOR PIGS: Stephen: "Remember that it is cheaper to buy seed than it is to buy feed. I have 2 different fenced in areas for my pigs. I used to plant garden vegetables in the one that the pigs would not be in, getting the advantage of their weeding and fertilizing, until I tried planting alfalfa 1 year. If you plant a legume you will be providing your pigs with protein. Protein supplements are the most expensive part of your balanced ration, so if you plant some legumes you can eliminate those too. I plant alfalfa in the field that the pigs will not be in during the year that I plant it. If you have only 1 field, then forage alfalfa will not work for you. But you can still plant something for your pigs to graze on. You can plant it the same year they'll eat it. That something is rapeseed, or the name I prefer, 'canola.' " (See [Chapter 4](#).) Ladino is another popular legume for pig pastures.

Farm Equipment. Stephen: "Now, as you might have already gathered, it is going to take a large amount of feed and bedding to make this operation go. You will also have a considerable amount of manure to spread on your land. You will need at the very least a manure spreader and something to work the land with. You can buy the feed and bedding, but that will not leave you with much profit unless you are the type of person who can manage the whole thing well.

"You can grow some feed, but you will have to buy a pig starter to insure that the little ones grow rapidly and get proper nutrition. You will have to buy some protein supplement to make sure that you feed a balanced ration, in addition to all of the things mentioned ... above. You can grow your own corn, oats and alfalfa and thereby cut your feed costs to a minimum. I believe that is the only way to go. You will have to have enough land and the right equipment to make it work.

"As the bare minimum you will need a tractor and a disc. This is a farm tractor; not a city-type lawn-mowing tractor. You might want to get a small used grain drill, but you can get by with a hand cranked broadcast seeder. They are still available from seed catalogs and farm supply stores. You will need an Esmay seeder to plant the corn with or an old farm-type corn-planter pulled by the tractor. You will need a corn-picker or you can pick it by hand. You will need something to cut down the hay and oats with, an old hay mower or one of the new walk-behind sickle bar mowers will do. I recommend that you cut the straw by hand and buy the oats to feed the pigs, unless you can find someone to come in and combine your oats for you. It would make your life easier if you had a baler to bale the straw and hay with but it is possible to get by without it if you are able to put the time in to pick up the hay by hand."

Crop Rotation. "Five acres of land should be enough to make the whole thing work. This depends, of course, upon how fertile the land is. You divide the land into 5 equal plots through which you will rotate the crops. In the first, which you have worked thoroughly in the fall, you plant oats and alfalfa seed ... as early in the spring as you can get on the land to give it one final working. In the second, you have alfalfa planted last year, which you will cut for hay, and from which you harvested oats last year. In the third, you have

alfalfa, which you will pasture this year, and from which you harvested hay last year. In the fourth you plant corn. It was last year's pasture, and you worked it last fall and again in spring until it dried out some and warmed up. In the fifth you will grow root crops for the pigs and vegetables for yourself. Last year it was corn and you worked it in fall and again in spring until it dried out and warmed up.

"This is all fine and dandy once you get the rotation going, but how do you start it? My brother worked all of the land in the fall. On one fifth he planted oats and alfalfa; on the second fifth he planted corn; on the third fifth he planted root crops and vegetables; and on the fourth fifth he pastured the pigs. The remaining fifth he worked every 10 days or so all summer long. The next year he planted oats and alfalfa on the one he worked all summer, pastured the pigs where the root crops were grown, cut the hay, planted corn where the pigs pastured, and planted root crops where the corn was the year before. Only in the first year did he have to buy extra protein supplement."

Keeping a Sow and Raising Piglets

Pigs are wonderful reproducers. Numerically, you could start with 1 sow and a boar. She will have 2 litters of average 10–12 piglets each year. If you keep all her female offspring, within a year her first babies will be farrowing also. And so on. Within 3 years you could have more than 700 pigs!

Keeping sows and raising little pigs is hard, harder than any other livestock breeding operation I think. Pigs can catch things pigs catch, plus practically every disease people get too. And they're most likely to get sick during the time between their birth and weaning. The first problem is birthing. At least 1 out of every dozen piglets is born dead. Even professional pig raisers lose an average of one-fourth of their piglets, counting those born dead. And feeding breeders is much more expensive than feeding a weaner pig, which is butchered at 200 lb. These are much bigger animals—maybe 500 lb. for a sow, up to 1,000 lb. for a boar. One of them will eat more than 2,000 lb. of feed per year. Infertility can be a problem also. About 1 out of 10 sows doesn't get pregnant. Costs can be brought down by keeping more sows—the average commercial operation keeps more than 50—but the more pigs you keep, the greater the risk of disease.

When breeding, consciously choose the genes you want to pass on. Cull pigs with problems of body or personality. You want a boar that can do his sexual job but is tame with you. You'll keep sows that have large litters of same-sized babies (runts are born dead or have trouble making it afterwards) and whose babies grow well and stay healthy.

Stephen: "It requires more planning and investment of time and money. It is as different from raising a few feeder pigs as swimming in the local swimming hole is from swimming the English Channel. At the local swimming hole you just plunge right in and flail away. In order to be successful on a swim across the channel you need to steel yourself against the icy waters and there are logistics to be considered.

"You will enter a business in which the price is set in Chicago. You can charge what you want if you raise organic pigs, but if you can't find enough buyers that are willing to pay your price you will have to sell at the market price. If you are forced to sell at the market price you will come up against the pork factory people. They can beat your head in with their cruel brand of efficiency. Pig prices fluctuate, at times wildly. You may have to take losses, which may cause you to want to get out of the business. As soon as you get out of the business, the prices may go back up and you may want to kick yourself for getting out. This happens all across America on a regular basis. The pork factories have the capital and the information provided by the Pork Producers Association to which they subscribe, to aid them in making decisions. You will be alone. They are ahead of the game,

and still from time to time even they get burned.

"You say that you will get into the pig-raising business on a small scale, and thereby be able to take the hits in the bad times and profit in the good times? But there are limits to how small you can go. My brother says you have to have at least 6 sows to make it worthwhile to keep a boar.... And you will also have to have an all-weather building, plenty of feed, lots of pasture—and straw bedding, which will have to be grown, and baled or chopped by you, or bought. You will have to handle tons of manure and must have a place to spread it and something to spread it with. You'll need a livestock trailer or some means to haul the pigs to market. In short, you will have to have a full pen and a thick checkbook, with the final question of profit and loss answered only in muffled tones. You will have to keep the books with a very sharp pencil over a long period of time to find out how you are doing.

"Well, I suppose if you had dreams of being a small-scale pig raiser, about now you are heading for the tissue box to dry your tears. Get a tissue ... and then read on. There's still hope. You could raise pigs in a family herd!"

RAISING PIGS IN A FAMILY GROUP: "Pigs are raised almost everywhere in the world and there are many ways to manage them. In Europe, they are still herded into the oak woods each day to fatten on the acorns that fall from the trees. In Asia, they are still kept in bamboo hutches at night and allowed out to pasture each day. In some places in America pigs are still raised under strawstacks and in barnyards with beef cattle.... It is up to us to use our ingenuity to find out how to raise pigs in a fashion that we can morally live with—and with a little work and a little luck still make a profit.

"We had a neighbor who raised pigs using the strawstack method. [See [Chapter 3](#).] He was the last one, besides us, who used a binder and a threshing machine to harvest grain. He pulled the threshing machine out into the barnyard and blew the straw into a stack over a 20 by 20 foot hutch that consisted of cedar posts dug into the ground and rough-sawn lumber nailed to the cedar posts. There was 1 door that faced to the south, and not much of a roof so that plenty of straw could fall through it onto the floor of the hutch. The pigs lived here year round, being let out onto pasture in the summer. Boars, sows, feeders, and weaners lived together under 1, sort of, roof.

"He raised corn, oats, and alfalfa for them.... the local cheese factory ... gladly gave him whey, some of which he fed directly to the pigs and some of which he used to wet their feed. He had 4 huge wooden barrels to which he added finely ground alfalfa, oats, corn, and whey. When 1 barrel was empty, he just filled it again with layers of more dry feed and more whey and then allowed it to sit until it began to ferment.

"I'm telling you it was pig heaven. People who wanted pigs to butcher, or feeders to raise for butchering, came from miles around to buy old Harwood's pigs. It worked, and he made money on the operation. He has since died and with him went the last of the pig raisers who used the strawstack method in this area. I mourn his passing.

"That kind of an operation must be run by a special person. Harwood got inside his pigs' heads and understood what it took to keep harmony in the community of pigs. He weeded out the potential troublemakers before they disrupted equilibrium in the family of pigs. It sounds crazy, but he was a real life pig psychologist.

KEEPING SOWS THE "MODERN WAY": Stephen: "For this system it takes harder work and more start-up money to have success. The hard work comes because we have to feed the pigs individually, fetch bedding for them, clean out their manure, and attend to their health. Money is necessary to build them a building, build pens in the building, build or buy

farrowing facilities, grow or buy feed for them to eat—and from time to time pay the veterinarian to restore their health.”

Keeping One Sow. Stephen: “If you are willing to go through all that to get her pregnant, you can raise a couple of batches of pigs from a single sow each year. You may raise the first batch of piglets up to butchering size for your family and sell the last batch as feeders. If you have a good sow and a little luck you could have 8 little ones each time your sow farrows. If you raise the first batch to butchering size, you can find buyers for the meat, and charge \$1 a pound dressed weight; you can expect to make \$1,240 on them. Add to that the 8 feeders from the second batch at \$35 apiece, and you come up with a grand total of \$1,520. This is, of course, before you subtract your costs. You might clear \$500 a year.”

Keeping a Boar and 6 Sows. Stephen: “If you want to keep a boar yourself, then you can get 6 sows, but you will either have to convert an existing building or build a building to house them. For this number of pigs you will have to build a building at least 20×30 feet. This allows for eight 4×8 -foot pens in one room, and a nursery and feed room in the other room. The 4×8 -foot pens are placed along the outside walls leaving a 4-foot aisle down the middle. The doors of the pens are 4 feet wide and must be made to swing out into the aisle. This is done so you can move pigs from one pen to the other as need be. The doors of the pens should have a hook on them to keep them shut and also so you can hook them to the pen across the aisle, and thereby block the aisle while moving the pigs around. The pens and doors should be made of at least inch-thick plywood or full inch-thick rough-sawn lumber. All of this has to be made very stoutly because pigs are very powerful and love to scratch themselves. Any weakly built pens will be reduced to kindling wood, posthaste.” Amen to that. A determined boar is a half-ton, 4-legged, thinking power-sausage. You’d be amazed what he can just walk through if he decides to!

Feeders and Waterers. Stephen: “Each pen will have to be equipped with a feeder and a waterer. The feeders can be the dry self-feeder type or a trough in which you will feed moistened feed. The waterer can be a trough that is secured to the pen or floor or a self-waterer called a nipple. One caution about these self-waterers; they have a tendency to stick ... your pig barn will become a very shallow swimming pool if this goes unnoticed. On the outside wall of each pen you may want to build doors so that the pigs can go from the pen directly out to the pasture in summer. Of course, the fences will have to keep each pig separate from the others so that they all get back to only their pen. A large walk-in door should be built at the end of the aisle to facilitate the loading of pigs when it is time to ship them. You will need a large barn fan to remove excess moisture both winter and summer.

The Nursery. Stephen: “On the other end of the aisle you will have another walk-in type door leading to the nursery. You should have 2 or 3 farrowing crates in the nursery. You can buy ready-made metal ones or build wooden ones. In the same room you will have space left over to put your feed and veterinary supplies. You will need a source of heat in the nursery to keep the newly born pigs warm in all conditions. My brother uses electric heat lamps ... expensive to operate but they get the job done. I recommend that you store the bedding in the form of chopped straw above the nursery and have holes cut in ceiling above each of the pens in the other part of the building. If you can’t get chopped straw you can use wood shavings. Growers can get shredded newspaper pressed into bales, but I would not use that because the ink will end up in the ground when you spread the bedding-manure mixture. I am an organic farmer and don’t want heavy metals from ink in my ground.”

Breeding Your Pig

THE BOAR: A boar matures sexually by 7–8 months old. *Boars are large, dangerous, and tusked. For safety most growers remove their tusks at 6-month intervals.* Fever, hot temperatures, and stress can cause a boar to become temporarily sterile. Stephen: “If you are going to have your own boar, you need 6 sows to support him. You can get by without a boar if you have a neighbor willing to let you use his boar.”

HEAT: Most gilts have their first heat by 9 months old. But hog breeders may wait until she is a year old or has had 3 or 4 heats before breeding because then she’ll produce more babies than if bred sooner. The first heat can be hard to detect. Once started, she will be in heat every 18–24 days for 2–3 days at a time. Signs of it are swollen, reddish vulva, possible discharge from it, and restless behavior including pacing around and noisiness (“barking”). An especially rich and plentiful diet right before breeding helps make her yield more eggs and have more piglets.

THE MATING: “*Don’t put a strange boar in your sow’s pen.* She will not be happy with an intruder in her home. You will have to use either a neutral pen at your place or take the sow to the neighbor’s boar. If you don’t have a livestock trailer you can borrow one or put the sow in a crate. If you put her in a crate you will have to lift her onto a pickup truck. She will have to stay with the boar until he has done his job. You can never be sure if she will settle and become pregnant, so you may have to repeat the process more than once.”

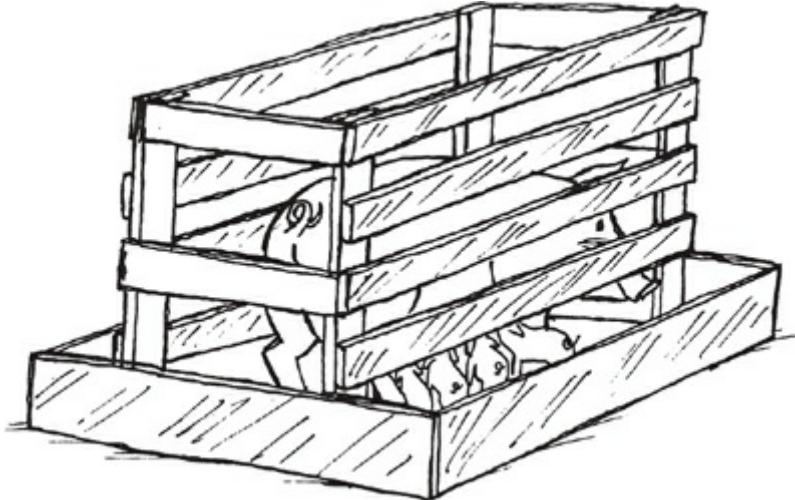

Mating Systems: Pen, Hand, and AI. The boar can be in a pen with as many as 10 sows for a time to accomplish breeding (this is called “pen-mating”). But then you’re not absolutely certain if the job got done. “Hand-mating” is surer. In this case you put the gilt or sow that’s in heat into a pen with the boar and watch until they’re done mating. Some growers give them a hand—literally—guiding the connection to target success. It’s even surer if you repeat the encounter again the next day. With hand-mating you know for sure it happened and you know for sure when so you can put her due date on your calendar. The third possible system for breeding is AI. AI hasn’t been as successful with pigs as with some other animals. Litters may be smaller, it’s expensive, and it’s difficult to manage the sow’s cooperation. However, it’s an option when you have no boar and a good way to introduce champion or exotic genes to your herd.

Pregnancy and Farrowing

After breeding is done, circle the calendar day 114 days away (3 months, 3 weeks, 3 days). With luck she’ll have babies then. Since there’s no way to know if she’s pregnant until she delivers, you now have to wait to find out for sure, although you can usually tell by around the 80-day-point. As she gets farther along she’ll get a larger belly and milk coming in. Failure to show heat signs suggests pregnancy but doesn’t prove it. Pregnancy usually goes well.

HOUSING FOR MOM AND PIGLETS: Your choice is a “farrowing crate” or a natural pen with plenty of straw for bedding, large enough for her to get some exercise, and to teach cleanliness, rooting, etc., to her babies. The “farrowing crate” is used by commercial producers—it’s easy to work around because of its smallness, it protects the babies from being laid down on because of its special side structure, and it makes it easy to give shots, take a temperature, and take out and work with piglets. The bad things about a farrowing crate are that mom will be unable to make the traditional nest that her instinct is urging her to make, she can’t exercise, and she can’t teach her babies anything. A major argument for

the farrowing crate is that it reduces losses from “overlaying,” which is when piglets are unintentionally smashed by a reclining big mama. However, if you provide heaps and heaps of straw for her nesting instinct, she’ll make such a deep nest that a squirmy little piglet can make its way safely out from under her through all of it. In cold weather a heat lamp that offers a 70–80°F area is nice for crated babies. In a natural pen situation, a heat lamp could provide it, but the piglets are likely to ignore your efforts and instead cuddle up to Mom for warmth.

THE FARROWING COUNTDOWN

1. Right before nest building, her mammary glands (“udders”) become distended with milk. If you squeeze a teat, milk will squirt. She shows signs of nest-building. If she isn’t there already, move her to where you want her to birth and live with her babies. Wash her.
2. In the 24–48 hours before birth the mother-to-be gets restless, tries to build a nest. Provide plenty of clean straw, which she will work hard biting into small pieces and piling up.
3. Labor begins. She is breathing faster. Her temperature rises. She discharges a little mucous and blood.
4. Before 2 hours the birthing of her sequence of piglets begins. It may take 30 minutes to as long as 5 hours, depending on how many piglets there are. She’ll be delivering a piglet about every quarter hour. An average sow has 10–12 babies, usually no more than 14. A gilt in her first birthing is likely to produce fewer—maybe 6.
5. It’s good for somebody to be there. The piglet comes out with a covering of thin individual placental skin. You can wipe it clean and dry or let it dry naturally. The wiping especially helps if the membrane or mucous are around the piglet’s nose or mouth. Piglet birth survival rate is better with this human attention. Problems with the delivery itself are more likely if she’s overweight, or if a baby gets caught in the delivery route. If that happens, pull on a rubber glove, lubricate it, and reach in and help. Most sows in labor will scarcely pay attention to what you’re doing. (However, the occasional exception to that rule can be dangerous. Make her into sausage; don’t pass on that trait!)
6. After she has delivered the very last piglet, the afterbirth will come out. Get it out of there.
7. Stephen: “Standard operating procedure is to cut and treat the umbilical cord, cut out

the baby teeth, give each piglet an iron shot, castrate the boar piglets, and dock the tails." They dip the umbilical stub into a container of iodine. They may also weigh the piglet. (See below.) A shot of deworming medicine is another option for this stage. *However, some family growers skip all this and have fine piglets.*

8. The babies will naturally find her teats and begin to nurse. It's important that all the babies get some of the first few days' milk production—the colostrum.
9. A "runt" is any piglet born weighing under 2 lb. Not all the mother's teats are equal in milk supply. Those nearest to her head give more milk. A runt or weak piglet who is always pushed back to a hind tit by more husky siblings is going to fall even farther behind in growth. In fact, 60 percent of runts die. It can help a runt to give bottle supplements, but some don't make it anyway—or they live but remain smaller than average in size.
10. The piglets need iron or they'll get anemia. If you have a natural pen with an outside run (real dirt), mom will soon take them out to the dirt. They'll scamper and play there, and they'll instinctively get their needed iron by eating dirt. *Piglets raised without access to dirt have to get iron in a shot or as a feed supplement, or you can give them nice, clean dirt several times a week.* Another system is to paint an iron solution on the sow's udder—if she'll lie still for that.

NOTE: Mother will be protective of her babies, and come worriedly running if one hollers—possibly with a dangerous attitude. Be careful! To take piglets from a pen wear heavy boots and thick gloves, and act quickly.

RAISING ORPHANED PIGLETS: If you get orphaned piggies you can raise them in the house. Spread some straw in your basement and provide some dirt in a box the same way you would for a kitty. A pig will use his litter box just the way he's supposed to. Start out feeding the piglet with teaspoons of milk thickened with a little farina and sweetened with a little light corn syrup. Soon the baby can move on to cream of wheat and oatmeal. If your little pig isn't doing well on this diet, or if you have a sick one, the best special diet of all for little pigs is eggs—just plain shelled eggs in a bowl—anywhere from 2 eggs on up to 7 or so. Offer them 3 times a day. If you want to bottle-feed a pig, use any quart bottle with a lamb nipple, less for a smaller pig. But a plain milk will tend to make them sick. They really need some grain mixed in.

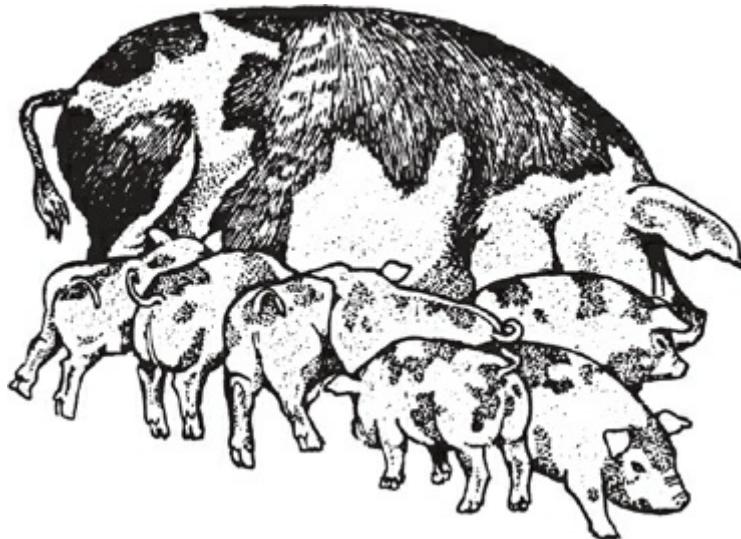

Margie Stroupe from Weingarten, MO, wrote: "... our mother sow had 15, came down with milk fever and almost died. She squashed nine because she couldn't handle herself and before I got nerve enough to get in with her and take the 6 living ones. Andy was down on his back and all he could do was storm because he was afraid she'd get me. But she couldn't even get to her feet. We called the vet and spent \$15 for the sow's shot and the vet said if she wasn't better by morning to knock her in the head and put her on a brush pile. Well, his medicine did her no good and we wound up giving her 7 ccs. Combiotic [animal antibiotic] night and morning for 4 days. She got well, we fed her out, and on May 11, 1974, she butchered out 306 lb. without head, feet, skin and the like. So though we hated to do without a brood sow, she wound up feeding us almost a year. The baby pigs, well, that's another story. The milk I fed them wasn't the right formula and I lost 4 with scours [diarrhea] and getting them too hot."

But you don't want to keep pigs in the house too long. The lady who used to own this house told me how once she had an orphaned litter of 6 pigs living in the basement. One day a salesman came to call upstairs at the front door. She rushed up the stairs to let him in and forgot to shut the basement door behind her. The now-not-so-little pigs charged up

the stairs behind her. When the door opened and the salesman saw her, and the 6 pigs charging up behind her, he looked really worried and sputtered, "Oh, I must have the wrong house," and literally ran away. You've got to be made of tough stuff to work door-to-door in the country!

A weaner-sized pig now needs other foods besides milk to be okay. Straight milk can cause them to bloat and die.

FEED SUPPLEMENTS FOR PIGLETS: Piglets can start eating supplementary "starter mash" at 1-2 weeks of age, but they'll never get a chance at it unless you use a creep feeder—a set-up where there's a hole to the starter mash supply big enough for piglets to "creep" through, but not big enough for mom to come and hog it—which she will if she can. Note: Commercial starter mash for piglets typically contains the antibiotic, sulfa. Pigs for slaughter fed the same thing would be condemned for sulfa residues.

WEANING AGE: It varies. Piglets would naturally nurse for about 12 weeks, or more, if allowed, but mom won't come into heat again while she's nursing, so commercial operations prefer to wean at 3-6 weeks. Early weaning can be hard, if not life-threatening, for young piglets, especially for underweight, hind-teat types. So, first wean the biggest few piglets of the litter and let smaller ones continue nursing and growing. Don't wean piglets who are under 12 lb.!

Pig Vetting

Stephen: "To learn proper pig vetting I suggest that you develop a relationship with your vet. He will be glad to show you the correct way to do all of the things that need to be done to insure that your little ones and the sow are taken care of properly. Or you could get hold of a neighbor and have him show you how." In addition to birthing help and piglet procedures there's also:

NEEDLE TEETH CLIPPING: Clip the needle teeth with wire cutters, making them $\frac{1}{2}$ inch shorter (don't crack teeth or cut gums!). Stephen: "A sharp pliers is used to cut the black teeth from the little pigs. These teeth are very sharp and will injure the sow's teats. If her teats hurt her too much the little ones will not get the nutrition they need because she won't let them nurse enough."

EAR NOTCHING: Ear notching is for pig outfits that can't keep straight who's who among their pigs. So they notch or tattoo ears for ID. (Follow your breeder organization guidelines.)

TAIL DOCKING: Tail “docking” means cutting off part of the tail with a wire cutter. The textbook argument is that the tail tip doesn’t have many nerves in it, and docking prevents bored littermates from biting and chewing on it—which can result in infection. Stephen says, “For a happy pig, look for curly tails and fresh dirt on the snout. Curly tails, as a measure of contentedness, comes from a time before mass-produced pork. The agribusiness farmer generally has no choice in the matter. Either he docks the tails or he is docked in price by the guy who buys the pigs from him.”

CASTRATION: Mike doesn’t dock pigs’ tails or castrate them. He says if a person is going to have just a few pigs, you’re going to have them controlled, and if you’re going to butcher at 200 lb., those procedures aren’t necessary. If you’re going to castrate, do it shortly after birth. An older pig bleeds more, and you can’t pull the testicles off the same way. Make a cut on one side of the testicles with a razor blade, pull that testicle and its “tunic” (a white membrane) out of the hole, and continue pulling until it pulls off. (The piglets bleed less with pulling off than with cutting.) Cut an opening on the other side with your razor blade, pull out that testicle, and pull it off. Then apply antiseptic to both cuts and you’re done.

WORMS: Whether your pigs have ever had worms or not, it’s best to give worming medicine immediately upon bringing new pigs of any age to your property and every 6 weeks thereafter because pigs are so prone to worm problems. Get a bottle of liquid worm medicine from your veterinary products supplier. The exact instructions are on the bottle. You withhold food and water for 24 hours, then mix the appropriate amount of medicine with water and serve in their food through the next day. They drink it down willingly. But Barb Ingram from Santa, ID, sent me this different advice: “After bringing your new pig home, worm it. Then feed it all the slag coal it wants, and there is never any need to worm again.”

Stephen gets the last word here: “Well, that is all there is to it. If this is your cup of tea, have at it. I hope to see you toiling in your own field some day. And remember, pigs are people too!”

BUTCHERING THE PIG

NOTE: Read all the relevant instructions over at least once before you begin.

Getting Ready

SEND IT OUT? Stephen hires his butchering done. “Our butcher doesn’t smoke the hams and bacon; he sends them out to somebody else. So we make 2 pickup trips, 1 to get the unsmoked meat and 1 to get the hams and bacon. Pork doesn’t have to hang for a week or so like beef, so 2 days after they butcher, the unsmoked stuff is ready to be picked up. It takes longer to make the smoked stuff, as much as 10 days to 2 weeks longer. I have the bacon cut thicker than store-bought, 5/16 of an inch. It fries up much nicer. You wind up with fewer pieces, but you have something to sink your teeth into. I like side pork, which is bacon that is not smoked. So we only have 1 side smoked and have 1 cut up fresh.”

Even this can have pitfalls. Lane Morgan says, “Years ago our next-door neighbor was loading his 3 pigs for the ride to the butcher. Two went in the truck fine; the third had other ideas. So Bill’s son, who was a state-champion high-school wrestler that year, put the hog in a headlock, and they heaved it into the truck. When they turned it loose, it was dead. The butcher legally can’t take a dead pig, and they weren’t set up to process the

meat, so they bled it, gutted it, and took it to the barbecue pit at the rodeo grounds. Bill and a friend stayed up all night roasting it, and the next day they invited the whole town for lunch. What he lost in meat for the family, he certainly gained in goodwill."

WORKING ALONE? One person working alone will need 2-3 hours to complete the slaughtering process. It will take about 1½ hours to kill, scrape, and gut the pig if you have help—and about 4 hours more to cut it up. If you have only 1 person doing this you'll want either to scald the pig by the "barrel-at-a-45½-angle-in-the-ground method," or skin it. Best of all would be if you can work together with 1 or more neighbors at a hog-butchering bee in your area. Then you can use their facilities and learn from their experience.

HOG BUTCHERING BEE: Up at a ranch on a nearby "ridge," which means on the land up out of our canyon (where there is gently rolling ground called "ridges"), there is a big hog-butchering bee held each fall. Last year when we went, there were 19 hogs butchered in 1 day by 10 men. The women brought food for lunch, potluck-style, and in the tool shed where we lunched there was coffee and a fire going all day for hand-and food-warming. The men who scalded and scraped and sprayed the pigs (they had a hose attachment) wore rubber raincoats, rubber waders, and woolen hats, since they couldn't help but get wet in those freezing temperatures. (Hog butchering bees are usually held between December 9 and February 12.)

BUTCHERING AGE: Ideal pork comes from a young, healthy, meaty hog that weighs from 175 to 240 lb. In this we-love-lean era, people are leaning toward the low side rather than the high side. Heavier, fatter hogs produce proportionately less lean meat and more fat. The average hog produces as much pork as a family of 2 will eat in about a year. The meat from boars has a strong odor during cooking and an off-flavor described as being "soapy." So males are typically butchered before they reach sexual maturity. If old boars are to be slaughtered, this problem can be eliminated by castrating them ("Not a job for the timid," Lane notes!) and allowing them to heal and get the hormones out of their system before slaughter.

TIME OF YEAR: It is best to butcher pigs in weather cool enough to cool the meat naturally but not so cold as to freeze it. One of the most common problems with home-butchering of hogs is that improper cooling of the meat results in a rank and strong taste. The other reason for typical November killing is that the feeding of pigs is best timed to coincide with the growing season and conclude after the last of the harvest surplus is eaten up. Of course, if you have an artificial cooler, and are buying feed, then neither of those would apply and you could butcher in any weather. But it's nice and clean to butcher on the snow compared to dirt.

SKIN OR SCALD? First of all you must decide if you're going to skin or scald your pig. I'm going to offer you a choice of 3 ways to proceed with the pig, and 3 sets of corresponding directions: First, directions for team scalding in a barrel or vat; second, directions for 1-person scalding using a barrel on the ground; and third, directions for skinning the pig. Whether you skin the pig or scald it, keep in mind that pigskin, unlike the skin of other large animals, is edible. You can package and freeze it. You can add some pigskin to boiled potatoes or to milk gravy; a piece of it can be used to flavor baked beans. Or you can cook it with the cracklings when you make lard. Or cook it in the oven to get all the grease out, then eat what's left for a snack.

➲ **PIGSKIN RULCHIS** From Donna Joehn, Blaine, WA: “Of the skins, my folks made ‘rulchis’ (little rolls). They cut the skins in strips (all fat removed) approximately 2 × 6 inches, rolled them up tightly, tied with string, then cooked and pickled them with the pigs’ feet. These were later enjoyed especially by us kids. If you wanted the crisp fried rinds you’d have to strip off all fat before frying them and cut in narrow strips. I do this with bacon rinds.”

Skinning Considerations. An inexperienced skinner is likely to lose a significant amount of lard and bacon because the bacon is right under the skin, and the skin does not strip away cleanly from the pig as it does from other animals. From a skinned pig, your bacons won’t have a rind, your hams won’t have a skin. And to skin a pig is a miserable job, especially around the head. There’s nothing worse to skin than a pig. Well, not much.

GETTING READY TO SCALD: You must have yourself all set up and ready before you kill the pig. Make sure you’ve thought of a good way to get the pig into the hot water because if you let it lie too long in cold air before getting it into the vat, the body heat starts out. Start early in the morning to heat your water. You can use snow if it’s clean. Use a good-sized scalding vat.

50-Gal. Barrel Vat. You can make do with this if it’s clean inside, but sometimes they have held insecticides; you need to know the history of the barrel. Set it up so you can heat the water in it by means of a fire under or around it. To scald in a single barrel, you have to get the pig in, then pull it out, turn it around, and then get the other end in to scald it. That’s almost impossible for 1 person to do alone and not easy for 2. A big hog won’t fit in the barrel. About 240 lb. is tops.

Permanent Vat. The best thing is to make a permanent vat. The nicest ones are made out of sheet metal. This is set up with plenty of space underneath to build a fire and with a platform on each side, made of something like old bridge timbers, that won’t catch on fire easily. The platform is for the men to stand on while they are rolling the pig in the water. An old steam-engine boiler also makes a good vat. Ours is made from half of an old steel hot-water tank. To make a really nifty vat, you can pick up some used firebricks (or even find some for free for hauling them away). Dig out a pit and line it with the brick; place your vat over the top. Be sure to leave enough room at both ends to be able to start your fire and to add more wood to keep the water hot.

Make a hole in the lower end of your scalding vat that you can plug with a whittled cork or some such. It helps mightily if the vat is located where you can get at it with a hose line from the house or some other water outlet. Rinse water through the cavity to clean it out a little. Then put water in it. You want to have a big enough vat and enough water in it so the pig is almost covered with water. Allow for losing some water by sloshing out at the side if you are doing more than 1 pig. You can’t add more water because then it will be too cool for the next pig—unless you’re willing to wait while it heats up again.

Test Water Temperature. It’s handy to have a dairy thermometer to get the water’s temperature. Between 150 and 165°F is right, but from 140 to 180°F works. The old-timers say that if you dip your hand through the water 3 times and on the third pass it feels so hot you can hardly stand it—it should be just right (if your hands are cold to start with). If the water is too hot, you’ll cook the hog, and, worse yet, the hair will set and be very hard to get out.

Add Lye to Water. Put in about half a can of lye to 200 gal. water. Makes it clean up easier. The old-timers used a couple shovelfuls of wood ashes for their lye solution. (Stir well.)

NOTE: When the water is the right temperature, it’s finally time to kill the pig.

Killing a Pig

SHOOTING: Make a mental X from the pig's left ear to its right eye and from its right ear to left eye; where it crosses, shoot. It helps to wait until the pig looks at you before you shoot. Shoot straight in because the brain is small. A pistol is by far the best for this job (which is a good reason why country people don't want their pistols taken away). Get the right angle so you'll do the job the first time because it's much harder to get it right if the pig is wounded and jumping around. A .22-caliber is the most economic on meat because it doesn't destroy much and is still big enough to do the job (on a 200-lb. pig).

Patricia Kenyon, Castlewood, VA, disagrees: "Don't use the .22-shot-to-the-imaginary-X-on-the-face technique. Instead, do not feed the hogs their evening meal. The next morning, lay out a sumptuous hog feast for them, walk up behind the happy, munching hogs, place the gun behind the nearest hog's ear, aim toward the diagonally opposite eye and shoot the hog. A .22 does not make enough noise to spook the other hogs. The shot hog will keel over, having died in [ecstasy]. The other hogs will move into its vacated position and you can dispatch the next hog without moving. This works better than the front shot because the skull is much thinner from this angle. I developed this technique after annoying a 600-lb. hog with the .22 front shot. As the screaming hog began charging around the barn, snapping viciously, my helpers (2 farmer neighbors) shinnied up the nearest support posts in my barn and left the rest to me. After that ordeal, I went to the local college and studied the hog skeleton they had on display."

STICKING: Now immediately, using a long narrow-bladed sharp knife (at least 7 inches long) cut open the hog's throat about 3 inches in front of the end of the breastbone, then cut down inside and slightly back under the breastbone, until you get the jugular vein or the aorta. You'll know because then the blood will pour out. If you haven't got it just right, keep cutting until you do find it. Killing them is no fun, anyway. Do it right. The animal has to be well-bled, and the sooner it dies after you first shoot it the better for you both. For a knife you can use a large hunting knife or a good stiff butcher knife. The best place to cut is right back of the jaws in the center of the throat. Cut toward the pig's left side to get the aorta. Now wait and let it bleed. Adjust the head so the opening is downhill from the body and so the jugular opening is not covered.

MARKING OWNERSHIP: If several families' pigs are being butchered together, you cut an ear of the dead pigs to distinguish your own—1 notch for theirs and 2 for yours, for example.

MOVING PIG TO WATER: At the big butchering bee they have 2 tractors with fork-lifts (“farmhand,” “front-end lift,” “buckrake”) working to move the carcasses around. The carcass is rolled into the hydraulically operated fork-lift on the tractor. You then raise the fork-lift and let the tractor take the hog to the scalding platform. If you don’t have a fork-lift, the next easiest method is to use an old-time hay hook. Insert the hook point in through the open mouth, then out through the jaw so that it will be pulling against the strong jawbone. Drag the animal by the hook over to your scalding vat.

Scalding a Pig

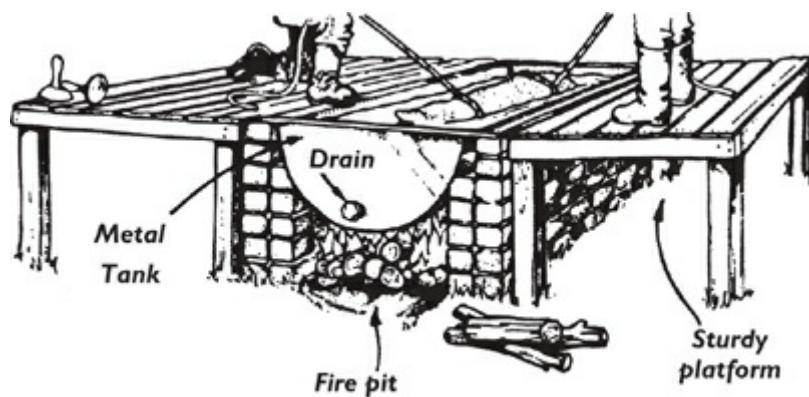

USING ROPES: Lay the pig on the platform by the scalding vat. You now need two 30-foot (more or less) ropes. Half-inch rope is fine. You can make do with 1, but 2 are much better. Smaller rope is harder to get hold of and to work with.

Rope the pig up before you put it into the vat. With 1 rope this is a 2-man job. (With 2 ropes you use 4 people to roll the pig.)

1. Make each rope have a U shape.
2. Lay the pig on ropes across the U shape.
3. Bring the 2 free ends of the U over the pig and through the inside of the U.
4. Now take those free U ends back to where they were.

This would be a double half hitch if you pulled the ropes tight. Have 2 people take hold of the bottom of the U’s, and 2 other people take the loose ends. You now have 4 people, each with a grip on the ropes, which cross the pig behind its front legs and in front of its hind legs. Two are on the platform on 1 side of the vat, and 2 are on the platform on the other side—with the pig inside the rope. This way you can let it into the vat, and roll it around in there.

Put the pig into the vat slowly so as not to splash. Roll the pig gently back and forth. Now turn it over. Continue the rolling in the water. Keep the rope just snug enough to see if the pig’s hair is “slipping” yet. “Slipping” means that you can pull it out. When both sides are scalded and the hair is slipping, then it’s ready to scrape. Now haul the pig out. If this is a 2-man job, hand over both rope ends to 1 side so that both can haul the pig out from that side.

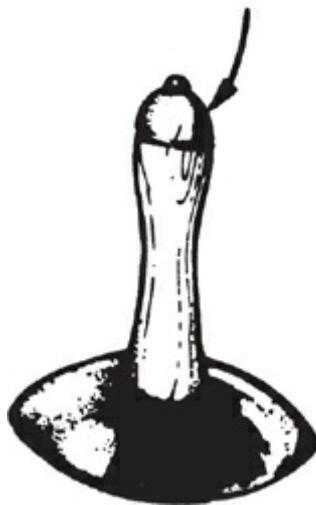

Knowing When It’s Ready. If the hair is worn off where the ropes are around the pig, it’s getting pretty close to being ready to come out. It will take 3–6 minutes of scalding to loosen the hair and scurf. The most difficult time of year to get the hair loosened is in the fall when the winter hair is beginning to grow. (That time of year you might benefit from higher water temperatures or longer submersion times.) If you can grab a handful of hair and the scarf skin comes off with it, it’s ready. Or better yet, take a hog scraper, or a knife,

and just scrape on part of it that's sticking out from the water while it's still in the vat. If the hair comes off, well, it's ready. If the dewclaws will snap off, the feet are scalded enough. If you start to scrape and find out you actually didn't scald the pig long enough you can put it back in to finish the process. If your water is too hot you can make it work by keeping the carcass in constant motion and pulling it from the barrel several times to prevent over-scalding. But if you leave the pig in the vat too long at too high a temperature the hair will set—which makes for quite a problem. The only answer, once the mischief is done, is to scrape as hard as you can and mutter a lot.

SCRAPING A PIG

Hog scraper

Scraping Tools. You'll need a hog scraper or several knives. The scraper is a 3½-inch-wide galvanized steel bell-shaped scraper with a 3¾-inch hardwood handle. If you have the sharpest scraping knife, you'll be the fastest scraper, but you'll also make the most cuts. It doesn't take long for a knife to get dull scraping on that hair though. Scrapers aren't as likely to make cuts. You can mail-order a hog scraper from Lehman's Hardware (also sausage grinders and butcher saws) 888-438-5346; www.lehmans.com.

Extra Hot Water. Scrape your pig right by the barrel or the vat so that you can get hot water for pouring over it. Plan to have hot water to spare, because it helps, especially when scraping older hogs (which get really tough to scrape, especially red-haired ones). The last resort, if scraping doesn't work, is to pour more hot water over them out of a bucket, then pull hair out as if you were pulling chicken feathers.

Scraping Method. As you scrape you get not only hair, but also dirt and the scurf skin. Scoop more water up in your bucket and pour over to keep the pores hot and soft so the hair will keep coming loose. Try not to cut through the hide. Work over the whole body this way. The best scraping motion with a knife is to hold the knife on both ends. Don't pull the way you would slice; that cuts the skins. Pull across (sideways). Scrape the hot carcass as quickly as possible, because the hair tends to "set" as it cools. If you come to a patch of hair that is difficult to scrape because it didn't scald enough (like the mid-section of the pig), cover it with a burlap bag and pour hot water over it until loosens up. It will also help with the scraping if you place the legs or head so as to stretch the skin and smooth out the wrinkles.

Scraping the Feet. *The feet are hardest to scrape. If you are planning to save the pig's feet for pickling or some such, do them first, while they're hot.* You can pull the toe nails and dewclaws from the front feet by inserting a hook into the top of the nail and pulling. Do

the same with the rear legs. Grip the legs with both hands and twist to pull off the hair. Leave the feet on for the time being. You can use the scraper on the rest of the carcass.

Scraping the Head. Do the head around the eyes, nose, and jaw next after the feet. On an old hog there will be bristles on the snout (whiskers). You can shave them off with a sharp knife, barber-style, or singe off as you would a chicken. More than 25 percent of your scraping time will be spent working on the head because it's hard to get around the parts of it. Save the ears. They are good to flavor a mess of beans or with kraut. There are a couple of pounds of meat in the jowl (cheeks) that will make good scrapple, headcheese, salt pork, or side meat. Most people leave on the ears.

Scraping the Body. After you're done with feet and head, do the rest. When you get one side of the pig done, roll it over and do the other side.

ONE-MAN SCALDING SYSTEM: This method is from a USDA booklet, "Pork: Slaughtering, Cutting, Preserving, and Cooking on the Farm" (Farmers' Bulletin Number 2265).

Read about scraping, above, before proceeding.

You'll need about 50 gal. of near-boiling water. Once you get the water into your scalding barrel, you can adjust to the more exact temperature (between 140 and 145½, recommended) by adding cold water. If you have 2 barrels, you can use 1, with a fire under it, for heating your water. You can have another one buried in the ground down almost to its lip at about a 45½ angle. Having the barrel buried makes it humanly possible without any other machinery or equipment to maneuver the pig in there and out again by hand. You'll have to get it in and out at least twice, once for the head end, while holding it by the rear legs, and once again for the rear end, while holding it by the front legs. Then scrape.

Skinning a Pig

The skinning procedure used for a pork carcass is similar to that used for beef carcasses. Skinning requires less equipment and can be done faster than scalding and scraping. To begin, place the carcass on a clean surface (plywood, concrete, straw); wash any blood and dirt off, turn the carcass on its back, and hold it in place with blocks placed on each side. Cut the hide around the rear legs, just below the dewclaws. Make a cut through only the hide, down the back of the leg, over the hocks, and to the midline at the center of the hams. Skin around each side of the leg, removing the hide to a point below the hock. Open the hide down the midline from the point where the animal was stuck in the neck, around each side of the pubic area and continue to the anus. Make this cut by inserting the point of the knife under the skin with the blade turned up. This procedure is a sort of cutting from inside out and will, you hope, protect against puncturing the intestines.

Remove the hide from the insides of the hams. Be careful. It is very easy to cut through the fat into the lean. Continue skinning along the sides toward the breast. Grasp the loosened hide in the opposite hand and pull it up and out. This places tension on the hide, removes wrinkles, and allows the knife to glide smoothly. Holding the knife firmly, place it against the hide with the blade turned slightly outward. Skin as far down the sides as possible, but not around the front legs. Return to the rear of the carcass and remove the hide left on the rear of the hams. Do not skin the outside of the hams at this time. Remove the rear feet by sawing through the bone about 2 inches above the hock. Insert the spreader (see "Hanging a Pig") under the large tendons on the rear legs and secure the legs to the spreader.

Hoist the carcass to a convenient working height for skin removal from the outside of the hams. Skin around the outsides of the hams, leaving as much fat as possible on the

carcass. Remove the hide around the anus, and cut through the tail at the joint closest to the body. Pull the hide down over the hips. The hide along the hips and back can be pulled off, leaving the fat on the carcass. Occasionally, you may need to use a knife to cut between the skin and the fat if large pieces of fat are being pulled off. Hoist the carcass to a fully extended position. Open the hide down the rear of the forelegs. Skin along the inside of the forelegs and neck. Skin along the outside of the shoulders and jowls to a point approximately halfway to the back of the carcass. Slowly pull out and down on the hide, removing it along the back. If the fat begins to tear, use a knife to correct the torn area, and then continue pulling the hide. Remove the hide as far down the back as possible. When it becomes difficult to pull along the top of the neck, complete removal with a knife. If the head is to be saved, skin over the poll and down the face. Remove the hide at the snout. Remove the front feet by sawing just below the knee joint.

Skip "Hanging" because you've already done that, and continue with "Gutting."

Hanging a Pig

After scraping, it's time to hang the pig up in order to gut it. (Of course, if you skinned it, it's already up.)

GAMBREL, "SINGLETREE," OR "SPREADER": This is what you hang the pig by. It can be any straight stick. Metal ones usually have metal hooks at each end. Wooden ones have a carved notch there. If you are making your own out of wood, basically all you need is a long enough, strong enough stick with a V-shaped notch on the topside near each end so the hamstrings won't slip off the end to the middle. A "singletree" is actually a piece of old-time horse harness that people found out made a great gambrel. Nobody around here knows what the word gambrel means. They all use a singletree and call it a singletree. We've used a neck yoke, too, and wired the legs onto it. One of these is an excellent investment if you are going to do home butchering of anything larger than a chicken or rabbit. The gambrel has to be long enough to spread the hind legs real tight, hence the other name of "spreader." For the average hog, that is about 30 inches.

WIRE, ROPE, OR CHAIN: You need something to hang the gambrel by. Use a wire, or rope, or chain around the center to hang it to your fork-lift, or to a tree limb, or a tripod, or a rafter beam when time comes to gut the animal after scalding. If you buy a ready-made gambrel, it will come equipped with something, usually a chain or rope, in the middle to hang it by.

GETTING THE HAMSTRINGS: The best system is to hang an animal by the hamstrings, or "Achilles tendons." They are located in the back of the hind legs. Make a vertical slit. Don't cut crosswise! There are actually 2 cords there. Get both of them, especially on a heavy hog. Use your singletree (gambrel) to hang the pig by the hamstrings. Put 1 hook from each end of the gambrel under each hamstring. If you are using just a stick, put each end of it through the space between the hamstrings and the bone.

After the pig is hung, now is your chance to put the final touches on your scraping job. Pour more hot water over where it is needed. Scrape up.

Gutting the Pig

When you butcher a pig you discard about 20 percent of its weight. This is the stage at which most of that goes. Have some twine ready or heavy string.

These instructions assume that the pig is hanging from its hind feet and that you are standing, facing the belly side of it.

It makes a difference in method whether you are butchering a male pig or a female.

A MALE: Cut around the penis, which is in the middle of the pig's belly, and slip the knife on up to around the rectum. Notice a cord running from the penis right under the skin up to the rectum. That cord runs right into the gut. Pick up the penis area and tie off the cord that connects to it with your twine. Cut the cord on out. Cut all around the anus to free the end of the gut and tie that. That's to prevent what's inside that part of the gut, which is not nice, from coming out on your meat at any stage of your work. When you cut around it, keep your knife sloping toward the meat and away from the anus so you don't cut the gut.

A FEMALE: Start by cutting around the anus so you can get hold of the end of the gut and tie that off with twine the same as for a male.

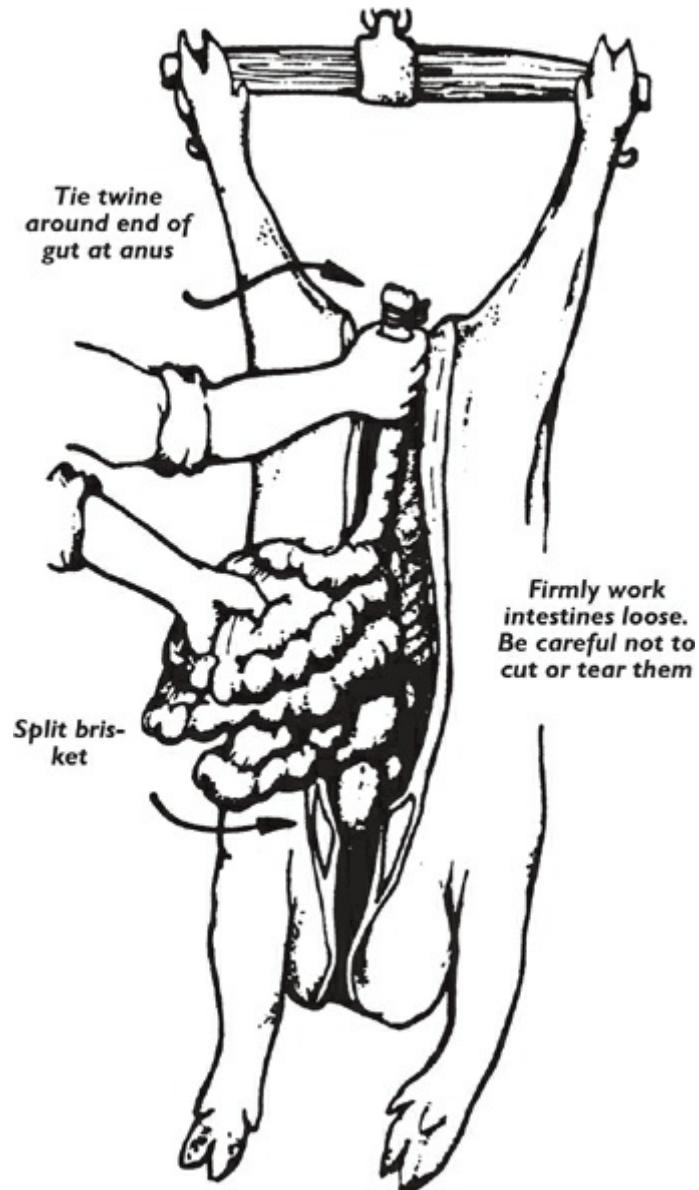

NEXT, ON EITHER SEX

1. Cut down the belly midline until you have the skin parted from up at the top to the jaw at the bottom. Be careful not to cut into an intestine.
2. Split the brisket or breastbone. Hammer on your knife to drive it through. The brisket is right in the center between the shoulder where the ribs join together in front of the heart, lungs, and liver. You're aiming to cut that pig into 2 separate and distinct halves, and the brisket ("breastbone") is the hard part in the front chest that you must cut through to accomplish that.
3. Cut between the hind legs starting on the midline.
4. Finish cutting on the belly by putting your hand inside, being careful that your hand is between the knife and the intestines. Believe it or not, it would be better to cut yourself than accidentally to cut the intestines, but you won't. Now bring the innards out of the hog, starting from the top. Have a big wash basin ready for the organs that you want to save: heart and liver.
5. Cut the diaphragm to bring out the rest of the organs. The diaphragm is a muscle layer separating the intestines area from the heart-lungs area.
6. Now deal with the organ meats: Trim off the top of the heart. Heart, trimmed, goes into a dishpan. Remove the gallbladder from the liver. If you are going to cut, then cut through the liver; if you accidentally cut into the gallbladder the bile escaping will ruin your meat. Old-timers just peel it out and they follow the duct up a ways and peel that out, too. The sweetbread looks like brains. It is attached between the stomach and liver. Leave the kidneys in until you cut up the meat. The long narrow liver-looking thing is the spleen, and it isn't used.
7. On a large, old, well-fattened hog the entrails will carry several pounds of fat, which you save for lard. Young hogs don't have enough to fool with. The "leaf lard" is inside the body cavity from midline to rear on each side. Peel it out. Don't leave it on the bacon because it's just pure lard.
8. When you're going to use the head, make sure that the cut is made clear down to the jaw. Then, when the innards fall out, you can pull out the whole mess from the neck, too—including the trachea, esophagus, jugular, and tongue. The last to come out will be the tongue as you bring out the windpipe and esophagus. Get the tongue out whether you plan to eat it or not, because if you don't, blood will collect there.
9. You have to cut the head off before you can make halves. Use the biggest, sharpest knife you have. Cut the head off about an inch behind the ears: Cut the meat down

until you have exposed the bone all the way around the neck. Grab the head firmly and twist it around and around until it just snaps off from the body.

10. Make halves by sawing with a meat saw right down through the middle of the backbone from top to bottom.

11. Now let the meat hang to cool. Don't cut it up while it is warm, but pork, unlike beef or goat, is not aged. By the next day you could—and probably should—proceed to cut it up. It is not harmed though by a reasonable wait—even as long as 1 week if you have really cold weather. But it doesn't keep as well as beef.

Preparing Suckling and Barbecue Pigs

SUCKLING PIG: This is in case you have an extra piglet. By waiting 5 months you could have all the meat of a big pig, but your sow may have had too many babies to nurse manageably. You could bottle-feed the extra, or you could kill, scald, scrape, and gut it on the same principles as a larger animal. After cleaning out the innards, rinse the pig in warm soda water. Leave on the head, but clean the passages of the head and throat with a wooden skewer wrapped in a small piece of soft cloth.

Cooking a Suckling Pig. Fill with stuffing. To stuff a 12-lb. suckling you might use 3 c. diced celery, 2 c. chopped onion, $\frac{1}{2}$ c. minced parsley—all fried in plenty of butter and then combined with about 7 c. dry bread crumbs. Sew and truss. Bend the forefeet backward from the knee and the hind legs forward. Make deep cuts in the skin in 3 places. Put a potato or apple in the mouth to hold it open. Roast at 350°F until the meat thermometer reaches 185°F (3–4 hours).

SPIT-BARBECUED PIG: This works best with a smallish pig, like about 40 lb. That will feed a huge family reunion or some similarly large group. Give it a good scraping, clean it, and scrape inside and out under running water an extra time. Optional: make a dressing to stuff it (about 2 gal.). Wrap feet and ears in foil to keep them from burning, and keep the

pig turning on the spit. A motorized spit is the easiest. The roasting will take 5 hours for the 40-lb. pig, more if it is bigger. Use a meat thermometer to check on how done the pig is, deep inside.

Now back to handling the 200-pounder. This one definitely must be cut up.

Cutting Up the Pig

Before freezers, the pig's fat was rendered into lard, with cracklings used as a people snack or animal feed; as much as possible was eaten fresh, and the rest was heavily salted for preservation. When saltpeter came along, what had been salted meat was shifted to "cured" ("corned" if it was beef) and the amount of salt and spices could be lessened. Now that we know more about saltpeter (all bad) and have freezing and canning options, the healthiest choice for your family is obviously to freeze all of the pig, or to make sausage (which will be frozen) of part or all of it—especially if it's a predictably tough old animal. By not curing what could have been cured for hams you'll have roasts, and what would have been cured for bacon is "side pork," which you can slice and fry much like bacon.

Some people start cutting it up while it is still hanging, but we bring the carcass in, a half at a time, and lay it on our big plywood cutting board, which is scrubbed in the tub with a scrub brush and then laid across the kitchen table. A pig is actually easy to cut up. I'll theoretically divide it into thirds. The front third is figured as if the head were still on.

HAVE CONTAINERS READY: I use 4-and 5-gal. plastic buckets. One holds meat to be cured if curing is planned. Another holds pieces that are to be ground for sausage. Another holds bones for making gelatin, or to cook up with sauerkraut or beans. And one holds fat that will be rendered into lard. I also have ready meat-type wrapping paper and freezer tape with which to wrap the roasts, chops, and ribs that will go directly into the freezer after being cut.

FIRST, TRIM: Trim off the dirty and bloodshot spots—everything that doesn't look like what you would want to eat.

THE HEAD: There are numerous good ways to use the meat of the pig's head. They all require similar preparatory steps. Options:

- Prepare it according to the directions under "Headcheese and Scrapple."
- Or cut off the jowl, which is the chin area, and make it into bacon, with the trimmings going into the sausage bucket (you want your bacon slab fairly neat-looking). Save the ears, too, to flavor a mess of beans, and you can discard the rest.
- Or cut off all the meat you can get at and put into your sausage bucket—and discard the rest.
- Or cut off all the meat you can get at and use it to make pork mincemeat.

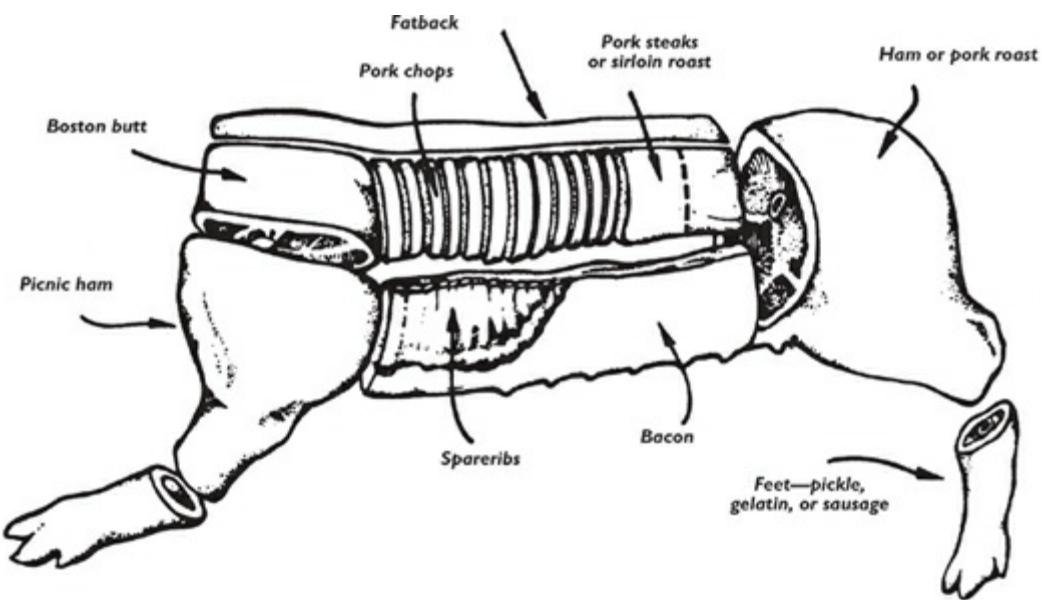

- Or cut off all the meat you can get at in thin slices, package, and freeze. You can fry the sliced scraps like side meat.
- Or clean out the ears, nose, and mouth passages well with a cloth on a stick or just a cloth on your finger and rinse well with water. Then, in a big kettle (I use my canner), cook the whole head for hours and hours and hours until the meat falls off the bones. Then remove the bones and the more strange-looking stuff like eyes and the lining of the mouth. Skim off every bit of the grease you can get to go with your lard renderings. Divide, package, and freeze what's left to go with kraut or beans. That is my favorite way of preparing the head.

THE HIND THIRD: This means one of the back legs.

NOTE: Instructions such as "front," "back," etc., are generally given as if the animal were standing up.

1. If you haven't done so already, saw off the hind foot through the ankle (hock) about a foot up from the hoof. You can either set aside the foot to make pickled pigs feet, or trim off the meat for sausage and put the rest into the gelatin bucket.
2. Now cut the hind leg (ham) away from the body. You'll have the tail end of the backbone included in your piece, which you can trim out later to make your ham look nice. You're cutting in front of the pig's hip bone and getting off all the hind leg with this cut. Cut the meaty areas with a knife. Finish going through the bone with a meat saw. On a sow you'll have 2 teats included plus about 2 inches. In person talk we'd call it the pig's thigh. On a young pig it will weigh about 20 lb.; on an old sow it will weigh about 30 lb.
3. Trim it around the top to make it look neat. Make sausage or lard of the trimmings (depending on whether they are meat and fat, or mostly fat). Sausage trimmings are generally cut into approximately 1-inch strips to go through the grinder better. If you are planning to cure the ham, the skin is generally left on. Put the ham into your curing bucket. If, instead of curing it, you want it to be pork roasts, trim the skin off (and place the skin into your sausage bucket). Cut the ham into roast-sized pieces; the only rigid rule is that a roast has to be small enough to fit into your pan with the lid on. Other than that, a chunk of meat is a chunk of meat no matter what the experts say. Incidentally, if you plan to cure your hams and bacons with the skin on and you have a propane torch, you can use it to burn any remaining hairs off them.

THE FRONT THIRD: These directions are meant for a young pig, the 200-lb. kind. If you are butchering an old hog, then you take the whole front third and cut up most of the meat to go through your grinder for sausage.

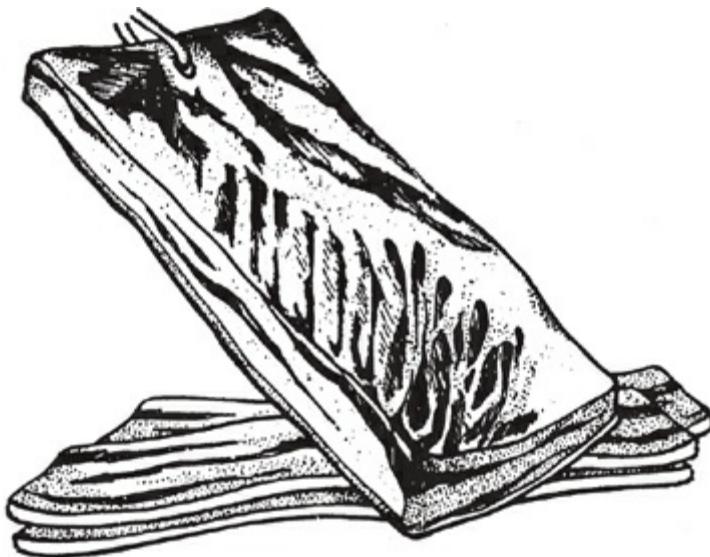

1. If you haven't done so already, cut off the foot at the ankle—about 8 inches above the hoof. Put it in the same place you did the hind foot.
2. Now cut off the leg plus the front shoulder. You'll find the right spot by cutting behind the third rib. You'll need your meat saw. You're cutting it off just back of the shoulder blade, straight up and down the body. If you are making hams to be cured, take the big piece that you cut off (minus the foot) and divide it in half horizontally to the ground just below the lower edge of the shoulder blade. The resulting half that has backbone in it is called the Boston butt ham or shoulder roast and the lower half is called the picnic ham. If you would rather make roasts than hams out of your Boston butt and picnic hams, again cut them down into roaster-sized pieces.
3. Now trim out the backbone. Trim off the meat left around the backbone for sausage and put the backbone itself into your gelatin pile or bones pile.
4. The 3 front ribs that get included in the cut can be packaged for short ribs. Saw them away from the rest.
5. That flap of meat attached to the lower half of the front leg is bacon or sausage (or side meat if you'd rather). For bacon, cut away and make the edges nice. For sausage, cut it into strips. For side meat, leave plain and don't cure.

THE MIDDLE THIRD: That's what's left.

Separate the ribs from the bacon. You can see where the ribs are. The bacon is the boneless flap of "skin" behind the ribs. Stay out of the thick meaty pork-chop area along the backbone. You can peel the meat off the outside of the ribs, too, and make bacon out of it. Or leave it on for very meaty spareribs. That's what I like to do.

The "Bacon" or "Side Pork." You can take the skin off the bacon or not. (Personally, I like the skin off.) If you plan to cut the skin off, whacking the whole bacon section on the table as hard as you can, skin side down, several times before you start makes it a little easier. I like the bacon cut into squarish sections about 6 inches on the side. You can make them bigger—it doesn't matter. Put the trimmings into the sausage pile. I've made triangular bacon, but it slices up more nicely if it is square. Side pork is the same cut not cured; you can slice and fry it just the same for breakfast only it won't have the cured

taste. Slice like bacon only thicker, season, and fry. Don't flour. Cook through. **The "Fatback."** This is the fat on the back of the pig, which you trim off with the skin for your lard pail, leaving only just the amount you like on your pork chops— $\frac{1}{4}$ – $\frac{3}{4}$ inch is plenty.

Chops. What's left looks like backbone. It includes the muscles that run right alongside of the backbone. You can either bone the chops out and have them with no bone, or saw them out and have a chunk of bone included with each one. I don't like bones out of chops, though that is easier to do. Boned-out chops don't look like chops anymore to me, and, though you only lose a little meat in the boning out process, on a chop that's a noticeable loss.

To bone them out: Cut the muscle away from the bone. Slice across the grain and package for the freezer in meal-sized numbers. The little muscle on the other side of the bone can be pulled out and cut across the grain into "tips," which means a mini-chop. The vertebrae can go into your bones department—the best thing I know for making gelatin.

To saw them out: The butcher does it with a power saw, which makes it easier for him, but you can do it by cutting the meat part with a knife and then finishing with a meat saw. Cut across the grain of the tenderloin the same way you would for boned-out chops.

The rear third of the "backbone" can be sawed into pork steaks (cut across the grain) or cut into a couple of sirloin roasts.

Headcheese and Scrapple

Headcheese is a homemade luncheon meat. It's quick and easy compared to scrapple. It's an all-meat product. You can add in the pig's tongue, skin, heart, and other scraps, if you want to. Headcheese makes a fine cold snack when cut in slices and served with hot mustard or horseradish. Or it can be dipped in egg and crumbs and fried like scrapple for your meat dish. Or you can make a kind of sausage out of it, if you know where to get casings (or how). Like all pork products it's on the bland side, so either while cooking or when serving you'll want to spice it up some.

SCRAPPLE: This, on the other hand, is a meat and meat soup mixture made firm by thickening it with a cereal and spicing it to taste. Almost everybody likes headcheese. Some people like scrapple and some don't.

If you'd like to make a trial run of something like scrapple, to see if you're going to like it, use some leftover ham to make it. Prepare 1½ c. ground cooked ham. Then mix

together 1 c. cornmeal, $\frac{1}{2}$ t. salt, pepper to taste, and 1 c. cold water. Boil $1\frac{3}{4}$ c. water and then slowly add the cold cornmeal mixture. Cook on low heat until the scrapple has thickened and is boiling, stirring all the time. Add the ground ham, mix it up well, and pour out into pans to set up. That takes at least several hours in a chilly place. Then you can turn it out of the pan, slice off some, and fry as described earlier.

Now that you've decided whether you're going to make headcheese or scrapple, there's the problem of what you're going to make it out of. If you have, or are going to have, a hog's head, that's fine. Some farmers don't want to bother with their hogs' heads and will sell them to you. Heads vary considerably in size depending on how old the animal was. An old brood sow can have a head almost twice as big as that of a pig of the more usual butchering age. If you don't have a hog's head, you can actually make headcheese or scrapple out of any pork-sausage-type scraps.

1. The head should be already scalded, scraped, and separated. But if the head fate has given you to work with is a still-hairy one, then you'll have to skin it—which is an awful, tedious, frustrating job, and you have my sympathy. Or you can try singeing the hairs off with a blow torch.
2. Take the head out to your chopping block and split it in half with the ax. If it looks like mincemeat before you finally manage to get the halves separated don't despair—that won't hurt the final product. Just collect the pieces off the chopping block and carry them back to the kitchen.
3. Remove and discard the eyes, nasal passages, teeth, jaw, and eardrums. You can use the ears, lips, and snout if they are well-cleaned. Scrape the ears to get them clean. Usually the jowl isn't used because it's so fatty. The "jowl" is the neck-cheek area. Remove all the fat you can and save it to render for cooking lard or soap. Make deep cuts in the thick meat pieces.
4. Put the meat into your kettle. A cast-iron kettle is best because it heats most evenly (so is an old-fashioned wood or coal burning range for the same reason). For 1 hog's head you'll need the equivalent of a canner or big 8-qt. pressure cooker to make this recipe. Cover the meat with water and simmer until it is ready to fall off the bones.
5. Remove the meat from the broth. Pick it over and separate the meat from the most of the fat, from all of the bones, and from the broth. Grind the meat. Up to this point the recipe is the same whether you are making headcheese or scrapple. Now it differs.

A Scrapple Recipe. Skim every bit of fat from the broth. Add to the broth one 2-lb. 10-oz. box of old-fashioned oatmeal. Don't use the instant kind since it won't make good scrapple for some reason. Or add enough cornmeal to make a soft mush. Or add half cornmeal and half buckwheat flour to make a soft mush. I prefer the oatmeal but you can vary the specific grain combination to suit yourself. If you are working with a large quantity of meat, rather than just 1 head, figure 1 part dry cereal and 3 parts soup to 7 parts ground cooked meat. If you use cornmeal, cool some of the broth and moisten the cornmeal with it before adding to prevent lumps.

Now season the scrapple. For the basic 1 pig's head and 1 box oatmeal recipe, add $\frac{1}{2}$ T. ground pepper and 2 T. salt, or vary the seasonings to suit yourself. Marjoram, sage, nutmeg, mace, and onions are all good in it. (If you use onions, grind them first and add at the beginning of the time the cereal will cook.) After your scrapple is thickened and seasoned, it has to be cooked about half an hour very slowly. Don't let it burn on the bottom. When it is done, pour it into chilled, wet leaf-type (or other shallow) pans. That's all there is to it.

Scrapple makes a good quick breakfast or lunch. You can cut it into sections sized appropriately for 1 meal for your family, package it in a plastic bag, and freeze. To serve the scrapple, thaw it, and cut into $\frac{1}{2}$ -inch slices. Some people like it dipped in egg or in egg and crumbs before frying. Fry it like cornmeal mush in a lightly buttered pan, about 10 minutes per side, over medium to low heat until browned on each side and crisp. Serve with maple syrup.

Scrapple Without a Pig's Head. From Ellen Currans of Douglas, OR: "Start with 1 lb. pork sausage, browned in a skillet with 1 large onion, chopped. Add 3 c. boiling water and 3 c. oatmeal. Salt and pepper to taste. Cook, stirring, until oatmeal has absorbed the water and tastes cooked. Our family eats as is, or it can be packed in a loaf pan, refrigerated and then sliced and fried in butter for breakfast. Makes a great first breakfast to take on camping trips."

HEADCHEESE: Mix the ground meat mass with seasonings to taste: salt, pepper, red pepper, ground cloves, coriander, and sweet marjoram all are possibilities. Take a little sample, spice it, and then taste it to see if you like your combination. Keep testing until you get it right, and then spice the whole mass accordingly. Red pepper is good in it if you have a cast-iron stomach. I grind my own, but if you do too be sure you get it fine because if somebody bites into a speck-sized bit of it, it'll take the top of his head off.

Pack the seasoned headcheese tightly in a bowl or loaf pan and press into as compact a mass as you can in the bottom of the bowl. For extra firmness, cover it with a weighted plate. Refrigerate. When it is very firm it is ready to slice and eat.

Still another way to use the pig's head is a combination of headcheese and panhas. Go ahead and make your headcheese. After making headcheese you have a soup broth left over anyway to use as you please or throw out. Add cornmeal and seasonings to that meat broth just as for scrapple and you get the meatless scrapple called panhas.

Headcheese Sausage. This is a variation you can try sometime. After the headcheese is seasoned to taste, stuff it into casings instead of pressing it into a bowl. Then recook the sausages in the pork soup until they float, 10–30 minutes. After they float, chill them in cold water. Store in a cool place. You can add a smoke flavor by giving them 4 hours in the smokehouse.

Sylta Headcheese. From the Johnsons of Wheaton, IL: "This serves 20 to 25. Use $\frac{1}{2}$ hog's head (5 lb.), 2 lb. lean pork and $2\frac{1}{2}$ lb. veal shoulder. Clean and singe off hair and bristles. Clean teeth with a stiff brush and cut off ears. Soak in cold water for 6 to 12 hours, changing water. Place meat and hocks in boiling water to which has been added 4 t. salt, 30 peppercorns, and 20 whole allspice. Simmer 2 to 3 hours, or until tender. Remove meat from broth, save broth, and cut meat in slices. Spread cloth or towel, wrung out in hot water, in a deep bowl. Line with cooked rind from pork hocks, rind side down. To sliced meat, add 3 to 4 T. crushed whole allspice (measure after crushing with rolling

pin). Add 3 to 4 T. salt. Arrange in cloth. Cover with rind if any is available. Pull cloth together tightly and tie with string. Put back in broth. Cook slowly 5 to 10 minutes. Lift out so it doesn't stick to the bottom. Remove to a platter, cover with a board and put weight on for 24 hours. Set in a cool place. Remove cloth after that time and wrap in a fresh cloth that has been soaked in salted water. Put in a plastic bag and refrigerate. Serve slice thin with pickled beets."

Chitlins

This is the small intestine of the pig. Some people think these are the best part. Others think they're too much work to clean, slippery, fragile, and bad smelling. Pull all the fat off, rinse, and scrape as to make sausage casings until they're really clean. Then boil until tender with salt, pepper, and a potato. Serve chitlins hot with cabbage slaw or potato salad.

Making Lard

White, creamy lard comes from high-quality pig fat that was trimmed and rendered fairly soon after the butchering. The fats that you got from around the internal organs of the pig are called the "caul" and "ruffle" fats. If they were washed promptly, and if none of the contents of the innards were spilled on them, they can also be made into lard, except their lard is a darker color. Besides your own butchering, you could probably get fat from a butcher shop for a cheap price, if you want it; just leave word that you are interested in buying. (They'll probably give it to you.) But it wouldn't be residue-free. It's best to render lard during cool weather. Work with about 15 lb. or so at a time.

I render our lard in a big pan in the oven. It takes more than 24 hours of slow heat. The grease will separate more easily from the tissue fibers if the fat is cut into pieces before putting it in your kettle. Some people even grind it through a meat chopper using a 2-or 3-blade knife and plate with a hole $\frac{3}{4}$ inch or larger. But that ruins your chance for cracklings.

CRACKLINGS: These are the little pieces of meat tissue that are left after you melt out the lard, like frying bacon. Some people like cracklings and some don't. They are packaged commercially and sold as a snack called "pork rinds." I remember vividly as a little girl my father's hog butchering and lard rendering and how good those fresh cracklings tasted. My husband loves them, too. If you want proper cracklings, cut your lard into strips. I do that when I'm getting ready to render the lard. I cut the fat and skin into strips—any sort of shape but I try to get them not more than $\frac{1}{2}$ inch wide.

THE HEATING: You can put pure fat in the kettle or else start out with a little water in the bottom. An iron kettle is fine. Burning is a problem. *Use only low to moderate heat.* It's safest to render with that kettle in the oven rather than on a burner. Or on the back of a wood cook stove, because there is such a gentle even heat back there. If you don't get done the first day, just let it set overnight and continue on the next day when you get the stove going again. *Don't stick your face in the kettle for a close examination.* There is an occasional "pop" as some moisture in the fat turns to steam, and you might get a grease burn in the eye. Remember the stuff is pure hot grease. *Make sure the pan is at the back of the stove and that the children stay away.*

Do not fill the kettle to the top so that there won't be any danger of it boiling over. Add $\frac{1}{2}$ t. baking soda to the fat when rendering is begun, which will darken the cracklings but whiten the lard. Be careful not to scorch. It happens so easily. The fat should be stirred

frequently and cooking should be very slow until the fat begins to melt and the mass can be stirred easily in the kettle. If you have a dairy thermometer you can watch the temperature.

Early in the process of rendering, the temperature of the fat will be 212°F. As the water contained in the fat tissue evaporates, the temperature will rise slowly until it reaches 245–255°F—the highest it should be allowed to go.

Microwave Rendering. Lois Rumrill, Forks of Salmon, CA, wrote: “A microwave oven works just super for rendering fat of any kind. Use a 2-qt. Pyrex, Corning Ware, or other glass pan. Fill pan about two-thirds to three-quarters full of fat. Cover and place in microwave oven. Set time for 12 minutes. When time is up, remove pan from oven. Pour hot lard into jars. I put a doubled piece of cheesecloth over top of jar and secure it with a rubber band. I set the jars in a 13 × 15-inch baking dish. The jars really don’t have to be scalded, just clean, and the lids should be hot. The grease is hot enough that when the lids and rings are put on the jars, they will readily seal. This method gives you a very clean, white lard. Also no smell, smoke from burnt grease, and almost no mess.”

AGAIN, CRACKLINGS: As rendering proceeds, the cracklings will first float, then gradually sink to the bottom. This is where trouble can really begin because they go down there and scorch. If you stop the rendering while the cracklings are still floating you’re safer. If you are saving the cracklings, scoop them out before they sink. As the lard renders out into a clear liquid in your pan the cracklings turn brown, shrivel, and float to the top. Don’t stir excessively if you want them for snacking or they’ll break up.

Be sure they’re done—that all the grease is rendered out. When they get visible bubbles in them they’re about done. Then scoop them out and finish them off separately. You can put them to drain in a hot place or in your oven in a colander set in a pan and they’ll drip awhile more. I freeze them loose in plastic bags, about half a cup in each.

➲ **CRACKLING CORN BREAD** Mix together 2 c. corn meal, 1 c. flour, 1 t. soda, and $\frac{1}{2}$ t. salt. Add enough buttermilk to get a heavy gravy consistency. Fold in 1- $\frac{1}{2}$ c. chopped cracklings. (Make sure that cracklings are broken into small pieces; you can make them more tender by soaking them in hot water then draining them.) Bake at 350°F until brown.

From Donna Joehn, Blaine, WA: “Cracklings are my very favorite breakfast accompaniment with eggs. Cracklings are not the skin or rind. They are what is left after rendering out ground-up lard. They are crumbly looking things—like coarse graham cracker crumbs. To eat, you reheat ‘til bubbly and crisp, then press dry of fat in a potato ricer or with a spoon in a strainer. Salt, pepper, and enjoy in place of bacon. They sell them in British Columbia grocery stores; we live near the border where there is a large Mennonite settlement and people speak ‘low German’ on the streets.”

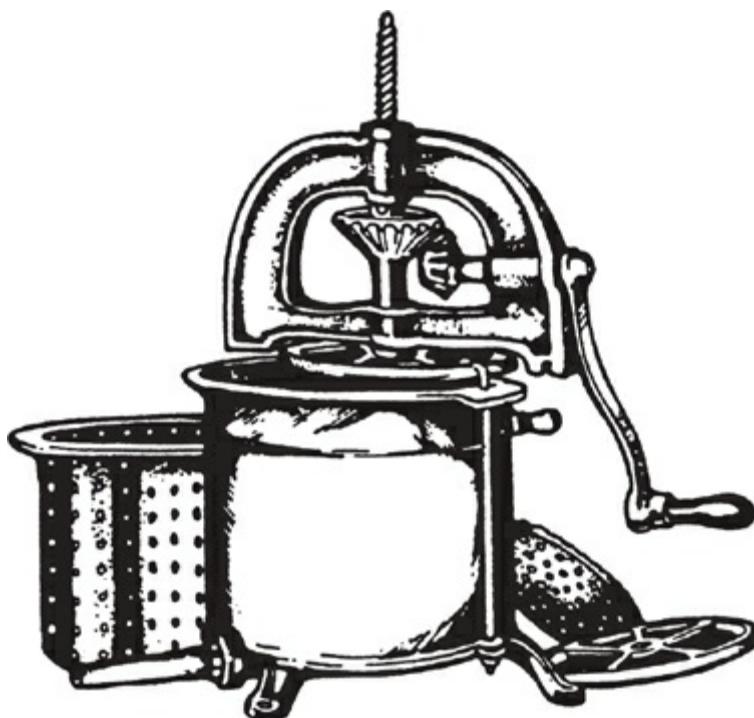

WHITENING LARD: For the whitest homemade lard you can possibly make, add a raw potato in the bucket and stir it for a while. Then remove the potato.

SKIMMING LARD: The more water left in your lard the less well it will keep. If you want really water-free lard without struggling on to the bitter and potentially scorched end, skim your lard off the top with a dairy skimmer since the water will all be on the bottom. By “dairy skimmer,” I mean a plain old soup ladle, which is what I skim the cream off my milk with.

STRAINING LARD: When your lard liquid is cooled down to only warm, it is ready to be put through a lard press, if you have one. They were common among the old-timers. I don’t have one and don’t know where you or I could find one except maybe as an expensive antique. I spread cloth in a wire sieve and strain through that into a bucket, and from the

bucket I pour into the containers. When you get near the bottom of your rendering pan, the sediment gets thicker. You should stop and switch cloths, this time adding a couple extra layers. Then you can pour it all out and squeeze heartily to get every last drop.

COOLING LARD: When your lard is ready to store, get it cooled down as soon as you can. It should be protected from light, air, and moisture. So if you are storing plain, put your lids on as tightly as if you were sealing them. If your containers are glass, store them on shelves in a dark cellar or inside brown paper bags.

Antique Lard Press

LARD WITHOUT SKIMMING: If you want your lard to keep just as it is—without canning or freezing it—then continue rendering, stirring occasionally to make sure no sediment is scorching on the kettle bottom. In this case it is important that all the water be evaporated unless you skim your lard off, which is a disagreeable job. When the cracklings are a deep golden brown the lard should be done. You can test for moisture by placing a lid on the kettle to see if moisture will accumulate on it. Remove from heat and let the sediment get quiet.

ABOUT RANCID LARD: *Rancid lard should be discarded. It tastes bad and isn't good for you.* But rancid lard does make fine soap.

HOW TO AVOID RANCIDITY: Air and light cause the chemical changes that lead to rancidity. You can improve the storage life of lard thus by keeping it in the dark and in air-tight packaging. And/or you can add a commercial anti-oxidant (check with your local locker plant). Adding hydrogenated vegetable shortening to lard while it is cooling also helps preserve it. One part vegetable shortening to 16 parts lard is about right.

CONTAINERS FOR LARD: Get ready your containers in which to pour the rendered lard. Clean gallon tin cans are good, even if you don't have lids, or widemouthed jars, especially half-gallons and gallons. Or the tall juice-type cans. Chill it quickly (to get a fine-grained lard) and store immediately in the coolest place you have. Seal tightly and keep in the dark.

FREEZING LARD: Water in the lard doesn't matter if you're going to freeze or can it. I freeze it.

It would probably keep okay outside the freezer, but I'm a shade surer that way. I take out 1 can at a time, and it lives on a shelf beside the kitchen stove until I've emptied it and am ready for another. Store lard in a dark cool place or in a freezer, inside a metal container or in a grease-proof freezer carton, sealed with a tight cover. I dip the melted lard off the top into bowls with my cream dipper and then put it into the refrigerator to chill. After the lard gets hard, I cut it into sections and put each one into a plastic bag and into the freezer. Or else, if I have enough coffee cans, I chill it in coffee cans. Then I put a plastic bag over the top of them for a lid and put can and all in the freezer. You can freeze lard wrapped just in freezer paper if you can get it solid enough to wrap first. Cool it, for example, in a big metal bucket. Then cut and repack in double layers of freezer paper or white butcher paper and freeze until wanted. It takes a lot of containers to store the lard from even one pig so be prepared.

USING LARD: A certain amount of lard is really very handy. You almost have to have lard to make pie crusts and good soap. You can use lard almost any place you would use oil once you get used to it. And if your animal was born to a residue-free mother and raised on all residue-free food, then you have fat that is pesticide-free and fairly low in cholesterol, and it makes a fine frying grease and baking fat. The only type of recipe I don't like to use lard as the fat in is salad dressings—except I like lard for wilted lettuce dressing. It's handy to keep most of it in the freezer, plus 1 large container in the refrigerator, and a small one by the stove, which you refill from the one in the refrigerator as needed.

LARD SUBSTITUTIONS: When substituting pure lard for "shortening" in baking, add an extra $\frac{1}{2}$ c. flour for every $\frac{1}{2}$ c. lard used because lard is "shorter" and needs more flour to take it up.

Deep-Fat Frying. Cheap homemade lard makes deep-fat frying a reasonable way to prepare some foods. Deep-fat fried foods are a favorite item with my family. My standard recipe is to batter whatever I deep-fry with beaten egg and flour and then fry it in grease hot enough to smoke. If the grease is hot enough before you start frying, the batter casing will immediately seal up and the food won't absorb excessive grease. It's frying at too low a temperature that results in greasy foods. See "Deep-Fat Frying Time/Temperature" table.

That lard for deep-fat frying can be used and reused. I sometimes just leave it in the kettle between uses. Or I strain it through a cloth or fine sieve to remove food particles and then store it in the refrigerator. After frying strongly flavored food, like fish or onions, a few slices of potatoes put in the cold lard and then heated until well browned will absorb the flavor. Then strain the hot lard.

Fat should never be heated above 400°F. Thaw frozen foods before you fry them to avoid lowering the fat temperature. Fry pieces of similar sizes at the same time. The kettle should about half full of fat and you should add fresh fat as needed. To avoid a greasy taste, don't overload the kettle, which would cause the temperature to drop and the frying time to increase. Test the fat's temperature with the fat-frying thermometer.

Accumulation of burnt particles will cause the fat to spoil sooner than it would otherwise. Remove this accumulation by straining the fat through several thicknesses of cheesecloth. For a clearer fat, draw it off into a separate container, and after it has cooled to below 200°F, sprinkle the surface with water. The water carries down to the bottom the particles of burnt food that have been suspended throughout the fat. The clear fat can then be poured off the sludge of water and burnt particles. Or the water, sediments, and thickness of fat can be drawn off the bottom of the container if it has an outlet at its base.

Test taste fat before returning it to the kettle so you're sure it isn't rancid.

Meat, fish, and chicken pieces are usually dipped in a frying batter of seasoned milk, egg, and flour and placed immediately into the hot fat. Or dip them into a seasoned water-egg or milk-egg mixture, then roll in flour, crumbs, or cornmeal. Foods with a moist surface (such as oysters) are dipped in crumbs, then batter, and again in crumbs. Croquette mixture should be chilled, shaped, then rolled in crumbs.

Fritters. These are a food dipped in batter and then fried in generous fat. You can make fritters out of just about anything—chicken, oysters, vegetables (of any kind), or fruits such as bananas, pineapples, and apples. They were very popular around the turn of the century. If you've got lot of lard, these are fun to experiment with.

Use clear oil or lard for frying, about 3 inches deep, to cook fritters. Heat the fat hot enough that a bit of batter dropped in will immediately rise to the surface and begin to brown. Don't put in too many fritters at once. Brown first on one side and then turn and do the other. Drain well and serve immediately.

⇒ **FRITTER BATTER** Combine 1 c. flour and $\frac{1}{2}$ t. salt; slowly add $\frac{1}{2}$ c. milk, then 1 T. cooking oil, and, finally, 2 well-beaten eggs.

⇒ **BAKING POWDER FRITTER BATTER** Combine 1 c. flour, $\frac{1}{2}$ t. salt, and $1\frac{1}{2}$ t. baking powder. Slowly add $\frac{1}{2}$ c. milk, then 1 T. cooking oil, and, finally, 2 well-beaten eggs. This gets puffier, but I like the plain batter best for taste.

⇒ **VEGETABLE FRITTERS** Cook, drain, and cut the vegetables into convenient-sized pieces before coating with the batter.

⇒ **APPLE FRITTERS** Peel and core tart apples and cut them into round, thin, slices. If you want to give them the gourmet treatment, marinate them briefly in a mixture of brandy, lemon juice, and sugar. Drain and dust with flour. Fry on both sides in butter, drain, and sprinkle with powdered sugar and cinnamon. Serve hot.

⇒ **BANANA FRITTERS** Peel bananas, cut in halves, and split each piece lengthwise. Sprinkle with lemon juice before coating.

⇒ **MEAT FRITTERS** Use cooked, cold meats. Parboil oysters and other shellfish.

⇒ **CORN FRITTERS** Combine leftover corn (1 c. more or less), 3 beaten eggs, 3 T. flour, seasoning, and 1 t. baking powder. No need for further batter; you've made your own. Drop by spoonfuls into the hot fat. You can substitute other leftover vegetables in this.

⇒ **LARDING MEAT** Marie Oesting of Ocean Park, WA, writes, "We used to lard meat on the farm. I called my mom (she's 88) and asked her the details. Here goes. Beef cans good, but pork doesn't can well because it's so fat. So, they would take the pork chops and also the fresh pork sausage (seasoned but not smoked) and lard them down in a 20-gal. crock. Fry the meat thoroughly, so it's dry and extremely well done. Mother said she always salted the pork chops and sausage but doesn't know whether that's really required for preservation or not. When they are thoroughly fried, layer them into the crock, covering with melted lard (not the fat they were cooked in)."

⇒ **PIECRUST** Basically, this is a mixture of flour and fat. The size of the bits of fat varies, as does the amount of water. For piecrusts, use $1\frac{1}{2}$ c. flour sifted with $\frac{1}{2}$ t. salt. Use 2 forks or knives to work in $\frac{1}{2}$ c. lard. When the fat has been worked in until it is more or less of uniform texture, add 4 or 5 T. cold water slowly until mixture becomes a stiff dough, which will hold together in one ball. Roll out and cut into the shape you need.

Pigs' Feet

Clean the pigs' feet. Be sure to remove the toes and dewclaws, the glandular tissue between the toes, the hair, and any dirt.

➲ **PICKLED PIGS' FEET** Cover pigs' feet with boiling water and simmer until tender, 2½—3 hours. In a large enamel pan combine 1 qt. vinegar, 6 whole cloves, 2 bay leaves, 1 stick cinnamon, 2 T. salt, ½ t. pepper, ½ c. brown sugar, and 1 onion, sliced. Simmer 1 hour. Strain liquid to remove spices. Add 2—4 c. liquid in which pigs' feet have been cooked. Pour over feet and chill 2 days, if possible. This is right for 8 pigs' feet. (You can also use pig hocks or knuckle bones to make this.)

The winter of 1946–47 we lived on a wheat ranch near Clyde Park, Montana. There I got my precious little goat, my first goat, on Christmas morning. That morning I heard a funny sound in the living room, jumped out of bed, ran in there—and there was a baby goat tied to the Christmas tree, trying to eat the tinsel. It was my beloved pet and pal from then on.

Late in January my birthday came, and I turned 8 years old. Later yet, spring finally came, the time of year when every few days we would hear the bleating baa-a-a-s as bands of sheep were hurried by up the blacktop highway a quarter mile away. The sheepherders were driving them off the valley bottom, where the sheep were wintered, up into the mountains, where the snow was now melting and the grass was coming on green and beautiful.

Every time we heard that sound, Mother gave me a bag of cookies and a thermos of hot chocolate (spring was by no means warm in Montana). Then I ran down our long lane to find the sheepherder who drove the flock. The herders always were happy when I came running up behind them with the cookies and cocoa. They never failed to share them with me. We'd sit inside their sheep wagon, that small summer home on wheels, or on its back steps. I'd eventually get around to asking if they had any bums.

I knew that herders of hundreds of sheep preferred not to be bothered with the ones that were orphaned and needed special feeding or that were sick or injured and unable to keep up with the flock's migration—that long walk up to summer pasture. I came home with so many bums that by spring's end, I had a flock of 7 lambs of my very own. I fed cow's milk to them in a pop bottle with a black rubber nipple pulled onto the end of it, and they all thrived. I had blind ones and lame ones, but they all knew who I was and loved me. I sure wasn't lonesome that summer. We were milking about 5 cows, so there was plenty of milk for them.

But those happy memories were followed by sad ones. In the hot August dog days of summer, a city-raised hired man who had just had his noon lunch in the house filled his tractor at our farm gas pump and then carelessly rubbed out his cigarette on the side of a tractor. As he pressed the hot butt on the place where gas had spilled time and again from the hose inlet above, the act instantly started a fire. In rapid succession, the fire burned the tractor, spread to the fuel-soaked ground in front of the pumps, and went on to the adjacent tool and coal-storage shed. From there it blew over to ignite our house's roof.

Because we had no phone and no car that day (Daddy and our single vehicle were away working in a far-off field), Mama sent me running down the lane as fast as I could to get help from our nearest neighbors, who lived not all that near. Mr. Steiner happened to be home, flagged down a car on the highway, told the driver to take me to town so I could spread the call for help there, and then left to help fight the fire. I ended up

spending hours at Chet's Service Station in Clyde Park with the old man who was left tending the station after everybody else had jumped into vehicles and zoomed away to our ranch. I was hoping not to be forgotten—waiting to be taken back home and wondering about my pets.

When I had left, the fire had been burning only the tractor and the ground around it. But I could see from town the big column of black smoke over our place. And I got to thinking about how my 7 bum lambs and the goat always sheltered from the noon heat in the rear of that shed, napping away the hottest hours. It worried me a lot, but I hoped somebody had thought to open the back door of the shed and let them out. Surely Mama or somebody had done that. If I had been there, I certainly would have.

I refused to believe they had all—every last one of them—been dead for a long time. I climbed up the big butte in back of our house and called them, evening after evening. I hoped that the big fire had merely frightened them off. Finally Daddy took me to the blackened rubble where the shed had been, and with his boot toe he pointed out bones in the fire debris. It was the first time creatures I'd loved so much and cared for so well had died—and all of them at once. All I had left were lifelong memories that would always be dear. But learning to let go is part of having animals, or people, that you love in your life.

How to Use an Antique Cookbook

Dictionary of Antique Cookbook Words

APPENDIX

How to Use an Antique Cookbook

This isn't the only recipe book that believes you get your eggs and meat from your own barnyard and your fruit and vegetables from your very own garden. Great Grandmother had the same problem you do. (I didn't really know any great grandmother of mine—I wish I could have. The "great grandmother" in this book is a pleasant figment of my imagination.) She needed cookbooks that told how to preserve homegrown produce, that listed from-scratch ingredients rather than processed, premixed ones, and that didn't assume she lived near all the specialty shops in New York City. Her cookbooks will work for you—if you know how to use them! This section is designed to make your antique recipe books a useful part of your kitchen library, not just sentimental curiosities on the shelf!

Leavening

Leavening is invariably a problem in using old-time recipes. (See "Acid-Base Leavenings" for lots more on old-time leavenings.) What's "old"? Well, 1900 is, 1870 more so. If baking powder is mentioned you may want to reduce the amount by $\frac{1}{2}$ or $\frac{1}{3}$ because modern baking powder is "double acting" and raises 2 or 3 times as much as the first versions (depending on which brand you use). If soda is in the recipe, it's quite likely the proportions aren't correct. For every cup of molasses, sour milk, or buttermilk, or for every tablespoon of vinegar or lemon juice, $\frac{1}{2}$ teaspoon of soda is appropriate. More soda won't react completely with the acid in the batter, and you risk a soda taste. There may even be soda included in the recipe without any acid. The author thought soda was a good thing and should be included. If you find soda listed without a corresponding acid (cream of tartar is an acid and sourdough starters and liquid yeasts all contain acid)—omit the soda unless it's tomato soup! Soda and cream of tartar combined in a recipe are a form of "baking powder." They react together and release bubbles of carbon dioxide gas, which leaven the mixture. The soda should be exactly half the amount of cream of tartar unless there is another acid present. Sometimes "saleratus" meant an old-time, coarse-grained baking soda. Sometimes it meant a homemade baking powder. (Recipes in the Grains

Chapter, Leavening section.)

If the recipe calls for yeast by the "teacup" or some such strong amount, it means liquid yeast; use any sourdough starter or homemade yeast recipe. Or, easier yet, substitute dry yeast. How much? For less than 6 c. flour, use 1 T. dry yeast. From 6 to 11 c. flour, use 2 T. From 11 to 26 c., use 3 T. Then fill the "teacup," or whatever, with water to match the desired liquid quantity. If the recipe calls for a yeast "cake," that means compressed yeast. Those pressed cakes of combined moist yeast and filler material rapidly disappeared from the marketplace after the introduction of dry yeast. For each "cake of yeast," substitute 1 T. dry yeast.

Temperatures

In the old days it was assumed that everyone knew how to cook, so instructions for baking and cooking were vague. Anyway, there were no temperature controls on campfires, fireplaces, or early-day ranges.

Measures

"Teaspoon" may not mean what you think. "Teaspoon" has changed from the old-time ratio of 4 t. per tablespoon to our present 3 t. per tablespoon. Worse yet, in some old books "teaspoon" and "tablespoon," when applied to dry materials, were understood to be a "rounded" quantity—meaning as much heaped above the rim of the spoon as below. "Heaping" meant as much of a dry ingredient as could be piled on the spoon without falling off. A "dessertspoon" was half a tablespoon. That means it was the equivalent of 2 t. when 4 t. equaled 1 tablespoon. A "salt-spoon" contained $\frac{1}{8}$ teaspoon. A "dash" meant one shake of the shaker. A "pinch" then and now was as much as can be taken between the top of your finger and thumb. If you're not comfortable with "salt to taste," add $\frac{1}{4}$ t. salt per 2 c. flour.

"Cup" in old recipe books meant about one-fifth less than our present 8 oz. cup. "Teacup" meant what we would call a half cup. "Wineglass" was the equivalent of our $\frac{1}{4}$ cup. When a recipe calls for "bowls," as some old mincemeat recipes do, use the same bowl consistently and guess from the quantity of ingredients how large a bowl is needed. (A 3 cup capacity is a good average guess.) There were 12 fluid oz. but 16 dry oz. per pound. Thus, a "pound" of molasses was 12 fluid oz., about $1\frac{1}{2}$ cups. Recipe amounts were often given by weight rather than volume. You can buy an adequate kitchen scale in most hardware stores. A "hen's egg of butter" is 3 to 4 tablespoons. A "walnut-sized lump of butter" is 2 tablespoons. For "tumbler," "large coffee cup," and "glassful," you can substitute 1 cup.

Flour

Flour consistencies have varied over the years and with the brand. (For amounts to add, see "Flour.") Whole wheat flour was formerly sold in 2 grades. "Graham" flour was the heavier, containing more bran and coarse particles, and was considered the lowest class of brown flour. "Entire wheat flour" was the other grade. The entire wheat flour was usually intended when whole wheat flour was mentioned in a recipe, unless graham flour was specifically named. In old recipe books, "1 cup flour" means unsifted flour unless the recipe directs you to sift it. You can freely substitute one kind of wheat flour for another. It changes the color and the taste a little, but that's all.

Sugar

"Loaf sugar" was sugar purchased in hard loaves or cones that averaged about 9 to 10 lb.

apiece in weight. That's way back when. One cone would last thrifty people a year. The sugar cone was cut into lumps of equal size and regular shape with special "sugar shears." For "1 lump loaf sugar," substitute a modern sugar cube. For loaf sugar "crushed," substitute granulated sugar. Loaf sugar "ground in a mortar" meant loaf sugar crushed only to a particle size, similar to sand or fine gravel. "Powdered sugar" in the old recipe books meant a grade of fineness between granulated and confectioners' sugar. Granulated sugar had a weight of 2 cups per pound; powdered sugar had a weight of $2\frac{2}{3}$ cups per pound.

When you see "syrup 32 deg." or some such number, it refers to a saccharometer reading. Saccharometers measure sweetness. They were commonly used in candymaking as well as home brewing. You can still buy a saccharometer from some big mail-order suppliers.

Flavoring

You are safest if you learn to use judgment in flavoring. Lemons and eggs are not always of the same size anyway; nor are fruits always of the same degree of sweetness or acidity. When your old-time cookbook was written, flavorings were commonly adulterated, so you may need to reduce the suggested quantity of spices. If the recipe calls for ginger and the amount seems large, it meant ginger root, which was purchased whole and ground at home as needed. Home-ground ginger is not as strong as the powdered commercial product. To substitute store-ground ginger for ground root, reduce the amount to one-fourth of the quantity given. For "1 grated nutmeg," substitute $2\frac{3}{4}$ T. store ground.

Get in the habit of tasting a pinch of mixture now and then, and you'll learn what to expect and be forewarned when all is not well. Be prepared to try an old recipe several times before getting all the kinks out of it. If the recipe is for a large amount, scale it down until your experimenting is done. After each trial, think about which measures may have been wrong and write down your guesses of what they should be. To be a real old-time cook, get to know what a teaspoon and tablespoon of a dry ingredient look like in the palm of your hand. Know how stiff or runny and how sweet, sour, or spicy you want your dish to be, and then trust your taste buds!

Mystery Words

Our great-grandmothers used a wide variety of wild and homegrown fruits, berries, nuts and herbs—and some vegetables that are not now usually sold in grocery stores. You can look for the names in your garden seed catalog and plant your own salsify, sorrel, leeks, and so on. In some cases the plant is the same but over the years the name has changed. "Pieplant" means rhubarb. "Vegetable marrow" means summer squash. "Oyster plant" is salsify. "File" means sassafras leaves dried, powdered, and used as a seasoning and for their thickening ability in soups. "Marron" means chestnut.

Here are some other terms that may have puzzled you. "Brine that will bear an egg" means water with enough salt in it that an egg will float when placed into it. "Boiled until it will spin" means syrup boiled to the thread stage (you dip the spoon into the syrup, pull it out, hold up the spoon, and one drop is attached to the next by a thread). "Gem irons" were iron muffin pans. An "ice cave" was a special pan used to make ice cream and other frozen desserts. "Lemon drill" means an old-time glass lemon and orange squeezer. Press half a lemon or orange down over the "hill" and twist to get your juice. Still mystified? Look up the word in the following "dictionary," and also try the index.

DICTIONARY OF ANTIQUE COOKBOOK WORDS

This dictionary covers the most puzzling cookbook vocabulary from Colonial times through the extravagant, all-in-French menus of the Victorian era (when "dyspepsia" was the national ailment). Entries are listed by the first word of a natural combination, no matter what part of speech it is. Check the index for possible further information. Whenever possible, appropriate instructions and recipes are provided.

A

A LA, AU, AUX: Food served in a certain style.

A LA CREOLE: With tomatoes.

A LA ITALIENNE: Garnished with cooked macaroni (or vermicelli, spaghetti, etc.), cut into rings.

A LA JARDINIERE: A dish garnished with vegetables diced or in natural small pieces such as peas and tiny sprigs of cauliflower.

A LA JULIENNE: Garnished with cooked carrot, turnip, onion, celery, cut into matchlike strips.

A LA KING: Prepared in a rich cream sauce.

A LA MODE: "In the fashion." Beef a la mode is beef larded and pot roasted. Pie a la mode is pie served with ice cream.

ABSINTHE: A green alcoholic liquor containing oils of wormwood and anise, and other aromatics.

ACIDULATED WATER: Water to which vinegar or lemon juice is added: 1 T. acid per quart water.

AGATE KETTLE: An enameled iron or steel cooking utensil mottled and veined to resemble agate.

ALLIGATOR PEAR: Avocado.

ALMOND PASTE: Formerly sold by dealers having confectioners' supplies. Used in making macaroons and small fancy cakes. (Recipe in Tree chapter.)

ALUM: Used to keep pickles crisp. An astringent obtainable from the alum root. (See Herbs.)

AMANDINE: With almonds.

AMERICAN ICE CREAM: Combination of custard and cream, sometimes also flour or cornstarch. Stir while freezing.

ANDIRONS: Iron fireplace furnishings used to help hold logs and cooking utensils.

ANGELICA: Herb. Confection made from its candied stem tips. Old-time sweet California wine.

ANTIPASTO: Assortment of Italian appetizers such as sardines, anchovies.

APOLLINARIES: An old-time soda water.

APOTHECARY: Druggist.

APPETIZER: A food or drink offered before the meal soon after the guest arrives.

ARROWROOT: A starch obtained by drying and powdering the root stocks of a plant that thrives on tidal flats. It is used for food, thickening, and used to be in baby formulas.

ASPIC: Clear, unsweetened gelatin molded to garnish cold dishes.

ATTAR: Fragrant essential oil extracted from rose petals. (See Herbs, Rose.)

AUBERGINE: Eggplant.

AU BEURRE: Cooked in, or with, butter.

AU GRATIN: Covered with sauce, topped with bread crumbs or cheese, then browned under the grill, or in oven. A shallow dish is used. Serve the food in the dish in which it is cooked.

AVENA: Rolled oats.

B

BAIL: The handle of a pail or pot. It is made of a wire looped over at each end around the vessel's "ears."

BAKE KETTLE: Dutch oven.

BAKER'S YEAST: Yeast used for making bread.

BALSAM OF PERU: An aromatic, oily preparation from a tropical American tree used in perfume and medicine.

BALSAM TOLU: A Tennessee plant product used for making chewing gum. No longer available.

BARBECUE (to): 1. Roast an animal slowly on a gridiron, spit, or over coals in a trench. The animal may be whole or in pieces. Baste while cooking with a highly seasoned sauce. 2. Any meal cooked in the open or on a spit.

BARCELONA NUT: A filbert variety, kiln dried for better keeping.

BASTE (to): Moisten meat, or other food, while cooking. This adds flavor and prevents surface drying. The basting liquid may be melted fat, meat drippings, water, or a sauce.

BATTER CAKES: Pancakes.

BATTER PUDDING: Custard made by boiling in a bag.

BAVARIAN CREAM: Flavored liquid, fruit pulp, gelatin, and whipped cream.

BEAT (to): This mixing motion brings food from the bottom of the bowl to the top, continually turning over and over the contents of a bowl. The purpose may be to enclose a large amount of air.

BELL PEPPERS: Large, hollow green or red peppers.

BENNE: Wild sesame seed.

BERGAMOT: A variety of pear. A variety of fruit furnishing an oil once used as a perfume.

BEURRE NOIR: "Black butter." To the fat remaining in the pan after frying meat, add enough butter to make $\frac{1}{3}$ cup total. Melt the butter. Add 1 t. lemon juice or vinegar. Salt and pepper to taste.

BILL-OF-FARE: Menu.

BISCUIT: 1. Combination of whipped cream, sugar, and flavoring. Macaroon or other crumbs were often added. This combo was frozen in individual molds, without stirring. 2. A type of quick bread.

BISQUE: 1. Soup thickened by adding minced meat and crumbs. 2. A cream soup made from fish that has been diced or mashed through a strainer.

BLACK TEA: This variety is made from tea leaves that have been withered, sweated, fermented, rolled, and then fired.

BLADE OF MACE: The unground inner envelope of a nutmeg.

BLANCH (to): 1. Dip in boiling water, drain, and rinse in cold water. 2. Boil for a brief period. Blanching is used to remove skins from nuts and fruits, and to prepare vegetables for freezing.

BLANCHING BASKET: A long-handled colander for immersing in hot water and quickly lifting out to drain and cool the contents.

BLANQUETTE: White meat in cream sauce thickened with eggs.

BLOW: “Boil sugar to the blow” means to 240°F.

BOHEA TEA: A black tea. This term first was applied to the choicest, then to the medium grade, finally to the poorest.

BOILER: A large, metal, oval container used for washing clothes, canning, or making cheese.

BOMBE: Combination of two or more mixtures previously frozen in a melon or other fancy mold. The bombe is then hardened in a freezer.

BOMBE MOLD: Line it evenly with one kind of ice cream. Put another in the center. Cover and freeze several hours before serving.

BONBON: This type of candy has a nut, fruit, or rolled fondant in its center. It is then dipped into melted fondant and cooled to harden.

BONE (to): Remove bones from meat or fish, leaving the flesh in its original shape.

BONING KNIFE: This is a narrow-bladed knife, the narrower the better.

BOUCHEES: Small pastry shells or cases filled with creamed meat or fish.

BOUILLON: A hot beef stock made from lean beef, clarified and seasoned.

BOUQUET GARNI: 3 sprigs parsley, 1 small stalk celery, 1 leek, $\frac{1}{2}$ bay leaf, 1 sprig dry thyme—or some variation thereof—tied together and added to a stew or sauce for flavoring.

BRAISE (or “braize”) (to): Brown meat in a small amount of fat, then cook it slowly in a covered pan with a small amount of liquid.

BRAMBLE: Blackberry.

BRAN: The outer covering of the grain. It is rich in minerals, protein, and vitamin B.

BRANDY: A concentrated (sometimes by distillation) wine.

BRAZIER: An open pan for holding live coals.

BREAD (to): Roll cutlet, croquette, or other food in crumbs.

BRINE: A strong salt and water solution.

BRINE THAT WILL BEAR AN EGG: Water with enough salt in it that an egg floats.

BRIOCHE: A roll made of sweet dough.

BRISKET: Breastbone or breastbone area.

BROCHETTE: 1. The skewer. 2. The skewer method of cooking.

BROIL (to): Cook by subjecting food to the direct heat of a fire of live coals (not smoky) or of a gas or electric burner or other direct heat.

BROILER: A $1\frac{1}{2}$ - to 2-pound chicken.

BROWNED FLOUR: Lightly brown wheat flour in the oven or on top of a stove in a dry pan. Old-time cooks preferred browned flour for gravy making.

BROWN SAUCE: This is now called "gravy." Thicken milk, water, or brown stock with browned or plain flour. Brown sauce usually contains meat drippings.

BROWN SOUP STOCK: This is a soup stock made from beef and highly seasoned with vegetables, spices, and herbs.

BROTH: A soup of meat, vegetables, and perhaps cereal, but no other thickening.

BRUISE (to): Pound or crush, as in a mortar.

BRUNSWICK STEW: Originally squirrel, corn, and lima beans.

BULGAR WHEAT: Precooked and dried wheat. It cooks quicker than whole or cracked wheat.

BUNG: 1. Stopper for the large hole through which a cask is filled. 2. The name of the hole itself.

BURGOO: A thick vegetable soup made with beef and chicken and cooked a long time.

BUTTER BEANS: The yellow kind of string beans.

BUTTER FRUIT (to): Make a fruit butter, cook the whole fruit until tender. Rub it through a sieve, add sugar and spice, and cook all together until smooth and thick.

BUTTERINE: Artificial butter, oleomargarine.

BUTTERMILK: The liquid that remains after the butter has come and been removed.

BUTTERSCOTCH: Flavored with brown sugar.

C

CAFE AU LAIT: Pour equal amounts of hot milk and hot coffee (double strength) together into a cup.

CAFE NOIR: Strong black coffee served in a demitasse in the living room after dinner. Use twice the usual amount of coffee, or half the water.

CAMPHENENE: A form of camphor.

CANAPE: 1. A tiny piece of toast, on which little savories are served. Cut slices of bread into squares, diamonds, or circles. Cover lightly with butter. Brown in the oven, or fry in deep fat until golden brown. Cover with seasoned mixture. Serve hot or cold. 2. A small, open-faced sandwich.

CANDY (to): 1. When applied to fruit, fruit peel, or ginger: to cook in a heavy syrup until plump and transparent, then drain and dry. 2. When applied to sweet potatoes and carrots: to cook in sugar or syrup.

CANNED COW: Evaporated milk.

CANNELON: Meat stuffed, rolled up, and roasted or basted.

CAPERS: 1. Unopened buds of *Capparis spinosa*, a European plant, preserved in vinegar and bottled for export.

CAPISCUM: Sweet pepper, red or green.

CAPON: Male chicken that, at an early age, was surgically deprived of testicles.

CAPSICINE: Paprika.

CASTOR SUGAR: I didn't know what this was until Margaret C. Bergstrom, Bellingham, Washington wrote me (in the early '70s): "My grandmother (and I am 57) always referred to granulated sugar as 'castor sugar,' and I presume that this was because when she was a young woman sugar was still sold in a loaf. The fine granulated kind was somewhat of a luxury and served from the 'sugar shaker' or the 'castor.' A lot of old cookbooks instruct you to break off so much loaf sugar and then beat the daylights out of it until it is workable enough for baking purposes." Then I learned that "castor" is the old-time word for a sort of sugar shaker. If you look on page 447 of the 1897 Sears catalog, there it is: "Special Drive in Quadruple Silver Plated Castors ... the best selling pieces in hollow silverware." And so I thought I understood all about castor sugar until David Streeter of Pomona, California, wrote that it was an English term that meant superfine granulated sugar. And then Hedy Herrick, Pullman, Washington, wrote that "castor" means a container for powders (she quoted Webster's dictionary on that) and "hence, castor means powdered sugar." So many folks have asked, "Where did you get all this information?" Now you know where I got the part about castor sugar!

CHAUD-FROID: Literally "hot-cold." A jellied sauce.

CHILI PEPPERS: Tiny red peppers with a very hot pungent flavor.

CHINE: Part of the pig corresponding to the loin in lamb and veal.

CHINESE CANE: Sorghum plant.

CHINQUAPIN: A dwarf species of chestnut, native to the southern United States.

CHOUX PASTE: Flour, butter, eggs, water, salt, and vanilla combine to make a basic dough for cream puffs, eclairs, and the like.

CHOWCHOW: A pickle made of mixed vegetables and mustard.

CHOWDER: Pieces of different vegetables or of fish and potatoes and various seasonings cooked in milk. A New England fish stew.

CHURN: 1. To make butter by agitating to separate the oily globules and gather them. 2. A container for doing this.

CHUTNEY: A spicy condiment or acid sauce made from apples, raisins, tomatoes, red pepper, ginger, garlic, lemons, vinegar, salt, and sugar.

CITRIC ACID: One-half ounce is usually equivalent to the juice of 4 lemons.

CITRON: A variety of melon that is pickled and candied for use in fruitcakes.

CLABBERED: Separated into curds and whey.

CLARIFY: 1. To remove impurities from fat or liquid, such as soup or gelatin. 2. To render fat. 3. To clarify butter means to melt and strain, or skim it.

CLEAVER: A butcher's chopper.

CLOCK-JACK: A device run by clockwork which turned the roast on its spit with regularity as it cooked over an open fire.

CLOTTED CREAM: Devonshire cream, an old-fashioned cream cheese.

CLUB SANDWICH: Uses three slices of bread per sandwich.

COAT (to): Dip in flour and crumbs (or the like) before frying.

COB IRONS: Andirons that supported the spit, sometimes having hooks to hold a dripping pan.

COCHINEAL: A small red Mediterranean insect. In the olden days it was crushed with a rolling pin to make a red food coloring.

COCOA BUTTER: The fat obtained from squeezing cocoa beans.

COCOA NIBS: Broken beans of cocoa, after roasting. Prepare by boiling in water for 2 hours, then strain.

COCOA SHELLS: The outer covering of the cocoa beans, removed after roasting. Make a beverage by boiling 3 hours, then straining.

CODDLED EGG: 1. Scramble in the top of a double boiler. 2. Place a fresh egg in the shell in boiling water. Immediately remove from the heat. The egg will cook slowly in the shell for 7 to 8 minutes. The white should then be the consistency of jelly.

COFFEE MILL: Hand mill for grinding coffee at home.

COFFEE SUGAR: A partially refined light brown sugar, coarse grained, and moist.

COLANDER: A pan with holes in it for straining liquids or draining solids.

COMFIT: A dry sweetmeat. Any kind of fruit, root, or seed preserved with sugar and dried.

CONFITURES: Preserves.

COMPOTE: Fresh fruit cooked in syrup, or a combination of two or more fresh or cooked fruits (whole or in large pieces).

COMPOTIER: A dish for serving compotes.

CONDENSED MILK: Canned milk from which more than half the water has been removed. It is heavily sweetened with sugar.

CONDIMENTS: Salt, spices, and various items used to add flavor to food.

CONFECTIONER: One who made or sold candy, sweetmeats, and, formerly, also ice creams, sherbets, nuts, pickles, and gelatin dishes.

CONFECTIONERS' SUGAR: A grade of sugar more fine than powdered. There were $3\frac{1}{2}$ cups confectioners' sugar per pound versus $2\frac{2}{3}$ cups powdered sugar or 2 cups granulated sugar.

CONFITURES: Preserves.

CONSERVE: Jam made from a mixture of fruits, usually including citrus fruit, often with raisins and nuts added.

CONSOMME: 1. Clarified beef stock. 2. A clarified soup made from two or three kinds of meat and highly seasoned with vegetables, spices, and herbs.

COOPER: One who makes barrels, tubs, and casks.

CORDIAL: A sweet and aromatic alcoholic beverage in the liqueur class.

CORN (to): Salt in brine and saltpeter. Corning is the same process as to make ham or bacon, only you're using beef instead of pork. Saltpeter causes the red color in corned beef and in hams.

CORN FLOUR: Finely ground corn. A finer grind than regular corn meal.

COURT BOUILLON: Simmered stock of white wine, water, herbs, fish bones, or vegetables. Victorians used it in poaching fish and making fish sauces.

CRACKED COCOA: See COCOA NIBS.

CRACKLINGS: The parts left that get brown and float when lard is rendered. Be careful not to burn them. Cracklings make a nice snack, especially the ones made from strips of pig skin.

CREAM: Old-time name for ice cream.

CREAM (to): Fat and sugar are creamed together. Put warm, but not melted fat into a

mixing bowl. The fat is usually lard or butter. Add sugar and work with hands or spoon until well mixed and soft.

CREAM A DISH (to): Mix it with white sauce. To each cup of medium to thick white sauce add 1 to 2½ cups vegetables, meat, fish, or hard-cooked eggs cut in pieces.

CREAM CANDIES: Simple fondant with nuts, fruits, and so on.

CREAM ICE: A frozen custard or frozen pudding.

CREPES: Very thin pancakes that have lots of eggs in them.

CRESS-SEED: Mustard seed.

CROISSANT: A rich, flaky, crescent-shaped roll.

CROQUETTE: Anything dipped in beaten egg, rolled in crumbs, and fried in hot fat until well browned. Or grind, or separate into shreds, cooked meat, fish, hard-cooked egg, or vegetables. Make a thick white sauce. Mix the white sauce with the ground or shredded food (1 c. sauce per 1, 2, or 3 c. ground food). Chill. Allow 1 to 2 T. of mix for each croquette. Form into cylinders, cones, etc. Dip each croquette into slightly beaten egg, diluted with 1 T. water. Then dip into crumbs. Dip again into egg. Fry in deep, hot fat until brown. Drain on absorbent material.

CROUSTADES: Cut slices of bread 3 inches thick. Remove crusts. Cut into squares or rounds. Remove the inside portion, leaving the sides and bottom ¼ inch thick. Brush inside and outside with melted butter. Brown in hot oven. Use as cases for serving creamed vegetables, fish, poultry, or meats.

CROUTONS: Cut bread in slices ⅓ inch thick. Remove crusts. Spread both sides lightly with butter. Cut slices in ⅓-inch strips. Cut again to make ⅓-inch cubes. Toast until lightly browned. Used to garnish soups or salads.

CRULLER: An elongated doughnut.

CRUMPET: A raised muffin baked on a griddle.

CURE (to): Preserve meat by salting or corning.

CURRIED: Seasoned with curry powder.

CUSTARD: A mixture containing raw eggs. When it is heated, the egg particles become solidified and the mixture is thickened.

CUTLET: Can be forcemeat or croquettes. It is cut or shaped to look like breaded chops or cutlets.

CUTTING IN: A process used to blend fat with flour. Cut the fat into the flour using a knife, or two knives, or forks. Cut in until the fat is distributed in as small particles as desired.

CYMLING: A summer squash variety.

D

DAMSON: A kind of plum.

DANZIG: A liqueur.

DARK RAISINS: Any but the golden kind.

DASH: One-eighth of a teaspoon, approximately. Or one shake of the container.

DAUB (to): Force large lardoons through meat from surface to surface.

DECOCTION: A liquid preparation made by boiling a substance. Coffee is a decoction.

DELMONICO STEAK: The rib eye.

DEMERA SUGAR: Coarse, raw, a tan color.

DEMIJOHN: A juglike glass vessel enclosed in wickerwork. Holds from 1 to 10 gallons.

DEMITASSE: Literally, half a cup. This term used to mean a small cup of black coffee. It was generally served at the end of a luncheon or dinner.

DESSERTSPOON: Two teaspoons, or half a tablespoon—in the days when four teaspoons equaled one tablespoon.

DEVIL: Use spicy seasoning or sauce to flavor.

DEVONSHIRE CREAM: Type of old-time cream cheese.

DEWBERRY: A blackberry-like fruit of trailing and climbing habit. About ten days ahead of any blackberry and twice as large.

DICE (to): Cut into cubes about $\frac{1}{4}$ inch on a side.

DIJON MUSTARD: I didn't used to have a definition for this word and said so in this chapter. A reader send me this: "Loosely, any of the descendants, direct or otherwise, of the famous compound of mustard perfected and preserved in the Dijon area of France. Alexandre Dumas's Grand Dictionnaire gives the Dijonnais credit for giving us their version of Palladius's 4th-century recipe (from his book *De Re Rustica*, a book not unlike yours). Reduce 12 pints of mustard to powder. Add 1 pound honey, 1 pound Spanish oil, a pint of strong vinegar. Blend thoroughly and use." Another reader told me it is made with white wine.

DOUBLE CREAM: The cream skimmed from milk that has stood for 24 hours after milking. Substitute whipping cream. ("Single cream" was skimmed after only 12 hours).

DOVER EGGBEATER: This was an old-time rotary beater, to be distinguished from a whip, a whisk, a fork, and other types of beaters.

DRACHM: Sixty grams. A teaspoonful.

DRAM: One-eighth of a fluid ounce.

DRAWN: The feathers and innards have been removed and probably head and feet too, but the bird is not yet cut up into serving pieces.

DRAWN BUTTER: 1. Clarified butter. 2. A sauce: Melt 2 T. butter. Sir in 2 T. flour. Add gradually, while stirring, 1 cup boiling water. Season with $\frac{1}{2}$ t. salt and a dash each of pepper and paprika.

DREDGE (to): Sprinkle or coat with flour or crumbs.

DRESSED: The feathers have been removed, but the head, feet, and entrails of the bird remain. That is what somebody told me. But, to me, it means innards out too. Same as the term "drawn." Doesn't make sense, because what you really did is undressed the bird.

DRIPPINGS: Meat fats and juices that come out during drying or broiling.

DUCHESS CRUSTS: Croutons.

DUCKLING: A ten-week old duck, considered prime for frying.

DUTCH OVEN: A pan made of heavy cast iron, 8 to 16 inches across, 4 to 6 inches deep. It may have three short legs. The pot has a bail and a tight-fitting lid with a handle in the middle of the dome. Ones with legs are good for camping, awful in the kitchen.

E

ECLAIR: A chocolate-covered elongated cream puff filled with whipped cream or custard.
EGG AND CRUMB (to): Dip food in egg, then coat with fine bread crumbs. Used for coating fish, cutlets, rissoles, croquettes, and so on. Use fresh bread crumbs for raw food, browned crumbs for food that is already cooked.

EGG-O-SEE: Brand name of a dry cereal, circa 1910.

EGGS BENEDICT: English muffin, ham, and poached egg, with Hollandaise sauce (thinned with cream).

EN BROCHETTE: Impaled on a skewer.

EN COQUILLE: Served in the shell, or in shells.

ENTIRE WHEAT FLOUR: A grade of whole wheat flour considered better than "graham." It did not contain bran or coarse particles.

ENTREMETS: Hot side dishes that accompany or follow the soup and are before the main course.

ESCALLOPED: See Scallop.

ESSENCE: Concentrated flavoring.

ESSENCE OF PEPSIN: Equivalent to liquid rennet or a junket tablet in its effect on milk. Used for making curds and whey.

EVAPORATED MILK: Canned milk from which a little more than half the water has been removed. Unsweetened.

EVERLASTING YEAST: Old fashioned homemade liquid yeast.

EXTRACT: A substance extracted by solution in water or alcohol.

F

FANCHONETTES: A variety of tart.

FARCI (Farcie): Stuffed.

FARINA: 1. Coarsely ground wheat used as a cereal. 2. A flour meal obtained from cereals, potatoes, or corn.

FENUGREEK: The seed, whole or ground, from a plant of the pea family, an ingredient of imitation maple extract.

FERMENTED BREAD: Bread made with yeast.

FIELD PEAS: Black-eyed peas.

FILE: Sassafras leaves dried, powdered, and used in gumbos as a seasoning and for their thickening properties.

FILLET: A long, thin piece of boneless meat or fish.

FINES HERBES: Mixture of chopped fresh or dried herbs, usually including parsley, chives, basil, and perhaps watercress and tarragon also, or basil, or burnet and thyme.

FINOCCHIO: Fennel.

FIRELESS COOKERY: Preparing food in a heavily insulated container, bought or homemade. Foods have to be thoroughly heated before placing in the well. The cooker can also be used to chill foods by packing in ice and salt.

FLAME (to): Warm a small amount of brandy. Pour it over the food. Pour a portion into a spoon and set that afire. Pour over the rest to ignite it also. Or ignite directly with a kitchen match. Spoon the burning brandy over the food until the flame dies down.

FLANGED LID: A lid turned up around the edges to hold hot coals (Dutch oven) or ice (ice cave).

FLAN: A round cake containing cheese, milk, cream, or fruit.

FLANK: The abdominal wall just “below” the ribs. In a pig this area furnishes the bacon.

FLAXSEED: The seed borne by common flax. Also called linseed.

FOIE GRAS: Goose liver pate.

FOLD IN (to): Combine stiffly whipped egg whites with batter in a bowl by folding in: With a metal spoon cut down to the bottom of the bowl, lift up a spoonful of batter mixture on top of the egg whites. Continue until the egg whites are mixed in. Don’t stir any extra, because the air held in the egg white is wanted to be a leavening agent and you don’t want to pop those little bubbles.

FONDANT: Sugar, cream of tartar, and water cooked together, then stirred and creamed. A base for cream candies when combined with color, flavor, chocolate, fruits and/or nuts.

FOOD CHOPPER: Grinder.

FOOD MILL: A grinder or a sieve-bottomed vessel with a blade turned by a handle that forces food through the sieve.

FOOL: A stewed fruit served with cream.

FORCEMEAT: Raw meat or fish; a panada; either butter, suet, or veal udder; eggs; and seasoning combined. The meat or fish is chopped fine and pounded to a paste, then forced through a wire puree sieve with a wooden masher. For a simpler version: mince fine bits of cooked meat or bird, season well, bind with egg, roll in crumbs. Make balls the size of an egg yolk. Fry in lard. Victorian, of course.

FRAPPE: Semifrozen. Sweetened fruit juices frozen to a coarse mushy stage. (“Ices” were frozen to a firmer texture.)

FRENCH CHOPS: Lamb rib chops that have the bone cut short and scraped clean, nearly to the lean meat.

FRENCH ICE CREAM: Combination of a rich custard and cream. Stir while freezing.

FRICASSEE: In Victorian usage: to saute and serve with a sauce. Tender meat is fricasseed without previous cooking. Less tender meat requires cooking in hot water first. (Often confused with “braise.”) It now means to stew.

FRITTER: A piece of fruit enclosed in a batter, then fried in deep hot fat. Or chopped fruits or vegetables stirred into the batter, then fried by spoonfuls. Or a bread fried in heated oil in a deep heavy kettle, using 1 T. batter for each fritter, cooked 3 to 4 minutes, or until golden brown, turned once during cooking. Drain on absorbent material.

FROMAGE: Cheese.

FROST (to frost a glass): Coat the rim of the glass by dipping it in orange juice or other liquid, then into sugar.

FRUMENTY: Cooked unground wheat, used as a cereal.

G

GALANTINE: Meat that has been boned, stuffed, rolled, and poached. Always served cold.

GAMBREL: A stick or iron used by butchers and homesteaders to suspend slaughtered animals by passing it between the Achilles tendon and the leg bones of front or hind legs.

GAME: Any wild animal or fowl used for food.

GARNISH: 1. "A garnish of pewter" was a favorite Colonial wedding gift. It meant a full set of pewter platters, plates, and dishes. 2. To decorate food with edible items.

GATEAU: Cake.

GELATIN: A transparent, tasteless substance obtained by boiling animal muscle, skin, cartilage in water.

GELEE: 1. Jelly. 2. Gelatin.

GEM IRONS: Iron muffin pans. Grease lightly and preheat in oven.

GERM: The portion of the seed in which new life is located and which will, under proper conditions, germinate.

GHERKIN: A small cucumber used for pickling.

GILL: Half a cup.

GLACE: 1. Frozen. 2. Glazed.

GLACE SYRUP: A thin sugar syrup cooked to the crack stage. When used for pies and certain breads it may contain thickening and is not cooked to such a concentrated form as for fruits and nuts. Use 2 cups sugar, 1 cup water, and $\frac{1}{8}$ t. cream of tartar. Heat on stove without stirring. Keep side of pan free from crystals by wiping with a damp cloth. Heat to 315°F. Remove from heat. Put one piece of fruit or nut at a time on a fork and dip it into the hot syrup. Quickly remove and place on waxed paper or oiled marble. When the syrup becomes too thick, reheat in a double boiler.

GLACES: 1. Ices. 2. Ice creams.

GLAZE (to): Per 3 cups cooked item: cover with a mixture of 2 T. butter, $\frac{1}{2}$ c. brown sugar, and 1 T. water in a heavy pan over low heat. Turn until coated.

GLAZE BREAD (to): Brush over the bread's top before it is fully baked with beaten egg, or with a mixture of water and sugar.

GLAZE PIE (to): Dot the top crust with butter before baking. Or brush the top with ice water or cream ten minutes before the pie is done.

GLUTEN FLOUR: This whole wheat flour was used by diabetics before they had insulin.

GOLDEN SYRUP: A pale golden molasses with very little flavor.

GOSLING: A very young goose.

GRAHAM FLOUR: An old-time grade of whole wheat flour. It contained bran and coarse particles.

GRANITE SUGAR: Loaf sugar crushed only to a particle size of coarse sand or gravel.

GRANITE WARE: Ironware that was coated with an enamel that resembled granite pattern.

GRAPE LEAVES: The regular large flat leaves of the grape are used in some old crock pickle recipes and in some Mediterranean dishes.

GRAPE SUGAR: A sugar made from cornstarch (Victorian).

GRATE (to): Finely divide food by rubbing it over a metal surface having sharp projections.

GREEN CORN: Green corn used to be more common than it now is. It was even canned and sold commercially during the early years of the canning industry.

GREEN TEA: Tea made from leaves consecutively withered, rolled, and dried (artificially or in sunshine).

GREENGAGE: A type of plum.

GREENS: Young tender beet tops, Swiss chard, dandelion greens, collards, kale, chicory, escarole, lettuce, spinach, turnip tops, mustard greens—in general, the green and leafy vegetables.

GRIDIRON: An iron grate used for broiling food over coals.

GRILL (to): Cook under broiler, or over direct heat.

GRISTMILL: 1. A small hand mill for grinding grain. The more times you put it through, and the more you tightened the screw, the finer the flour became. 2. A larger mill for grinding grain into meal or flour, usually set up by a short sharp fall of water for a power source.

GRITS: Ground hominy.

GRUEL: A very thin, watery cereal.

GUM ACACIA: The powdered dried gummy exudation of an African plant. Can be ordered through your druggist. Formerly used to make marshmallows.

GUM ARABIC: Another name for gum acacia.

GUM MASTIC: A gum made from paraffin.

GUM TRAGACANTH: A powdered white vegetable gum used in confectionery (gum paste formulas).

H

HAIR SIEVE: A sieve or strainer with a haircloth bottom. (Haircloth was woven from camel or horsehair.)

HARDTACK: A Swedish bread. Moisten whole wheat flour (or any freshly ground grain flour) with any liquid. Add a little salt. Roll out as for thin cookies. Cut into squares. Bake at 350°F, then dry in a slow oven until completely dry. Store dry and in an airtight container.

HARICOTS: A bean variety.

HASTY PUDDING: Boiled cereal of cornmeal and water. This is a joking name since the cornmeal actually needs long boiling or baking.

HAUNCH: The hindquarters or “thigh.” The haunch of a pig is made into hams.

HAZELNUTS: Also known as “filberts.”

HERB SPIRIT: An infusion of herbs bottled with brandy.

HOCK: Second joint above the hoof of the hind leg. (On front leg it's the “hoof” and “ankle” and the “knee.”)

HOECAKES: Unleavened cornbread, a contribution of Indian women to the pioneer

kitchen.

HOG SCRAPER: A bell-shaped hand instrument for removing hair and dirt from the pig's skin after slaughter and scalding.

HOGSHEAD: A large cask. Or a liquid measure—63 wine gallons or 52½ Imperial gallons.

HOLLANDAISE SAUCE: Three egg yolks, beaten; 2 T. lemon juice; ½ c. butter, melted; 2 T. hot water; a few grains cayenne—all thickened for 5 minutes over low heat.
(Homegrown eggs only!)

HOOCH: If you mix 1 cup flour, 1 cup water, and 2 T. molasses, then allow it to complete a natural fermentation, the deadly looking fluid floating on top is "hooch," named in Alaskan sourdough days when it was the miners' liquor.

HORS D'OEUVRES: Small dainties served as the first course at lunch or dinner.

HOTCHPOT: A thick broth made of meat and various vegetables.

HUCKLEBERRY: A wild variety of blueberry. It has a rich, strong flavor.

HULLED CORN: Hominy.

HYPERION TEA: Raspberry leaves made into tea during the Revolutionary War.

I

ICE: Combination of water, fruit juice, and sugar. Stir while freezing.

ICE CAVE: Usually made of copper or tin, ice caves were either round or square, from 1 to 2 feet in diameter, and about as deep. They had a tightly fitting lid, flanged, so that ice could be placed on top. The cave was buried in an ice tub that was filled with pounded ice mixed with salt in order to freeze its contents.

ICED: Frozen.

ICED CONFECTION: Ice cream.

INDIAN MEAL: Yellow cornmeal.

INDIAN PUDDING: A steamed pudding made of cornmeal, molasses, and milk.

INDIGO: A plant product formerly used as a blue dye.

INFUSION: Made by pouring boiling water over dried leaves, flowers, or other plant parts, and then straining. (Tea is one.)

INVERT SUGAR: Acid sugar. Put 8 pounds of granulated sugar into 4 c. water. Add the juice of four lemons. Slowly bring to a boil, stirring, until the sugar is all dissolved. Hold at a gentle boil ½ hour. Stir only occasionally. Cool. Make up to exactly one gallon by adding boiled water.

IRISH MOSS: A substance from which a gelatin-like dish can be made.

ISINGLASS: 1. A preparation of nearly pure gelatin, made from the viscera of fish. 2. Mica.

ITALIAN PASTE: The paste of wheat flour and water from which macaroni, spaghetti, vermicelli, etc., are made.

J

JAM: Crushed or sliced fruit that has been cooked with sugar until it is thick and even

textured. Sugar is added in the proportion of $\frac{3}{4}$ pound per one pound fruit.

JAR CHEESE: This is an old term for commercially prepared soft cheese spreads such as Club House or McLaren's (antique brand names).

JARDINIERE: Mixed vegetables served in their own sauce.

JELLY: Flavored liquid plus gelatin. Or a pectin-jellied fruit juice, the product being clear and firm enough to hold its shape when removed from the container.

JELLY BAG: To make an old-fashioned jelly bag, fold two opposite corners of a piece of cotton or flannel three-fourths yard long. Sew up in the form of a cornucopia, round at the end. Make sure the seam is tightly sewn. It is helpful if the jelly bag has two or three heavy loops at the top by which to hang it. Strain the fruit for jelly through a jelly bag. The jelly itself is made from the juice that manages to drip through.

JOHNNYCAKE: Unleavened corn bread, a contribution of the Indian women to the pioneers.

JUJUBE: 1. An edible fruit from the Mediterranean region. 2. A jelly made from jujubes. 3. A lozenge flavored with jujubes.

JULIENNE: A clear vegetable soup containing vegetables cut into matchlike strips.

JULIENNE STRIPS: Food pieces about the size and shape of wooden kitchen matches.

JUNKET: 1. Contains rennet, which curdles milk. 2. A pudding made from milk set with junket.

K

KABOB: A food broiled on a skewer.

KEG: A small, strong barrel, usually of five-to ten-gallon capacity.

KETTLE: The great pot of the colonist, of brass or copper, often holding 15 gallons. Iron ones sometimes weighed 40 pounds.

KICKSHAW: An unsubstantial, fancy, or unrecognizable dish of food.

KILLING TIME: For the cows and swine that had been fattened for slaughter—November.

KIPPER: To smoke at a relatively high temperature.

KNEAD (to): Apply a stretching motion to dough. Kneading can work in more flour than can be either stirred or beaten into the mixture. Kneading also makes a dough smooth, even in texture, and develops the gluten.

KORNLET: Green corn pulp. Used to be available on the market, canned.

KOUMISS: 1. A beverage of soured and fermented mare's milk. 2. Milk fermented with yeast.

L

LADLE: A cup-shaped vessel with a long handle, for serving liquids.

LAMB: Flesh of sheep from 6 weeks to 1 year old.

LARD: 1. Pig fat rendered for kitchen use. 2. Insert strips of fat (lardoons) into lean meat or fish—or place slices of fat on top of it. Larding gave flavor and prevented dryness. Fat salt pork was usually used.

LARDER: A room where meat and other foods were stored.

LARDING NEEDLE: To use a larding needle, insert one end of a lardoons into the hinged end of the needle. With its pointed end take a stitch $\frac{1}{3}$ inch deep and $\frac{3}{4}$ inch wide. Draw needle through.

LARDOONS: Strips of fat used to lard meat. To prepare lardoons, remove rind from chilled pork and cut slices $\frac{1}{4}$ inch thick, $\frac{1}{4}$ inch wide, and $2\frac{1}{2}$ inches long.

LAWN SIEVE: A sieve made from a fine, thin linen cambric (lawn).

LEAF LARD: Made from the leaf-shaped pieces of solid fat that lie inside a pig's abdominal cavity.

LEAVEN: To lighten a mixture by adding yeast, baking powder, or beaten eggs.

LEAVENING: A substance used to make foods light and porous.

LEMON BUTTER: Cream butter until very light and fluffy. Season with a few drops of lemon juice.

LEMON DRILL: A glass lemon squeezer. Press half a lemon or orange down over the "hill" and twist to get the juice.

LIBERTY TEA: Tea made from the four-leaved loosestrife (Revolutionary term).

LICORICE: The extract made from the dried root of the licorice plant.

LIME WATER: Dissolve 1 T. calcium oxide in 2 qts. cold water. Or pour 2 qts. boiling water over an inch cube of unslackened lime. Stir thoroughly and let stand overnight. In the morning, pour off the liquid that is clear and use.

LINGONBERRIES: "Mountain cranberry." These small, bright red berries resemble miniature cranberries and can be substituted in any cranberry recipe.

LIQUID YEAST: 1. Potato water, sugar, and a speck of salt, in which yeast lives. 2. Any homemade yeast.

LIQUOR: Liquid from shellfish, or from food in which shellfish have cooked.

LITTLE PIG: Pigs 4 weeks old, killed, dressed, and roasted whole.

LOAF SUGAR: Sugar purchased in loaves or cones. They averaged about 9 to 10 lb. apiece in weight. One cone would last thrifty people a year. The sugar cone was cut into lumps of equal size and regular shape by the mistress and daughters of the house and used to sweeten beverages. Various shaped "sugar shears" were used.

LOQUAT: Tree bearing a yellowish (or reddish) sweet, apple-shaped fruit. Does not bear unless it has a completely frost-free year. See also Medlar.

LOZENGE SUGAR: Confectioner's sugar. (Granulated sugar ground extremely fine.)

M

MACAROON: A onetime popular confection made of egg white, sugar, and almond paste.

MACEUDOINE: 1. A mixture, usually vegetables, with or without meat. 2. A fruit mixture. 3. Vegetables cut in strips or fancy shapes.

MAGNUM BONUM: A variety of large plum.

MAITRE D' HOTEL BUTTER: Work some lemon juice and a teaspoon of minced parsley into $\frac{1}{2}$ c. butter.

MAIZE: Corn.

MALT: A grain, generally barley, that has been softened by steeping it in water and then allowing it to sprout. At this stage it is called “green malt.” The green malt is usually dried in a kiln and sometimes roasted like coffee. The sprouting develops the enzyme diastase, which is capable of saccharifying the starch of the malt, and also that of the raw grain mixed with it. Hence, malt has been important in brewing. A simplified homemade malt can be prepared by cracking the green malt by going over it with a rolling pin and then toasting or roasting it to obtain the desired effect: pale, medium, dark, or very dark.

MALT EXTRACT: Extract of malt sold canned as a liquid in the form of syrups characterized as extra pale, light, and dark.

MALTED MILK: Evaporized milk in combination with extracts of malted barley and wheat.

MANGEL: A large “stock” beet.

MANGO: In Victorian usage: a young musk or nutmeg melon, pickled (cantaloupe or honeydew).

MARINATE (to): Add salt, pepper, oil, vinegar, and seasonings to a food item. Let soak until well seasoned.

MARINADE: A savory sauce in which a meat or vegetable is sometimes soaked before cooking or serving. Usually a blend of seasonings, oil, and an acid.

MARASCHINO: A liqueur.

MARCHPANE (Marchepane): This term evolved to “marzipan.” A paste of pounded almonds, sugar, and white of eggs, made into little molded confections.

MARMALADE: A tender jelly with small pieces of fruit distributed throughout.

MARRONS GLACES: Candied French chestnuts.

MARROW: A variety of summer squash.

MEAD: A fermented drink made from honey and water.

MEAL: The coarse, ground seeds of edible grains such as oats and corn. Or a dry ground substance like bone or fish meal.

MEAT FORK: A three-tined fork.

MEDLAR: A tree fruit, resembling a crab apple. It was much used for preserves in Victorian days. Also, the loquat.

MELON MOLD: See bombe.

MERINGUE: Beat 2 egg whites. Gradually add 4 T. sugar, then $\frac{1}{2}$ t. vanilla. Spread over pie or pudding. Bake in oven at 300°F for about 20 minutes.

METHEGLIN: A drink made from honey, yeast, water, and locust-beans.

MIDDLINGS: A combination of the coarser parts of wheat with the bran.

MINCE (to): Finely divide food with a sharp knife or scissors.

MINERAL WATERS: Alkaline beverages such as soda and seltzer, impregnated with carbon dioxide.

MOCK TURTLE SOUP: Soup made of a calf’s head.

MORTAR: A deep, heavy bowl in which spices, herbs, and other things can be crushed and ground by hand using a pestle.

MOTHER (of vinegar): A gelatinous film that is developed from the surface of alcoholic

liquids undergoing acetous fermentation. It is made of bacteria actively growing. When the bacteria reach a final stage, the mother usually thickens and settles to the bottom. Mother is added to wine or cider to hasten the vinegar production.

MOULD (mold): A dish in which to shape gelatin-stiffened mixtures. Or a container in which to freeze ices and ice creams into desired shapes. Or a container in which to steam puddings.

MOUSSE: A combination of whipped cream, sugar, and flavoring. Freeze without stirring.

MULBERRY: An edible fruit. Can be made into jelly. The leaves can be fed to silk worms.

MULL (to): Gently heat a beverage such as fruit juice or wine and add sugar and spices.

MULLIGAN: Stew.

MUSKMELON: Cantaloupe.

MUTTON: Sheep meat.

N

NEAPOLITAN: Combination of 2, 3, or 4 flavors of ice cream, or ices, frozen in layers and hardened in a mold.

NEWBURG SAUCE: A basic flour and butter paste diluted with cream and egg yolks (homegrown only), and flavored with sherry.

NITRE: Saltpeter.

NOCAKE (or nookick): Corn parched (popped) in the hot ashes, the ashes being then sifted out of it. The popped corn was beaten to a powder, the powder put into a leather bag for a traveler's food. The nocake was mixed with snow in winter, water in summer. When the Pilgrims in famine time were allotted 5 kernels of corn apiece each day, some say that this is how they prepared it.

NOUGAT: A confection made usually of almonds or pistachio nuts, stirred into a sugar paste.

NOYEAR: A liqueur.

NUTMEG: A honeydew melon or cantaloupe (Victorian term).

O

OILS: Of lemon, anise, wintergreen, and spearmint, etc. are now widely available.

OIL OF ANISE: Obtained from the seeds of the fennel plant.

OIL OF CASSIA: An imitation cinnamon flavoring.

OIL OF CLOVES: Obtained by distilling with water the buds and flower stalks of the clove tree.

OIL OF NEROLI: The oil of orange flowers, once obtained either by distillation or enfleurage. Used as the basis of perfumes and in liqueurs.

OILSTONE: A whetstone used with oil.

ORANGE WATER: An alcoholic beverage distilled from orange peels and sweetened, once a popular cordial.

ORRIS ROOT: Powdered root of the blue flag. Deadly poisonous. Used as a fixative to hold

fragrances as in potpourri.

OTTO OF ROSES: See ATTAR.

OX: Cow. Especially any bovine (bull, steer, or cow) that has been taught to pull.

OYSTER PLANT: Salsify.

P

PANADA: A thick paste used for binding mixtures such as croquettes and quenelles and the basis of hot souffles and choux pastry. Recipe 1: In the proportion of half as much bread as liquid combine bread with cream, milk, or stock. Cook until a smooth paste is formed. Recipe 2: Use $\frac{1}{2}$ c. meat or vegetable stock, 2 T. drippings or butter, 4 heaping T. flour, and salt/pepper to taste. Melt fat. Stir in flour until smooth. Cook 2 or 3 minutes. Gradually add stock, stirring constantly until smooth. Boil gently for 2 or 3 minutes.

PARBOIL (to): Boil a few minutes, or until partially cooked, in preparation for next step of recipe.

PARCH (to): Brown by means of dry heat—applied to grains, as in popping corn. Some people claim that “parched corn” was an early term for popped corn. Others say that shelled sweet corn kernels were dropped on a hot griddle without water or grease. They were turned or stirred frequently enough to prevent burning, and done when brown and crunchy.

PARE (to): Cut off the skin of a vegetable or fruit.

PARFAIT: 1. A layered dessert such as whipped cream and pudding. 2. Or alternate layers of ice and ice cream. 3. Or of ice cream with fruit or syrup topped with whipped cream. 4. A combination of egg white, water, sugar, and whipped cream frozen unstirred.

PASTE: 1. Dough for crusts. 2. Mixture of flour and liquid. 3. Ground nuts and fruits or combinations of these with sugar.

PASTIL: Drop candy made of clarified sugar syrup with a little water and flavoring.

PASTRY: Dough to be made into pie or tart shells. Basically a mixture of flour and fat. Size of the bits of fat varies, also the amount of water. For pie crusts: Sift $1\frac{1}{2}$ c. flour with $\frac{1}{2}$ t. salt. Use two forks or knives to work in $\frac{1}{2}$ c. lard. When the fat has been worked in until it is of uniform texture, add 4 to 5 T. cold water slowly until mixture becomes a stiff dough that will hold together in one ball. Roll out and cut into the shape you need.

PASTRY FLOUR: You can make your own by sifting 4 T. cornstarch or potato flour into each 2 c. plain flour (sifted before measuring).

PATE: 1. Paste. 2. Patty. 3. Seasoned liver paste.

PATE A CHOUX: Cream puffs.

PEACH KERNELS: The kernel is the seed inside the peach stone. It was sometimes mashed and added to peach ice cream for flavor.

PEARL BARLEY: Barley reduced to a round, shotlike form by removing the outer coat of the grain.

PECTIN: A jellylike substance found in some fruits, especially in their “green” stage. You can make your own (see index), or buy it, or use the right fruits at the right stage.

PENUCHE (panocha): 1. Mexican brown sugar. 2. A sweetmeat usually made of brown sugar, cream, and nutmeats.

PEPPERGRASS: Upland cress, not watercress. Used in salads.

PETTIJOHN: A partly precooked cereal of 1910.

PFARVEL: Into the yolk of one egg stir enough flour to make it too stiff to knead more.

Grate on a coarse grater and spread the bits out to dry. Put in soup and boil ten minutes before serving.

PHILADELPHIA ICE CREAM: Combine cream, flavoring or fruits, and sweetening. Stir while freezing.

PICCALILLI (Pickle Lily): A mixed relish.

PICKLE (to): Preserve in salt or vinegar.

PIECE DE RESISTANCE: The main dish in a meal. Or the roast. Especially if tough!

PIE PLANT: Rhubarb.

PIGNOLIA: Imported pine nut. When the same thing is grown in the Southwest United States, it is called pine, pinon, or Indian nut.

PILAU: An East Indian or Turkish dish of meat and rice.

PIMENTO: Skin of the large red pepper, preserved in oil or by freezing. Recipe in Vegetables Chapter under Peppers.

PINCH: One-eighth teaspoon, more or less.

PIPS: Seeds.

PISTACHIO: A nut imported from the Middle East. Now grown also in inland California.

PIT (to): Remove the stone from fruit.

PITH: White stuff between the skin of the orange and the orange itself.

PLANK: 1. Specially made planks could formerly be purchased for cooking. The problem was that, if forgotten in the oven, they burned. They were about one inch thick, made of seasoned hickory or oak. Fish and steak were favorite planked dishes. 2. To plank meat, oil the plank, especially where it will not be covered. Put meat on it. Brown steak quickly under the broiler heat, then turn and crisp the other side. Then set plank farther from flame and finish cooking more slowly. To season a new plank, soak overnight in cold water. Brush with cooking oil. Warm one hour in a 250°F oven. To clean a plank after using, scrape thoroughly and wipe with a paper towel, but do not wash. Store in a cool place.

PLANTAIN: A banana variety considered by Victorians suitable only for eating boiled, roasted, or in preserves (not raw)

PLATE-WARMER: A three-legged metal stand meant to stand near or in the coals of a fireplace and hold the plates for warming.

PLUM PUDDING: A steamed bread with raisins or other fruit in it.

PLUMP: To enlarge and fill out fruit by letting it stand in a thin syrup before cooking to make jam or preserves. The fruit then plumps without being toughened by extra cooking. Of chickens: to let soak in water a few minutes before cleaning. (I don't.)

POACH: To cook in water, milk, or stock just below the boiling temperature for a short time. Eggs and fish are often prepared this way.

POLENTA: A mush made of cornmeal or of ground chestnuts. (Italian name.)

POMACE: Ground apple that will be pressed to extract cider.

POMPION: Pumpkin (in Colonial recipes).

POPCORN POPPER: A tool designed to pop corn kernels.

POPOVER: A quick muffin leavened only with the air bubbles introduced by hard beating just before baking.

PORCELAIN WARE: Iron lined with a hard, smooth enamel.

PORRIDGE: A very thick cereal.

PORRINGER: A child's dish in Colonial times. A pretty little shallow circular dish with a flat pierced handle or a fishtail handle. It varied in size from 2 to 9 inches across.

POT CHEESE: An old name for a commercially processed cheese spread sold in small "pots."

POTAGE: A family soup.

POTATO BOILER: A wrought-iron basket meant to hold potatoes, or any vegetable, in place within the huge general pot of colonial days.

POTATO RICER: A utensil for squeezing potato or other soft material through a perforated plate.

POTATO WATER: The water in which potatoes were cooked.

POTHOOK: The iron hook or chain with a hook from which the pot could be swung over the fireplace. From such hooks pots could be hung at varying heights over the fire.

POTPOURRI: A highly seasoned stew of many ingredients. Or a fragrant concoction of flower petals meant to be smelled, not eaten!

POTTED: Cooked, boned, chopped, seasoned, possibly jellied meat. (Usually packed in small crocks or cans. Hence, "potted.")

POULT: A young turkey.

POULTRY: Chicken, turkey, duck, goose, squab, pheasant, or guinea hen.

POUND CAKE: A cake containing a considerable quantity of butter, eggs, and sugar—"a pound" of each.

POWDER: A pulverized ingredient.

POWDERED SUGAR: A grade of sugar in fineness between our present granulated and confectioners' sugars. A total $2\frac{2}{3}$ cups of powdered sugar weighed a pound; $3\frac{1}{2}$ c. of confectioners' sugar weighed a pound.

POWDERING TUB: A tub in which meat was salted and pickled.

PRAIRIE CHICKEN: Grouse.

PRAWLING (variation of praline): 1. A confection of nut kernels, usually of almonds, roasted in boiling sugar until brown and crisp. 2. Any of various other confections, such as a cake of brown sugar containing pecan meats.

PRESERVES: Whole fruits, or pieces of fruit, cooked in a heavy syrup until clear and tender. The fruit is preserved in a thick syrup of jellied juice by the sugar's effect.

PRESSURE COOKING: Cooking by steam under pressure. Steam under pressure increases the temperature and shortens the cooking period. Especially useful for canning nonacid vegetables and meats.

PRUNELLES (Prunella): A variety of fine dried plums.

PUDDING CLOTH: A bag in which to boil "pudding" (really a bread).

PUFF PASTE: Used for pastry shells and small pastries. Four cups flour, 1 t. salt, 2 c. butter, ice water enough to mix into a dough.

PULSE FOODS: Dried peas, beans, and lentils.

PUNCH: 1. A water ice to which was added "spirit" and spice. 2. Mixed fruit juices.

PUREE (to): Rub cooked fruit, vegetables, etc., through a sieve to remove skins, seeds, and mash.

PUREE SOUP: The solid material is rubbed through a sieve and then reheated with the liquid, and a little thickening agent added.

PUT DOWN (to): Corn (beef) or cure (pork).

Q

QUENELLES: Portions of any kind of forcemeat, shaped into small balls and poached in boiling water or stock. They were served as a garnish to soups and other dishes or were served with a sauce as an entree.

QUICK LIME: Unslackened lime.

QUICK OVEN: About 450°F; a hot oven.

QUIDDANY (Quiddony): 1. Quince. 2. A syrup or jelly containing quince.

QUINCE DRINK: Hot rum, sugar, and quince marmalade or preserves (Colonial).

R

RACK (to): Pour off from the lees (sediment), as of wine.

RAGOUT: A thick, highly seasoned stew.

RAILROAD YEAST: Homemade liquid yeast.

RAMEKIN (Ramequin): A small individual baking dish or little saucer.

RANGE: A stove suitable to use either wood or coal.

RASPINGS: Fine, browned bread crumbs.

RATAFIA LIQUEURS: These cordials were made by mixing 3 pints filtered fruit juice, 1 qt. cognac brandy, 3 lb. sugar, and a bag of vanilla, cinnamon, and cloves. Cork and store. It was ready after 6 to 12 months.

RAVIGOTE: Green mayonnaise. To make it, boil watercress, spinach, and/or parsley, and force through a sieve. Add to mayonnaise.

RAW MILK: Milk that has not been pasteurized or otherwise changed from the way it came from the cow or goat.

RECHAUFFE: Warmed over. Fancy name for leftovers.

RECTIFIED SPIRIT: An alcoholic beverage "rectified" (concentrated) by redistillation. Brandy.

RED WHEAT: A hard wheat variety.

REFLECTOR: A curved metal plate put on the side away from the fire of a roast or other item to be cooked by the heat of an open fireplace.

REFRIGERATOR ICE CREAM: An ice cream or sherbet containing a stabilizer to retard development of ice crystals. It can be frozen in a refrigerator tray without stirring. The stabilizer is usually egg. (Homegrown only.)

RELEVE: A “course” or food item that replaces another.

RELISH: Relishes include piccalilli, chutney, horseradish, and corn relish. They are prepared from fruits and vegetables that are chopped, seasoned, and then cooked to the desired consistency, and pickled.

RENDER (to): Free fat from connective tissue by cooking or heating the meat until the fat liquefies and can be strained off.

RENNET: Was prepared from the fourth stomach of calves and used to curdle milk as in cheesemaking, or to make junket.

RICE (to): Force cooked food through a ricer or sieve.

RICE FLOUR: Grind rice in your flour grinder.

RISSOLES: 1. Thick pieces of meat placed on a spit and rotated before an open fire. 2. Certain baked meats, or chestnuts. The baking is usually done in an oven, but may be in ashes, under coals, or on heated stones.

ROASTING KITCHEN: A boxlike metal structure open on one side that was kept turned to the fireplace. It stood on legs and in it birds or joints could be roasted or bread could be baked. It was an early “reflector oven.”

ROCK-CANDY: This was used in the making of rich brandy sauces for plum puddings or as a marchpane ornamentation for desserts. Rock-candy was large crystals or crystalline masses of sugar obtained by slow evaporation of a sugar solution.

ROE: Fish eggs.

ROLLICHE (Rolejee, rolliche): A kind of sausage, made in a bag of tripe, sliced and fried, famous among the Dutch of New Amsterdam.

ROPY: This term describes a liquid having a viscous or glutinous formation of unwanted bacteria. Boil the liquid to kill the organisms. Rope may appear in bread after the bread is baked during hot, damp weather. The bread has a bad smell and is unusable. Sterilize all your bread-making utensils and storage containers. Use 1 T. vinegar per 6 c. flour until that batch of flour is used up.

ROSETTE CASES: See timbales.

ROTISSERIE: 1. A restaurant where patrons selected uncooked food and had it roasted and served to them. 2. A store where food was roasted. 3. A machine for cooking meat on a turning spit.

ROUNDED SPOONFUL: As much above the rim of the spoon as below.

ROUX: Pronounced “roo.” A paste of flour and melted butter or any other shortening used as a foundation for a sauce or gravy. Can be made ahead of time and stored in a refrigerator.

ROYAL CUSTARD: A custard cut and served in consomme or chicken broth.

ROYALE: Garnished with custard dice.

RUB IN (to): This method of mixing flour and fat was used in making cakes and pastries. Chop the fat coarsely into the flour with a knife. Using only the tips of the fingers and thumbs, rub lightly until the contents of the bowl look like the bread crumbs. Have utensils and ingredients as cold as possible.

RUNNER BEANS: Now mostly sold as a flower. They are vigorous climbers with lots of pretty orange blossoms all season long. But the beans inside the pod, and the immature pods, are edible.

RUSK: Sliced bread baked until dry and crisp. Or browned crumbs sprinkled into cold milk.

S

SACCHAROMETER: A syrup gauge to indicate the sweetness of a fluid used in candy making and in brewing.

SADDLE OF MUTTON: The loin removed whole before splitting the rest of the animal. It is made into a roast by removing some bones, rolling the flank ends, and tying the whole securely.

SAFFRON: A deep orange-colored substance consisting of the dried stigmas of a species of crocus cultivated in Southern Europe. It was used to color confectionery, liquors, and in cookery.

SAGO: Sago flour was a dry granulated starch imported from the East Indies. It was used in puddings, other foods, and for stiffening textiles. It was made from the trunk of the sago palm and several other palms.

SALERATUS: Potassium nitrate, KNO_3 (nitre) is a strong oxidizer used to preserve color in cured meats and to inhibit bacterial action.

SALT PORK: This is made from the flesh on either side of the pig's backbone, and heavily salted to preserve.

SALTSPOON: One-eighth teaspoon.

SAMOVAR: Tea kettle.

SAMP: Hulled corn (hominy) pounded or milled to a coarsely ground powder.

SAMP MILL: A simple hand mill for grinding corn.

SARATOGA CHIPS: Homemade potato chips. The potatoes are sliced thin and french fried.

SARMA: Seasoned minced meat and rice, stewed while wrapped in a scalded grape leaf.

SASSAFRAS: A tree growing in the Eastern and Southern United States.

SAUSAGE: Trimmings of mixed lean and fat meat, ground, seasoned, and forced into thin casings. Or made into patties.

SAUSAGE CASES: Originally entrails, cleaned and ready to be stuffed with sausage. There were three sizes: mutton, pig, or cow. Now also made of plastic.

SAUSAGE GUN: Also called a sausage stuffer. The sausage meat is forced out through the nozzle into a sausage casing.

SAUTE (to): Fry quickly in a small quantity of fat, first on one side, then on the other.

SAVORY: Summer savory is an herb used for food flavoring.

SAVOURY: Savouries were tasty dishes served either at the end of a meal, or as a luncheon or supper dish, or with cocktails. If served at a formal dinner, the savouries came after the sweet. At an informal meal they could easily replace it. Usually cheese dishes or canapes.

SCALLOP (to): For each cup of medium to thick white sauce, add 1 or 2 c. cooked vegetables, meat, fish, hard-cooked eggs, cooked macaroni or rice, etc. Put into a baking dish. Sprinkle with buttered crumbs, and bake until brown on top.

SCANT: A little less than full measure.

SCHMIERKASE (Schmier-Kaese): Homemade cottage cheese.

SCORE (to): Cut across the surface of a food in several places.

SCRAG: 1. The neck, as of venison or mutton. 2. Anything lean and tough.

SCRUPLE: 1. A unit of weight: 20 grains, $\frac{1}{24}$ ounce, $\frac{1}{3}$ dram. 2. A minute quantity.

SEAR (to): Brown the surface of meat by a short application of intense heat (fry it).

Searing develops flavor, improves appearance, and seals in juices, especially before roasting meat.

SELTZER WATER: The original Seltzer water was bottled from mineral springs at Niederselters, Germany, which contains considerable carbon dioxide in solution.

SEMOLINA: Flour made from durum wheat, used in making pasta and for thickening (Italian term).

SERVICE PLATE: Plate used with appetizer and soup, removed before the main course.

SET UP (to): When candy hardens to the desired final consistency it is said to "set up." The same when gelatin "jells."

SHEEP'S OIL: Lanolin. Obtained from sheep wool.

SHERBET: 1. A combination of water, fruit juice, sugar, and a small amount of gelatin or egg white (homegrown only) for body. Sometimes milk is used instead of water. Stir while freezing. 2. A refreshing drink made of fruit juice, diluted, sweetened, and flavored.

SHERBET POWDER: This was a preparation of bicarbonate of soda, tartaric acid, and sugar, flavored, and ready to make an effervescent drink when liquid was added.

SHIRR (to): Bake whole eggs with cream and crumbs in a small dish or muffin tin (usually 2 eggs per "hole") in the oven.

SHORTBREAD: A cookie made with flour, butter, and much shortening. The fat content made it sandy and somewhat crumbly in texture.

SHORTENING: Fat of any kind used in pastry, doughs, batters: butter (reduce salt in recipe), vegetable fats, oils, lard, drippings (not ham, bacon or sausage drippings though because of seasonings).

SHORTS: 1. The part of milled grain next finer than the bran. Sometimes the term meant middlings. Occasionally it meant reground bran, practically free from floury particles and sometimes containing mill sweepings. 2. "Short oats" is a European variety of oats.

SHRED (to): Cut food into long thin strips with a scissors or sharp knife.

SHRUB: A beverage of sweetened fruit juice, sometimes intended to be diluted with water before drinking.

SIMMER: Cook slowly at a temperature just below boiling (about 185°F at sea level). Bubbles form slowly and rise slowly to the surface.

SIMPLE SYRUP: Boil 2 c. sugar with 2 c. water for 5 minutes. Chill and store in a covered jar. This was used for flavoring old-time summer drinks because the sugar was already in solution and you didn't have trouble with sugar settling in the bottom of the glass.

SINGE: Remove hair and down by holding the bird over a flame and constantly changing its position until all surfaces have been exposed to the flame.

SINGLE CREAM: The cream that can be skimmed off after milk has stood 12 hours after milking.

SIRUP (syrup): Originally, a thick viscid liquid made from the juice of fruits, herbs, and the

like, boiled with sugar.

SKEWER: Skewers range from rapier-like “swords” to wooden pins. A heavy wire with a loop at one end for a handle would work. The skewer holds foods over an open fire and is used to cook hot dogs, marshmallows, and shish kabob (a series of meats and vegetables).

SKILLET: 1. Originally, a small kettle or pot with 3 or 4 legs and a handle. 2. Or a shallow pan such as a saucepan. 3. Now, usually means a light frying pan.

SKIM (to): Clear a liquid from floating scum or substance. Cream is skimmed off the top of the milk.

SKIMMER: A utensil for skimming liquids, similar to a ladle.

SKIM MILK: Milk from which the cream has been taken.

SLAB: A marble slab for pouring candy mixes to cool.

SLACK LIME: Quick lime with water added: $\text{Ca}(\text{OH})_2$. Powdered lime (purified calcium hydroxide) is available at some drug stores.

SLIPPERY ELM: The fragrant, mucilaginous inner bark of an American elm.

SLUMGULLION: Stew.

SMOKEHOUSE: Where beef, ham, bacon, etc., are smoked.

SMOKE (to): Some foods, after being salted, are hung in a closed room or container for several hours, or more, hanging in the smoke of hard wood. In the South, the meat was sometimes hung in constant smoke until it was used.

SMORGASBORD: A hearty buffet meal, a Scandinavian custom.

SNOW: Flavored liquid plus gelatin, whipped as it begins to set.

SOAPSTONE (of griddles): A kind of soft stone with a soapy feel (steatite).

SODA: “Baking soda,” “cooking soda,” “soda saleratus” all mean sodium carbonate. “Caustic soda” means sodium hydroxide (NaOH). “Carbonate of soda,” “soda alum,” “soda salts” all mean sodium oxide. “Soda” also means soda water: fizzy water.

SODA WATER: 1. A beverage consisting of a weak solution of sodium bicarbonate with some acid to cause effervescence. 2. A beverage consisting of water highly charged with carbon dioxide.

SORBET: A frozen punch (water ice where several kinds of fruit were used). Also, a sherbet.

SORGHUM: A variety of molasses made from a cereal grass, sorghum.

SOURDOUGH: A type of leavening. Usually, a fermenting starch and water mixture.

SPANISH CREAM: A custard set with gelatin.

SPERMACETI: A yellowish or white waxy solid that was separated from the oil obtained from the sperm whale. It was used in making candles, ointments, etc.

SPICE MILL: An old-fashioned grinder for spices.

SPIDER: An iron pan with a long handle, used in frying food. Originally, it had long legs and was used to cook over coals on the hearth. Also, a trivet on tripod legs to support pans or pots over a fire.

SPIN: “Boiled until it will spin” means boiled to the thread stage when working with sugar solutions. That’s when you hold up your spoon and one drop is attached to the next by a thread.

SPINACH GREEN: A green food coloring made by simply cooking and pureeing spinach.

SPIT: This is a pointed metal rod on which poultry or roasts are fastened and can be rotated while barbecuing or roasting.

SPONGE: This is a method of making bread: Add one-half of the flour to the liquid and yeast mixture. Beat thoroughly. Set in a warm place. When the batter has become light (usually takes a couple of hours), add the remaining flour, or enough to make a dough of the desired stiffness. Knead, shape, let rise again, and bake.

SPRING CHICKEN: Chickens that appeared in the market during January after development of artificial incubation. They weighed about 1½ lb.

SQUAB: A pigeon just grown up: young, plump, and tender.

STARTER YEAST: See liquid yeast.

STEAM (to): Cook food over, or surrounded by steam (with or without pressure). The steam comes from boiling water.

STEELING THE KNIFE: Sharpening the blade on a smooth, high quality 9–14-inch steel.

STEEP (to): Allow a substance to stand in liquid below the boiling point. The purpose is to extract flavor, color, or other qualities.

STOCK: Liquid made from meat, vegetables, fish, or poultry. Use as a foundation for soups, sauces, and stews.

STOMACH SWEETBREAD: Pancreas.

STONE (to): Remove the pits.

STONE JAR: A crock.

STRAINER: A wire mesh.

SUCCOTASH: A corn and lima bean dish.

SUCKLING PIG: From 3 to 6 weeks old, roasted.

SUET: The fatty tissues about the loins and kidneys of sheep, cows, etc., used in cookery and for making tallow. And the leaf lard from pigs. Sometimes applied to any firm fat.

SUGAR SHEARS: A tool for cutting loaf sugar into pieces of regular size and shape.

SULTANA: Imported (Turkish) seedless raisins (Victorian).

SUPPAWN: A favorite dish of the New England settlers. It was a thick cornmeal and milk porridge.

SWEETBREADS: The thymus glands, made up of two parts: the heart sweetbread and the throat (or neck) sweetbread. They are white and soft and have a very delicate taste. Since the thymus gland disappears as the animal matures, sweetbreads are available only from very young beef.

SWEET PEPPER: The large, hollow, green one.

SWEET PICKLES: Ripe cucumbers, or melon rind, pickled in a sweet spiced vinegar solution.

SYRUP: A solution of sugar, more or less strong, according to the purpose.

T

TALLOW: The suet (fat) of a large animal that has firm fat—such as the goat, sheep, or cow. Tallow is firmer than lard, the fat of the pig.

TAMARIND: A fruit, formerly imported from India, now grown in the southern part of Florida and in Hawaii. The fruit has an outer shell with seeds inside embedded in a tasty flesh (resembles a date). The pulp can be substituted for lemon because it is very tart, but sweet. It has been used in drinks, preserves, and chutney.

TARTA: Miniature pie. Roll pastry $\frac{1}{8}$ inch thick. Cut into pieces $3\frac{1}{2}$ inches long by 3 inches wide. Put 2 t. filling on each piece. Moisten edge with cold water halfway round. Fold over. Press edges together with a meat fork (first dipped in flour). Bake about 20 minutes in a slow oven.

TARTLET: A small tart.

TEACUP: The amount of $\frac{1}{2}$ cup.

THREAD STAGE: A candy making term. It is reached when the boiling sugar begins to form a hair between drips as it drips from a spoon. 220°F.

TIE DOWN: To cover. Usually, with a piece of paper which was tied around the "neck" of the container with a string to hold it on.

TIMBALE: An unsweetened custard, usually seasoned with fish, meat, or vegetables baked in a timbale case.

TIMBALE CASE: "Timbale rosette" and "rosette case" mean the same thing: a small crust case of fried batter in which creamed mixtures and desserts were served. A timbale or rosette iron is needed to make them.

⇒ **TIMBALES** Make the batter of $\frac{1}{2}$ c. flour, 1 egg, $\frac{1}{2}$ t. cooking oil, $\frac{1}{2}$ c. milk, $\frac{1}{2}$ t. salt, and 1 t. sugar. Let batter set one hour until it is free of bubbles. Heat the timbale iron by immersing it in deep hot fat (360°F). Dip heated iron into batter. Hold at an angle until the bottom is covered. Then lower the iron into batter until a half inch from top. Hold iron straight and lower into hot fat. Cook until case is crisp and brown. Remove from fat. Slip case from iron. Drain case on absorbent material. If batter slips from iron back into bowl, the iron is not hot enough. If case slips from iron back into fat, the fat is too hot.

TINCTURE: An alcohol or a mixture of alcohol and water, in which herbs have been soaked until the wanted property is dissolved out of them.

⇒ **YE OLDEN TINCTURE** To 1 oz. of chipped or pounded herb, add 2 oz. water and 2 oz. pure alcohol. (Nowadays you can't buy pure alcohol even to make vanilla extract unless you get a license, post a bond, pay a tax, and buy a minimum of one barrel of the stuff. So folks usually substitute vodka.) Let mixture soak in a bottle 8–14 days in a cool place. Then strain out solids and bottle for use.

TINCTURE (to): Flavor.

TOASTING FORKS: Long, wooden-handled forks to impale or clamp on a slice of bread, or something else, and hold it over an open fire without also cooking the holder.

TONGS: A device to turn broiling meat, etc., without poking a hole as a fork would do. Good for other purposes too.

TONIC: Flavored with quinine.

TONKA BEANS: Once used to make a cheap imitation vanilla.

TORTE: A rich, often rather heavy, cake.

TORTILLA: An unleavened thin flat bread made of flour or cornmeal and water.

TOURNEDOS OF BEEF: Made by wiping a fillet of beef, cutting it into $\frac{3}{4}$ -inch-thick slices, and trimming them into circular shapes.

TREACLE (black or green): 1. A dark, strongly flavored molasses (English term). 2. Sulphur and molasses. Enough powdered sulphur was stirred into dark molasses to make a thick paste.

TRENCHER: Made of wood, about 10–12 inches square and 3–4 inches deep, hollowed down into a bowl in the middle. Used as a plate, usually shared by two people such as the man and his wife or two children: a Colonial term.

TRIPE: The plain or smooth lining from the first beef stomach, the honeycombed lining from the second stomach, and the pocket-shaped part from the end of the second stomach, all from the cow. The pocket-shaped section is smooth on the outside and the honeycombed inside.

TRIVETS: Three-legged stands, of varying heights through which the pot could be raised to the exactly desired proximity to the coals when cooking over an open fire.

TRUFFLE: A species of fungi, similar to mushrooms, growing in clusters some inches below the surface of the ground in France. Used for seasoning or a garnish.

TRUSS (to): Of a bird. Draw the thighs and wings close against the body and fasten securely with skewers or tie with string. If the neck has been removed draw the skin of the neck to the back and fasten with a small skewer. This will hold the bird in shape during roasting. A suckling pig may also be trussed.

TRY OUT (to): Render.

TUB: A half barrel.

TUBERS: 1. White potatoes. 2. Jerusalem artichokes.

TURBINADO SUGAR: Very coarse and dry cane sugar.

TURN IN: To pour in.

TURNSPIT DOG: A dog trained to run in a revolving cylinder, the mechanism of which kept a roasting joint turning before a fire, allowing meat to cook evenly (Colonial term).

TUTTI FRUTTI: Fermented mixed fruits.

U

UNFERMENTED WINE: Grape juice.

V

VANILLA POD: A slender pod 6–12 inches long containing a number of small round vanilla beans.

VEAL: Meat from a calf 6–8 weeks old.

VEGETABLE GELATIN: Pectin.

VEGETABLE MARROW: A variety of summer squash.

VEGETABLE OYSTER: Salsify.

VEGETABLE PRESS: Used as a potato and vegetable masher, a sauce and gravy strainer, a

fruit press, and any other purpose for which a colander or strainer is needed with pressure forcing the food through the holes.

VELOUTE SAUCE: A basic flour and butter diluted with chicken stock and cream.

VENISON: 1. Originally, meat of any animal or bird of the chase. 2. Meat of antlered animals such as deer, elk, antelope, moose, and reindeer. 3. Now, deer meat.

VERMICELLI: Made from flour moistened to a stiff dough with water and forced through small apertures in a plate by means of a press. Thinner in diameter than spaghetti.

VERMICELLIED: Rubbed through a coarse wire sieve to create a fine “spaghetti” effect.

VICHY WATER: Originally, bottled water from a mineral springs at Vichy, France, which contained carbon dioxide in solution.

VIENNA COFFEE: Coffee served with whipped cream.

VINEGAR: An acid liquid used in seasoning and pickling ($C_2H_3O_2$).

VOL-AU-VENT: A case of puff pastry, round or oval, which may be filled with either a meat or fruit filling. The pastry baked in a mold.

W

WAFER: Cracker.

WASH OVER WITH EGG: Brush with egg whites.

WATERLESS COOKING: Cooking slowly in a tightly covered container. Most foods require the addition of a small quantity ($\frac{1}{4}$ to $\frac{1}{2}$ c.) of water.

WHEY: Watery liquid separated from solids in cheesemaking.

WHIP: A flavored liquid, plus gelatin, whisked as it begins to set.

WHITE SAUCE: One made from milk or white stock or part of each, thickened with plain flour or cornstarch.

WHITE SOUP STOCK: A soup stock made from chicken or veal with delicate seasonings.

WHITE WHEAT: Soft varieties (versus red, hard wheats).

WHORTLE BERRY: A variety of blueberry. Sometimes the term meant huckleberry.

WILD CHERRY: Choke cherry. The bark was used to make homemade root beers. The cherries make wonderful pancake syrup or jelly. The leaves, however, contain poisonous amounts of prussic acid.

WINEGLASS: One-fourth cup.

Y

YOGURT: Thick cultured milk made by adding yogurt-making bacteria to warm milk, allowing it to stay in a warm place until the desired thickness. Believe it or not, once I didn't know what this term meant.

YOUNGBERRY: A blackberry variety. The fruit is large, dark, and sweet.

Z

ZEST: Citrus fruit skin oil, especially that of lemon and orange. Obtained by bending the skin sharply to squeeze it out. Zest is the stuff that squirts in your eye when you peel an orange.

CHRONOLOGY OF THIS BOOK

December 25, 1969.

For Christmas, my mother-in-law gave my husband Mike and me a subscription to *Organic Gardening*, along with some back issues.

February 12, 1970.

Rebecca Neoma Emery was born.

Summer 1970.

“Old Fashioned Recipe Book” idea came to me.

September 1970.

Wrote the table of contents. (Believed I could finish the book in 2 months.) Placed an ad to appear in the November and December 1970 issues of *Organic Gardening*.

November and December 1970.

Received about 250 orders. Wrote all the people saying I’d send the book when done and promised them it would be only a couple more months.

March 1971.

First “issue” mailed to the “subscribers.” It consisted of chapters on herbs, definitions and measures, and home industries except a still-to-be-written section on candles.

September 1, 1971.

Luke Carl Emery was born.

December 17, 1971.

Second “issue” mailed after I raised funds to do so by advertising to get more subscribers. About 200 more people ordered. The second issue consisted of beverages and half of a chapter on meats. Then I was sick for a while. We traded our 3 acres and a house as a down payment on 115 acres and a house.

September—December 1971.

Printed and mailed the third issue: chapters on oddments and food preservation and half of a chapter on dairying. Also sent larger binding rings because the book was turning out to be bigger than I’d expected. Then stopped writing.

May 17, 1973.

Sara Ann Emery was born. Sold goats on neighbor’s request. Bought Nelly the cow.

This is Carla with baby Sara out milking Nelly right on the green grass (into a bucket) where Nelly and I decided would be a good place to be.

November 1973.

After a long break I prayed, felt directed, and went back to work on the book.

January 1974.

Dolly became very sick. Sara was also sick.

February 18, 1974.

The book was finally finished. Dolly was better, Sara was well, and I was happy! But I still had to manage printing the book.

Dolly and the rabbit love each other. Farm children learn to love the animals, and yet to let them go when it becomes necessary. But this rabbit will be a mama many times and doesn't have to be butchered.

March 1, 1974.

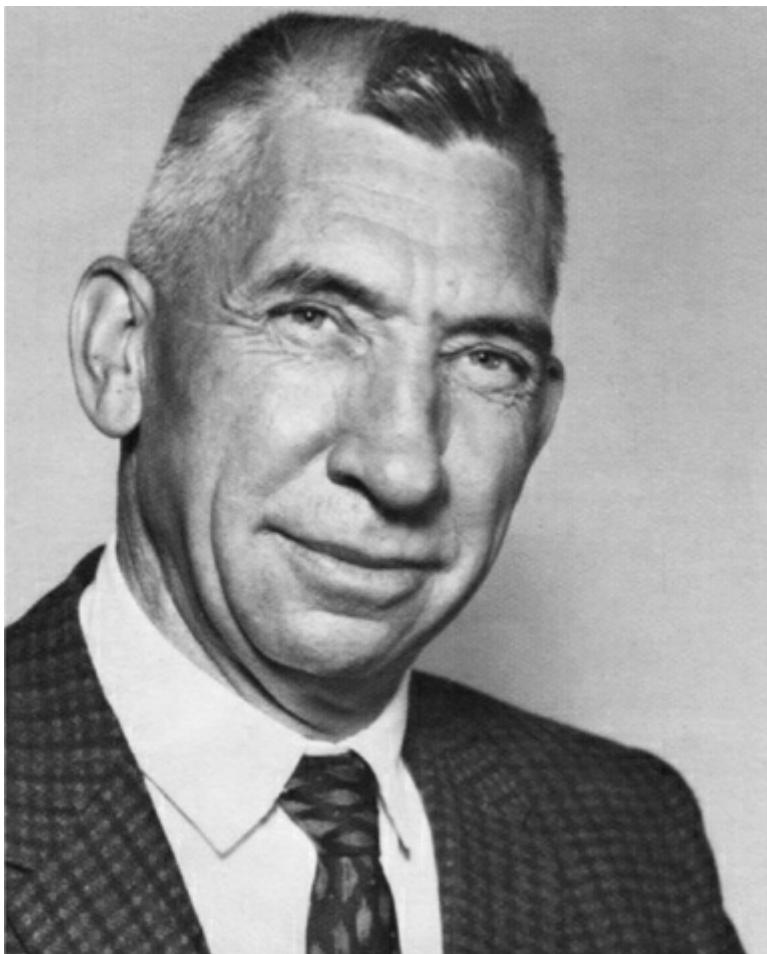

The first edition (the one that came out in issues) and the second edition (the first whole book) were printed and put in the mail to my customers, thanks to Diann, Darlene, and the good collators.

By the late February, Diann had been mimeographing for weeks. Then there was a collating bee, organized by a librarian at the Moscow Public Library. I didn't know her, but she had heard of me. About 6 ladies came to the bee, which was in an empty apartment in the old folks' home that Viola Johns (Diann's mother) ran; I'd never met most of them before.

Diann introduced me: "This is our author." Everybody looked at me hard for a minute to see what an author looks like. I said, "Hello" and "Thanks for coming to help," and that was pretty much the end of it. They kept walking around that table collating, probably because they hadn't anticipated such huge piles of paper and they wanted to get home for dinner. We were doing 200 copies of what I called the fourth issue of the first edition, and then we put together 200 more of the "second edition," which would have the improvement of being an all-at-the-same-time book, to say

nothing of the text additions and improvements I'd made in the earlier chapters.

My job was hauling boxes full of envelopes holding the fourth issue in the back of my pickup from the work area to the post office. When I got back for the next load and walked in the door, they nodded and kept going around the table. I saw they had already finished about 8 of the whole books. They had no way of knowing what was going on inside me. I had sort of thought I'd be the person to put the first whole book together. But no matter. I elbowed my way into the line that was going around and around the table and picked up the first of the 12 chapters. I couldn't say a word. I couldn't smile. The emotion in me was so intense and huge. I took a step, picked up the second chapter from its pile and laid it on top, and so on around the table until the last chapter, "Definitions and Measures," and then the back cover. And now I held it in my hands—a completed copy of the *Old Fashioned Recipe Book*. The first one I had ever held in my hands, a miracle!

This is a picture of my father in his later years when he was teaching school. I feel a kind of awe whenever I see his face now. The first word I think of in relation to him is "character." Daddy was a man of principle. If you had put him to the test he would have laid down his life. Right was right and wrong was wrong. He gave loyalty to his God, his country, his wife and child, and he always gave an honest day's work for his daily bread. He was so strong, yet so gentle and loving. The only time I ever saw him weep (until the day I grew up and left home) was when he found a kitten had crawled in by the fan belt and got killed when he started an engine.

I clutched it to me, turned, and walked back out the door alone, so full of feeling I thought I'd burst. Just up the hall I found an empty laundry room, went in, and closed the door behind me. There I knelt down, crying with gratitude, and talked to God and thanked Him.

There was more work to be done, hauling boxes to the post office. So then I went back to the collating place, and things just took up again as if nothing spectacular had happened. Only my heart knew better.

April 10, 1974.

Third edition finished. (As soon as I finished the first two, I thought of more things I wanted to include!)

I tried another classified ad in *Organic Gardening*—2 months at \$200/month, and this time only one order. I tried selling to libraries and bookstores, working from mail-order lists, but they wouldn't buy at a high enough price to allow me a profit. There had to be another way to reach potential buyers with no middleperson. In the meantime, Viola rented her apartment. We moved the bookmaking to Diann's home, but it outgrew her living room. We had to find another place to do it. We rented an empty restaurant on Main Street in Kendrick for \$75 a month. We collated on the abandoned counters and, with great care, settled in the precious new \$1,200 mimeograph machine which, by the grace of God, had been allowed to us on time payments of \$45 a month. Diann and Darlene started keeping regular office hours at the store, even though I owed each of them anywhere from \$300 to \$700 depending on which day or month you looked at, and the whole town was telling them they were fools. We painted huge, brave red-and-white signs on the outside of our new home advertising the *Recipe Book*, and did a little off-the-street business. I desperately needed to sell more books, and directly to readers. But how?

Then some college boys from the University of Idaho at Moscow visited me and urged me to take part in a craft fair they were organizing for Moscow's Main Street. I never turn anybody down, and as usual we were in a situation where if I didn't find \$250 somewhere, we wouldn't be able to pay our paper bill and would have to shut down forever on the following Monday. So I took a folding table and all the children, and we set up shop there in the sunshine. I passed out hundreds of brochures and sold \$300 worth of books at \$9.95 each. It was a long day but great fun, and I had the money! From then on ...

May 15–September 15, 1974.

The children and I were out every weekend at town fairs, art and craft fairs, and county fairs, peddling copies of the books and passing out brochures about how to mail-order them.

May 24, 1974.

Colored photos were added to the book, and that became the fourth edition. (We were constantly producing books. There actually were some fourth editions turned out before the fifth came along.)

One of Grandpa Harshbarger's ranches in Montana.

May 26, 1974.

An index was added, and then we called it the fifth edition.

But the Idaho fairs just weren't big enough to support the kind of volume I needed to pay Diann and Darlene, the rent for the Living Room Mimeographer, and the payment on the machine. Once again, it looked like the end. Then we heard of a 3-day craft fair 500 miles away, near the Pacific coast, in Bellevue, Washington (a suburb of Seattle). It was to take place on Thursday through Saturday. I said to Diann and Darlene, "I'll try it just this one more time. I'll go clear to Seattle. If I don't make it this time, I'll submit to the inevitable—I'll give it all up." That week's mail-order money was just enough to pay gas one way to Seattle. As usual, I took all 5 children (ranging in age from 1 to 10) plus blankets, a bag of groceries, and so many books I was afraid my poor old car wouldn't make it over the long, steep Alpowa grade over the Blue Mountains just west of Lewiston, Idaho. But it did. That night the children and I slept squeezed like sardines in the car, parked behind a shopping center. A policeman saw us, came over, and got very uptight about the whole idea of it, though he didn't arrest me.

The next day I found out I had the date wrong. The fair existed, but it didn't start until Friday. So I had Thursday to kill. I decided to try to get on TV. At a shopping center, I hunted for a phone. A nice secretary in a real estate office let me use theirs. I looked in the Yellow Pages for TV stations and called the "Seattle Today" TV show people to ask if I could get on that weekend. Meanwhile, my kids were kind of getting into things. At that moment, the bosses at the real estate office came in. The

"Seattle Today" people told me on the phone they had an unexpected cancellation that day, and I should be there in 1 hour! The real estate people told me to please take my children and leave, and I did.

We headed for the KING studio; we'd never been there before. By a split second we found it in time. The children couldn't find all their shoes, so I made them stay in the car in the parking lot, looked after by the nice parking attendant. I rushed into the studio, and there you had a study in contrasts. The hostess of the live show was in an evening gown, her makeup expertly done, her hairdo lovely. I was in work clothes and tennis shoes, with bags under my eyes. The show was a smashing success!

Afterward, we headed back to the shopping center. The children had supper and I didn't, because we were getting low on food. The next day, bright and early, we set up for our fair. We sold \$300 worth of books that Friday, plus I met some people who became my good friends before the summer was over—people who make quickie trips to Mexico and buy up goods there to sell at fairs here, and people who spend long winter months working in their basement craft shops (or some such places) painstakingly creating beautiful things and then, all summer long, weekend after weekend, take those things to one craft fair after another trying to sell them for enough money to get through another winter.

It's a very special way to make a living, and there's a warm camaraderie among the folks who live that way. They took me in as a sister and began to teach me the things I so badly needed to know: when the big, good shows were; what you had to do to get into them; the fine points of just where to put your table to catch the best crowd flow; how to hawk your wares; and how to get along with the management. They told me that, although the fair there in Bellevue seemed so good, there was going to be an even better one Saturday and Sunday up in the Fremont district of Seattle. They were all going there, some leaving a friend to tend their tables in Bellevue. I went along, and Fremont was a whole new experience for me.

Here are Danny, Mike, and our Border Collie dog, Thor, in the field where we raised a combo of peas, oats, and alfalfa for winter feed. (It hasn't grown very high yet.) The field overlooks Kendrick and the Potlatch River. The tall buildings are grain elevators where wheat farmers on the highlands above the canyon take their harvest.

I thought I was arriving in Fremont plenty early Saturday morning at 6, but wow was I late! There were hundreds of craftspeople already there—600, according to the brochure I saw later. Mobile TV cameras and reporters were already out getting stories for the morning news. All the good spots were already taken. I had to settle for a spot out on the edge of the fair. Nonetheless, I did \$500 worth of business that day. The kids and I slept in the car again that night, and nobody minded. The next day, business was even better. I ran out of books, so then I took orders. So many would-be customers were crowding in wanting my book that I felt just overwhelmed. But then people appeared from nowhere to help me. They passed out brochures, took orders, and helped with the children. They begged and insisted until finally I went off and bought myself a 7-Up in a little nearby restaurant while they continued selling books back at my table.

I started to feel like a small sort of celebrity. People would come up and say, "Everybody's talking about your book." I walked back with my drink and saw them gathered here and there around one of my brochures, eagerly talking. That night the children and I slept in a motel, and we all had showers and reveled in our comfort. We bought a big bag of groceries—including luxuries like avocados and fruit juice—to celebrate. After the little ones were put to bed, my oldest daughter, Dolly, and I sat up and totaled the money we were taking home. We could scarcely believe our eyes—it was over \$1,000. I remembered how once I had numbly apologized to Darlene because I still had no money to pay her, and I knew how much she needed it. She responded with words I'll never forget: "Oh, Carla, I just wish I had some money of my own so I could lend it to you." But now I could give Diann and Darlene all their much-deserved and long-awaited wages, and catch up on the other bills too!

After that I went to Pacific coast fairs every weekend. There was always one—or more—going on out in that heavily populated region. The biggest problem was getting over Alpowa while heavily laden with outward-bound books. Once when I was driving the family truck, it caught on fire. Flames and black smoke were coming up through the crack all around the outside edge of the hood, and I could see flames in the floorboard insulation around the brake and gas pedals. I stopped as soon as I could get over to the side of the road. I got out and raised the hood—and there was my engine burning merrily away.

I didn't know what to do next. I was no mechanic. I depended on Mike for things like that. Just then a Greyhound bus saw us and stopped right in front of us; the driver got out and ran toward us, holding a fire extinguisher. It shot a white powder all over the engine and put out the fire. We thanked him, and he drove off in his big bus.

Then we realized the fire had gotten going again, down in the floorboard insulation. We had no liquid; we tried to put dirt on it, but that was no good because the dirt couldn't get down to the places where the fire was smoldering. A farmer stopped, said he'd get us some water, and drove away. We kept moving the dirt, trying to hold down the flames until he could get back. He came back and soaked the thing out good and final. The truck engine was ruined. We ended up going over Alpowa in the wee small hours in the car, pulling a U-Haul trailer full of books.

That was the time we were going to do 5 fairs on the coast in the same weekend, so

it was an extra heavy load of books. Darlene and her 5 kids in her car came along with me and mine and some extra young people to do the selling. Once we got to Seattle, I had to lead Darlene to the fair site in Tacoma where she was going to sell books. We happened to get on the freeway at rush hour. I had already been introduced to freeways and had learned how different they were from our 2-lane country roads at home, and I'd forgotten what a shock they could be. I found out later that Darlene drove down that freeway behind me crying all the way. But she hung in there behind me, and we got there okay.

From May 15 until December, I was home only 1 weekend. That was in August, when I was just too sick and exhausted to go out. That week Mike and I talked it over, and we decided to submit to the necessities. I had been leaving home just in time to get to the fair, generally on the late side because I had so much I wanted to do at home: time with Mike, working in the garden, all the canning and freezing, catching up with my milk cow. Mike tried to keep the cow going while I was gone, but she and Mike just couldn't get along. Then a pile of mail was always waiting for me, and there were people to call and decisions to make and, of course, I always had all 5 children with me whether I was at home or on the road. So I generally didn't get any sleep the night going to the fair, because I'd leave late and drive all night. And I generally didn't get any sleep the night coming home, because I was always so anxious to be with Mike again that I'd just drive straight home without sleeping.

But after I got sick, we talked it over and decided I wouldn't try to come home every week, as I had been doing. Instead I would go out for a few weeks at a time—or more. I did that, and my cow went dry, and the stock cows got into the garden about 3 different times and ate everything to the ground (everything that they didn't trample, that is). We had to get rid of some animals because no one could stay home with them, and some of my young fruit trees died for lack of water.

Sometimes I got home and felt like bawling because it all looked yellow with dryness, deserted, and rundown, as if nobody lived there. Here I was out telling everybody about the great country life and raising your own food, and there wasn't anything in my own cellar but the green beans, turnips, and peas I'd put up during the first part of the summer. But then I'd think about how people had come up to me and told me about the first garden they'd ever had, or their new home in the country and what a joy it was to them, and how my book had helped them. Then I'd feel so good, and I'd tell myself I'd have a milk cow and a garden again for sure the next year.

October 1–December 1, 1974.

First trip to California. We got a press agent, Julaine, and some TV and radio interviews—and a red-and-white van to sleep in when away from home.

December 31, 1974.

I publicly announced my plans to build a School of Country Living after Mike and I made the down payment on a beautiful 386-acre ranch nearby. I wrote the first schedule of classes and planned to open it in May.

January 1, 1975.

The children and I left for 4½ months on the road, circling the entire United States, doing radio and TV and newspaper interviews, telling people about the book and the School of Country Living.

Summer 1975.

First session of the School of Country Living.

Fall 1975.

Went back on the road until Christmas to sell books and recover expenses: another national tour with children in van.

January 10, 1976.

Sold rights to Bantam for \$115,000 cash advance. With that money I planned to do a School of Country Living again.

Summer 1976.

Second school session. Flash flood washed away much of the school. I gave up.

Fall 1976.

Went back on road (pregnant) to pay off the debts—once more the big circle all around the United States.

February 15, 1977.

Jacob Michael Emery was born.

August–December 1977.

Toured to promote the Bantam edition (the seventh). Traveled with the 6 children and, for TV demos, a nanny, a milk goat, a turkey, a goose, and some rabbits. I was becoming a popular and sometimes paid performer on TV talk shows (Johnny Carson, Mike Douglas) with my comedic country-girl routines. Actually, I didn't so much deliberately set out to be funny as that's just how it happened. I was generally late and had no time to get nervous. And I'd have my baby in my arms. (I *always* had my baby.)

Jacob at about six months.

February 1978.

Mike Douglas's TV show flew me down to Los Angeles. Here's how it happened:

My fourth nationwide tour was the longest and most successful yet. Back home from that tour, I was still busy and still responsible for the Living Room Mimeographer's production, even though Bantam was now producing a commercial edition. I was still willing to do interviews and farm-girl comedy routines. The staff of Mike Douglas's show kept calling me up. I'd done several shows for them before, but I wasn't planning to tour again for a while. So they asked me to fly to Los Angeles and perform especially for them again. I agreed. After all, it's ever onward and upward, right? And they would pay me \$250 a minute *and* foot the bill for my plane fare,

hotel room, and a chauffeur and limousine while I was in town.

I certainly was climbing the ladder of success. It was flattering to realize I was good at something—TV comedy. That I could stand before all those cameras and be relaxed, interesting, and funny—even when I wasn't selling the *Recipe Book*. Fame, fortune, success ... and back home we always needed more money. My husband had long since quit his town job. The girls at the Mimeographer ... the kids ... all expecting me to make money ... more money. Like a monkey on my back ... all those expectations and needs. Getting money was becoming the big thing in my life. Couldn't be poor.

The Mike Douglas staff was adamant about one thing: I couldn't bring my children, not even my baby. That hurt. I'd never left my children behind before. I didn't want to be separated from my baby, not even for 36 hours. But they wouldn't accommodate me on that point. "That's how it's done," I was told. I figured I'd better bend to fit them: \$250 a minute. So I agreed. I left and flew in a jet to Los Angeles.

There were 2 big reasons why I had previously driven around the United States, again and again, in a van—above and beyond the fact that I wanted to get my books to people in towns of all sizes. First, I couldn't bear the idea of being separated from my children and needed a way to bring them along. And second, I am the ultimate white-knuckled flyer. But here I was, without even my baby, umpteen-thousand feet above terra firma in a vibrating jumbo jet. I pulled a magazine out of my handbag. It had a feature article about me, written by a local journalist, a woman who'd followed the *Recipe Book* saga from the very beginning. I read it, and it's a wonder I didn't punch a hole in the aluminum floor of the airplane and fall through to Earth—all of a sudden I felt so heavy. The gist of her message was that Carla had gone Hollywood, turned hypocrite, apostatized her own dream of country peace and quiet. There was more truth to her angle than I was comfortable with. Lord, what a gift the press can give us, to see ourselves as others see us.

The plane landed. My chauffeur met me at the gate, and drove me in a long black car to an elegant hotel with a doorman. This uniformed character stood outside under a long, narrow, sideless awning that seemed determinedly pretentious. I was conveyed to my suite and left alone. Not just a room—a suite! Room after empty, elegant, Hollywood-gaudy room. In the bedroom was an enormous, triple-sized bed with a carved and gilded headboard. I could have fitted all the kids into it with me. There was a well-appointed kitchen; does a "star" bring her own chef? And a spacious, luxurious, outer sitting room. For the throngs of reporters? None present. For the throngs of fans? Mine wouldn't look for me in such a place. I was alone. It was deadly, depressingly lonely. I wasn't used to ever being alone. I didn't feel right. I wanted my baby.

Time to do my show. Chauffeur and limo again ... excitement ... being fussed over by the show's staff. The make-up room to make me beautiful. The Green Room where I'd await my turn in the spotlight. I was brought out to wait just offstage early enough to overhear the last few minutes of the episode preceding mine. Mike Douglas was talking with 2 major female stars in the movie-theatrical sky. He asked one, "If you could live your life all over again and have it be any way you wanted, what would you do differently?"

One day Mama Emery and the children decided to make bread! We made loaves and rolls. Part of our dough is in the oven baking. Dolly (left) and Becca (right) are concentrating hard on getting their rolls smooth and round.

She answered, "I'd be a man."

He asked the other, "If you could live your life all over again, what would you do differently?"

She answered, "I wouldn't have any children."

Her words chilled me to the soul. Like everyone else, I knew that actress through media reports. She had 5 children. I wondered if they were at home watching her performance on this live TV show, the way mine sometimes had. Or perhaps her children were bored with Mom as a celebrity and no longer bothered watching, as had later happened with mine. How might it affect them if they heard, or heard of, her words? What a chance she was taking.

Oh, I understood well enough. It was all the performance game. The conversation probably was sketched out ahead of time with the show's staff. Or the staff may have trusted those 2 professional women to do as required to put on an exciting show. Those words were the smashing finale, something shocking to get people's attention and keep them from switching channels. Attention equals success, fame, money. And that's show business, right?

But the chill in me wouldn't be explained away. It was my turn to go on, and I had to suddenly be upbeat and witty and whatever else it was that I can be that people can love and that was worth \$250 a minute to the Mike Douglas staff. I can't remember what I did or what I said. I do remember that I was fighting a feeling that I

had just seen the devil under the tinsel, the gaping maw of corruption and moral danger. I felt that, above all, I had to save my children from thinking that this was what I wanted, believed in, stood for, and wanted them to believe in and become.

Then it was time for the limo back to the celeb hotel and a sleepless night in that cavernous bed; next came white-knuckled flying back to Idaho. When I got home I told Mike it was all over for me, that what I wanted more than anything else in the world was to be a good mother and a good wife and to practice what I preached. I pulled the plug on the whole career thing and let it run down the drain. I folded the Living Room Mimeographer and let Bantam make all the books. Eventually sales slowed to a minuscule trickle because I did no more book-selling interviews or tours. Mike Douglas's staff soon quit calling after I steadfastly refused to come back. I heard from a Hollywood screenwriter interested in turning my book-writing and selling adventures into a movie. I said no.

Instead, Mike and I agreed to work on an exciting new personal project together: a seventh baby.

April 18, 1979.

Esther Marie Emery was born.

September 1985.

Mike left. Five days later, I began writing again—a diary this time.

December 2, 1985.

I was divorced with custody of the children.

January 1986.

I began work on an eighth edition of this book and continued working on the diary.

January 27, 1988.

Last night I had to do some heavy deciding about the new edition of this old book that has been almost like a combination of life's work and diary to me over the years. In 3 weeks Mike is having a beautiful church wedding with a couple hundred invited guests. It's my job to make sure our 7 children are there, looking appropriately well-dressed and in suitably positive moods for a festive occasion.

The old-timers I've so revered got married, had big families, and stayed together until death did them part, maybe whether they were happy or not. I was born into a different era. I'm certainly not the only woman—or man—this ever happened to. Each of us then has to find our own way of adapting to the transition, of making a positive restructuring of our lives by discovering a new vision to live for and strive toward. Because you gotta have a dream.

What do I do about new editions of this book? After our divorce, the first time I was editing the book and came to a passage in which I spoke of my love for Mike, I deleted it. And then another such. But the next day I realized I had to put them back and not do that any more. My marriage to Mike is history and, in more than one sense, this book is history. You don't change history. That's dishonest. What I am free to change, or try to change, is the future. When Mike asked for his freedom, by default I also received the gift of mine.

What do I do about the future—of this book and of my life? Well, I keep on living for the positive, convinced that it is always better to heal than to wound, to love than to hate, to make peace than to make war. And yet I am now perhaps more aware of subtle and necessary distinctions in the practice of those ideals. I have a clean conscience about my marriage: over those many years, I gave it the best I could. I honestly put my husband and children first.

My younger children want me to go out and find another man, convinced that

normalcy can be restored simply by creating another married-family unit. But life has stages, and I feel finished with that time for loving a man and bearing and rearing his children. I can't have children any more. I can't be young again. I can't go back to the beginning of a fullscale life's love and companionship the way you can go back to the starting point in a child's board game and play the course again. I'm 49. I can't be 26 again. For someone else it may be feel right—it may be right—to love once more, to serve again in the very real bonds of matrimony. But that's not for me.

Here are my mother and father. I don't have any really good pictures of them together. This is my best. The background looks like a train station. Maybe they were there to see somebody off. Daddy loved to take us on car trips. I drove all over the United States with them when I was a child. They never left me behind. I didn't know what a babysitter was and would have been shocked and broken-hearted at the notion of my parents doing such a thing.

Now that I no longer have the responsibilities of a wife, and my mothering gets lighter all the time as my children grow older, I'm going to write! I want to write more books, print more books, sell more books, to travel and do fairs and say "Hello" to America again across my book-laden selling table. It's going to be a marvelous adventure. I'll love and be loved by so many unique, wonderful people—male and female, young and old—as I share my writing with them. It's a completely different thing from loving and marrying one man—I'm going to love and be loved by masses of people: these readers whom I want to serve. I'll give myself to my readers with the same fire, loyalty, and dedication with which I once gave myself to a single person—Mike. Yes, now I want to belong to you, as I once thought of myself as belonging to him.

With this transition I'm going to be freer to think than I was before. I want to

daringly reconsider both the given and the forbidden, to live a challenging life of the mind, searching for both open and obscure facts, for I'm a lover of data. The coming years may well be the best, happiest ones of all my life. I'm truly looking forward to them.

July 1988.

Bantam lets the *Recipe Book* go out of print. All rights return to me. The book is now "out of print." But people still write and want copies.

January 1989.

I begin selling a copier-produced eighth edition by mail.

October 1989.

Three different universities have asked to be designated as the repository for my papers, manuscripts, etc. I choose the University of Idaho. I take them all my old newspaper-clipping and photo scrapbooks, copies of the old editions, etc. We create a separate, closed depository, its contents to be made public only with my consent or upon my death. I begin doing research for another book, related to the diary materials.

August 1992.

Chad Haight of Sasquatch Books, a Seattle publisher, wrote and asked me for permission to publish a new commercial edition of the book. I agreed. From then until now I've been going to their office every Wednesday morning at 9:30 to turn in another chunk of revised or new text. I'm working with Lane Morgan, a fine author in her own right, who looks over the manuscript for problems; Anne Depue, editor-in-chief, who organizes the process; and Pam Milberg, intern, who helps sort material and keep the order of it sensible. Coming up, yet to be met, are a noble copy editor and a talented artist. I've never before produced the book with so much skillful help, and I think you're going to be impressed by the miracles that team effort can achieve! This new edition is definitely becoming the book of my dreams, the one I was trying to write from the very first day—after all these years.

VARIOUS EDITIONS DESCRIBED

If you're looking at an older copy of this book and wonder which edition it is, here are some hints:

First Edition. By subscription only, arriving in 4 consecutive shipments, mimeographed on Fibertint; 875 copies finished about March 1, 1974.

Second Edition. Mimeographed on Carlton and Mustang paper with an ivory Plastisheen cover; 185 copies finished April 10, 1974.

Third Edition. Contents expanded; 500 mimeo copies finished April 10, 1974.

Fourth Edition. Colored photos added; 1,000 mimeo copies finished May 24, 1974.

Fifth Edition. Index added; 13,000 mimeo copies started May 26, 1974.

Sixth Edition. Black-and-white photos added; 34,000 mimeo copies started January 16, 1975.

Sixth-Seventh Edition. Half new paging and half old paging; rewrites added. Index dropped due to confused paging; 4,000 mimeo copies started November 22, 1976.

Seventh Edition. All chapters fully revised and also now illustrated by Cindy Davis; 25,000 (?) mimeo copies started March 12, 1977.

The first 7 editions (before the Bantam edition) were 3-hole-punched and usually were bound with a bent length of plastic-coated copper wire in pretty colors or were Velo-

bound (with a soft or hard cover).

Bantam Printing of Seventh Edition. A different set of drawings by Cindy because a better printing method allowed more detail; same contents. Bantam first printed on alternating sections of yellow and green; in later press runs, all pages were green. A total of 200,000 printed in 6 different runs—November 1977, December 1977, September 1978, September 1979, April 1980, and March 1981. Softcover only.

Eighth Edition. Chapters called “Poultry,” “Meats,” “Definitions and Measures,” “Home Industries,” “Vegetables,” “Sweets,” and “Oddments” were revised. Starting March 1990, about 3,000 copies were made by copy machine. Gradually upgraded through various printings; another 1,000 done by offset. Again 3-hole-punched, bound with 2-inch metal binder rings.

Proto-Ninth Edition. All 12 chapters thoroughly revised, updated, and expanded.

Chapters called “Sours” and “Home Industries” integrated with other chapters. Chapters called “Introduction to Plants” and “Bee, Rabbit, Sheep, and Pig” added. “Sweets” chapter renamed “Tree, Vine, Bush, and Bramble,” “Meats” now called “Introduction to Animals.” First time book ever printed on white paper. Bound like eighth edition.

Ninth Edition. Title and much of “Definitions and Measures” chapter dropped to make room for new information. Indexed and fully illustrated; *el supremo* version so far. And massaged by Sasquatch’s editors to make my writing follow (most of) the rules that in the past I’ve been famous (infamous?) for spurning. No more world records for typos. Oh, well.

Updated Ninth Edition. More than 1,500 mail-order sources, checked and updated, with the addition of websites and e-mail addresses.

Tenth Edition. Coinciding with the thirty-fifth anniversary of the book’s beginning, many photos, text sections, and Cindy’s pictures from earlier editions are back, all recipes tested by the amazing volunteer team of testers, plus 200,000 new words, a recipe index, and new pictures by various artists, including many delightful new ones by Dan Emery!

Updated Tenth Edition. Coinciding with the fortieth anniversary of the book’s beginning, all resource information has been brought up to date.

WORLD RECORDS THIS BOOK **MAY** HAVE SET

1. More typographical errors, run-on sentences, general horrors of composition, handwritten inserts, and inky fingerprints in the first edition and others than any other book on record. (I wrote the *Guinness Book of World Records* people and they said the number of typos did represent a world record, “but you have to count them.” Never had time.)
2. Weirdest page numbers ... Where else have you seen “½” pages? Or “26c”? That’s because with each edition, I kept adding more material and didn’t want to mess up the existing page numbering.
3. First author in history to have had 3 babies in the same 4½ years during which she gave intellectual birth to a 5-lb. book.
4. Biggest mimeographed book in general circulation: 936 pages at its largest. Then I discovered elite type! Then I discovered pica condensed. (The book stayed at 900-some pages; I just kept squeezing in more words.)

5. Most self-published copies sold. Even if it's not a record, it's a lot. And most copies of a mimeographed book sold: 88,000 (I'm sure that's a record). (That figure doesn't include the sales of the Bantam and Sasquatch editions.)
6. Most words (now over a million) by 1 person in 1 book.
7. Longest time spent writing 1 book (32 years).

YOUR ACHIEVEMENT CHECKLIST

1. Grind a handful of grain coarsely for cereal. Grind finely for flour.
2. Mix, knead, raise, punch down, raise, and bake a loaf of bread.
3. Put on a bee suit and open a hive.
4. Make yogurt.
5. Start with cream and take it through every step until it has become a salted ball of butter and a glass of buttermilk.
6. Make cottage cheese.
7. Make a hard cheese.
8. Milk a goat.
9. Put a cow in the stanchion and milk her.
10. Feed the poultry and gather eggs.
11. Clean out a rabbit hutch.
12. Plan and cook a meal in which the food is 100 percent home-grown. Breakfast
Lunch Dinner
13. Raise, catch, kill, scald, pick, singe, cut up, and cook a chicken.
14. Dry a batch of fruit or vegetables in a food dryer.
15. Take out the ashes. Build a fire in a wood stove. Adjust the dampers.
16. Freeze a batch of a fruit or vegetable.
17. Make a batch of sourdough starter. Cook a meal of sourdough pancakes using that starter.
18. Make homemade noodles. Crackers
19. Dry and save seeds from an annual. A biennial
20. Separate milk. Take apart, wash, dry, and reassemble the separator.
21. Make a batch of homemade ice cream using a crank freezer.
22. Harness a team of horses (or oxen). Hitch them up to an implement or wagon.
 Till a field with them.
23. Build housing for animals. Repair or build a fence.
24. Correctly identify 10 different herbs from sprigs laid out on a table.
25. Make a pot of herb tea from herbs you have grown and harvested.

A FINAL EXAM FOR YOU

1. What is the basic bread recipe?
2. How can you start one beehive off another?
3. How do you make cottage cheese?
4. If you had no livestock feed store to buy commercial feeds at, what would you grow, and approximately how much of it or what proportions would you feed your goat every day in winter? Rabbit? Cow? Chicken? Pig?
5. What's a "potato onion"? How do you grow garlic? What prevents motion sickness?
6. What can you use to make a variety of home-grown, caffeine-free coffee?
7. If you have no electricity, gas, or other "modern" energy source, how can you preserve meat? Fruits? Root vegetables? Squash and pumpkins?
8. What do you use for potato seed? How do you plant potatoes?
9. What is the correct weight at which to butcher a broiler chicken? A rabbit? A pig?
10. State the advantages and disadvantages of keeping a goat or a cow for home dairy use.
11. What aspect of soap making is very dangerous, and how can you minimize that risk?
12. What can whole wheat be used for?
13. How do you make a homemade cheese press?
14. What is the best way to house an expectant doe rabbit?
15. How would you grow and harvest a grass grain without using any fossil fuel in the process?

The answers are all in this book!

Carla Emery grew up on a sheep ranch in Montana and was educated at Columbia University. In the early 1970s she settled on a farm in northern Idaho, where she wrote the first edition of the *Encyclopedia of Country Living*. Originally entitled *Carla Emery's Old Fashioned Recipe Book* and produced on a mimeograph machine in the living room, this book launched its author to the forefront of the back-to-the-land movement. She remained a tireless advocate of self-sufficiency and environmental stewardship until her death in 2005.
